Summary:

The Wind Claim Group is immediately north of the Midway property of Regional Resources Ltd. (Amax-Procan option), and has a geological setting similar to that of the nearby Midway silver-lead-zinc-barite deposits. Considering the proximity of the Wind Claim Area to the Midway deposit, a basic (Stage I) exploration program of prospecting, mapping, rock and soil geochemistry and geophysics is highly recommended for the property. The Stage I program is estimated to cost $48,000. If the Stage I program is successful in defining strong anomalies or silver-lead-zinc or barite mineralization, then a Stage II trenching and diamond drilling program will be warranted. A 500 meter diamond drilling program is estimated to cost $120,000.

Introduction:

The Wind 1-30 mineral claims are situated immediately north of the Midway property of Regional Resources Ltd. (Amax-Procan option) and seven miles north of the "Midway" silver-lead-zinc deposit. Discovery of the "Midway" silver-lead-zinc-stratiform mineral deposit near the Tootsee River in 1981 by Regional Resources has encouraged re-evaluation of adjacent areas with similar geology for silver-lead-zinc-barite deposits. The Wind claims cover some of the favourably situated adjacent ground. Figure I compiled by B. J. Price (1983) shows the location of the Wind property with respect to the Midway and other significant deposits in Northern British Columbia and the Yukon Territory.

This report reviews the general geological setting of the Wind Claims and other silver-lead-zinc properties in the area, and outlines a recommended initial (Stage I) program and a follow-up (Stage II) program for evaluating the economic potential of the Wind Claim Area. Snow conditions prevent a useful examination of the property at this time, and therefore the Stage I program is based on the writer's experience with other Selwyn Basin and Kechika Trough exploration programs. Cost estimates are based on a minimum use of helicopter time which will require careful planning. Casual helicopters are available at Watson Lake or periodically at Rancheria (13 miles), Swift River (64 km) and the Pine Lake air strip (55 km).
Location and Access: (Figures I & II)

The Wind Claims are situated between 2.4 kilometers and 5.6 kilometers east of the Tootsee River about 115 kilometers (72 miles) west of Watson Lake, Y.T. and 20 kilometers (12.4 miles) east of Rancheria, a small settlement on the Alaska Highway. The Tootsee Lake Road, a gravel access road which leaves the Alaska Highway at mile post 701 provides four wheel drive access to within 3 kilometers of the Wind Claims and the Alaska Highway passes within 6 kilometers of the claims. Equipment and supplies can be shipped to within 3 kilometers, but helicopter support will be required because crossing the Tootsee River or Rancheria River makes road construction costs prohibitive for an initial exploration program.

Fuel and accommodation are available at Rancheria, and most supplies and services are available at Watson Lake, Y.T. which is serviced by daily jet flights from Whitehorse and Vancouver.

Topography:

The Wind Claims lie between 1085 meters (3560 feet) and 1512 meters (4960 feet) which gives the claim area a moderate relief of 427 meters. The claims are dissected by a small westerly flowing tributary of the Tootsee River. The Claim area is mainly above timber line.

Claims and History:

The Wind Claims with grant numbers pending were recorded in February, 1983. Table I provides a summary of pertinent claim data. Snow cover prevented field confirmation of claim data obtained from claim map 105-B-1 (Department of Northern Affairs and Natural Resources). The maximum possible ground coverage of 20.9 hectares (51.65 acres) per claim will be reduced if claims overlap or posts are placed at less than maximum permissible spacing. Field checking claim post locations and placing of identity tags is required and should be part of the 1983 field program.

The writer suspects that the area has been staked in the past, but has been unable to find any records of previous exploration work.

REGIONAL GEOLOGY (FIGURE 3)

The area of interest is situated on the east flank of the Cassiar batholith which extends over 300 km southeasterly from Wolf Lake map sheet in the Yukon to the Kechika map area in British Columbia. In the Jennings River and Cassiar-McDame map areas and the south part of Wolf Lake area the eastern flank is underlain by Paleozoic rocks from Cambrian to Carboniferous in age and separable into two or more contrasting assemblages, some of which are believed to be "allochthonous" (i.e. deposited elsewhere and moved into place along flat lying faults) (Gabrielse and Mansy, 1980).

