SUMMARY

In January 2015, BMC Minerals Ltd ("BMC") purchased the Kudz Ze Kayah ("KZK") Property from Teck Mining Worldwide Holdings Ltd ("Teck"). The KZK Property consists of 879 quartz claims that cover 16005 hectares (160 km^2) of south-central Yukon, and is centred at 61° 31' N latitude and 130° 33' W longitude on NTS map sheets 105G/7-10, within the Watson Lake Mining District. It is notable for containing the ABM and GP4F volcanogenic massive sulphide (VMS) deposits, which are located 5 km apart. Following the 2015 exploration work, BMC announced resources of 20.1 Mt at 0.9% Cu, 2.0% Pb, 6.4% Zn, 1.4 g/t Au and 151 g/t Ag (Indicated and Inferred) for the ABM deposit (Green et al., 2016) and 1.7 Mt at 0.2% Cu, 2.6% Pb, 6.1% Zn, 1.4 g/t Au and 145 g/t Ag (Inferred) for the GP4F deposit (Green, 2015).

Following its purchase of the project, BMC embarked on an aggressive exploration program that included upgrading and building new exploration infrastructure, compiling historical data, re-logging historical drill core, LiDAR surveying, differential global positioning system (DGPS) surveying of the tote road and historical and 2015 drill collars, geophysical surveying (airborne, ground-based, downhole), resource and exploration drilling, metallurgical drilling and sampling, petrographic studies, geotechnical drilling and engineering, hydrogeological drilling and environmental baseline studies (Table 1).

The 2015 historical core re-logging program logged 174 out of the 201 historical DDHs (87%) drilled on the KZK Property, for a total of 24952.8 m, and collected 1656 samples for geochemical assay. The re-logging program used the same lithological, mineralization, alteration and veining coding system as the 2015 core logging program in order to incorporate the historical data into the current drill hole database and facilitate geological interpretation and resource estimation. Samples sent for assay include 998 half-core shoulder samples, 449 half-core grade confirmation samples and 209 samples for QA/QC. Shoulder samples were taken to further characterize ABM waste rock and assay previously un-sampled mineralization, with 17% of shoulder samples returning at least one precious (Ag, Au) or base (Cu, Pb, Zn) metal assay exceeding the "mineralized" threshold. Results of the grade confirmation assays indicate a strong correlation between historical and 2015 results, although a detailed comparison is beyond the scope of this report.

Geophysical surveys for the 2015 KZK Project included airborne magnetic and VTEM, ground-based gravity and downhole EM. The airborne survey comprised 304 line-km that covered 37 km^2 of two survey blocks on the KZK Property. A 1623 station ground-based gravity survey focussed on the prospective stratigraphy that extends from GP4F through ABM to the Rhyolite Peak area. Downhole EM surveys were undertaken on seven of the 10 DDHs drilled in the GP4F area, and one of the ABM DDHs. Results from all three geophysical surveys were integrated to identify single- and multi-parameter targets including Tarawera (VTEM, gravity), Tambora (VTEM), Tarumae (magnetic, gravity) and Lakagigar (VTEM, magnetic).

The exploration, infill and expansion drill program on the KZK Property comprised 99 DDHs for 21279.7 m of diamond drilling, with work focussed on the ABM lens (59 DDHs, 10334 m), the Santorini target also within the ABM Zone (2 DDHs, 457 m), the newly discovered Krakatoa Zone immediately east of the ABM Zone (26 holes, 6816 m), the nearby Fault Creek target (2 holes, 382 m) and the GP4F deposit (10 holes, 3291 m). A total of 3513 half-core samples were collected and submitted for assay (Cu, Fe, Pb, Zn, Au, Ag ± Ba, S, As, Bi, Hg, Sb, Se), along with 443 QA/QC samples and the previously mentioned 1656 samples from the re-logging program for a grand total of 5603 samples. In addition, 4990 bulk density measurements were taken using the water immersion method. The additional drilling and more accurate bulk density measurements than used historically added 1.3 Mt to the Indicated and Inferred resource total on the ABM Zone. Several areas were also identified for future expansion drilling including the western, northern (down-dip) and eastern margins of the ABM lens.

ABM Zone targets include Santorini and the ABM deep horizon inferred to lie stratigraphically beneath the ABM lens. The two holes drilled into the Santorini target intersected thin intervals of sulphide mineralization that could be stratigraphically equivalent to the Krakatoa Main lens and this remains open to the north-northeast. Work on the ABM deep target, which comprised a review of historical intercepts and drill testing with one hole piggy-backed onto an ABM resource hole, suggests some potential for small mineralized pods along this horizon, and follow-up work is recommended for several untested areas.

The discovery of the Krakatoa Zone was the highlight of the 2015 KZK field season, with the most recent resource estimate (Green et al., 2016) showing that it adds 5.1 Mt of combined Indicated and Inferred resources at 0.6% Cu, 3.2% Pb, 7.5% Zn, 1.7 g/t Au and 213 g/t Ag. The Krakatoa Zone lies east of the East Fault which separates it from the ABM Zone, principally within a mafic sill that occurs immediately below the ABM lens stratigraphic horizon. Collectively the ABM and Krakatoa zones comprise the ABM deposit. The 2015 program defined the Krakatoa Zone from its discovery depth (~300 m) to the surface and to the east and west, where it is bound by the late-stage Sunda fault and East faults respectively. However, the Krakatoa Main lens remains open down-dip and additional expansion drilling is recommended.

The two holes drilled at the nearby Fault Creek target were less successful, although they did support the structural re-interpretation of the area.

Resource and exploration drilling in the GP4F area expanded the GP4F lens, identified two related lenses (Upper and Lower targets) and possibly intersected the northern strike extension of the R-15 deposit, located off the Property 600 m to the southeast, within KZK claims. Further work in this area is recommended to focus on expanding the GP4F lens to the north-northeast and testing the ground between the GP4F and R-15 deposits.

The metallurgical (29 holes, 3406 m), geotechnical (9 holes, 955.4 m) and hydrogeological (11 holes, 325 m) drilling programs were successfully completed as part of the 2015 KZK field season although no additional results were available at the time of this report.

Table 1: Summary of work done and filed for the 2015 KZK Project

Program	Work Type	Description	Filed?
Pre-work program construction	Tote road rehabilitation	Repair of bridge platform and culverts, rehab along 24 km length	Yes
	Camp construction	49 person exploration camp, septic field, bulk fuel storage	Yes
Re-logging and compilation	Historical core re-logging	Re-logged 174 out of 201 historical holes (87%) for 24952.8 m	Yes
	Data compilation	Scanned and digitized numerous boxes of Cominco data, constructed database of historical drilling and sampling data	No
Terrain surveys	LiDAR survey	33 km² survey over the ABM deposit and mine infrastructure locations	Yes
	Drill hole collar survey	Surveyed most 2015 and historical drill collars	Yes
	Tote road survey	Surveyed full 24 km length of tote road	Yes
Geophysics	Airborne magnetics and EM	304 line-km VTEM and magnetic survey	Yes
	Ground-based gravity	1792 gravity stations on three targets	Yes
	Downhole EM	8 holes	Yes
Resource and exploration drilling	ABM lens	59 holes for 10333.6 m	Yes
	ABM-proximal (Krakatoa., Santorini, Fault Creek)	30 holes for 7655.1 m	Yes
	GP4F	10 holes for 3291 m	Yes
Metallurgical drilling and sampling	Drilling and sampling	29 holes for 3406 m plus 27 piggy-backed holes, 1012 samples collected	Yes
	EDTA	312 sample pulps	Yes
Petrographic studies	Polished thin section analysis	96 thin sections analyzed, some microprobe and LA-ICP-MS analysis	Yes
Geotechnical drilling and engineering	Drilling and down hole test work	9 holes for 955.4 m; geotechnical characterisation reporting for waste infrastructure sites in progress at time of report writing	Yes
Hydrogeological drilling and environmental	Hydrogeological drilling	11 holes for 325 m plus seven piggy-backed holes; data analysis in progress at time of report writing	Yes
	ARD kinetic testing	236, 3 kg samples collected for static tests + 123 samples collected for field barrel kinetic tests; geochemical testing and data analysis ongoing at time of report writing	Yes
	Baseline environmental studies	Water quality, wetland, vegetation and wildlife surveys	Yes

1.0 INTRODUCTION

This report has been prepared for BMC Minerals (No. 1) Ltd ("BMC") in order to document the procedures and results of the 2015 exploration work undertaken on the KZK Property and to satisfy assessment reporting requirements for the Yukon Department of Energy, Mines and Resources ("EMR"). Equity Exploration Consultants Ltd. ("Equity") was engaged by BMC to undertake the 2015 KZK fieldwork and to prepare this assessment report. The report has been prepared on the basis of personal observations, assessment reports filed with EMR, data and reports supplied by BMC, regional geological publications by the EMR, and on the 2015 fieldwork undertaken by Equity under the direct supervision of the authors. A complete list of references is provided in Appendix A.

Units and abbreviations used in this report are as follows:

Units:

cm	centimetre
C$	Canadian dollar
g	gram
g/t	grams/tonne
km	kilometre
kg	kilogram
Koz	thousand troy ounces
Kt	thousand tonnes
kW	kilowatt
m	metre
mGal	milligal
mm	millimetre
Mt	million tonnes
Moz	million troy ounces
nT	nanotesla
ppm	part per million
psi	pounds per square inch
"	inch

Abbreviations:

AAS	atomic absorption spectroscopy (an analytical technique)
AES	atomic emission spectroscopy (an analytical technique)
Ag	silver
APS	azimuth pointing system (a DDH orientation system)
ARD	acid rock drainage
As	arsenic
Au	gold
Ba	barium
Bi	bismuth
CRM	certified reference material (QA/QC standard)
CV_{AVR}	average coefficient of variation
Cu	copper
DDH	diamond drill hole
DGPS	differential global positioning system
DO	dissolved oxygen
E	east
EM	electromagnetic
EDTA	ethylenediaminetetraacetic acid (a metallurgical test)
EMR	Yukon Department of Energy, Mines and Resources
Fe	iron

GNSS	global navigation satellite system
GPS	global positioning system (a location method)
Hg	mercury
HLEM	horizontal loop EM
HQ	drill core measuring 63.6 mm in diameter
HQ3	drill core measuring 61.2 mm in diameter
ICP	inductively coupled plasma (an analytical technique)
ID	identification
KZK	Kudz Ze Kayah
LiDAR	Light Detection And Ranging (a remote topographical surveying method)
MS	mass spectrometry (an analytical technique)
Ma	million years ago
N	north
NAD83	North American Datum (1983)
NNE	north-northeast
NQ3	drill core measuring 45.2 mm in diameter
ODEX	overburden drilling excentric (a drilling technique)
ORP	oxidation-reduction potential
Pb	lead
pH	measure of hydrogen ion concentration (acidity)
PVC	polyvinyl chloride (a plastic)
QA	quality assurance
QC	quality control
RQD	rock quality designation
RTK	real-time kinetic (a GPS enhancement)
S	sulphur
Sb	antimony
Se	selenium
SEPA	2004 Socio-Economic Participation Agreement between BMC and Ross River Dena Council
SEM	scanning electron microscope
SPC	specific conductivity
SPT	Standard Penetration Test
SW	southwest
TSF	tailings storage facility
UTEM	University of Toronto electromagnetic (a geophysical technique)
UTM	Universal Transverse Mercator
UV	ultraviolet
VMS	volcanogenic massive sulphide
VTEM	versatile time-domain electromagnetic (a geophysical survey system)
VWP	vibrating wire piezometer
WAAS	wide area augmentation system (a GPS enhancement)
WAD	weak acid dissociable
wt%	weight per cent
X	a horizontal axis
XRF	X-ray diffraction (an analytical technique)
Z	vertical axis
Zn	zinc

2.0 RELIANCE ON OTHER EXPERTS

In Section 3.0, the authors have relied entirely upon information provided by BMC concerning their purchase agreement with Teck and the extent of any underlying interests and royalties. Also in Section 3.0, the authors have relied entirely on the Geomatics Yukon website for downloaded shapefile tenure data. Also in Section 3.0, the authors have relied entirely upon information provided by BMC regarding their Socio-Economic Participation Agreement ("SEPA") with the Ross River Dena Council. The authors have not relied upon a report, opinion or statement of another expert concerning legal, political, environmental or tax matters relevant to this assessment report.

3.0 PROPERTY DESCRIPTION AND LOCATION

Two properties (KZK and Pelly) are controlled by BMC in the Finlayson Lake area of Yukon, but this report covers only the KZK Property. The KZK Property consists of 879 quartz claims that cover an area of approximately 16005 hectares (160 km^2) of south-central Yukon (Figure 1). It is centred at 61˚ 31' N latitude and 130˚ 33' W longitude (NAD83 UTM Zone 9: 416000E 6817000N) on NTS map sheets 105G/7–10, within the Watson Lake Mining District.

The KZK Property consists of three separate claim blocks. The main claim block, with 864 contiguous claims, covers an area of about 11 km x 20 km and hosts the ABM and GP4F deposits. A single line of claims extends north-easterly from the main claim block for 14 km to Finlayson Lake in proximity to the tote road. The EL 1–8 and Limy 1–9 claim blocks are not contiguous with the other claim blocks, lying a few kilometres to the west and east of the tote road respectively (Figure 2). Mineral claim data is summarized in Appendix C. All claims were acquired through staking on the ground. The area covered by each claim is determined by the location of the two claim posts on the ground. A professional surveyor surveyed the key claims in the vicinity of the ABM deposit (Schultze, 2001) in 1994 but the survey was never filed with the government and there is some discrepancy between the location of claims from the 1994 survey and the shapefile tenure data obtained from the Geomatics Yukon website and used in this report.

All claims are registered in the name of BMC Minerals (No. 1) Ltd. ("BMC"). BMC purchased the KZK Property 100% from Teck on 24th January, 2015 and there are no residual royalties across the known mineral resources. The KZK Property area is covered by a 2004 SEPA between BMC and the Ross River Dena Council on behalf of the Kaska First Nation. No significant environmental liabilities were noted by the authors on the KZK Property other than the tote road.

The claims confer title to hard rock mineral tenure only. Surface rights are held by the Crown, as administered by the Yukon Territory. Trapping rights over the western portion of the KZK Property are held by the Ross River Dena Council under Group Trapline #405, while Ted and Franklin Charlie hold trapping rights over the rest of the Property under Single Holder Trapline #250. KZK overlaps with part of Outfitter Concession #20, held by Yukon Big Game Outfitters. There are several parcels of land in the vicinity of the KZK Property which have been reserved for a future land claim settlement with the Ross River Dena Council. Most importantly, a parcel of Interim Protected Land (RRDC-R15A) adjoins the southern boundary of the KZK Property and covers the along-strike continuation of host stratigraphy for the GP4F deposit. Teck explored the RRDC-R15A parcel in 2004, successfully identifying the R-15 VMS prospect (MacRobbie and Holroyd, 2005a). Currently, staking is not permitted within a large area surrounding the KZK Property due to a government moratorium.

Yukon law requires eligible assessment expenditures of C$100/claim/year on the KZK Property to extend tenure ownership past the current expiry dates. Five claim groupings, containing a maximum of 750 contiguous claims, making up the KZK Property were filed with EMR to allow the representation of work done on one or more claims to be distributed to other claims where work was not done.

Exploration programs in Yukon are divided into Class 1 (grassroots) through Class 4 (advanced), depending on threshold levels of camp man-days, fuel storage and extent of exploration activities. In the KZK area, notification of EMR is required for Classes 1 and 2, but submittal of a plan of operations and granting of a Quartz Mining Land Use Permit by EMR is necessary prior to undertaking Class 3 and 4 programs. The 2015 KZK exploration work was carried out under Class 3 Quartz Mining Land Use Permit LQ00424, which is valid from June, 2015 to June, 2020.

The KZK Property lies within the traditional territory of the Ross River Dena Council. Land claims have not been settled in this part of Yukon and their future impact on the Property's access, title or the right and ability to perform work remain unknown. However, the SEPA provides assurances that the Ross River Dena Council will support exploration and mining of the Property, subject to certain terms and conditions.

4.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, PHYSIOGRAPHY

4.1 Accessibility

Access to the KZK Property is via a 24 km long, gated, single-lane gravel tote road that connects to the Robert Campbell Highway (Highway 4) near Finlayson Lake, at a point 135 road-km east of Ross River and 237 road-km northwest of Watson Lake. Fixed wing aircraft can land on Finlayson Lake or at an airstrip located at its northwestern end.

The mainly gravel Robert Campbell Highway connects the Property to Watson Lake on the paved Alaska Highway and Carmacks on the paved Klondike Highway, giving access to Whitehorse and points south (Figure 1). All highways are maintained by the government for use year-round but maintenance of the tote road is the responsibility of the KZK Project operator. The ABM deposit on the KZK Property is accessible by the tote road for tractor-supported drilling, but helicopters are still necessary for access to most of the remainder of the Property, including the GP4F deposit.

4.2 Local Resources and infrastructure

Ross River, the nearest settlement to the KZK Property, has a population of about 300 and provides basic services (groceries, fuel, accommodation and meals). Whitehorse (population 25000), which is located 260 km west of KZK, offers a full range of services and supplies for mineral exploration and mining, including skilled and unskilled labour, bulk fuel, freight, heavy equipment, groceries, hardware and daily jet service to Vancouver (Figure 1).

The Yukon electrical grid supplies 138 kV electrical power to Faro, located 170 km northwest of the KZK Property but only 25–34 kV electricity to Ross River. Concentrates from the Wolverine Mine, located 25 kilometres to the east of KZK, were trucked 900 kilometres south to port facilities at Stewart, BC prior to Wolverine's temporary shutdown in early 2015.

4.3 Physiography and climate

The KZK Property, which lies in the Pelly Mountains, covers portions of several creeks which ultimately drain north-easterly into the Finlayson River. The ABM deposit lies near the head of Geona Creek and the tote road and the north-easterly trending "tail" of claims follows the Geona Creek valley northeast towards Finlayson Lake. The topography is fairly rugged, and typical of mountainous terrain. Elevations range from 1000 m ASL near Finlayson Lake to over 2000 m ASL on the peaks southwest of the ABM deposit. The surface elevations in the vicinity of the ABM and GP4F deposits are between 1300 and 1500 m ASL.

Below the tree line (1350–1500 m), white and black spruce are the most common tree types. Black spruce is usually dominant in wetter areas; white spruce predominates in drier areas. Paper birch, aspen,

balsam and lodgepole pine are also present. Alpine fir grows near the tree line. In dense coniferous stands, feather moss dominates the understory, but in more open areas willows and heath-like shrubs become prevalent.

Sedge or sphagnum tussocks are common in wetlands and under black spruce. Shrub birch and willow occur in the sub-alpine and extend well above the tree line.

The climate is cold continental with a mean daily summer temperature of 15˚C and a mean daily winter temperature of -25˚C. Precipitation falls fairly evenly throughout the year, predominantly as rain from May through September, and snow for the balance of the year. The mean annual precipitation is 655 mm. Groundwork on the property is possible from June until October, while snow may cover parts of higher elevations late into the summer. Drilling can be conducted year round by using heated water for drilling.

During the last glacial period, ice moved across the eastern part of the area in a northwesterly to westerly direction and extended to heights of about 1525 m (Ritson, 2000).

5.0 HISTORY

The following description of pre-2004 exploration history of the KZK Property has been adapted from MacRobbie and Holroyd (2005a).

No work had been reported in the KZK area prior to 1992, when Cominco Ltd. (“Cominco”), which merged with Teck Corp. in 2001 to form Teck Cominco Ltd. (and ultimately Teck Resources Ltd., both of which are referred to as “Teck” in this report), collected soil and silt geochemical samples along Geona Creek. This work confirmed an anomalous regional silt sample from earlier work (Hornbrook and Friske, 1988) and expanded the extent of geochemical anomalism. In the following year prospector A. B. Mawer discovered a well-mineralized, layered sulphide cobble in the anomalous drainage area. This was immediately followed by a reconnaissance UTEM geophysical survey over the projected trace of the suspected host stratigraphy, thereby outlining an EM conductor. Staking of the first TAG claims over the conductor was accompanied by a ground magnetic survey. Further magnetic and horizontal loop EM and soil surveys were completed later that fall, defining a compelling drill target (Schultze, 1993).

The target was drilled in April 1994, with the first hole intersecting 22.5 m of massive sulphide in two sections (Schultze, 1995). Three additional holes were drilled in April, and each of them intersected sulphide mineralization over significant widths. The weighted average grade of sulphides in the discovery hole was 0.5% Cu, 2.8% Pb, 10.0% Zn, 278 g/t Ag and 2.9 g/t Au. The sulphide body was named ABM after A. B. Mawer, the long-time Cominco prospector who made the initial float discovery.

In total, 52 diamond drill holes (DDHs) (8485 m) were drilled in 1994 along with ground and airborne geophysical surveys, detailed mapping in the vicinity of the deposit, regional and detailed exploration geochemistry and baseline environmental sampling (Schultze, 1996).

In 1995 an additional 133 DDHs (16178 m), were completed at the ABM deposit and on regional targets. Additional exploration soil sampling, minor geological mapping and ground geophysical surveys were completed (Schultze, 1996). Geotechnical investigations (Stacey, 1996), detailed engineering/mine planning, bulk metallurgical sampling, environmental monitoring and archaeological studies were well underway or completed, as well as the construction of a 24 km all-weather tote road from the Robert Campbell Highway. A pre-feasibility engineering study was completed by Cominco in July 1995 (Brown, 1995).

The 1996 program involved regional, 1:20,000 scale geological mapping outside the immediate ABM deposit area, minor line cutting, ground geophysical surveys and soil geochemistry over the northeastern part of the TAG Property. Diamond drilling of a DDH (99 m) was completed in the southwest corner of the current KZK Property. Minor structural mapping and core logging were completed at the ABM deposit.

The 1997 program consisted of 2 main components: line cutting/ground geophysical surveys and diamond drilling. Extensive ground geophysical surveys (UTEM/magnetics) were conducted over the newly cut extension of the Main Grid to the east of the ABM deposit. Minor HLEM/magnetics and gravity surveys were conducted over existing EM/magnetics targets proximal to ABM. A total of 17 DDHs (K97-172 to 187; 3566 m)

were completed; 7 DDHs tested the down dip/plunge and fault offset margins of the ABM deposit, 2 DDHs tested regional targets and 8 DDHs were completed in the Fault Creek area. Discovery of the Fault Creek target (DDH K97-181; 6.4 m at 5.2% Cu, 1.0% Pb, 5.6% Zn, 141 g/t Ag and 2.4 g/t Au), a poorly defined occurrence of massive to semi-massive sulphide mineralization, was significant as it represented the first discovery of significant sulphides south of the Fault Creek Fault (MacRobbie and Bannister, 1998).

To the end of 1997 a total of 168 exploration DDHs and 15 metallurgical DDHs had been completed in the immediate ABM deposit area and another 20 DDHs were completed elsewhere on the property, including 8 DDHs in the Fault Creek target area. Environmental studies, metallurgical testing and permitting activities were ongoing.

In 1998 additional line cutting, soil sampling and limited ground geophysical surveys were completed in several areas. A further 11 DDHs (K98-188 to 198; 1755 m) were completed; 9 DDHs tested the immediate GP4F area and 2 DDHs tested a UTEM/HLEM/magnetics feature northeast of the GP4F deposit (MacRobbie and Holroyd, 1999). The most significant result was the discovery of the GP4F deposit (with a non-compliant estimate by Cominco comprising 1.5 Mt grading 0.1% Cu, 3.1% Pb, 6.4% Zn, 89.7 g/t Ag and 2.0 g/t Au) located 5 km southeast of ABM. Additional airborne EM and magnetic surveys over the eastern half of the R-15 block south of the KZK Property indicated several excellent airborne EM/magnetic targets in the GP4F area (MacRobbie and Holroyd, 2000).

In 1999 a small geophysical program was completed, including an In-Loop UTEM survey over the GP4F deposit and minor HLEM/magnetics in the GP4F deposit area (MacRobbie and Holroyd, 2000).

In 2000 the KZK Property and properties in the Wolverine Lake area were optioned to Expatriate Resources Ltd. (“Expatriate”), a predecessor company to Yukon Zinc Corporation, which currently owns the Wolverine VMS deposit located 23 km east of ABM (Schultze, 2001). Expatriate carried out ground geophysical surveys (UTEM/magnetics) in the area south of the ABM deposit and extending south of the Fault Creek target (Klein, 2000). Expatriate allowed the option to lapse in late 2001.

In 2004 Teck optioned the R-15 block, immediately south of the KZK Property, from Kaska Minerals Corporation, an entity controlled by the Kaska First Nation in Ross River. That summer, Teck carried out mapping, ground geophysical (UTEM and magnetic) surveying and drilled 7 DDHs (1481 m) on the R-15 block, discovering the R-15 deposit. The program extended north into the area of the GP4F deposit on the KZK Property, which received 6.8 line-km of UTEM, 0.4 line-km of magnetics and one DDH (K-199; 246 m) (MacRobbie and Holroyd, 2005a).

The R-15 option was subsequently terminated and no further exploration was done on the KZK Property until January, 2015, when BMC purchased it from Teck.

Several mineral resource estimates have been completed for the ABM and GP4F deposits both historically by Cominco and Teck and more recently by CSA Global Pty Ltd (“CSA”) for BMC when they acquired the project in 2015. Table 2 shows the mineral resource estimates reported for the two deposits.

Table 2: Historical mineral resource estimates for the ABM and GP4F deposits

Deposit	Year	Category	Mt	Cu (wt%)	Pb (wt%)	Zn (wt%)	Au (g/t)	Ag (g/t)	Reference
ABM	Nov 1994	pre-NI43-101	14.04	0.88	1.33	5.61	1.17	125.0	(Green et al., 2016)
	Nov 1994	pre-NI43-101	13.85	0.97	1.30	5.45	1.19	126.9	(Green et al., 2016)
	Apr 1995	pre-NI43-101	13.7	0.98	1.3	5.5	1.24	128	Cominco, 1995

6.0 2015 WORK PROGRAM DESIGN

Work at KZK during 2015 comprised a multi-faceted exploration and development program that included maintenance of historical and construction of new exploration trails, compilation of historical data, re-logging of historical drill core, LiDAR survey, differential global positioning system survey of the tote road and historical drill collars, geophysical surveys (airborne, ground-based, downhole), resource and exploration drilling, metallurgical drilling and sampling, petrographic studies, geotechnical drilling and engineering, hydrogeological drilling and environmental baseline studies.

6.1 Pre-work program construction

Pre-work program construction work included rehabilitation of the 24 km gated tote road that connects the Robert Campbell highway to the former Cominco exploration camp near the ABM deposit and the construction of a new temporary exploration camp for the 2015 work program away from the principal work area

An assessment of the tote road was completed by Onsite Engineering Ltd. (“Onsite”) on 27th May, 2015 to ensure that the exploration activities, including heavy machinery (drill rigs, earthworks equipment and transport trucks) and light vehicles, would have safe access to the project site without degrading the existing road conditions. An engineer’s report detailing the tote road assessment is attached in Appendix D. Rehabilitation earthworks involved repairing two wash outs with new and additional culverts and the road was re-ballasted as needed. The road surface was also re-established to an appropriate profile and cross drain culvert sumps were all cleaned out. The bridge that crosses Finlayson Creek at the 17 km marker was also repaired due to failed abutments and inappropriate decking for heavy loads. Work was undertaken by Moon contracting from Ross River, Yukon, between 30th June and 9th July, 2015 using 250 and 290 excavators. Ongoing road maintenance continued throughout the season using a grader to maintain the road surface as required.

No established camp facilities were present on the KZK Property prior to commencing the 2015 work program so facilities had to be constructed appropriate for the magnitude and scale of the project. A relatively flat site was selected just off the tote road at kilometre 19.5 (from the gatehouse) that was centrally located away from the immediate ABM work area and a relatively short helicopter flight to GP4F. Camp construction was completed by Equity with a 15 person team between 8th July and 31st July, 2015 using numerous contractors from both Whitehorse and Ross River, Yukon. For a detailed description of camp facilities that have been established on the KZK Property refer to section 8.1.

6.2 Data compilation and re-logging

Data compilation and re-logging work programs were initiated prior to the start of the 2015 field season. Much of this work continued through the duration of the field program and for up to several weeks afterwards.

Data compilation work included scanning of all paper documents obtained from Teck, digitizing of selected maps and sections and the aggregation of geological and geochemical data into digital databases. ScanHouse Canada, of Burnaby, BC was sub-contracted to complete the scanning. All documents scanned by ScanHouse have been catalogued into an Excel spreadsheet that is indexed with searchable keywords.

Digital compilation work was completed in MapInfo, MicroMine and Microsoft Access. A database of historical drilling and surface sample campaigns conducted by Cominco and Teck between 1994 and 2004 was developed by OMI Pty Ltd of Hobart, Tasmania, Australia using data supplied by BMC after validation against scanned hard copy documents and drill logs. As neither the data nor digital compilation work will be filed for assessment credits there will be no further mention of this work in this report.

Re-logging of historical drill core was completed to bring historical logs into context, confirm historical assays, understand and improve the ABM geological model, as well as establish consistent logging procedures and protocols for the 2015 drill program. The re-logging program was undertaken by Equity personnel from July 2nd to October 6th 2015, based out of a tent camp established near Cominco's historical core archive. This archive was found to be in generally good shape and required only minimal restorative work (e.g. replacing worn out core boxes, metal tags). Core was re-logged outdoors, generally at ground level by a team of up to six geologists. Information was collected on ruggedized computers using GeoSpark core logging software. Hard copy sections were updated and working geological interpretations were used to elucidate the larger deposit features. A total of 174 DDHs were re-logged for a total of 24953 m, comprising most of the historical ABM and Fault Creek drilling as well as two DDHs from GP4F. To establish the quality of historical assay results, the remaining half-core was sampled from all of the mineralized intervals on sections 414750E, 414850E and 415050E. Historically un-sampled intervals of weakly mineralized to barren, wall rock lying 4.5–6.0 m outward from the massive sulphide contacts were also sampled as part of the 2015 core re-logging program. These samples were submitted to the SGS laboratory in Burnaby, BC for geochemical analysis using the same procedures as core samples collected as part of the 2015 resource and exploration drilling program (see section 6.1.5). Historical core was also re-photographed after logging and prior to sampling.

6.3 Terrain surveys

Terrain surveys included an airborne LiDAR survey and differential GPS (DGPS) surveys of both historical and 2015 DDH collar locations as well as the tote road. Procedures and methods used for these programs are summarized below.

A 33 km² airborne LiDAR survey was completed over the ABM deposit and potential mine infrastructure locations to provide a high resolution topographic surface that can be used for detailed mine design work. The survey was completed by Airborne Imaging from Calgary, Alberta, on the 27th September, 2015 using a fixed wing aircraft equipped with a Leica ALS70 LiDAR system. The survey was flown at a height of 1300 m and a speed of 160 knots with a scan angle of 50° below the aircraft. Nine-and-a-half points per square meter were recorded during the survey providing a horizontal and vertical accuracy of approximately 35 cm and 15 cm respectively. To statistically quantify the accuracy of the survey, LiDAR elevations were compared with ground points independently surveyed by Challenger Geomatics Ltd. ("Challenger") of Whitehorse, Yukon from a base station positioned in the survey area between 24th September and 28th September, 2015. A report detailing the LiDAR survey methodology is attached as Appendix F.

Both the drill collar and tote road surveys were completed by Challenger with the historic collar survey and tote road survey occurring between 14th July and 6th August, 2015 followed by surveying of completed 2015 drill collars from 6th October to 9th October, 2015. Both surveys were completed in NAD83 UTM Zone 9 with Leica Geomatics Ltd. Real Time Kinematic (RTK) DGPS survey equipment and Leica Viva Global Navigation Satellite Systems (GNSS). Radio base stations were set up in proximity to the survey sites providing RTK corrections for most of the KZK survey measurements when radio contact was possible. For the GP4F drill collar survey radio contact with base stations was not possible so the GNSS vectors were post-processed

to provide the final survey location. Due to time constraints several 2015 DDHs were not surveyed by Challenger therefore the final collar location presented in the drill logs is derived by integrating eastings and northings derived from an azimuth positioning system (APS) with elevations corrected to the LiDAR topographic surface. Metallurgical wedge DDHs drilled from the same collar location as the parent DDH were given the same finalized collar locations as the parent.

The tote road survey mapped out its full length at 20 m-spaced points along the centre line between the Robert Campbell Highway and the ABM exploration site. A survey methodology letter provided by Challenger is attached as Appendix G, and coordinates for all surveyed 2015 and historical drill collars on the KZK Property are presented in Appendix H.

6.4 Geophysical surveys

Geophysical surveys completed as part of the 2015 work program included an airborne electromagnetic (EM) and magnetic survey, ground-based gravity and downhole EM. The procedures and methods used for each of these surveys is summarized below and described in more detail within the attached logistical reports (Appendices I, J and K respectively).

A 304 line-km airborne EM and magnetic survey was flown over the KZK Property to follow up on several historical ground-based EM and magnetic targets, as well as to identify anomalous areas that could reflect additional VMS targets. Work was undertaken by Geotech Ltd. from North Aurora, Ontario, between 22nd August and 7th September, 2015 with helicopter service provided by Access Helicopters of Red Deer, Alberta, using an Astar 350 B3. The survey was flown as part of a larger survey on all of BMC's property holdings in the area. Only the KZK and Limy airborne survey blocks will be mentioned in this report.

The KZK airborne geophysical survey covered an area of approximately 35 km² and was flown in a northeast to southwest direction (azimuth 15° east of north). The Limy survey covered an area of 2 km² and was flown in a north-south direction. Both survey blocks consisted of a traverse line spacing of 150 m. Tie lines were flown perpendicular to the traverse lines at a spacing of 1500 m (KZK) and 2000 m (Limy) respectively. Navigation was achieved using a NovAtel WAAS enabled GPS receiver and screen display for the pilot and a NovAtel GPS antenna mounted on the helicopter tail. During the survey an average altitude of 77 m above ground surface was maintained using a Terra TRA 3000/TRI 40 radar mounted beneath the bubble of the helicopter cockpit. The survey was flown at an average speed of 80 km/hr.

Data acquisition was made with a Geotech VTEMplus system with receiver and transmitter coils in a concentric-coplanar and Z direction oriented configuration. The receiver system also included a coincident-coaxial X direction coil. The transmitter-receiver loop was towed at a mean distance of 31 meters below the helicopter with measurements consisting of the vertical (Z) and In-line horizontal (X) components of the EM fields. The aeromagnetic total field was measured using a horizontal magnetic gradiometer with two caesium sensors. The sensors are mounted 12.5 meters apart on a separate loop, 10 meters above the transmitter-receiver loop. A GPS and gyro inclinometer are also installed on this loop to accurately record the tilt and position of the magnetic bird. A magnetometer/GPS base station was also utilised for the survey and set up away from all infrastructure. Base station data was used during the post-processing of survey data at the end of each day. A logistics report provided by Geotech is attached as Appendix I.

A ground-based gravity survey was completed over a 6 km x 2 km area, covering Rhyolite Peak as well as the ABM and GP4F deposits, with the aim of identifying positive gravity anomalies that might reflect additional VMS targets. Work was undertaken by Aurora Geosciences Ltd. ("Aurora") from Whitehorse, Yukon, between 9th August and 16th October, 2015. Gravity crews accessed the survey grid by either truck or side-by-side ATV, and at times required helicopter support provided by Trans North Helicopters ("Trans North") from Whitehorse, Yukon, depending on the proximity of the survey grid to the tote road.

The gravity survey over the ABM deposit consisted of a single line (line 7) that runs north up the Geona valley. The survey in the GP4F area comprised 25 NNE-trending lines spaced 200 m apart (lines 8–32) as well as two short lines (lines 37 and 38) running ESE over the GP4F deposit and the area to the west of the deposit. The Rhyolite Peak survey area was split into two blocks. Lines 1–6 covered a plateau area and have a line

spacing of 300 m whereas lines 33–36 were spaced at 200 m and covered a VTEM anomaly west of the ABM deposit (the “Tarawera target”).

Each survey station was located in the field with a handheld GPS at 50 m separations, with the station preferentially located on rock outcrop. If no outcrop was found the site was cleared of vegetation prior to surveying. The gravity meters were levelled on the site and allowed to settle for a minimum of 90 seconds (instrument 1368) or five minutes (instrument 349) prior to survey. A total of 1792 gravity stations were surveyed with a Scintrex CG-5 Gravimeter comprising 1602 planned stations, 21 unplanned stations and 169 repeat stations. A minimum of two readings were stacked for a minimum of 20 seconds at each station with repeat readings kept to less than 0.03 mGal if possible. If this was not possible then three readings were taken to ensure that data was repeatable to within 0.03 mGal. Filters were used to remove seismic and wind noise, and physical wind blocks were used to reduce wind noise as necessary. Prior to, and following, daily surveying, readings were taken at control stations established within the project area. These readings were repeated until they fell within 0.01 mGal.