Rocks are described by Poole (Map 10-1960) and by Gabrielse (GSC Paper 68-55, 1968); brief descriptions of the mapped units are summarized below:

Units 1 and 2: (Lower Cambrian)

Unit 1 consists of biotite schists, quartzite, marble and skarn, with areas of extensive sills, dykes and irregular bodies of pegmatites, particularly near the contact with the Cassiar batholith.

Unit 2 contains quartzite, slate and phyllite, quartz grit and fine pebble conglomerate. Adjacent to the batholith the rocks are hornfelsed.

Unit 3: (Lower Cambrian)

This unit, which is host to numerous lead-zinc-silver showings in the area, contains grey limestone, grey to green argillite and slate, and dolomite. The unit is converted to skarn adjacent to the batholith.

Unit 4: (Middle Cambrian to Silurian)

Slates, phyllites and limestone, buff to dark grey, with dolomite and dolomitic limestone partly converted to skarn forms a unit which is difficult to separate from units 2 and 3.
**LEGEND**

**QUATERNARY**
- Glaciofluvial and Recent
  - Glacial till, gravel, sand, and silt, lake clay, volcanic ash

**TERTIARY AND QUATERNARY**
- Vascular alpine beets

**CRETACEOUS OR TERTIARY**
- Uppermost Cretaceous or Lowermost Tertiary
- Seagull and Hake Batholiths and Stocks
  - Mainly basaltic andesite, quartz monzonite, and aplitic
- Jurassic and/or Cretaceous
  - Cassiar Batholith
    - Mainly basaltic andesite, quartz monzonite, and aplitic
- Jurassic
  - Mainly basaltic andesite, quartz monzonite, and aplitic
- Jurassic
  - Mainly basaltic andesite, quartz monzonite, and aplitic

**PERMIAN TO JURASSIC**
- Lime stone, dolomite, and quartzite

**MISSISSIPPIAN**
- Lower and Middle Mississippian
  - Red Beds: arkose, siltstone, and shale
- Devonian and Mississippian
  - Upper Devonian: arkose, siltstone, and shale

**DEVONIAN AND MISSISSIPPIAN**
- Upper Devonian: arkose, siltstone, and shale
- Lower Devonian: arkose, siltstone, and shale

**MISSOURIANS AND DEVONIAN**
- Upper Missourians: arkose, siltstone, and shale
- Lower Missourians: arkose, siltstone, and shale

**SILURIAN AND DEVONIAN**
- Upper part: grey and white quartzite and sandstone
- Lower part: quartzite and sandstone

**MIDDLE SILURIAN**
- Upper part: grey and white quartzite and sandstone
- Lower part: quartzite and sandstone

**CAMBRIAN TO SILURIAN**
- Middle Cambrian to Middle Silurian
  - Thin-bedded bed and grey slate, phyllite, and vein quartz
  - Thin-bedded siltstone and quartzite

**CAMBRIAN**
- Lower Cambrian
  - Thin-bedded bed and grey slate, phyllite, and vein quartz
  - Thin-bedded siltstone and quartzite

**CAMBRIAN AND (?) EARLIER**
- Lower Cambrian and (?) Earlier
  - Quartzite, minor slate and phyllite, quartzites and felsic pebbles

- Rutile: RT

Unit 5: (Ordovician-Silurian)

This unit contains mainly quartzites, dolomitic siltstone and thin-bedded shale and limestone, and is probably equivalent to unit 4 in the adjacent Jennings River map sheet.

McDame Group-Unit 6:

The McDame Group, dark, fetid, dolomites and limestones with abundant fossil debris, forms a distinctive marker unit. Dolomite (intraformational?) breccia is common and white vuggy dolomite may represent reefoid accumulations of fossils, representing shoals in a shallow platform environment. Fossil evidence indicates that the McDame Group is Middle Devonian in age.

Lower Sylvester Group - Unit 7b:

According to Gabrielse (1968) "the contact of the McDame Group with the overlying Sylvester Group is almost invariably a fault." The lower part of the unit is fine-grained, black, locally graphitic slates and phyllites, with grey to black bedded and ribbon cherts. The upper part contains argillites, interbedded with sandstones, grit and conglomerate. Cherty, fine-grained limestone may be present near the top of the unit.

Several barite-silica "exhalite" horizons are present within the lower Sylvester Group in the vicinity of the "Midway" property. Stratigraphy in this area, within the Sylvester Group is described in detail by Hylands (1981), and is shown on the following page, with a diagrammatic stratigraphic section (Figure 4).

Upper Sylvester Group - Units 7a & 8:

Massive volcanic rocks, including flows, breccias, tuffs and agglomerates with aggregate thickness of over 1500 feet form Unit 7; with ultramafic bodies (Unit 8) cutting the volcanics. The volcanics include basalt, dacite and rhyolite flows and coarse-grained equivalent intrusive rocks are said to exist in the unit (Gordey, et al 1982). Most rocks are pervasively altered to "greenstones", making them appear massive.
Cassiar Batholith:

The northwesterly trending elongate Cassiar Batholith underlies the most rugged terrain in the map area. Much of the batholith consists of massive, homogeneous biotite quartz-monzonite, grey in color and medium to coarse grained in texture. Other varieties include muscovite quartz-monzonite, augen gneisses, and later pegmatitic dykes. Alteration and shearing are commonly associated features - sericitization, chloritization and albitionization are prevalent in some areas.

Other granitoid rock types occur in the Jennings River map sheet but are not within the scope of this report.

Dykes:

Greenstone dykes are common in the batholith and also within the adjacent Paleozoic rock units. Some of the dykes are known to be lamprophyres.

Structure:

The Sylvester "allochthon" is characterized by a broad, northwesterly-trending synclinal feature commonly referred to as the McDame Synclinorium. This feature parallels the contact of the Cassiar batholith in a general way but is modified by smaller scale folds conforming to embayments in the batholith, as is seen near the Marbaco property. Tight folding in Cambrian-Silurian rocks is present near Tootsee Lake. Strong northwest to northeast faulting has also affected the area, as is seen in the accompanying geological map (figure 3). Most faults are steep, normal faults such as the north-trending, easterly dipping fault cutting through the western portion of the Midway property. Faults are marked by depressions and green dykes, some of which are schistose, indicating continued movement.

Low angle faults, probably related to the hypothesized sole fault of the allochthon, are known to cut the Sylvester sequence in the vicinity of the Midway deposit (Hylands, 1981)

A strong shear zone trends northwest through the Cassiar batholith west of Tootsee Lake, and along this feature pervasive shearing and mylonization occurs over widths of 2 miles.
The Sylvester allochthon appears to pinch out in the vicinity of the Alaska Highway in Wolf Lake map area (Figure 3). Major faults mark the northern limit at Spencer Creek. South of Rancheria River, a broad area of Sylvester and McDame group rocks is thought to represent the same mineralized units as at the Midway and Marbaco properties.

Mineral Deposits in the Area:

The most significant development in mineral exploration in the southern Yukon and northern B.C. within the last few years has been the discovery of stratiform silver-lead-zinc mineralization within "exhalite" massive sulphide and silica/barite horizons in the lower portion of the Mississippian-Devonian Sylvester group.

The discovery, by Regional Resources Ltd. and partners Amax of Canada and Procan Exploration Ltd. has resulted in an extensive staking program and re-evaluation of geological data concerning mineral showings adjacent to the "Midway" property.

Several other silver-lead-zinc deposits not as yet of economic size or grade, occur in close proximity, in Cambrian to Middle Devonian strata, and also in high grade veins within the Cassiar Batholith. Several of these deposits are described briefly, following a description of the Midway property.

Vein mineralization occurring at the Silver Tip showing is discussed under a separate heading.

Midway Deposit:

The "Midway" deposit, staked by Regional Resources in 1980 and drilled in 1981 and 1982 was discovered as a result of careful exploration of the previously explored Silverknife (Silver Tip) silver-lead-zinc showing, following investigation of strongly anomalous silt sample results in the 1980 regional geochemical survey.

Six drill holes in 1981, totalling 853 meters indicated the presence of 3 mineralized zones dipping southeasterly at about 30 degrees. The lowermost zone observed only in drill core over lies the McDame Limestone and varies from 1 to 1.5 meters thick and contains from 2.65 to 23.39% combined lead-zinc and from 1.24 to 22.59 oz/ton silver. This zone is locally absent and may grade
laterally into siliceous, pyritic, exhalite. Four of the 6 holes encountered a "dry cavernous opening 15 cm to 150 cm wide" near the McDame-Sylvester contact.