Each gravity station was surveyed with an RTK DGPS to provide vertical control for the gravity reductions when processing the data. DGPS readings were taken in the same location as the gravity readings using a Leica GS15 RTK DGPS system. Survey base stations were established in conjunction with the gravity control stations providing RTK corrections via a radio link as well as recording the data to disk. A logistics report describing the 2015 gravity survey and processing procedures used by Aurora is attached as Appendix J.

A downhole EM survey was completed on seven exploration DDHs in the GP4F area and one exploration DDH at Krakatoa in an attempt to detect off-hole EM conductors that could represent sulphide mineralization and provide additional drill targets. Work was undertaken by Aurora between August 21st and October 16th, 2015. Downhole EM measurements were made using a Digi-Atlantis downhole EM probe with a Geonics TEM-67 transmitter and SMARTem24 Receiver with power supplied by a Honda 5 kW generator. Surveyed DDHs were located inside the transmitter loop with the loop positioned to have good coupling with the expected conductor geometry. Three loops were utilised at GP4F during the course of the program that were expanded to incorporate all surveyed DDHs. A single 400 m² loop was used at Krakatoa. Survey stations were located via a winch counter usually at 5 m intervals with the EM probe set to zero at the top of the drill collar. Some survey stations were completed at 2.5 m intervals where anomalous areas were noticed by the operator. Measurements were made for three components at each survey station: (downhole, cross-hole parallel to dip and cross hole perpendicular to dip) utilising 27 channels (channel 1 = early time, channel 27 = late time). A logistics report provided by Aurora is attached as Appendix K.

6.5 Geological resource and exploration drilling

The 2015 resource and exploration drilling program included confirmation, infill and expansion drilling at the ABM lens, infill and exploration drilling on several ABM-proximal targets (Santorini, Krakatoa, Fault Creek) as well as infill and exploration drilling at the GP4F deposit, located about 5 km to the southeast of ABM. A total of 99 DDHs, for 21279.7 m, were completed, 59 of which were on the ABM lens, 30 on ABM-proximal targets (with 26 on the Krakatoa Zone) and 10 on the GP4F deposit (Table 3). Thirty-two of the ABM resource DDHs also met objectives for the metallurgical and hydrogeological work programs (see sections 6.6 and 6.9).

At the ABM lens, confirmation DDHs were designed to twin mineralized intersections to confirm the existence and tenor of massive sulphide mineralization in historical DDHs on sections 414750E, 414850E and 415050E, and to permit resampling of historic DDH intercepts on these sections for analytical quality assurance purposes in relation to the historic assay data. In this process these sections were completely re-drilled. The remaining ABM infill drilling was designed to reduce the drill spacing to nominal 25–30 m pierce points and to infill between widely spaced historical DDHs. An extension program was designed to expand the ABM lens to the east, west and down-dip of the historically-defined resource, in an effort to add to the mineral inventory. Exploration drilling at Krakatoa and Fault Creek were designed to follow up on geological targets and at Santorini was designed to follow up on geophysical targets identified from the 2015 airborne VTEM survey. A resource definition program was also completed at Krakatoa to follow up on the discovery DDH K15-282, which hit three 2 m to 9 m thick massive sulphide lenses between 243 m and 315 m down hole. Widely spaced infill

drilling at GP4F was completed on sections 419400E and 419500E, and step-out exploration drilling was completed up to 200 m east and northwest of the GP4F deposit.

All diamond drilling was completed by Geotech Drilling Ltd. ("Geotech") of Prince George, BC, from 30th July to 28th November, 2015. Drilling on the ABM lens and ABM-proximal targets was completed with three skid-mounted diamond drill rigs (one Zinex A5 and two Hydracore 2000 machines). Drilling at GP4F was completed with one Hydracore 2000 helicopter-portable rig, with helicopter support provided by Trans North. Surveyed drill collar locations are presented in Appendix H and drill logs are attached as Appendix L. Sectional interpretation of all drilling is attached as Appendix M.

Table 3: Summary of the 2015 KZK Project exploration and resource drilling program

Deposit	Zone	Target	Type	N.o. DDHs	Metres	Comments
ABM	ABM	ABM lens	Resource*	26	4466.6	Includes 1 abandoned DDH for 47 m
			Resource*/hydrogeological	5	1161.0	
			Resource*/metallurgical	25	4112.0	Includes 1 abandoned DDH for 72.7 m
			Resource*/metallurgical/hydrogeological	2	232.0	
			Exploration	1	362.0	
		Santorini	Exploration	2	457.0	
	Krakatoa		Resource*	15	3254.4	
			Exploration	11	3561.7	
		Fault Creek	Exploration	2	382.0	
GP4F	GP4F		Resource*	5	1506.0	
			Exploration	5	1785.0	
		2015 Total		**99**	**21279.7**	

Notes: * includes resource confirmation and resource definition DDHs

DDH collars were spotted with either handheld GPS, DGPS or the GPS attached to the Reflex APS. The majority of collar coordinates were also measured with an RTK DGPS as part of the post-drilling collar survey (see Section 6.3 and 8.3.1). All collar coordinates, including re-surveyed historical DDHs, as well as hole orientations are presented in Appendix H. Prior to drilling, the drill rig was aligned to the planned azimuth using an APS provided by Reflex Instruments. The APS is a GPS based compass that is not affected by local magnetic interference and produces true north azimuth measurements to within 0.5° with good GPS integrity.

Downhole surveys were completed using a Reflex EZ-Shot system, a 'single-shot' high precision magnetic instrument that measures the drill hole azimuth relative to magnetic north as well as the drill hole dip and magnetic field strength. Magnetic north azimuth readings were corrected to grid north azimuths by adding 22.5°. The first downhole survey was done once the drill hole had penetrated several meters into bedrock, followed by 25 m intervals for the rest of the hole. In general, magnetic field strengths of 5600–6000 nT were accepted whereas those below 5600 nT and above 6000 nT indicated magnetic interference and were rejected.

Drill core was oriented for most drill holes with the exception of metallurgical twin, metallurgical wedge and 11 shallow hydrogeological monitoring well holes (see sections 6.6 and 6.9). At ABM, core orientation was completed from approximately 20 m above the lens until end of hole using Reflex ACTII RD core orientation systems. Alpha and beta angles of structural features were recorded during logging along with a confidence level estimated by the core logging geologist. Percentage of total recovered core ("core recovery") and length of recovered core with pieces >10 cm ("rock quality designation" or RQD) measurements were recorded for each drill run.

Geological drill hole data was captured using GeoSpark software, an Access-based relational database system that stores drill hole and geological data in individual data tables. Attention was paid to identifying mineralization style, deposit alteration types, hanging wall and footwall lithology as well as sulphide minerals,

carbonate content and oxidation intensity. All drill core was photographed prior to sampling and is stored at the KZK exploration camp. The historic core remains at the Cominco storage area.

A total of 3513 HQ3 and NQ3 half-core samples from 96 resource and exploration DDHs were collected during the 2015 program. Geologists identified all core samples with a unique sample ID number and marked all sample intervals with sample tags in the core box. All mineralized intersections were sampled, including approximately 10 m of the immediate hanging wall and footwall host rock in an effort to characterize waste rock dilution that could be encountered during mining. Primary core samples conformed to lithological boundaries where possible, with core loggers making an attempt to constrain alteration and mineralization features within the sample boundaries as well. Mineralized samples had a nominal sample length of 1.0 m and a minimum length of 0.3 m with barren or poorly mineralized host rock samples typically having maximum and minimum sample lengths of 1.5 m and 0.5 m respectively.

Drill core samples were cut using an open circulation rock saw. Split core was consistently sampled from the same side and placed into labelled plastic sample bags that were sealed with a plastic zip tie and shipped in labelled rice bags sealed with individually numbered security tags. A list of required quartz washes was submitted to the analysis lab that would follow suspected high-grade samples in order to avoid contaminating adjacent lower grade samples. These quartz washes were completed at the crush and pulveriser stage of sample preparation.

A total of 4990 bulk density measurements were completed on resource, exploration, geotechnical and metallurgical parent drill DDHs. Individual measurements were completed on the entire half-core sample submitted for analysis and on representative 10–15 cm long whole core samples of various hanging wall and footwall lithologies. Each sample was weighed in air on a metric balance and then suspended from the balance and weighed whilst immersed in water (i.e. the “water immersion method”). When half-core samples were either too friable or broken, bulk density measurements were not completed as material could be lost and would not be representative. Calibration readings were taken on a 20 cm long piece of metal rebar at approximately every 10th reading and as the last bulk density measurement for each drill hole. Additional bulk density measurements were completed on 50 sample pulps using a pycnometer at SGS Labs of Burnaby, BC, (SGS) as an independent confirmation of the accuracy of field measurements obtained via the water immersion method.

Drill core samples were sent to SGS laboratory in Burnaby, BC for geochemical analysis of base (Cu, Fe, Pb, Zn) and precious (Ag, Au) metals for use in the resource calculation and various trace elements (As, Ba, Bi, Hg, S, Sb, Se). All certificates of analysis are attached in Appendix N. Quality assurance and quality control (QA/QC) of these analyses was monitored through the insertion of Certified Reference Materials (CRM) and blanks into the sample sequence and through various duplicate analyses. A QA/QC analysis based on the assay results for these CRMs and blanks is attached as Appendix O.

A total of 4960 half-core samples – split between 3513 samples of new core and 1447 historical core samples – in addition to 289 blank and 363 CRM samples for QA/QC (12% of total) were submitted for precious, base metal and Fe analysis. These samples were weighed, dried and crushed to 75% passing 2 mm, with a 250 g split pulverized to 85% passing 75 microns. Gold was analysed by 30 g fire assay with an Atomic Absorption Spectroscopy (AAS) finish and silver analysed by Inductively Coupled Plasma (ICP) with an AAS finish on a two gram 2-acid digest aliquot. Gold and silver over limits were triggered at Au >5 g/t and Ag >150 g/t respectively, resulting in re-analysis using a 30 g fire assay with gravimetric finish. Over limits for Ag were subsequently adjusted to 200 g/t when it was clear that acceptable precision was achievable up to 200 g/t using ICP-AAS. Assay results for copper, lead, zinc and iron were completed using a Na peroxide fusion and ICP-AES analysis. This fusion was chosen as it results in the complete digestion of the sample providing a near total chemical analysis. Detection limits for each analytical method used during the 2015 program are shown in Table 4.

Table 4: Analytical methods and range for precious and base metals of interest

Element	SGS code	Analytical method	Analytical range
Cu	GO_ICP90Q	Na peroxide fusion/ICP-AES	0.01–30%
Fe	GO_ICP90Q	Na peroxide fusion/ICP-AES	0.05–30%
Pb	GO_ICP90Q	Na peroxide fusion/ICP-AES	0.01–30%
Zn	GO_ICP90Q	Na peroxide fusion/ICP-AES	0.01–30%
Au	GE_FAA313	30 g fire assay/AAS finish	0.005–10 ppm
	GO_FAG303	Au over limit (>5 g/t): 30 g fire assay/gravimetric finish	0.5–3000 ppm
Ag	GE_AAS12E	2 g 2-acid digest/ICP-AAS	0.3–300 ppm
	GO_FAG313	Ag over limit (>150 ppm): 30 g fire assay/gravimetric finish	10–5000 ppm

Out of the 4951 core samples submitted for precious and base metal analysis, 3337 were also analysed for Ba, 3286 for sulphur, and 1129 for As, Bi, Hg, Sb and Se. The preparation methods were the same as those used for the base and precious metal assays, with analysis completed by ICP-MS on a two-acid aqua regia digest of 3:1 $HCl:HNO_3$. For samples with relatively high Ba and S, a lower weight was used in order to prevent the precipitation of Pb along with $BaSO_4$. Samples with >5% Ba and low base metals were fused with pyrosulphate and analysed by XRF.

CRM and blank samples were inserted at alternating 20th sample intervals within the drill core sample sequence. All CRMs were manufactured from sulphide ores with a similar mineralogy to ABM (i.e. containing pyrite, pyrrhotite, chalcopyrite, sphalerite, galena, minor sulpho-salts) and are generally certified for Cu, Pb, Zn and Fe at the percentile level and Au and Ag at the ppm level. CRMs were picked to match low, medium and high cut-off grades for the elements of economic interest. A minimum weight of 100 g was used for CRM samples so that reanalysis could be completed on the CRM if required. Blank material used for QA/QC consisted of barren landscaping stone acquired from Premier Horticulture Ltd. in 18 kg bags.

One-hundred and sixty-five coarse reject samples, including 5 blanks and 10 CRMs, from both 2015 DDHs and historical DDHs were submitted to ALS Minerals in North Vancouver, BC, for a check analysis program on the results received from SGS. Analyses were completed for Au, Ag, Cu, Pb, Zn and Fe using essentially the same analytical methods as SGS, and the resulting data was analysed by CSA as part of their updated resource estimate for the ABM deposit.

6.6 Metallurgical drilling and sampling

The 2015 metallurgical drilling program consisted of 29 dedicated diamond DDHs, for a total of 3406 m, aimed at providing representative sample material from an initial seven geodomains based on visual logging and Cu:Pb grade ratios (Hughes et al., 2015). Twenty seven parent DDHs were also completed in conjunction with this program to help guide metallurgical drilling and sampling, although their principal purpose was to meet resource definition and hydrogeological work program objectives at ABM (Table 5).

The metallurgical drill program consisted of a combination of twinned and wedge DDHs spread across the ABM deposit with a plan to collect samples in both the potentially oxidized and deeper non-oxidized zones. All DDHs were of HQ3 size core to ensure enough material for metallurgical testing, including comminution and flotation test work. Triple tube coring with inner split tubes was used to maximize core recovery. Due to cost consideration, wedge holes were completed where the target zone was located at >130 m depth down hole, typically at the down dip extent of the deposit. These wedge holes comprise an initial HQ3-sized “parent” hole for resource definition work followed by HQ3 “daughter” holes deflected by a wedge to collect the metallurgical sample. Standard procedure was to allow the daughter holes to deflect in any direction around the parent hole but with minimal separation (one to several metres was acceptable). For mineralization <130 m, twin holes were completed with an NQ3 “parent” for resource definition followed by an adjacent HQ3 “twin” hole for metallurgical sampling.

Drilling was completed by Geotech Drilling of Prince George, BC, utilising three skid-mounted diamond drill rigs (one Zinex A5 and two Hydracore 2000 machines). Drilling alignment, down hole and collar survey procedures as well as core logging procedures were the same as those used for the "resource and exploration drilling program" described in section 6.5, although in this case the drill core was generally not oriented. Collar coordinates and DDH orientations are presented in Appendix H.

Table 5: Summary of the 2015 KZK Project metallurgical drilling program

Target	Type	N.o. DDHs	Metres	Comments
ABM lens	Metallurgical*	29	3406.0	Includes 1 abandoned DDH for 34 m
	Resource/metallurgical	25**	4112.0**	Includes 1 abandoned DDH for 72.7 m
	Resource/metallurgical/hydrogeological	2**	232.0**	
2015 Total		**29**	**3406**	

Notes: * includes dedicated, twinned and wedged holes; ** previously counted as part of "resource and exploration drilling" (Table 3)

One-thousand and twelve HQ3 whole core samples were collected from metallurgical twin and wedge DDHs. All metallurgical samples were identified with a unique sample ID number and marked with a wax coated sample tag in the core box. Samples were collected from mineralized zones, hanging wall and footwall waste rock as well as between mineralized lenses that correlate to the same, or similar, zones and intervals in resource parent holes. The same sampling constraints, including nominal 1.0 m length and respecting lithological contacts and mineralized boundaries, were applied. Metallurgical samples are full core samples, the start and end of which were cut with an open circulation rock saw oriented perpendicular to the core axis. Core samples were placed into labelled plastic sample bags that were left open during the summer months to prevent moisture buildup. Prior to transport and storage the plastic sample bags were sealed with a plastic zip tie and stored in a cool place. A list of metallurgical samples collected during 2015 is presented in Appendix P.

To gain an understanding of possible near-surface oxidation of the sulfide ores at ABM prior to metallurgical studies three hundred and twelve sample pulps of shallow (<50 m) sulphide mineralization from the 2015 resource drill program were submitted to SGS for ethylenediaminetetraacetic acid (EDTA) leach analysis. EDTA provides a quantitative measure of the potential degree of oxidation by forming complexes with the oxidation products of sulphide minerals (Bicak and Ekmekci, 2012). The EDTA test work will be primarily used for assessing the presence of water soluble oxide minerals that might otherwise not be visible in hand specimen, and the effect that such minerals may have on flotation during metallurgical testing. No comprehensive review of the analytical results was completed during this work program and there will be no further mention of it in this report. Certificates of analysis for the EDTA test work are attached in Appendix N.

6.7 Petrography

Four petrographic studies (Table 6) were commissioned in an effort to confirm and/or determine, among other things, the ore mineralogy, gangue minerals, host rock mineralogy, typical grain sizes and textures of samples from the ABM, Krakatoa and GP4F zones (Leitch, 2015, 2016a, b; Townend and Townend, 2015). Townend and Townend (2015) examined polished thin sections in transmitted and reflected light, and used a scanning electron microscope (SEM) to obtain semi-quantitative and quantitative mineral analyses to understand metal deportment among the sulphide minerals. Quantitative analyses were obtained by energy dispersive X-ray spectroscopy (EDS). Most of the samples examined by Townend and Townend (2015) consist of massive (>60% sulphide) to semi-massive (20–60%) sulphide from the ABM lens.

Leitch (2015, 2016a, b) also examined polished thin sections in transmitted and reflected light with a particular focus on the Krakatoa Main lens and GP4F lens to confirm the occurrence of similar ore types to that of the ABM lens. Additional petrographic descriptions were included for unmineralized rocks in support of whole rock geochemical analyses. All four petrographic reports are attached as Appendix Q.

Table 6: Summary of petrographic reports commissioned for 2015 KZK Property

Report	Methods	Samples	Zone			% sulphide in samples		
			ABM	*Krakatoa*	*GP4F*	*>60%*	*20–60%*	*<20%*
Townend and Townend 2015	Petrography*, SEM analysis	37	37			25	8	4
Leitch 2015	Petrography*	17		13	4	10	6	1
Leitch 2016a	Petrography*	11	7	4		7	4	
Leitch 2016b	Petrography*	31		16	15	4	10	17
Totals		**96**	**44**	**33**	**19**	**46**	**28**	**22**

Notes:* includes transmitted light and reflected light microscopy on polished thin sections

6.8 Geotechnical drilling

The 2015 geotechnical drilling program comprised nine DDHs for 955 m (Table 7) that focussed on gaining a better understanding of the location of the East Fault and the competency of the surrounding rock mass (3 DDHs), as well as characterising and confirming historical geotechnical information in the area of Cominco's designed surface infrastructure (6 DDHs). The tested infrastructure sites included the waste dumps and tailings storage facility ("TSF") proposed in a prefeasibility study undertaken by Cominco in 1995, including two alternative sites for the TSF located 200 m south and 200 m north of the original facility, in the Geona Creek valley.

East Fault drilling was undertaken by Geotech of Prince George, BC, between 11th September and 20th October, 2015, using a single Hydracore 2000 machine. Geotechnical drilling at surface infrastructure sites was also completed by Geotech between 25th November and 7th December, 2015 using two Hydracore 2000 machines retrofitted with Standard Penetration Test (SPT) hammers.

Drilling alignment, downhole survey and collar survey procedures were the same as those used for the resource and exploration drilling program described in section 6.5. The three DDHs drilled on the East Fault were oriented at an azimuth of 125° to intersect the fault as perpendicularly as possible and all drill core was oriented from the base of the overburden to end of hole. Geotechnical logging of DDH K15-300 was undertaken at the drill site, with recovery, RQD, metre marks, fractures and fracture frequency, structures and gouge zones logged whilst the core was still in the splits. The primary objective of the waste infrastructure DDHs was to drill through the overburden into competent bedrock to characterize the geotechnical conditions of the subsurface and assist with structural design work. SPTs were done to determine the geotechnical engineering properties of the overburden and packer tests were undertaken, in overburden, transition and bedrock to measure the hydraulic conductivity of these materials. Piezometers were installed for ongoing monitoring of seasonal water levels and thermistors will be installed at a later date in several of the DDHs to evaluate the presence (or not) of permafrost.

Table 7: Summary of the 2015 KZK Project geotechnical drilling program

Target	Type	N.o. DDHs	Metres	Comments
ABM	Geotechnical – East Fault	3	668.1	Includes 1 abandoned DDH for 120.0 m
Infrastructure	Geotechnical – waste infrastructure	6	287.3	
2015 Total		**9**	**955.4**	

6.9 Hydrogeological drilling and environmental studies

The 2015 hydrogeology and environmental work program included hydrogeological drilling, identification of waste rock geodomains to characterize their acid generating potential, construction of acid rock drainage (ARD) kinetic testing facility and collection of baseline environmental data. Procedures and methods used to carry out these program elements are described in more detail below.

The 2015 hydrogeological drill program was designed by Tetra Tech EBA Inc. ("Tetra Tech") and consisted of 11 shallow monitoring well holes for a total of 325 m (Table 8) to characterize the hydrogeological baseline conditions at proposed mine infrastructure locations and within the proposed ABM open pit. Seven additional hydrogeology holes, located within the proposed open pit, "piggy-backed" on resource definition DDHs. The 2015 DDHs were located where gaps were identified in the existing coverage of a network of monitoring wells emplaced by Cominco. Two large 8" diameter pumping wells for a total of 53.3 m were also drilled as part of the hydrogeology program serving a dual purpose for both long-term constant rate pumping tests and future dewatering of the ABM open pit.

Drilling of all hydrogeological DDHs was completed by Geotech of Prince George, BC, between 30th July and 7th November 2015, using one Zinex A5 and two Hydracore 2000 machines. The two large 8" diameter pumping wells were drilled by Midnight Sun Drilling Inc. ("Midnight Sun") of Whitehorse, Yukon, between 30th July and 2nd August, 2015 using one truck-mounted Sandvik Marlin M5 air rotary machine fitted with an ODEX casing system.

Shallow monitoring wells were drilled with HQ size rods and fitted with 1.25" PVC piezometers in either the shallow bedrock or overburden. Packer testing was conducted in each borehole as the hole advanced to infer subsurface hydraulic conductivities. Steel casing was installed at surface to protect the piezometers. Two resource DDHs within the limits of the proposed ABM open pit (K15-200, K15-248) were completed with vibrating wire piezometers (VWP) to determine *in situ* pore pressure and temperature as well as test vertical hydraulic gradients. Packer testing was also completed in an additional 5 DDHs within the proposed ABM pit in an effort to determine the hydraulic conductivity of the fractured bedrock aquifer. Collar coordinates and elevation for the shallow monitoring well holes were acquired with a handheld GPS and LiDAR surface respectively. Subsurface material classification and screen selection for the piezometers was determined by the onsite Tetra Tech hydrogeologist.

Table 8: Summary of the 2015 KZK Project hydrogeological drilling program

Target	Type	N.o. DDHs	Metres	Comments
Infrastructure/engineering	Hydrogeological	10	290.0	Shallow monitoring wells
Krakatoa	Hydrogeological	1	35.0	Shallow monitoring well
ABM	Resource/hydrogeological	5*	1161*	"Piggy-backed" DDHs
	Resource/metallurgical/hydrogeological	2*	232*	"Piggy-backed" DDHs
2015 Total		**11**	**325**	

Notes: * previously counted in "resource and exploration drilling" (Table 3)

Nine waste rock geodomains were defined in 2015 in order to support a geochemical characterization sampling program at the ABM deposit (Baker, 2015a). The main geological features considered in the geodomain interpretation include lithology and mineralogy, the latter focussed mostly on the abundance of carbonate, disseminated pyrite, disseminated pyrrhotite, muscovite and chlorite (± cordierite).

A geochemical characterization program was implemented to support mine plan design and environmental management work at ABM based upon the aforementioned waste rock and metallurgical geodomains. More specifically; the program was designed to understand and evaluate any potential environmental impacts from a future mining operation including the acid generation and/or metal leaching behaviour and management of waste rock, exposed pit wall rock, ore stockpiles, construction rock and tailings. The program involved collection of various waste rock and ore samples as well as construction of a field barrel test stand between 11th November and 19th November, 2015 for static and kinetic laboratory testing as well as field based kinetic testing.

Static tests are intended to characterize the chemical, mineralogical and physical properties of the rock at the time of sampling. Laboratory kinetic tests, including humidity cell sub-aerial leach columns and flooded column tests, are longer term experiments that typically run for a minimum of 40 weeks with sampling events taking place weekly. Field barrel kinetic tests (Figure 3) are used to reflect variable conditions present on site and upscale lab based kinetic tests. Furthermore they can be sampled for the life of the project to anticipate future changes in drainage water chemistry.

Drill core from both historical and 2015 ABM DDHs was sampled for laboratory static and kinetic tests. In total 236 samples, each weighing around 3 kg, were collected from the different waste rock geodomains and ore types. In addition one-hundred and twenty-three 25 kg samples from 2015 ABM drill core only, representing nine waste rock geo-domains and three replicate geodomains, were collected and placed into separate natural rain water filter bins for long term kinetic testing. The field barrel test stand is located on drill pad MW15-01 for shallow monitoring well K15-211, with water from each bin intended to be sampled every two weeks for the duration of the project. Sample tags were placed into the core box where samples were taken and the weights and length of all samples were measured. Photographs of all core samples were also taken. This work will be primarily used as part of a pre-feasibility study on the KZK Project to be completed by BMC in 2016.

Figure 3: Field barrel test stand positioned on drill pad MW15-01 for kinetic testing of the 9 recognized waste rock geodomains.

Several environmental and social studies were initiated as part of the 2015 work program in an effort to characterize the baseline conditions of the project area. These studies include on-going monitoring of surface and groundwater water quality and quantity, wildlife and wildlife habitat surveys (caribou, moose, bears, beavers, collared pikas, hoary marmots, bats, raptors, breeding birds, and waterfowl), aquatic ecosystems, wetland surveys, vegetation and soil surveys, as well as climate and heritage surveys. The majority of the wildlife, vegetation aquatic and water quality studies in 2015 were conducted by Alexco Environmental of Whitehorse, Yukon with parts of the Caribou and Moose surveys also completed by EDI Dynamics Inc. of Whitehorse, Yukon. A summary of the 2015 field activities is provided below.

Surface water quality and quantity monitoring was reinitiated in April 2015 and will continue monthly over the next year. Samples are collected from ten stations on the property and analyzed for pH, specific conductivity, colour, total suspended solids, anions, alkalinity and acidity, ammonia, dissolved organic carbon, total and dissolved metals, total and weak acid dissociable (WAD) cyanide. Field measurements at each station included pH, specific conductivity, temperature, oxidation-reduction potential, and dissolved oxygen. Eight continuous data collection hydrometric stations were also installed on the property (six at historical locations and two at new locations that correspond to historical sampling locations) and water seeps/artesian conditions were evaluated in the ABM deposit area.

Several caribou and moose surveys were conducted to assess the distribution of the Finlayson Caribou Herd. Three surveys were completed at different seasonal periods including a winter aerial survey from March 25–27 as well as post-calving and post-rut surveys in July and October respectively. Moose surveys comprised a late winter survey from March 25–27 and a post-rut survey from November 18–21.

Aerial bear surveys were conducted on April 24, May 4 and May 15, 2015, in areas perceived as moderate to high quality denning habitat.

A beaver habitat and sign survey was completed for the upper Geona Creek Valley on 7th July 2015. As part of the aerial survey, several passes were flown over the creek and all beaver signs (dams, lodges, caches) were marked by GPS and photographed from the air. Signs of beaver activity were also recorded

during a vegetation cover and rare plant survey within the riparian corridor on the 8th July and 15th July, 2015, as well as during a vegetation baseline study completed between 30th July and 2nd August, 2015.

Fish and aquatic surveys were completed on the Geona Creek from June 22-24, August 26-28 and October 14-15. All work was conducted in accordance with Fisheries and Oceans Canada (DFO) Licence to Fish for Scientific Purposes XR 141 2015. Captured fish were identified and enumerated, measured for length (± 1 mm), observed for abnormalities, and released at the location of capture. Additional supporting information collected included: physical description and photo documentation of sampling locations and in situ water parameters (temperature, dissolved oxygen, conductivity). Benthic invertebrates and Periphyton samples were collected from September 9-11 and sent to Cordillera Consulting in Summerland, BC and G3 Consulting Ltd. in Surrey BC respectively for taxonomic identification.

A survey for collared pika and marmots was undertaken in four pre-identified locations (based on habitat suitability) in July, 2015. The survey included cataloguing pika sightings and calls, as well as noting hay piles and searching for burrows or signs of burrows.

A desktop study, which included searching Environment Yukon databases and contacting a small mammal biologist with the Yukon Government, revealed that it would be unlikely for the little brown bat to be present at the elevation of the ABM/GP4F area (≥1350 m). If bats were present they would most likely be concentrated near wetland areas due to the presence of insect food sources. To survey for the presence of bats, an AnaBat remote acoustic recorder unit was set up in a wetland. The unit was installed on the 14th August and retrieved one week later on the 21st August, 2015. The recorder was timed to operate over a six hour period between dusk and dawn, for a total of 42 hours.

A breeding bird survey was completed at 16 sites within the mine infrastructure footprint on 23rd June, 2015. Birds detected by sight and sound were documented by two qualified observers in a five minute standardized point count survey. Wetland areas were assessed the next day (June 24), and include Jim lake (the most eastern lake of the North lakes), the north and south ends of the South lakes, and a beaver dam area at the headwaters of Geona Creek. These surveys comprised a comprehensive scan of the wetland or lake using a spotting scope as well as a standard five minute point count.

A raptor survey was completed from June 23–24 in elevated areas that may provide suitable habitat for cliff nesting. These areas were examined from afar with binoculars and spotting scope, and flyovers were completed to confirm the habitat type for raptor usage. The sky was also scanned for raptors at various times during the day.

A wetlands site assessment was conducted by Contango Strategies Ltd. (“Contango”) of Saskatoon, Saskatchewan, between the 25th and 28th of August, 2015. Eleven locations were sampled *in situ*, resulting in the collection of 10 water, five soil, nine vegetation, and 15 microbiological samples for off-site analytical testing. Above-ground biomass was sampled as it is considered indicative of plant uptake and the cycling of elements and nutrients through decomposition. The below-ground biomass was sampled to assess associated microbial populations and to determine which plants host beneficial microbes. Collected microbial samples consisting of plant roots, soils/sediments, mosses and biofilms were analyzed for beneficial microbes in the context of water remediation and to identify latent potential for treatment. Field measurements were completed at the sampling sites using a YSI ProPlus meter that measures temperature, dissolved oxygen (DO), conductivity (and specific conductivity; SPC), pH, and oxidation-reduction potential (ORP). Additionally, relative soil redox potential measurements were taken using platinum tip probes and Calomel electrodes to measure the flux of electrons between the sediment/soil/pore water and overlying water column.

A weather station was installed on the property in September, 2015, that includes a data logger, satellite communication base station, total precipitation gauge, wind sensor, temperature and relative humidity sensor and a barometric pressure sensor. A manual evaporation pan was also installed but removed at the end of September due to the onset of night time freezing conditions. The evaporation pan required regular maintenance and measurements by Equity camp personnel.

A heritage survey was completed by Ecofor Consulting Ltd. (“Ecofor”) of Whitehorse, Yukon, in August, 2015, at sites considered to have high heritage potential, both within the footprint of the proposed mine

infrastructure as well as the larger property area. An archaeological assessment of alpine localities, particularly in or near ice patch features, was also completed.

7.0 GEOLOGICAL SETTING AND MINERALIZATION

7.1 Regional geology

The KZK Property is underlain by polydeformed metamorphosed sedimentary, volcanic and plutonic rocks assigned to the Yukon - Tanana terrane which extends from central British Columbia to eastern Alaska. These rocks are interpreted as the product of middle Palaeozoic continental arc magmatism in a peri-cratonic setting that was separated from Ancestral North America by a back-arc rift basin occupied by the Slide Mountain Ocean. In central Yukon the Finlayson Lake belt is comprised of lithologies assigned to both the Yukon Tanana and Slide Mountain terranes (Nelson et al., 2013). Syngenetic volcanogenic massive sulphide (VMS) mineralization occurs in both terranes hosted in multiple settings in this belt.

The Finlayson Lake belt is a crescent-shaped area, approximately 300 km long and 50 km wide, extending from Ross River in the north to Watson Lake in the south, and is composed of Devonian to Mississippian volcanic, intrusive and sedimentary rocks. It is juxtaposed with Proterozoic and Palaeozoic strata of the ancient North American continental margin along the Tintina Fault Zone to the southwest and with Carboniferous rocks of the Slide Mountain Terrane to the northeast (Figure 4). The main part of the Yukon-Tanana terrane, which underlies most of west-central Yukon, is contiguous with the Finlayson Lake district, after restoration of 456 km of Late Cretaceous right lateral strike-slip movement along the Tintina Fault (Layton-Matthews et al., 2008).

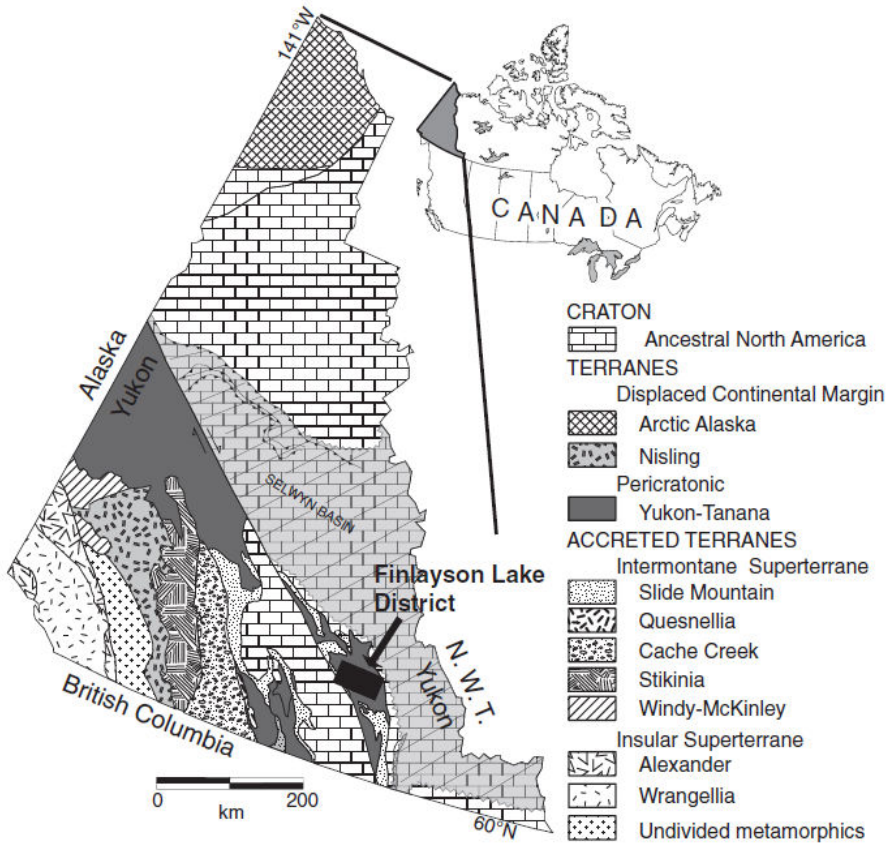

Figure 4: Regional geology of the Finlayson Lake District, taken from Layton-Matthews et al (2008)

7.2 Local geology

The Yukon-Tanana terrane in the Finlayson Lake belt is composed of foliated and lineated greenschist- to lower amphibolite-grade metasedimentary, metavolcanic and metaplutonic rocks (Figure 5). This part of the Yukon-Tanana terrane was imbricated by Permian thrust faulting into the Cleaver Lake, Money and Big Campbell thrust sheets. The final stage of thrusting placed this rock package onto North America and occurred along the Big Campbell and Inconnu thrusts in Late Triassic to Early Jurassic time (MacRobbie and Holroyd, 2005a). With the exception of the Limy 1–9 claim block and the line of claims along the tote road to the Robert Campbell Highway, the KZK Property lies entirely within the Big Campbell thrust sheet in what is the structurally deepest part of the Yukon-Tanana terrane. The Big Campbell thrust sheet lies below the Early Permian Money Creek thrust, which has greater than 35 km of northeast-directed displacement (Murphy, 2004). Two middle Palaeozoic unconformity-bounded groups (Grass Lake and Wolverine) are exposed within the Big Campbell thrust sheet.