The lower zone consists of weakly bedded to brecciated pyrite, galena, sphalerite and carbonate fragments in an argillaceous matrix.

The middle, or "Discovery" zone, found in outcrop, occurs about 70 meters stratigraphically above the lower zone, within argillite and sandstones.

This zone varies from 0.5m to 11.2 meters in thickness and ranges in grade from 4.56 to 13.36 percent combined Pb-Zn and 1.26 to 5.03 oz/ton silver.

The Upper Zone is about 10-20 meters above the Discovery zone, ranges in thickness from 0.40m to 3.17m in thickness and has combined lead-zinc grades ranging from 2.62% to 13.15% and silver grades.

Drilling of 18 additional holes in 1982 has proven 2.78 million tonnes (3.05 M. tons) averaging 13.3 oz/tonne silver, 12% zinc and 6.1% lead with minor but possibly economic quantities of tin, bismith, gold and copper. (Richardson, Greenshields, Canada Ltd. - research report).

Composite samples from core from 8 holes averaged 0.023 oz/tonne gold, 0.35% copper, and 0.14% tin. The deposit is now known to exist over an area 2,000 feet (600 m) square through a geological section of 100 ft. (30m). Definition of the deposit is not complete.

The exhalite horizons can be traced for at least 14 km along strike on the southwest part of the property and similar horizons are seen 10 km to the northeast. On the northeast side of the property a barite exhalite 4 m-thick has been traced for 5 km in float and outcrop.

The mineralized horizons are believed to represent sulfide rich exhalations deposited on the floor of a rift-controlled basin up to 14 km wide (Hylands, 1981).

The showings respond well to standard geochemical soil and silt sampling techniques; the Discovery showing has a broad coincident Pb-Zn-Ag-Ba anomaly, and seven additional areas have coincident Pb-Zn-Ag anomalies. Airborne EM and
magnetometer surveys were flown and ground EM and gravity surveys were done. Two pulse EM anomalies and one vector EM anomaly were verified by drilling.

An idealized stratigraphic section prepared by D.G. McIntyre from company plans is reproduced in figure 3A and a stratigraphic section used by J. Hylands for the Midway property is reproduced in Figure 4.

Amy (Fosco) Showings:

The Amy deposit occurs approximately 18 miles south of the Tom claims and two miles north west of the north end of Tootsee Lake. The showings were discovered in 1948 and staked by Hudson Bay Exploration as the Gem Group. In 1949, 8 diamond drill holes were completed totalling 2,935 feet, and seven deep trenches traced the mineralized zone for 550 feet with maximum width 7 feet in DDH - 2. The mineralization, galena, tetrahedrite, sphalerite, pyrrhotite and ankerite occurs as a replacement zone in limestone along a limestone-argillite contact and near the surface trace of the granite contact. The zone occupies a shear zone striking north 55-65 degrees west and dipping 60 degrees southwest.

Further work on the property in 1964 by Rancheria Mining Company consisted of soil surveys, magnetometer surveys and underground development.

In the underground workings, the vein in a 66 foot section averaged 5.9 feet wide and assayed 27.4 oz/ton silver, 7.5% Zinc and 7.5% lead. Further drifting along the vein in 1965 disclosed a vein length of at least 419 feet. Additional bulldozer trenching on other geochemical anomalies disclosed other veins. Diamond drilling to test continuity consisted of 24 holes totalling 7,500 feet.

The claims lapsed in 1969 and in 1970 the property was restaked by Fosco Mining Limited. Further underground work and drilling was done and a feasibility study was done by Dolmage, Campbell and Associates, who concluded that the deposit contained the following tonnages (diluted):

Midway Property

Stratigraphic Section

(Source: Hylands, J. 1981)

November 1981
The consultants further stated that "A comparison between the grade of drill intercepts near the underground workings and assays from channel samples taken from the drift suggests that the estimated grade in the drill indicated category is probably low by an unknown but significant amount. The reserve estimate outlined in this report should not be considered as limiting the ultimate potential of the deposit."

Bench scale mill tests produced a concentrate acceptable to custom smelters. A detailed underground exploration program was recommended, but immediate production was not recommended at that time because of the weak price for silver ($1.29 to $2.57 per ounce).