Figure 5b

The lowermost part of the Grass Lakes Group (North River Formation) consists of pre-Early Mississippian (pre-365 Ma) quartz-rich, non-carbonaceous metaclastic rocks (**Dm**, **Dfv**, **Dqm** and **Dq**) dominated by quartzite psammite and metapelite with minor felsic metavolcanic schist, calcareous schist/metapelite and marble members. The North River Formation is conformably overlain by 30 to >200 metres of the *c.* 365 to 360 Ma mafic-dominated arc- and back-arc-related Fire Lake Formation (**DF**), which consists of mafic metavolcanic schist and phyllite with very minor carbonaceous phyllite and quartzite, rare marble and felsic metavolcanic muscovite-quartz schist, and locally significant meta-gabbro, meta-pyroxenite and meta-ultramafic bodies. The Besshi-style Fyre Lake Cu-Co-Au VMS deposit is hosted in boninite at the top of the Fire Lake Formation. Conformably overlying the Fire Lake Formation is the felsic volcanic and sedimentary rock-dominated Kudz Ze Kayah ("KZK") Formation (**DK**, **DKcp** and **DKcs**), whose lower parts consist predominantly of Devono-Mississippian (*c.* 360–356 Ma) felsic volcanic and variably carbonaceous sedimentary rocks. The thickest accumulation of felsic metavolcanic rocks within the KZK Formation occur on the KZK Property. Rocks within the KZK Formation are interpreted to have formed within a continental back-arc rift to back-arc basin (Layton-Matthews et al., 2008). The ABM and GP4F VMS deposits are hosted by different stratigraphic levels of this Formation. The KZK Formation grades conformably upwards into a thick sequence of carbonaceous to locally calcareous phyllite and lesser siltstone and mafic metavolcanic phyllite/schist with minor blue quartz-bearing grits, conglomerate, psammite and quartzite (**DMq**, **DMm**, **DMcp**, and **DMcg**) of the Wind Lake Formation. Coeval with the KZK and Wind Lake formations are Devonian-Mississippian (360±1 Ma) peraluminous K-feldspar porphyritic to megacrystic granites of the Grass Lakes suite of intrusions (**MGg** and **MGag**), which are inferred to be subvolcanic feeders to the volcanic rocks (MacRobbie and Holroyd, 2005b; Murphy et al., 2001; Piercey et al., 2001).

The Wolverine Group unconformably overlies the Grass Lakes Group and consists predominantly of Early Mississippian (*c.* 356–346 Ma) felsic volcanic and carbonaceous sedimentary rocks (**MWb**, **MWt**, **MWf**, **MWcp** and **MWcl**). The succession contains, from bottom to top, a lower conglomerate unit, a lower felsic volcanic-dominated unit, a regional carbonaceous argillite unit, the immediate footwall felsic volcanic and subvolcanic rocks to the Wolverine VMS deposit, and a hanging wall consisting of aphyric rhyolite and carbonaceous sedimentary rocks that, near their top, host basalt flows. Rocks of the Wolverine succession are interpreted to have formed within an ensialic back-arc rift basin that evolved to sea-floor spreading (Layton-Matthews et al., 2008). The Wolverine Kuroko-style VMS deposit occurs at the contact between footwall felsic volcaniclastic rocks and either hanging wall carbonaceous argillite or exhalative rocks (Murphy et al., 2001; Piercey et al., 2001).

A sub-horizontal to moderately steep north to northeast dipping, penetrative ductile deformation fabric and locally preserved isoclinal folding with associated middle greenschist facies (chlorite-biotite grade) metamorphism affects all Grass Lakes Group lithologies. It is less prominent or absent in the Wolverine Group. These fabrics and the metamorphism may reflect two phases of deformation: an early Mississippian event; and, an event related to continent arc collision during the Late Permian to early Triassic time (Schultze, 2001).

7.3 Property geology

The KZK Property was fully mapped in 1996 at 1:20,000 scale by Cominco geologists (Schultze and Hall, 1997). Since then, no property-wide geological mapping has been reported, although more detailed mapping has been done locally. The following discussion is modified from Schultze and Hall (1997). Lithologic codes used on the 2015 KZK Project are summarized in Table 9.

Stratigraphy within the Grass Lakes Group on the KZK Property is divided into three main components: the Kudz Ze Kayah Formation felsic volcanic package, which hosts all significant VMS mineralization on the Property; the overlying "Upper Sedimentary and Mafic Volcanic Sequence" metasedimentary package (equivalent to Wind Lake Formation of Murphy et al . (2001)); and the underlying "Lower Sedimentary Sequence" metasediment package (MacRobbie and Holroyd, 2000) that also forms part of the KZK Formation and is equivalent to the **DKcp** unit in Murphy et al (2001) (Figure 6). VMS mineralization occurs at various levels within the KZK Formation with, for example, the GP4F lens occurring at a lower stratigraphic level than the ABM lens. In a gross sense, stratigraphy trends easterly, dips moderately to the north and is right way up.

The Lower Sedimentary Sequence (**CLS**) comprises mainly siltstone, phyllitic schist, light grey quartzite and more massive tuffaceous wacke that is interfingered with feldspar porphyry. Non-carbonaceous to carbonaceous mudstone occurs locally as does thin felsic tuff. Mafic sills and dykes (flows?) (**MAFi**) are common and locally associated with thinly banded cherty layers. The thickness and extent of these units are undetermined.

The KZK Formation, as defined on the Property, is a thick felsic epiclastic and intrusive/flow (dome) complex with minor mafic sills and flows and rare interbedded sediments. The sediments comprise tuffaceous and carbonaceous mudstone, wacke and orthoquartzite.

The KZK Formation can be subdivided into mappable units, namely: felsic tuff (**RHYv**), coherent felsic flows/intrusives (**RHYc**), feldspar-quartz porphyry intrusive (**RHYi**), mudstone (**MDS**) and undifferentiated mafic volcanic (**MAFi**). Felsic tuff (**RHYv**) is the most abundant. Thin-bedded tuffs are present near the top of this package and at stratigraphic levels where argillaceous pelitic sediments are present as thin intercalations. Thinly banded (bedded?) siliceous felsic ash tuffs are generally rare in outcrop. With increasing grain size the fine felsic tuffs grade into crystal-rich ash tuffs containing up to 35% light grey to white feldspar and clear grey quartz crystals. Feldspar-augen crystal tuffs are well exposed along ridges southeast of ABM. The fissile character and internal variations of feldspar augen content and lateral extent suggest that this unit may be a crystal rich tuff rather than an intrusive.

Rhyolite flows and associated intrusives (**RHYc**) are thickest, most abundant and best exposed on Rhyolite Peak, west of the ABM deposit. These units are typically very dense, siliceous, and aphanitic. Some outcrops along Fault Creek contain up to 70%, 5–25 mm spherulites.

Feldspar-quartz porphyry intrusions (**RHYi**), likely cogenetic with the epiclastic units, contains 15 to 30%, 3 to 18 mm euhedral light grey feldspar phenocrysts and 5 to 20% 2 to 4 mm clear grey, subhedral quartz phenocrysts set in very fine-grained quartz-sericite-feldspar-chlorite-ankerite matrix.

Mafic components (**MAFi**) are mapped throughout the KZK Formation. Two distinct units are present low on the slopes and in the footwall of the ABM deposit. A strongly foliated porphyroblastic chlorite-biotite-calcite schist occurs beneath the ABM ore body and is likely to be the remnant of a mafic sill. Outcrop of porphyroblastic chlorite-biotite-calcite schist exposed to the west along strike from the ABM deposit are interpreted to be equivalent to similar rocks in the footwall. The second unit is a coarse-grained mafic schist with less deformed enclaves exhibiting a presumably relict gabbroic texture. Both these units trend westward into thinner, fine-grained schists. Felsic tuffs and intrusives are cut by numerous dark brown-grey, biotite-clinopyroxene-hornblende schists. Mafic tuffs are volumetrically minor in the KZK Formation, generally forming fine-grained, chlorite-calcite phyllitic schist.

The base of the Upper Sedimentary and Mafic Volcanic Sequence lies about 200 m above the ABM deposit. It is finer-grained than the Lower Sedimentary Sequence and comprises variably carbonaceous and calcareous mudstones (**MDU**) with minor quartzite, siltstone and limestone(?), intercalated with mafic volcanic (**MAFt**) and minor felsic volcanic units. The package is regionally extensive and very thick.

The Yukon-Tanana rocks on the KZK Property are strongly structurally transposed, polydeformed, and overprinted by mid-greenschist and higher grade metamorphism. Cominco noted evidence of five distinct phases of deformation. The first three phases (D1, D2. D3) were regionally penetrative and involved ductile simple-shearing, faulting and folding. Early-stage fabrics (S1), represented by weak, bedding-parallel schistosity to a well-developed mylonitic fabric, have been transposed into a strong, shallowly dipping, axial plane crenulation cleavage (S2) which was formed during the development of south- to southeast-verging F2 folds. North- to northeast dipping S3 cleavage and shear bands commonly offset S2 fabrics in a top-to-the-south/southeast shear sense.

The last two phases of deformation (D4, D5) were relatively minor and involved non-penetrative compression and extension. D4 deformation is characterized by broad open folds whereas D5 deformation is characterized by late-stage, commonly north- and northeast-striking, brittle-style normal faults. In addition, early thrust faults commonly display late-stage (D5) extensional reactivation.

Table 9: Lithological legend for KZK Project

Formation	Code	Sub-code	Lithology	Description
	OVBN		Overburden	Unconsolidated overburden.
Wind Lake	MAFt		Mafic volcaniclastic	Confined to Upper Sedimentary and Mafic Volcanic Sequence
	MDU		Mudstone and tuffaceous mudstone	Calcareous carbonaceous and mafic tuffaceous mudstones of the Upper Sedimentary and Mafic Volcanic Sequence
KZK	RHYi		Aphanitic rhyolite	Aphyric massive to semi-massive siliceous rhyolite interpreted as intrusive dykes and sills
	RHYc		Coherent rhyolite	Undifferentiated coherent rhyolite
		RHYcw	Curdy-textured and/or flow-banded	Flows or sub-volcanic intrusions with definitive siliceous flow banding or relict flow banding textures
		RHYcf	Feldspar ± quartz porphyry	Medium to coarse-grained feldspar and quartz porphyritic texture rhyolite
		RHYcq	Quartz porphyry	Medium to coarse-grained quartz-phyric texture
	MAFi		Mafic intrusions	Chlorite-altered mafic intrusion, primarily in the footwall but also occurs as narrow dykes or sills within the felsic sequence
	RHYv		Volcaniclastic rhyolite	Undifferentiated fine to medium-grained volcaniclastic
		RHYvl	Lapilli tuff	Heterolithic tuff with >15% lapilli typically in an ash-dominated groundmass
		RHYva	Coarse-grained to ash tuff	Phaneritic ash tuff with >10% of crystals occurring as >1–<2mm typically in an ash-dominated groundmass
		RHYvx	Quartz ± feldspar crystal tuff	Quartz, ± feldspar-phyric (>10%) in an ash-dominated groundmass
	RHY		Undifferentiated rhyolite	Typically altered and difficult to identify
	MDS		Mudstone, tuff and rhyolite	Undifferentiated carbonaceous mudstone, tuffaceous mudstone and carbonaceous coherent rhyolite
		MDSt	Rhyolite tuff-dominant mudstone	<15% carbonaceous component, heterolithic appearance with rare mudstone laminae
		MDSc	Carbonaceous mudstone	>15% carbonaceous component, weakly heterolithic to semi massive mudstone with slaty cleavage
		MDSw	Coherent rhyolite with minor carbonaceous mudstone	<15% carbonaceous component, laminae of mudstone intercalated with coherent rhyolite
	SED		Undifferentiated sedimentary rock	Variable; includes locally calcareous sandstone, wacke, recrystallized limestone
		SEDc	Calc-silicate sedimentary rock	
	CLS		Lower Sedimentary Sequence	Carbonaceous mudstone, siltstone, tuffaceous schist, biotite metapelite, calc-silicate, mafic dykes

7.3.1 ABM deposit

The 2015 work program has expanded on Cominco's work and now recognizes that the ABM deposit comprises two major zones: the ABM Zone and the Krakatoa Zone, which are separated by the north-northeast striking East Fault (Figures 7, 8). The ABM Zone consists of the resource-stage ABM lens and the less-explored Santorini and ABM deep targets. The ABM lens is defined as massive sulphide and stringer-style sulphide mineralization primarily hosted within a package of felsic volcanic rocks that occurs in the immediate hanging wall to a chlorite altered mafic schist (MAFi) while the Krakatoa Zone is primarily hosted at or near the lower contact of the MAFi unit (Baker, 2015b). West of the East Fault only the ABM lens has been well-explored and, although scattered occurrences of mineralized mafic footwall have been intersected, a lens of coherent massive sulphide (the ABM Deep target) stratigraphically analogous to the Krakatoa Main lens has yet to be identified. To the east of the East Fault the predominant mineralization of the Krakatoa Zone is in the MAFi, however several occurrences of much thinner mineralization are also hosted in the felsic volcanic rocks in the hanging wall to the MAFi (the Krakatoa Upper lens) in a stratigraphic position analogous to the ABM lens west of the fault (Duncan and Baker, 2015). Krakatoa Zone mineralization is bound to the west by the East fault and to the east by the Sunda Fault (likely a splay off the Fault Creek Fault), and is interpreted to lie within an obliquely down-faulted block of KZK Formation (Duncan and Baker, 2015).

The ABM lens is larger than Krakatoa and consists of polymetallic (Cu-Pb-Zn-Au-Ag-rich) massive and stringer-style sulphide mineralization that is up to 39 m in true thickness, strikes at approximately 290° and has a minimum strike length of 700 m (Hughes and Baknes, 2015). The mineralized zone is coherent from section 414550E in the west to section 415225E in the east (Appendix M), forming a series of stacked lenses that coalesce into a single mineralized horizon at 415025E. The ABM lens dips ~35° to the north with a 400 m down dip extent, with a flexure occurring around 200 m down dip that flattens the dip to 10–15°.

Krakatoa Main lens mineralization is generally concordant to stratigraphy within the faulted block with a similar strike and dip to the ABM lens (~300º/35º NNE) and a true thickness of up to 22 m. Mineralization extends to the top of bedrock where it is buried under 2–30 m of glacial overburden.

The down dip margin of the ABM lens appears to transition into a mixed volcanic-sedimentary package, whereas the Krakatoa Main lens remains open down dip. The most recent mineral resource estimate for the ABM deposit was completed in January, 2016 by CSA (Green et al., 2016) in accordance with the JORC Code 2012 and is reported in Table 10.

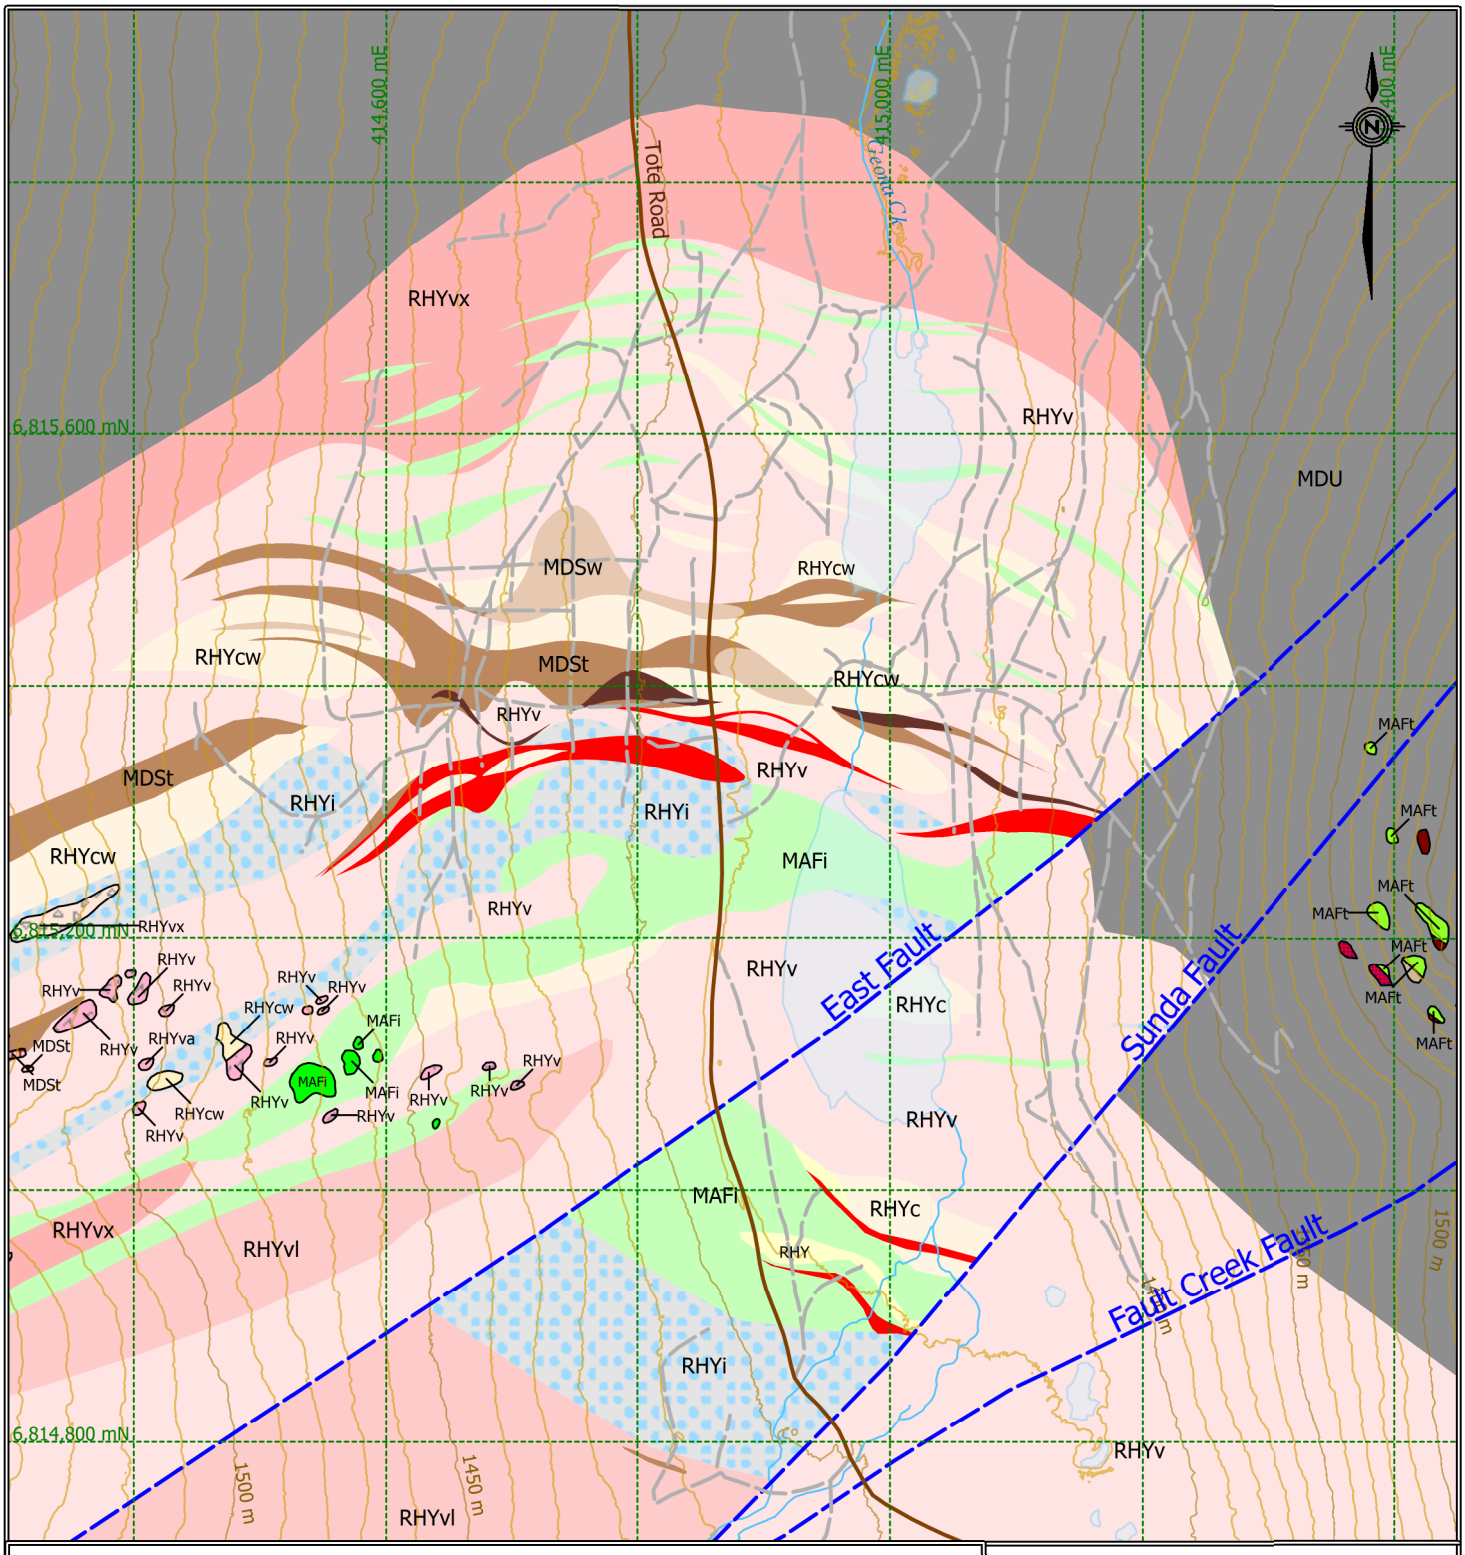
ABM lens sulphide mineralization is dominated by pyrite, sphalerite, pyrrhotite, galena and chalcopyrite, with gangue minerals consisting of chlorite, magnetite, quartz, Fe-carbonate, calcite, sericite, cordierite, albite, celsian and barite. Mineralized lenses typically occur within an envelope of chlorite and muscovite alteration and are subdivided into massive and stringer/disseminated sulphide styles. These two mineralization styles are further sub-divided into nine end member "ore" types based on observable mineralogical and textural characteristics (Schultze, 1995), with massive sulphide consisting mostly of OA, OB and OH types and the stringer/disseminated style including the OC, OF, OG, OI, and OJ types. Characteristics of each of these end-members are summarized in Table 11.