In 1973, additional surface work was done, confirming sampling completed on the 4450 level, and a 1400 foot crosscut and 220 feet of drifting done on the 4200 feet level.

A second estimate or ore reserves was done by Chapman Wood and Griswold in 1974, who concluded that total ore reserves now were + 140,000 tons as follows:

<table>

The claims were acquired by Marbaco Mines Ltd. in 1980 along with adjacent claims owned by D. Schellenberg. Marbaco performed geochemical surveys and trenching which indicated additional zones could be present.

At present metal prices ($15/oz Ag, 28¢/lb Pb, 49¢/lb Zn), gross metal value per ton of ore (1974 reserve data) is $235.50. (The estimated grade of drill indicated reserves is probably still low compared with measured reserves, as in the 1971 calculations). Few recent assays exist for gold but several samples taken from 1949 to 1967 contain 0.01 to 0.02 oz/ton.
Prospects are considered encouraging for discovery of additional mineralized zones at this property.

Some similarities exist between the Amy deposit and the lower most "exhalite" zone at the Midway deposit:

1) Both deposits occur near limestone - phyllite contacts;

2) Solution caves are found adjacent to both deposits.

3) Mineralogy and reserve grades are similar.

4) Mineralization is parallel with bedding in both deposits.

The Amy deposit is described in most reports as a strike fault system with characteristics of quartz-siderite-sulphide replacement of limestone in a Shear zone. However, the possibility exists that the deposit represents a remobilized stratiform exhalite deposit, with potential for augmentation of reserves along strike and dip.

Silver Tip Showing (Midway Property)

The Silver Tip showing, a vein or replacement deposit, is situated three miles northeast of Tootsee Lake. Extensive work was done on the property from 1956 to 1968 by several large companies including Conwest, Canex, Noranda, Bralorne Mines and Peerless Oil and Gas. It now forms part of the Midway property of Regional Resources and partners.

The area is underlain by thick-bedded McDame limestone of Devonian age, overlain by Mississippian-Devonian Sylvester Group phyllites. Gossan zones and galena float are found in several zones trending north-easterly. The largest gossan zone, No. 2, ranges from 15 to 65 feet wide and is 700 feet long and was reported to average 5.7 oz/ton silver, 6.2% lead and 2.9% zinc. Individual pieces of galena from the zone assay about 150 oz/ton silver and 70% lead (BCMM Ann. Report 1968, p.25-33). The same zone intersected in several drill holes consisted of "frozen mineralized gossan". No. 4 zone, intersected in the upper adit was sampled over 38 feet by taking muck from 175 cars, the average was 13.84 oz/ton silver, and 15.4% lead. The average of the channel samples along 40 feet in the west drift was over five feet, 0.02 oz/ton gold, 12.0 oz/ton silver, and 14.5% lead. The same zone, intersected in the
lower adit, approximately 650 feet down the dip of the fault zone, is almost completely oxidized and resembles "soft brown sugar". This almost completely leached material assays 0.2 oz/ton silver, 0.1% lead and 4.5% zinc.

Mineralized zones such as the above are localized on strong faults and fractures in the McDame limestone, along the crest of an anticline and appear to be almost completely oxidised to depths exceeding 600 feet from the surface. Apart from the gossan zones, considerable pyrite with minor sphalerite and galena occurs in the holes drilled in the phyllite, (presumably Sylvester Group), and minor galena and sphalerite occur in quartz and calcite veins and in limestone. To the writer's knowledge, fresh vein material from which the gossans resulted has not been seen on the property.

This vein-replacement deposit, as yet untested by Regional Resources has strong similarities to the Amy deposit of Marbaco Resources. Mineralogy and grades are similar and probable origin by replacement along fault zones in limy horizons seems almost certain. Considering the presence of mineralization over a vertical range of over 650 feet and 5 foot mining width, the eventual development of economic reserves on this portion of the property seems certain.