- MAFi: mafic intrusions
- MDU: mudstone and tuffaceous mudstone
- MDSc: carbonaceous mudstone
- MDSt: rhyolite tuff-dominant mudstone
- MDSw: coherent rhyolite with minor carbonaceous mudstone
- MXSX: massive sulphide
- RHY: undifferentiated rhyolite
- RHYc: undifferentiated coherent rhyolite
- RHYcw: coherent rhyolite, curdy-textured and/or flow-banded
- RHYi: aphanitic rhyolite
- RHYv: undifferentiated volcaniclastic rhyolite
- RHYvl: rhyolite lapilli tuff
- RHYvx: rhyolite quartz ± feldspar crystal tuff

OJ	20-60% sulphide	Semi-massive	Disseminated, stringer	Maj.	<5	<5	Maj.	Maj.		Chl-Crd
OD	Brecciated	Brecciated	Brecciated	Variable						

Note: all mineral abbreviations are after Kretz (1983); Brt = barite, Cb = carbonate, Ccp = chalcopyrite, Chl = chlorite, Crd = cordierite, Gn = galena, Mag = magnetite, Py = pyrite, Po = pyrrhotite, Qtz = quartz, Sp = sphalerite, Maj = dominant sulphide component ranging from 5-30%.

Massive sulphide mineralization comprises approximately 85% of the ABM lens by volume. Pyrite is the predominant sulphide mineral, comprising 60–70% of the mode, and is fine to coarse-grained while mostly showing a buckshot texture. The upper parts of the ABM lens are strongly magnetic, containing up to 10% fine to coarse-grained magnetite as laminar bands and heavily disseminated pods. Magnetite also occurs throughout the Krakatoa Zone but, in contrast to ABM, typically only occurs within the MAFi-hosted Main lens or the ABM lens-equivalent Upper lens. Sphalerite forms two distinct types: (1) dark brown sphalerite inter-grown with magnetite in the upper parts of the ABM lens and (2) red-brown sphalerite occurring as wispy laminations and/or disseminations within pyrite. Galena is difficult to identify but occurs throughout the ABM and Krakatoa zones as fine- to medium-sized grains. Chalcopyrite is generally minor and occurs as coarse-grained clots, blebs and disseminations. Silica, barite and carbonate gangue are most abundant within the lower portions of the massive sulphide lenses in both zones, with Krakatoa containing more barite than ABM. Portions of Krakatoa massive sulphide appear similar to the up dip 50m of the ABM lens in terms of base and precious metal grades. However deleterious trace element concentration of Sb, Se, Hg and As appear to be higher in Krakatoa than ABM (Duncan, 2015b).

Stringer/disseminated style mineralization is present at both the ABM and Krakatoa zones but is more restricted and less abundant at Krakatoa. In the ABM lens, stringer/disseminated style mineralization occurs as a 1–10 m thick horizon localized at the hanging wall and footwall contacts of the massive sulphide lens. Additional zones of stringer/disseminated style mineralization also occur between lenses where they are stacked, as they are on sections 414625E, 414825E, 414900E and 414925E. At both ABM and Krakatoa this mineralization style has the appearance of a deformed stockwork-style zone and almost always has strong to intense chlorite ± cordierite alteration. The sulphide mineral assemblage consists of chalcopyrite + pyrrhotite + pyrite ± sphalerite ± galena with trace magnetite, and occurs as a combination of deformed sulphide stringers, massive chalcopyrite-pyrrhotite and heavily disseminated sulphide. In the ABM lens, Cu grades are generally relatively high at >2% but can range anywhere from 0.1–14% Cu. This variability in grade appears to correlate with the textural diversity seen in mineralization styles, which ranges from thick chalcopyrite-rich stringers to Cu-poor disseminated sulphide. Cu, Au and Ag grades can be lower in stringer/disseminated style mineralization at Krakatoa than ABM (Duncan and Baker, 2015).

In some localized Krakatoa Main lens drill intercepts an incomplete sulphide replacement of the MAFi host occurs but, more commonly, partial replacement of felsic (ash) tuffs sandwiched between MAFi can be observed in core. These occurrences typically comprise a combination of OB-type ore with higher gangue content than at the ABM lens, and OI-type with relic lapilli or felsic ash groundmass. This appears to provide direct evidence that Krakatoa is a replacement-style deposit and the observation that the ABM lens transitions down-dip into sedimentary/epiclastic lithologies adds support to the hypothesis that ABM is as well (Duncan and Baker, 2015) (Hughes and Baknes, 2015).

Our current understanding of alteration at the ABM deposit extends from the alteration definitions established by Cominco as summarized by Schultze (2001). This work recognized five superimposed silicate alteration zones within the structural hanging wall of the deposit. Of these five alteration assemblages, only the weak pyrrhotite assemblage (Type 1) was not systematically logged during 2015, as this alteration is pervasive and did not appear to display any obvious variability. The other four main alteration types that were identified and logged during 2015 are summarized in Table 12.

Table 12: Summary of ABM deposit alteration types

Alteration type	Description
Type 1 ("Weak Pyrrhotite")	Disseminated weak pyrrhotite (~1%) as elongated, foliation-parallel wisps in a compact felsic groundmass with vague sericitic partings
Type 2 ("Greenish-Grey Alteration")	Greenish-grey, chloritic-streaked, sericitic, that is spatially – and we believe genetically – related to bodies of aphanitic rhyolite (RHYi). This association is particularly evident where RHYi intrudes MAFi manifest as strongly developed green-grey alteration and locally bright green Cr-mica (fuchsite) indicating a mafic protolith. Locally type 2 alteration obliterates the contact area between massive sulphides and MAFi where it is intruded by RHYi, making it impossible to distinguish from pervasive muscovite alteration. This style of alteration has not been interpreted on the accompanying cross sections in Appendix M.
Type 3 ("Pervasive Muscovite/sericite/ankerite")	Distinctive pervasive silvery grey to waxy greyish-yellow-green well developed muscovite/sericite with associated disseminated sulphide occurring peripheral to massive sulphide mineralization. Best developed examples are manifest as muscovite/sericite well-foliated schists with disseminated grains of pyrite or pyrrhotite with minor galena, sphalerite and chalcopyrite. Gauging the intensity of alteration is subjective, but there is a clear and continuous outward dissipation of intensity so that it rarely extends 50 m beyond the edge of the massive sulphide. Most of the pervasive muscovite alteration appears to be in the hanging wall of the deposit although it is likely that similar alteration in the footwall has been obliterated by strong Type 2 alteration. The intensity of pervasive muscovite alteration exhibits an inverse relationship with ankerite abundance in the hanging wall, possibly because the muscovite alteration stripped the components necessary for the formation of carbonate or, conversely, dissolved any pre-existing carbonate.
Type 4 ("Proximal Chlorite Alteration")	Dark green chlorite restricted to narrow (typically <5 m) intense alteration envelopes marginal to the massive sulphide body, primarily in the hanging wall and within the massive sulphide itself. Associated minerals include biotite, feldspar, quartz, ankerite, magnetite and sulphide, the latter typically pyrrhotite + chalcopyrite as disseminated grains, clots or wisps. Broader zones of weak to moderate chlorite also occur as strata-bound zones marginal and distal to massive sulphide lenses particularly down dip. Cominco did not recognize that proximal chlorite alters the footwall MAFi, indicating that MAFi pre-dates massive sulphide deposition. Proximal alteration rarely extends far into the MAFi, likely because it is impermeable relative to the host felsic volcaniclastic.
Type 5 ("Restricted Cordierite Alteration")	Is less widespread than the other alteration types and is spatially associated with proximal chlorite. Cordierite typically occurs as grey glassy porphyroblastic crystals up to 2 centimeters across within a chlorite matrix that are often partially or completely retrograde altered to chlorite and quartz and rarely tourmaline. It is frequently associated with coarse ferroan dolomite and silicification. Two distinctive styles of this restricted cordierite have been identified: (1) in association with proximal chlorite alteration as thin zones marginal to, and extending into, the massive sulphide, and (2) as relatively distal strata-bound zones extending beyond the massive sulphide where porphyroblastic type growth occurs in fine-grained carbonaceous and tuffaceous mudstones and ash tuffs with or without chlorite. It is thought the strata-bound occurrence of this alteration type may represent more of a distal halo, signifying the outer limits of fluid penetration.

Most host rocks of the ABM deposit show a penetrative schistosity (foliation or fabric are used synonymously for schistosity), the intensity of which is dependent on host rock type. For example, the coherent facies rhyolite unit (e.g. RHYc) typically lacks tightly-spaced penetrative schistosity whereas the volcaniclastic facies rhyolite units (e.g. RHYv), which were presumably ash-rich, generally exhibit an intense, tightly-spaced, penetrative foliation. Most foliation is broadly concordant to the main lithological layering of rocks hosting the ABM deposit.

Schistosity is folded about tight to isoclinal parasitic folds that are widespread. In drill core, these folds are common and are typically centimetre-scale. Similar but larger (e.g. metre-scale) folds are more difficult to see in drill core but are present in outcrops west of the ABM (Szybinski, 1996). Within fold hinges, an earlier foliation that is concordant to probable primary layering (bedding) is preserved and both the primary layering and early foliation define the folds. Along fold limbs, however, the folded fabrics and later axial-planar foliation are transposed together and are co planar. This composite fabric is the dominant tectonic foliation throughout the ABM deposit.

Brittle faulting along both the East and Sunda faults truncate early ductile foliation. Although no direct age of this faulting exists, it is likely these faults formed during the ~425 km of Eocene dextral slip along the Tintina Fault, located about 30 km southwest of the ABM deposit (Baker, 2015b). The East Fault is taken as the boundary between the ABM and Krakatoa zones of the ABM deposit.

7.3.2 GP4F deposit

The GP4F deposit is located about 5 km southeast of the ABM deposit and is interpreted to occur within an interval of KZK felsic metavolcanic that lies stratigraphically below the ABM deposit (Jones, 2016) (Figure 9). An inferred resource calculated by CSA (Green, 2015) in July, 2015, and reported in accordance with the JORC code, is summarized in Table 13. The resource estimate is based on data obtained from 10 historical DDHs that were drilled in 1998 and the resource has as yet not been updated with the 2015 diamond drilling results.

Table 13: Inferred mineral resource estimate for the GP4F deposit

Resource category	Mt	Cu (wt%)	Pb (wt%)	Zn (wt%)	Au (g/t)	Ag (g/t)	Cu metal (Kt)	Pb metal (Kt)	Zn metal (Kt)	Au (Koz)	Ag (Moz)
Inferred	1.7	0.2	2.6	6.1	1.0	76	2.6	44.7	104.5	54.3	4.2

The most-explored portion of the GP4F deposit (the “GP4F lens”) comprises thin lenses of massive sulphide hosted within a much larger, tabular body of disseminated mineralization and alteration; resources reported for the GP4F deposit are contained entirely within the GP4F lens. The GP4F lens is typically 5–10 m thick and is best-developed in a “central area” (where most drilling has been completed) that measures 500 m in a north-south direction, 300 m from east to west and strikes ~300° with a dip to the north ranging from 20-30°. It also appears to be present within DDH K15-247 located 400 m to the west of the central area (Jones, 2016). A second mineralized zone, recognized during 2015, occurs structurally below the GP4F deposit and is termed the Lower target (Jones, 2016).

Mineralization in the GP4F lens consists of narrow, high-grade, lenses of massive sulphide (pyrite + pyrrhotite + sphalerite + galena) within an envelope of stringers and blebby to disseminated bands of sphalerite + pyrite ± pyrrhotite + galena + chalcopyrite concentrated between sections 419400E and 491560E (Jones, 2016). These massive sulphide lenses are similar to the OB ore type at the ABM deposit (as defined in Table 11), with 50–70% massive to buckshot textured pyrite along with semi-massive to massive bands of sphalerite and/or pyrrhotite. Sphalerite also occurs as larger blebs and small masses whereas galena and chalcopyrite occur mostly as interstitial fillings and disseminated blebs. Massive sulphide mineralization typically contains relatively high zinc and silver grades with some of the best grades returned from historical DDH K98-188, where mineralization comprises several stacked 0.1–0.4 m thick massive sulphide bands (OB type) within an interval of heavily disseminated and stringer sulphide (OJ type) associated with strong chlorite + biotite + cordierite + garnet alteration. This interval returned 9.7% Zn, 4.1% Pb, 0.2% Cu, 117 g/t Ag and 1.7 g/t Au over 8.9 m. Similar mineralization was intersected in DDH K15-306, which returned 7.4% Zn, 2.8% Pb, 0.15% Cu, 123 g/t Ag, and 1.0 g/t Au over 4.65 m (Jones, 2016).

More typically, the GP4F lens consists of stringer/disseminated-style sulphide mineralization hosted by strongly chlorite + biotite altered host rocks (Jones, 2016). This mineralization style typically consists of 0.1 to 1 cm wide sulphide stringers and 1–4 cm wide bands of 5–40% blebby to disseminated sulphides ranging from sphalerite to sphalerite + galena to pyrrhotite + pyrite + chalcopyrite and various combinations in between. Chalcopyrite also occurs in fractures, commonly with pyrrhotite or pyrite (Jones, 2016). There is some evidence of the sulphides overprinting the altered groundmass (Boulton, 2002), suggesting a replacement-style of sulphide mineralization. Alternatively, the lack of banding and preferred orientations for sulphide minerals could also be the result of recrystallization through regional metamorphism.

The Lower target consists of thin semi-massive to massive sulphide (pyrrhotite + sphalerite + pyrite) associated with deformed quartz veins and more widespread stringer/disseminated sulphide mineralization similar to the GP4F lens (Jones, 2016). In some places the Lower target only comprises stringer to disseminated sulphide mineralization. The Lower target is also characterized by variable weak to strong

alteration, variable thicknesses ranging from 1.5 to 20 m and varying stratigraphic position from 15–40 m below the GP4F lens (Jones, 2016). The best results for the Lower target come from DDH K15-306 on Section 419500E that returned 6.25% Zn, 1.03% Pb, 0.16% Cu, 18.7 g/t Ag, and 0.023 g/t Au over 5 m true thickness.

Figure
9

The dominant alteration type in the GP4F deposit is considered equivalent to the “Proximal Chlorite Alteration” (see Table 11) at the ABM deposit (Hughes and Baknes, 2015), characterized by chlorite, cordierite and minor biotite although slightly modified by the presence of (in places zinc-rich) garnet porphyroblasts, modal biotite that is greater than or equal to chlorite, and gahnite (Boulton, 2002). Alteration is typically strongest above the massive sulphide lenses of the GP4F lens but is ubiquitous throughout and below the GP4F lens as well.

Cordierite is present in the alteration assemblage although it was not noted by Cominco and only described in one thin section by Boulton (2002). Cominco make numerous references to albite alteration, commonly where cordierite has been seen in re-logging of 1998 DDHs. This “albite” is described as whitish porphyroblasts and vitreous masses, which is similar to cordierite habits seen at the ABM and GP4F deposits.

Muscovite is an important part of the alteration assemblage and commonly occurs peripherally to the strongest alteration and mineralization, just like it does at ABM although in somewhat lower abundance. It generally occurs as strong bands and patches in felsic rocks and tuff immediately adjoining and within the GP4F lens.

8.0 RESULTS OF THE 2015 WORK PROGRAM

The 2015 KZK Project comprised a multifaceted exploration and development program primarily geared towards completion of a new mineral resource estimate for the ABM deposit that is compliant with modern reporting standards. In addition, the program aimed to collect data to allow various end users to advance engineering, mine and environmental designs for completion of a pre-feasibility study and eventual mining operations. The following sections describe significant results from the 2015 program available at the time of reporting.

8.1 Road rehabilitation and camp construction

Pre-work program construction involved rehabilitation of the tote road, which connects the Robert Campbell Highway to the project area, and building of a temporary exploration camp. Only the camp construction is described here.

The KZK exploration camp was constructed to accommodate up to 49 people (Figure 10). Camp facilities consist of 15 sleeper tents (each capable of sleeping up to 4 people), one Level III first aid tent, two dry tents containing shower and facilities for washing and drying clothes, four pit privy ablution facilities, a septic system and dispersal field for grey water, a mess tent and kitchen facility, an 8” diameter water well with UV water filter system to provide potable water, three dedicated office tents, a core logging and processing facility, Jet A1 and diesel bulk fuel storage and a helicopter landing area.

8.2 Historical core re-logging

A re-logging program of archived drill core from all historical DDHs at the ABM deposit was undertaken ahead of and during the 2015 drilling program. The aim of this program was to design and implement a system of standardized logging for historical and 2015 drilling, improve the geological model for the deposit and confirm historical assay data. The major categories of data collected through core logging include lithology, oxidation, mineralization, structure, veins and carbonate content, as shown in the drill logs included as Appendix E. Other elements of this program included logging the footage blocks, re-labelling boxes with aluminium tags, completing an inventory of boxes and creating a map of the core storage area. The re-logging program was completed in October.

The core archive was found to be in good shape with core boxes stored in metal racks and generally in order. No inventory or core shack map was available, however, so a box-by-box inventory was completed during the 2015 program with notes included on labelling or missing core issues. The vast majority of original Dymo-style metal tags are intact and only about 10 boxes were damaged to the point of needing to be replaced. Minor damage to boxes, mostly due to chewing by rodents, resulted in some minor core spillage to the ground. In addition, numerous specialized studies requiring core samples resulted in a lack of core for several DDHs as well as short wall rock intervals throughout the deposit, with the broader of these intervals recorded as “no core” during core re-logging.

A total of 174 DDHs were re-logged for a total of 24953 m (Table 14), comprising most of the historical ABM and Fault Creek drilling as well as two DDHs from GP4F. Six ABM DDHs were not re-logged, including three DDHs that could not be located (K94-001, K94-002, K95-169), one DDH abandoned at 10 m depth (K97-183A), one with too much missing core (K95-168) and one that was found but inadvertently not logged (K97-176). An additional nineteen historical DDHs fell outside of the ABM and GP4F deposit areas and were also not re-logged.

The historical core re-logging program began on July 2nd, nearly four weeks before the 2015 resource and infill drilling program began. As such, the re-logging program served as a testing ground for the newly implemented set of lithological and ore-type codes that were produced prior to fieldwork and which are shown in Tables 9 and 11.

A total of 1656 samples were submitted for geochemical assay to SGS in Burnaby, BC, comprising 1447 half-core samples, 120 CRMs (or standards) and 89 blanks. A QA/QC analysis for these CRMs and blanks is presented in Appendix N, together with the QA/QC data returned for newly drilled core samples (see Section 8.5). The 1447 core samples taken from historical drill core can be split into shoulder samples (N = 998) and grade confirmation samples (N = 449).

Shoulder sampling targeted the historically unsampled intervals of weakly mineralized to barren wall rock lying 4.5–6.0 m outward from the massive sulphide contacts. Out of the 998 shoulder samples that were taken, 170 returned at least one precious (Ag, Au) or base (Cu, Pb, Zn) metal assay exceeding the “mineralized” threshold, which was set at 20 g/t Ag, 0.1 g/t Au, 0.1% Cu, 0.5% Pb and 0.5% Zn. Ten of the best assays returned from the shoulder sampling program are shown in Table 15.

An important aspect of the re-logging program was to establish the quality of historical assay results for the 2016 resource estimate. Some of the historical assay data will be superseded by new assay results from 2015, but where this is not possible due to missing core or where re-sampling was not completed, the historical assay data will be the only data available. The remaining half-core was sampled from all of the mineralized intervals on sections 414750E, 414850E and 415050E (Appendix M), which were considered to be representative of mineralization over the breadth of the deposit. These sections include historical DDH K94-007, 008, 009, 010, 013, 014, 020, 021, 022, 023, 039, 047, 049, 052, K95-070, 071, 075, 081, 087, 088, 092, 149, 150, 156 and 157.

The historical assay results and 2015 re-assays were compared for 417 samples using traditional scatter plots and quantile-quantile (Q-Q) plots (Arne, 2015). Pearson correlation coefficients (ρ) for historical assays and 2015 re-assays are 0.852 for Ag, 0.701 for Au, 0.948 for Cu, 0.909 for Pb and 0.897 for Zn. Further comparison of 2015 re-assays to historical assay results indicates no analytical bias for Cu up to 3%, a slight positive bias for Pb in the re-assays worsening above 2%, a positive bias for Zn in the re-assays >2.6%, good agreement for Ag up to 250 ppm and a good agreement for Au up to 3 ppm followed by a negative bias in the re-assays >3ppm (i.e. historical results were higher than re-assays) (Arne, 2015).

Historical core was also re-photographed since the Cominco pictures were of inconsistent quality. Re-taking of these photographs was especially important for those intervals where the remaining half-core was sampled as part of the re-sampling program.

8.3 Terrain surveys

Terrain surveys include an airborne LiDAR survey and DGPS survey of both historical and 2015 DDH collar locations as well as the tote road.

8.3.1 DGPS collar survey

The drill collar survey located 87 2015 DDHs including 81 ABM and Krakatoa Zone DDH collars and 6 GP4F collars. Eight of the ABM DDHs comprise metallurgical wedge holes and therefore have the same collar location as their parent hole. Ninety-one historical DDH casings were also surveyed, most of which fall within the KZK Property boundary (Figures 11a, 11b). Two historical DDH collars (R12-09, R12-12) are located outside the KZK Property and were surveyed by mistake. Coordinates for all DGPS surveyed 2015 and historical DDH collars on the KZK Property are presented in Appendix G.

8.3.2 DGPS tote road survey

The tote road was surveyed along the centre line at 20 m-spaced points for its full 24 km length from the intersection with the Robert Campbell Highway to the terminus at the historical Cominco exploration camp that lies just to the south of the ABM deposit.

8.3.3 LiDAR survey

A 33 km² airborne LiDAR survey was completed over the ABM deposit and potential mine infrastructure locations to provide a high resolution topographic surface that can be used for detailed mine design work.

8.4 Geophysics

Geophysical work done as part of the 2015 work program include airborne VTEM and magnetic, ground-based gravity and downhole EM surveys. Most of the following results are taken from reviews by Lajoie (2015a, b) of both the 2015 and historical geophysical surveys.

8.4.1 Airborne magnetics and EM

An airborne magnetic and VTEM survey was flown in 2015 targeting primarily the KZK Formation from several kilometres west of the ABM deposit to east of the GP4F deposit (Figures 12a, 12b). Several stratigraphic units were outlined by the airborne geophysical survey. In particular, the Wind Lakes Formation, which lies in the northern part of the survey area and stratigraphically above the KZK Formation, shows relatively high magnetic and reduced resistivity responses that reflect its constituent mafic sills, mafic volcanic and carbonaceous sedimentary rocks. In the central part of the survey area, the felsic volcanic-dominated KZK Formation shows relatively subdued magnetic and resistivity response except where cut by large sills(?) of the Grass Lakes Suite, which have enhanced magnetic susceptibility.

The ABM Zone is a strong, well-defined conductive and magnetic target. The airborne survey shows untested areas of enhanced conductivity at the edges of the deposit opening the possibility of incremental extensions to the known mineralization.

More significantly, the VTEM survey highlighted an area of conductivity and magnetic response on the southeast edge of the ABM Zone. The VTEM response matches well with earlier UTEM surveys conducted in the area (Lajoie, 2015). Testing of a geologically defined target in 2015 in the same area as this anomaly resulted in the discovery of the Krakatoa Zone, which added significantly to the ABM deposit resource (see section 8.5.2). The geophysical response was subsequently recognised as being linked to the up-dip extent of Main lens sulphide mineralization where it came into range of the geophysical survey technique.

Another mineralized zone, the Fault Creek target, occurs about 800 m south of the ABM deposit and was detected on one of the VTEM lines. Results are consistent with a flat lying zone and seem to limit the extent of the Fault Creek target to an area of about 100 m by 100 m, centred about 45 m southeast of DDH K97-181. This is corroborated by results of a HLEM survey in the area (Lajoie, 2015b). A separate, smaller anomaly occurs about 100 metres south of the Fault Creek target. This anomaly lies north of the collar for DDH K97-182, which apparently missed the south edge of the anomaly. However, there is simply not enough resolution at a VTEM line spacing of 150 metres to define these smaller targets properly and they are too small to be of much economic interest (Lajoie, personal communication).

There is a small but prominent EM response about 1.5 kilometres southwest of the ABM deposit at 413300E, 6814850N, which is also associated with a gravity high but only a weak magnetic response. This anomaly, which is referred to as the Tarawera target (Figures 12a, 12b), is a potential drill target as it lies roughly on strike from the ABM deposit and is hosted by similar lithologies.

Located about 5 km southeast of the ABM deposit, the GP4F deposit is marked by an EM and magnetic bulls-eye anomaly that is centred on the so-called “central area”. However, there is not an obvious extension of the anomaly outside of this central area of mineralization, which is corroborated by the downhole EM surveys discussed below. As well, there is no clear connection to conductors lying northeast of the GP4F deposit towards DDH K04-199 (Lajoie, 2015b).

Southeast of the GP4F deposit, the airborne survey detected the north edge of the R-15 deposit. The response suggests that the R-15 extends down dip in a northwest direction. The geophysical results also suggest that R-15 is not on the same horizon as the GP4F deposit and may match a conductor trend passing about 200 metres south of GP4F and extending southwest. Beyond that, the VTEM trend shifts northwest (faulted?) where it correlates along its south side with EM contacts detected in earlier UTEM surveys (Lajoie, 2015b).

Figure
12b

There is a combined VTEM and magnetic response about 750 m northwest of the GP4F deposit that roughly correlates with a broad gravity high (the “Lakagigar target”). Progressing to later times (deeper source?), the VTEM response migrates further northwest. Drilling showed this anomaly to be caused by shallowly north to northeast dipping, carbonaceous sedimentary rocks with slightly elevated bulk density (Jones, 2016).

There is a strong conductor (the “Tambora target”) below Jim Lake at the south edge of the airborne survey. There is no obvious connection between the Jim Lake conductor and the R-15 or GP4F deposits.

8.4.2 Ground-based gravity

A ground-based gravity survey was completed over a 6 km x 2 km area extending from Rhyolite Peak over the ABM and GP4F deposits to identify positive gravity anomalies that could represent additional VMS mineralization. Processed results of this survey (Lebel, 2015b) show a strong positive gradient trending to the north half of the grid (Figure 13a). With the trend removed by processing, more detail is apparent. In particular, the third order trend-removed map (Figure 13b) shows a small residual gravity high at GP4F deposit subcrop, corresponding with the airborne EM and magnetic response. The north edge of the R-15 deposit is apparent at the south-eastern limit of the gravity survey in this area.

The ABM Deposit has a strong gravity response and this was demonstrated by the one 2015 gravity survey line that crossed it. The Krakatoa Zone was not surveyed in 2015. Southwest of the ABM deposit, there is a roughly east-west gravity high on the north slope of Rhyolite Peak. This gravity response correlates with the Tarawera target, a single line VTEM response and weak magnetic high at 413300E, 6814850N (see section 8.4.1).

The Fault Creek target is crossed by a single gravity survey line and does show a weakly elevated response. To the east across the valley, another small residual gravity high appears on Line 8E, roughly coincident with a magnetic high response (the “Tarumae target”). There is not any obvious EM signature associated with this gravity anomaly. However, the anomaly merits consideration given the proximity of the Fault Creek target and the possibility that this area could represent fault offset stratigraphy equivalent to the Krakatoa Zone.

8.4.3 Downhole EM

Downhole EM surveys were completed in seven of the ten 2015 DDHs drilled in the GP4F area and one of the ABM DDHs (Lebel, 2015a). Under ideal conditions this type of survey can detect a conductor up to 150 m away from the drill hole. However, it is more likely that the survey will recognize conductors within about 100 m of the drill hole.

The surveys generally confirmed targets within the central area of the GP4F deposit (Figure 14), representing GP4F lens mineralization. No strong conductors were identified outside of the central GP4F area. Intriguingly, a possible conductor response was detected down dip from DDH K15-247, which currently marks the western-most extent of the GP4F deposit. Another weak off-hole conductor was detected to the north and west of K15-234, probably corresponding to a narrow interval of massive pyrrhotite that was intersected in this hole. However, there is no alteration or other indications of a significant mineralized horizon in K15-234 to suggest this off-hole anomaly is significant.

Carbonaceous sediment units showed up well in the downhole EM surveys. In particular, the sediment unit at the base of the Upper Sequence, intersected in DDHs K15-247 and 268, was highlighted. Also, there is a good conductor off-hole to the east and north of K15-261, around 280 m depth, that correlates with the carbonaceous mudstone occurring at the top of the Lower Sediment Sequence. This conductor lies well below the mineralized horizon intersected in K15-261 but there is some possibility that this conductor represents the northwest fringe of the R-15 deposit.

DDH K15-292 in the area just southeast of the main ABM deposit was also surveyed. This DDH cut the Krakatoa Zone and the extremely strong response from this mineralization obscured detailed interpretation at that level. Nonetheless, there were indications of the conductor continuing to the north, and down dip, results

that were borne out by further drilling in the area. Further up-hole, a smaller EM anomaly was detected that likely corresponds to the Upper lens that overlies the Krakatoa Main lens.

8.5 Resource and exploration drilling

The 2015 resource and exploration drilling program included confirmation, infill and expansion drilling of the ABM lens of the ABM Zone, exploration followed by infill drilling on the Krakatoa Zone, exploration drilling on two ABM-proximal targets (Santorini and Fault Creek) as well as infill and exploration drilling at the GP4F deposit. The following sections describe significant results from these drill programs.

8.5.1 ABM Zone

The majority of the 2015 drilling on the ABM Zone was directed at the resource-stage ABM lens (59 holes), with the other two holes directed at the Santorini target. Several of the historical and 2015 holes targeting the ABM lens were long enough to also test the ABM deep target.

8.5.1.1 ABM lens

The 2015 ABM lens resource confirmation, infill and exploration drilling program consisted of 59 DDHs for a total of 10333.6 m (Table 3, Figure 15), including two DDHs (for 119.7 m) stopped and re-drilled due to excessive deviation (K15-235) and intersection of a historical DDH (K15-269). Interpretive cross sections through the ABM lens are listed in Table 16 and shown in Appendix M. The interpretations presented below are derived from drill logs generated as part of the 2015 drilling and historical re-logging programs.

Resource confirmation DDHs were designed to twin mineralized intersections in historical DDHs on sections 414750E, 414850E and 415050E, with the aim of confirming the existence and tenor of massive sulphide mineralization in the historical resource. The program was successful in corroborating massive sulphide mineralization intersected by Cominco and in reproducing the assay results (see Section 8.2).

Resource infill drilling was designed to reduce the drill spacing to nominal 25–30 m pierce points and was also intended to expand the ABM lens to the east, west and down dip of the historically-defined resource. Infill drilling demonstrated that intersections of mineralization are predictable based on the historical pierce point distribution and density, and no significant departures existed except where mineralization was closed off. DDH intercepts of the ABM lens drill program are displayed in Table 17.

The resource expansion program intersected additional massive sulphide mineralization in DDHs K15-204 and K15-207 on section 414550E, providing confidence that the ABM lens continues along strike 25 m further west from DDH K95-102 (section 414575E). The intersections are located close to surface and contain appreciable Cu and Zn grades associated with OI-, OD-, OJ- and OA-style mineralization in association with a strong chlorite and locally cordierite-bearing alteration envelope (i.e. Proximal and Restricted alteration types in Table 12). However, precious metal grades are negligible. These intersections suggest that the ABM lens is still open to the west and further exploration drilling at this western extent is warranted.

Infill drilling was also successful in expanding the ABM lens to the north at its down dip extents from section 414800E to 415000E, with significant sulphide mineralization intersected in DDHs K15-233, K15-243 and K15-291 (Table 17). In K15-233, OJ-, OI- and OA-style sulphide mineralization was intersected from 175.20–181.36 m, immediately above the MAFi footwall unit and in an envelope of strong chlorite and cordierite alteration. K15-243 intersected OI-, OG-, OJ-, OA-, OB- and OC-style mineralization from 165.20–185.52 m in association with well-developed Proximal and locally-developed Restricted alteration. K15-291 extended mineralization a further 50 m down dip from K95-077, with OI- and OB-style mineralization intersected from 218.34–221.24 m and in association with moderate Proximal Alteration. The intersection of new mineralization in DDHs K15-233, K15-243 and K15-291 as well as the intersection in K94-027 shows that the ABM lens is still open for ~200 m of down dip extent from section 414800E to 415000E. The northern-most limits of ABM lens mineralization appear to be constrained by drill DDH K97-172 on section 414950E but there is room to extend and close of the ABM lens mineralization.

8.5.1.2 Other ABM Zone targets (Santorini, ABM deep)

The Santorini target is located immediately south-southwest of the ABM lens (Figure 16). The target is largely defined by favourable stratigraphy of the KZK Formation and a moderately well-developed VTEM conductor recognized from the 2015 airborne geophysical survey (Duncan and Rabb, 2015). Exploration work in 2015 comprised drilling of two DDHs (K15-327, K15-328) for 457 m (see Table 3, Figure 16) that tested the VTEM anomaly in the optimum location of a modeled EM plate conductor. Interpretive cross sections of the Santorini target drilling, depicting lithology and alteration, are listed in Table 18 and shown in Appendix M.

Table 18: List of sections through the Santorini target

Section	Target	Orientation	Looking	Width	Figure reference	2015 DDH
414625E	Santorini	000°	270°	+14/-16.5 m	Appendix M - Figure 25	K15-327
414675E	Santorini	000°	270°	+12.5/-30.0 m	Appendix M - Figure 26	K15-328

Both Santorini DDHs intersected rhyolite units (RHYva) cut by a mafic intrusive (MAFi) that is interpreted as the equivalent of the MAFi unit in the ABM lens footwall and the host to the Krakatoa Main lens (Duncan and Baker, 2015). No significant mineralization was present at this equivalent horizon at Santorini. However, several narrow intersections of OJ-style stringer mineralization associated with moderate to strong chlorite alteration occur at a stratigraphic position below, but near to, that of the Krakatoa Main lens, and which could be equivalent to the Krakatoa Lower lens. The best-developed mineralization was encountered in K15-327 and is coincident with the position of a modelled EM plate (Duncan and Rabb, 2015). A summary of Santorini assay results is presented in Table 19. The Santorini target remains open to the north-northeast where it coalesces with the VTEM anomaly produced by ABM. Further exploration drilling in this direction is warranted if the target size is thought to be significant.