YP Property:

The YP property, adjacent to the Flo and Lydia claims, situated 4 km south of mile 701 on the Alaska Highway, owned by Flame Petro Minerals Ltd. and currently being explored by Butler Mountain Resources Ltd., has several oxidized vein or replacement zones in limestone of unknown, but probable Cambrian age. Some solid galena was hand-cobbled and shipped from the property in the 1960's. Several large gossan zones, with residual argentiferous galena, are thought to represent oxidized replacement zones of galena-tetrahedrite-sphalerite and other sulphides in siderite gangue, comparable with zones present on the Silver Tip showing of the Midway property. Geochemical surveys, geologic mapping, trenching and drilling were recommended by B.J. Price in 1980. The property was reviewed in 1982 by Glen E. White, P.Eng., who suggested pulse EM surveys in addition to geology and geochemistry, with a 2-stage program with $40,000 expenditure in Stage I and $110,000 in Stage II (drilling).

The program is expected to proceed in 1983.
A + B Claims:

The A + B deposit, situated 6 km north of the Alaska highway, is owned by Delphi Resources Ltd. and was explored by SEREM LTD. Strongly folded limestone and phyllites of Cambrian or Devonian age are host to Stratiform massive zinc-lead-silver zones, highly irregular in shape. The best intersection to date has been in hole 3 (1962) drilled by Scurry Rainbow Oils Ltd.: 39 feet of 1.66 oz/ton silver, 1.47% lead and 8.32% zinc. Cross cutting quartz calcite veins have significant scheelite content.

Sue Claims:

The Sue claims, 5 km south of the Lydia claims, were originally explored by Duport of Canada Exploration as the JCS 1 and 2 claims. Although most attention was paid to molybdenum/tungsten mineralization at the contact of the Cassiar batholith with skarnifield Kechika Group rocks, lead-zinc-silver mineralization was noted in a quartzite breccia. The breccia is briefly described by Eccles (1980) as a possible pipe. One sample from the breccia assayed over 10 oz/ton silver.

Noranda Claims:

Silver-lead-zinc mineralization is also present on the Root, Toot, Boot, Loot and Road claims, north and west of Tootsee River (see figure 2). Mineralization is present in quartz veins within the Cassiar batholith, but is also present in carbonate breccias. Strong lead-zinc geochemical anomalies may be associated with lamprophyric dykes, a relationship also seen on the Ag claims.

Freer Creek Areas

Numerous silver-lead-zinc veins occur near Freer Creek, approximately 10 km west of the Flo and Lydia claims. On the Luck prospect, between 3,500 and 4,000 feet elevation on the Creek, argentiferous galena, sphalerite and chalcoprite are found in quartz veins in the Cassiar batholith quartz monzonite. The veins are associated with a lamprophyre dyke, and are outlined by EM-16 surveys and geochemical soil sampling. Hand cobbled material was shipped from one of the occurrences on the IDA property in 1970. A 25 ton shipment assayed 80 oz/ton silver, 56% lead, 5% zinc and 0.6% copper (Report by D. Parent, 1973).
The veins are presently being explored by Klondyke Silver Mines Ltd. based in Whitehorse, Yukon Territories, who plan to start an exploration and development program, early in 1983. (Whitehorse Star, January 4, 1983).

**Bear and Ag Claims:**

The Bear claims were staked by Douglas Schellenberg in 1978 and explored by Dupont Exploration in 1979. The Ag 1 and 2 claims were also staked by Schellenberg, in 1982. The claims are situated 2 km west of the Marbaco silver-lead-zinc deposit and are surrounded by the Fly Claims.

The only record of work done on the Bear and Ag claims is contained in an unpublished report by L. K. Eccles in 1979. Work done by Dupont included line cutting from three well-cut baselines, geological mapping, trenching and soil sampling. A total of 585 samples were collected and analyzed for molybdenum, tungsten, lead, zinc and silver. The samples outlined several molybdenum-tungsten targets and one main lead-zinc-silver anomaly. The Mo-W anomalies were trenched uncovering 2 stratiform skarn bodies up to 1 meter wide and 10 meters apart. Although mineralized with scheelite, molybdenite, powellite and galena, the showings are considered uneconomic.

Trenching in the Pb-Zn-Ag anomaly revealed a narrow high-grade vein in limestone mineralized with galena, sphalerite and ruby silver (pyrargyrite), spatially associated with a dark green, possibly lamprophyric dyke. Assays from its occurrence (selected) are as follows:

Schellenberg (1983 - personal communication) suggests that the mineralization may be stratiform and may extend outward from the Ag claims into the Fly claims.
Discussion of the Wind Claims:

The Wind Claims are mainly underlain by map units 6 and 7b (Poole et al., map 10-1960) which correlate with the favourable Devonian age, McDame and Sylvester groups which host the Midway deposit on the adjoining property of Regional Resources. Unit 6 includes grey and black dolomitic rocks and unit 7b includes argillite, sandstone, conglomerate and chert. Strong northeast and northwest faults are shown on map 10-1960 in the Wind Claim area. Geological Survey of Canada mapping of the Wind Claim area needs refining for detailed property work, but indicates a similar geological setting to the nearby Midway deposit. The presence of strong fault structures needed to channel mineral bearing solutions is an encouraging future.

The writer has not field examined the Wind Claim area, but has worked on several silver-lead-zinc-barite deposits in northern British Columbia and the Yukon Territory. Stratabound deposits tend to occur in clusters (eg. Anvil Camp; MacMillian Pass; Howards Pass; Akie River Area) with higher silver contents generally found in deposits hosted by Devonian Rocks (eg. Tom, Jason and Cirque deposits). Search for a base metal deposit on the Wind Claims is warranted because of the proximity of the Midway deposit, a stratabound deposit with high silver values in a similar sedimentary sequence of Devonian age.

Exploration of the Wind Claim area should start with careful geological mapping and prospecting. The following key prospecting guides should be carefully recorded:

1. Section thickening associated with growth faults;
2. Intraformational breccias, conglomerates and turbidites occurring because of fault controlled relief;
3. Siliceous - pyritic areas near faults;
4. Stringer mineralization with possibly higher copper values;
5. A characteristic porous or pumice-like rock of white colour is associated with baritic outcrops that have leached carbonate or sulphides;
6. Vegetative kill zones are associated with baritic horizons; and

7. Siliceous or baritic exhalite deposits should be carefully checked for lead content (galena).

Silt and soil samples should be checked for lead, zinc, copper, silver and barium. Lead is generally the best indicator for stratabound base metal deposits but other elements may help in defining zoning.

Conclusions and Recommendations:

Considering the proximity of the Wind Claims to the exciting new Midway silver-lead-zinc-barite discovery and similar geological settings, a basic (Stage I) exploration program of mapping, soil and rock geochemistry, geophysics and trenching is highly recommended. If the Stage I program is successful in locating mineralization or strong anomalies then a follow-up (Stage II) trenching and diamond drilling program will be warranted. If broad or poorly defined anomalies result from Stage I, then a Stage II percussion drilling program should be considered.

Geological mapping should be conducted at a base map scale of 1:5000 with more detailed grid mapping as required. Soil samples should be collected at 25 meter intervals along lines as normal to geological strike as possible. Rock and soil samples should be analysed for Cu, Pb, Zn, Ag and Ba. Lead is usually the best indicator element, but typical zoning from an iron rich core to zinc-copper to lead-zinc to silver-lead and marginal barite should be considered when evaluating geochemical data. Electromagnetic and magnetic readings should be collected along all soil lines to allow for comparison of results.
Cost Estimates

Stage I - Prospecting, Geological, Geophysical and Geochemical

Geologist/Manager 20 days @ 300 ea $ 6,000
Assistant/Prospector 20 days @ 150 ea 3,000
Sampler/Helper 20 days @ 100 ea 2,000
Geophysical Crew (includes Magnetometer & EM) 10 days 8,000
Mobilization/demob Vehicle 2 days @ 100 ea 3,000
Materials (Camp, sampling, lines etc.) 3,000
Board/Camp costs 80 days @ 40/day 3,200
Base Map Preparation 200
Geochemical Analyses
500 soils @ 12 ea (Pb, Zn, Ag, Cu, Ba, analyses) 6,000
50 rocks @ 20 ea 1,000
Helicopter 10 hours @ 500 ea 5,000
Report Preparation 3,000
Contingency 4,400
Total Stage I $48,000

Stage II - Drilling and Trenching

Cat (trenching, drill sites & moves) $ 8,000
Helicopter 20 hours @ 500 ea 10,000
Diamond Drilling 500 meters @ 180 ea $90,000
all inclusive: drilling, engineering, geochem etc. $108,000
Contingency 12,000
Total Stage II $120,000

Total Stage I & II $168,000