Table 19: Notable assay composites from 2015 drilling on the Santorini target

DDH ID	From (m)	To (m)	Length (m)	Cu (%)	Pb (%)	Zn (%)	Au (g/t)	Ag (g/t)	Lens	Comments

	84.67	85.50	0.83	0.15	0.06	2.62	0.03	8.1	Lower Krakatoa?	OJ-hosted

The discovery of the Krakatoa Main lens (see Section 8.5.2) within the mafic footwall unit (MAFi) on the east side of the East Fault raised the possibility that the MAFi unit immediately west of the East Fault, where it occurs directly beneath the ABM lens, might also be mineralized ("ABM deep target") even though it was seen to be only weakly mineralised further west. To investigate this possibility, historical drilling throughout the ABM Zone was reviewed for evidence of mineralization and/or alteration within underlying MAFi and the felsic-MAFi contact zone (Duncan, 2015a). The review identified 13 historical DDHs that had mineralization associated with the MAFi unit. Several other DDHs also intersected muscovite-altered tuffaceous rhyolite units intercalated with the MAFi, and these were interpreted as distal-altered examples of the same favourable replacement unit that hosts the Krakatoa Main lens (Duncan, 2015a).

To test the Krakatoa Main lens stratigraphic position west of the East Fault (i.e. the ABM deep target), DDH K15-324 was drilled on section 415075E at the eastern extent of ABM, close to the East Fault and proximal to the Krakatoa Main lens itself. This section also contained a mostly untested and thick MAFi unit, as well as potentially porous tuffaceous rhyolite units preserved within MAFi considered favourable for replacement-style mineralization (Duncan, 2015a). K15-324 also occurs 100–300 m east of relatively narrow, and possibly distal, mineralized Krakatoa Main lens equivalent intercepts between sections 414950E and 414750E. K15-324 intersected 15.85 m of ABM lens massive sulphide from 100.65–116.50 m followed by 31.65 m of MAFi-hosted RHYi, from 136.15–167.8 m core depth, on what is now interpreted as the Krakatoa Main lens equivalent horizon. The base of the mafic footwall occurs 7 m below this 31.65 m interval of rhyolite, and is marked by strong muscovite alteration as well as minor stringer-style sulphide mineralization that includes 1–3% sphalerite, 1% galena and 1% pyrite. No samples were submitted for assay analysis.

8.5.2 Krakatoa Zone

Cominco originally intersected the “KZK-Offset” (now Upper lens) east of East Fault in DDHs K95-124 and K97-173 and considered the narrow intercepts in these DDHs to represent the up dip edge of the ABM lens (Schultze, 2001). BMC recognized this faulted part of ABM as a high-priority near-deposit exploration target and drilling in 2015 resulted in the discovery of the Krakatoa Main lens.

The Krakatoa Main lens discovery was made on the basis of geological targeting that identified an area potentially hosting the obliquely down-thrown portion of the ABM lens. This resulted in the discovery intersection in DDH K15-282 in what was only the second DDH drilled in 2015 east of the East Fault (the first DDH failed to penetrate deep enough to intersect mineralization in the MAFi unit). Follow-up drilling and refinement of drill targeting at shallower depths was made possible with the 2015 airborne VTEM data, which was delivered after the initial discovery intersection. Continued exploration success on the Krakatoa Main lens led to a resource definition program comprising 26 DDHs for a total of 6816.1 m (see Table 3, Figure 16). A series of geological sections through the Krakatoa Zone, depicting lithology and alteration, are listed in Table 20 and shown in Appendix M. DDH intercepts from Krakatoa Zone drilling are displayed in Table 21.

K-N	060°	300°	±25 m	Appendix M - Figure 24	K15-282, 325

Step-out drilling has demonstrated that the Krakatoa Zone is generally concordant to stratigraphic layering, oriented at 300º/35º NNE, within a faulted block of KZK Formation that is bound by the East and Sunda faults (Duncan and Baker, 2015). Massive sulphide mineralization continues to the top of bedrock, where it is truncated and buried under 20–30 m of glacial overburden, and remains open down-dip.

The Krakatoa Zone consists of three massive sulphide lenses: (1) the “Upper lens” interpreted as the stratigraphic equivalent to the ABM lens; (2) the MAFi-hosted “Main” lens with a true thickness up to 22 m; and (3) the “Lower lens” hosted at or near the contact between the base of the MAFi and underlying felsic rocks (Duncan and Baker, 2015). The Krakatoa Upper lens is hosted in felsic rocks and was originally intersected by Cominco in DDHs K95-124 and K97-173. The Krakatoa Main lens sits below this and is hosted both directly within the mafic footwall sill (i.e. MAFi) or within its intercalated felsic ash tuff units (RHYva) (Duncan and Baker, 2015).

The host rock types and alteration styles of the Krakatoa Main lens are mostly similar to those characterizing the ABM lens but with a few important differences. Firstly, the dominant host rocks for the Krakatoa Main lens are either felsic ash tuff sandwiched by mafic footwall or the MAFi itself (Duncan and Baker, 2015), in contrast to the ABM lens which is typically hosted in felsic rocks overlying MAFi. Mineralization styles in the Krakatoa Main lens typically comprise a combination of OB-style mineralization with higher gangue content than ABM, and OI-style associated with relic lapilli or felsic ash groundmass. It is thought that this characteristic provides direct evidence that the Krakatoa Main lens is a replacement style deposit and, by extension, adds support to the hypothesis that the ABM lens is also replacement (Duncan and Baker, 2015). Portions of Krakatoa appear similar to the up dip 50m of the ABM lens in terms of base and precious metal grades but Krakatoa also contains significantly higher barite content than ABM mineralization. Krakatoa also appears to have higher trace element concentrations of Sb, Se, Hg and As. Ongoing petrographic and metallurgical work will aid in the understanding and nature of these important differences (Duncan, 2015b).

Intercepts: length-weighted average with maximum 3m internal waste (true thickness). When assay value is below the detection limit, half the detection limit is used. Assay value composited if Cu>1%, Pb>2%, Zn>2%.

8.5.3 Other targets proximal to the ABM Deposit (Fault Creek)

The Fault Creek target is located approximately 400 m southwest of the Krakatoa Zone on the south side of the Sunda Fault (Figure 16). The target is marked by a coincident magnetic high and UTEM conductor that was first drilled in 1997. DDH K97-181 discovered massive sulphide mineralization just below the overburden surface that returned an assay composite of 6.4 m averaging 5.15% Cu, 1.02% Pb, 5.59% Zn, 140.5 g/t Ag and 2.4 g/t Au. Additional drilling failed to intersect more mineralization and led to the interpretation that mineralization was east-west striking and north dipping. Re-logging of historical Fault Creek DDHs, along with new 2015 VTEM geophysical data, provided an alternative interpretation for the orientation of mineralization as northwest striking and northeast dipping, thereby re-opening the target for additional drilling (Duncan, 2016). Interpretive cross sections of the Fault Creek target drilling, depicting lithology and alteration, are listed in Table 22 and shown in Appendix M.

Table 22: List of sections through the Fault Creek target

Section	Target	Orientation	Looking	Width	Figure reference	2015 DDHs
414800E	Fault Creek	000°	270°	±15 m	Appendix M - Figure 27	K15-329, 332
414750E	Fault Creek	000°	270°	±15 m	Appendix M - Figure 28	None

Two DDHs (K15-329, K15-332) for 382 m were drilled 50 m east of K97-181, on section 414800E, to test the alternative orientation of Fault Creek mineralization. Both DDHs intersected felsic and minor mafic volcanic rocks of the KZK Formation, but neither DDH intersected massive or stringer-style sulphide mineralization equivalent to the Fault Creek target intersected in K97-181 (Duncan, 2016). Weakly developed OJ-style mineralization was intersected in K15-329 at 158.00 m, hosted within RHYv units, while weakly disseminated sulphide was intersected in K15-332, at 174.15 m depth, within a SED unit just below its contact with overlying RHYv. Mineralization in both DDHs occurs within an envelope of moderate chlorite alteration and correlates well with similar OJ and disseminated stringer-style mineralization observed in DDH K97-182, located 160 m to the south. The 2015 drilling corroborates the new interpretation that stratigraphy strikes northwest and dips northeast. Key assay results are summarized in Table 23.

Table 23: Notable assay composites from 2015 drilling on the FCZ target

8.5.4 GP4F deposit

The 2015 work program on the GP4F deposit included exploration and infill drilling as well as borehole EM surveys (Section 8.4.3), a ground gravity survey between ABM and GP4F (Section 8.4.2) and an airborne VTEM survey (Section 8.4.1). The aim of these surveys was to assess both the resource expansion and exploration potential of the GP4F deposit and surrounding area. Significant results from the 2015 drilling program are described below. Interpretive cross-sections through the GP4F deposit, showing both lithology and alteration, are listed in Table 24 and shown in Appendix M. Significant assay composites from the 2015 work program are displayed in Table 25.

Table 24: List of sections through GP4F deposit

Section	Orientation	Looking	Width	Figure reference	2015 DDH

419560E	000°	270°	±25 m	Appendix M - Figure 34	None
419650E	000°	270°	±25 m	Appendix M - Figure 35	K15-261, 280, 285

Drilling consisted of 10 DDHs for a total of 3291 m (Figure 17) with borehole EM surveys completed in seven of those holes. Drilling was completed on three sections within the central area at GP4F on sections 419400E, 419500E and 419650E. The three DDHs on section 419400E were designed to infill between historical drilling (K15-224, K15-294) and test the GP4F deposit 200 m further down dip to the north (K15-234), Drilling on section 419500E (K15-302, K15-306) was done as 50 m step-outs from historical drilling in an attempt to expand the resource. The three DDHs drilled on 419650E were designed to expand the deposit to the east and northeast with 100–200 m step-outs. Additionally, two widely spaced DDHs (K15-247, K15-268) on sections 418750E and 418950E tested geophysical targets outside the deposit area and are shown together on one section (Figure 29 in Appendix M).

The 2015 drill program intersected the GP4F lens in all but one DDH and showed that it remains open to the northeast, southeast and southwest. The GP4F lens is tabular and marked by zinc-lead-copper sulphide mineralization as well as strong chlorite + biotite ± garnet ± cordierite alteration. The core of the GP4F lens forms the so-called “central area”, which extends 500 m down dip from surface and 300 m east to west. Within the central area massive sulphide mineralization is volumetrically subordinate to stringer and disseminated mineralization styles and consists of narrow lenses (thickest being 3.3 m true thickness) concentrated between sections 419400E and 491560E, and up dip from DDHs K98-193 and K15-306 (Jones, 2016). Assays returned from massive sulphide in K15-306 form a composite of 4.65 m grading 7.43% Zn, 2.83% Pb, 0.15% Cu, 122.6 g/t Ag, and 1.04 g/t Au.

A second, similar but less intense, altered and mineralized zone occurs underneath the GP4F lens and is referred to as the “Lower target”. This Lower target is present in most DDHs that were drilled deep enough (mostly the 2015 DDHs) but is quite variable in appearance and location, ranging from 1.5-20 m in thickness, occurring 15-40 m below the GP4F lens and associated with weak to strong alteration. The Lower target consists of either thin, massive to semi-massive sulphide lenses within a more widespread stringer/disseminated sulphide mineralization zone similar to the GP4F lens or stringer and disseminated sulphide mineralization only. The best assay composite for the Lower target was from K15-306, which ran 5 m of 6.25% Zn, 1.03% Pb, 0.16% Cu, 18.7 g/t Ag, and 0.023 g/t Au.

There is some evidence for a weakly-defined Upper target above the GP4F lens, especially on section 419650E, but more work is needed to determine if it has any continuity (Jones, 2016).

DDH K15-261, collared 100 m east-southeast of the GP4F central area on Section 419650E, intersected mineralization that may be equivalent in stratigraphic position to the R-15 deposit, located 600 m to the

southeast off the KZK Property. The R-15 deposit is still considered open in this direction with geophysics suggesting that there is additional potential for the GP4F deposit to continue along strike towards the R-15 deposit (Jones, 2016).

The 2015 drilling has shown that there is still additional exploration potential for expanding the GP4F lens. It remains open to the north-northeast from K15-306 and although the intensity of alteration does wane in this direction, as it does to the west and north-northwest of the central area as well, the GP4F lens is still identifiable in DDH K15-247 several hundred metres beyond the central area (Jones, 2016).

8.6 Drill site rehabilitation

All DDHs that intersected sulphide mineralization were plugged and grouted 20m below and 20m above the sulphide intersection and completed with a concrete cap at surface. In cases where the DDH were shallow it was more practical to grout the entire hole to surface.

Drill cuttings management was used for all DDHs that intersected massive sulphide mineralization. Whilst drilling through horizons of massive sulphide mineralization the drill return water was filtered and sulphide drill cuttings were removed and stored in bags. Upon completion of the DDH the drill return water was pumped from the sumps and the filtered drill cuttings were buried in the sump during drill site rehabilitation.

During the course of field work 7 historic Cominco DDHs (K94-013, 034, 041, 042, 049, K95-160, K97-182) were found to have flowing artesian conditions. The DDHs were plugged with a combination of neat cement and bentonite slurry grouts, depending on the flow pressure, and sealed with a casing cap.

8.7 Metallurgical sampling

Diamond drilling to collect whole core samples was the first step in a comprehensive metallurgical testing program for the ABM deposit that also included the definition of four major metallurgical geodomains, EDTA analysis and metallurgical test work (Black, 2015). Only the drilling and sampling is described here, however, as it is the only element of this work program that will be filed for assessment credit.

The 2015 metallurgical drilling program collected representative HQ3 whole core samples of seven geological subdomains based on observable mineralogy, texture and Cu:Pb grades that were interpreted from a desktop study prior to the field program commencing (Hughes et al., 2015). Drilling consisted of 29 DDHs for 3406.0 m (see Table 5, Figure 18) and comprised a combination of twin and wedge holes spread across the ABM lens to collect samples of both potentially oxidized and deeper non-oxidized geodomains.

A total of 1012 samples of HQ3 whole core were collected during the program that will be used to prepare representative composites of the four major metallurgical geodomains for test work. A list of the samples collected is presented in Appendix P.

8.8 Petrographic work

Petrographic analysis for the 2015 KZK Project was done on 96 polished thin sections (see Table 6), with 44 of these taken from the ABM Zone, 33 from Krakatoa Zone and 19 from GP4F deposit. Results are summarized below in terms of ore and gangue mineralogy for each zone/deposit, split into samples of massive sulphide (>60% sulphide), semi-massive sulphide (20–60% sulphide) and siliceous/carbonate rocks with <20% sulphide. Significantly more detail on the petrographic work, including descriptions and photos for each of the 96 polished thin sections, is presented in the reports attached in Appendix Q.

A total of 46 samples of massive sulphide (>60% sulphide) were sent for petrographic analysis, with modal abundances estimated for 42 of these (Table 25). Mineral abundances for the remaining four samples were qualified instead of quantified. The 42 samples with quantified modes include 26 from the ABM Zone, 11 from the Krakatoa Zone and four from GP4F. All three have massive sulphide assemblages that are dominated by pyrite (50–65% of sulphide) and sphalerite (15–30% of sulphide). The ABM and Krakatoa samples have higher magnetite and chalcopyrite contents whereas GP4F samples contain more pyrrhotite and galena. Trace amounts of sulphosalts occur in all three sulphide deposits, with SEM analysis (Townend and Townend, 2015) indicating that mineral species include freibergite ($Cu_{12}Sb_4S_{13}$), bournonite ($PbCuSbS_3$), tetrahedrite ($(Cu,Fe)_{12}Sb_4S_{13}$), stannite (Cu_2FeSnS_4), tennantite ($Cu_{12}As_4S_{13}$) and an unnamed PbSbS species. Native gold, electrum and argentite (Ag_2S) were also found (Townend and Townend, 2015). Gangue mineralogy in all three deposits is dominated by carbonate minerals (50–75%) along with minor abundances of quartz (10–15%) and chlorite (5%). GP4F gangue is characterized by higher sericite/muscovite (15%) and biotite (20%) whereas the ABM and Krakatoa samples contain an average of around 10% barite.

Samples of semi-massive sulphide (N = 28) appear to mirror the main mineralogical differences shown by the three groups of massive sulphide samples. Sulphide assemblages for the ABM and Krakatoa zones are dominated by pyrite (50–70%) and sphalerite (20%) with minor abundances of magnetite, chalcopyrite and sulphosalts in ABM as well as galena and arsenopyrite at Krakatoa (Table 26). Samples from the GP4F deposit, however, have a sulphide assemblage dominated by sphalerite (35%) and pyrrhotite (40%) with only minor pyrite, galena and chalcopyrite (Table 25). Gangue mineralogy for ABM and Krakatoa samples is dominated by carbonate with minor to major abundances of quartz, sericite/muscovite and barite, in addition to minor albite and chlorite at ABM. GP4F gangue mineralogy, on the other hand, comprises subequal amounts (10–20%) of carbonate, quartz, chlorite, sericite/muscovite, biotite, cordierite and amphibole, and also includes higher proportions of accessory minerals like apatite, tourmaline, allanite/monazite and spinel (gahnite?).

Unmineralized samples, which can still contain up to 20% sulphide, associated with the ABM Zone consist mostly of sericite/muscovite (60%) and quartz (25%) with minor chlorite. Samples from the Krakatoa Zone and GP4F deposit, on the other hand, generally comprise subequal (10–20%) amounts of carbonate, quartz, chlorite, sericite/muscovite and biotite, with Krakatoa also containing significant (10–15%) K-feldspar and plagioclase from the MAFi. Unmineralized GP4F samples are, again, also notable for their diverse accessory mineral assemblage that includes sphene, tourmaline, spinel (gahnite?), allanite/monazite and apatite. The sulphide assemblages are pyrite- and pyrrhotite-rich (each 30–40%) for ABM and GP4F whereas they are pyrite dominant (85%) for Krakatoa. ABM samples also contain significant (10–15%) proportions of chalcopyrite, sphalerite and marcasite whereas GP4F samples contain between 5–15% sphalerite, galena and magnetite. Krakatoa samples contain between 5–10% chalcopyrite and pyrrhotite.

8.9 Hydrogeological and geotechnical

The 2015 hydrogeological drilling program was designed to characterize the hydrogeological baseline conditions within the proposed ABM open pit area and mine infrastructure locations. The DDHs were located to tie into a network of re-developed historical monitoring wells and “piggyback” on ABM resource DDHs. At the time of writing this report no results characterizing the hydrogeological conditions of the project area had been received from Tetra Tech. A summary of the 2015 hydrogeological drilling program is provided below.

Eleven shallow monitoring wells were drilled for a total of 325.00 m (Table 8, Figure 19) at locations of proposed mine infrastructure and above the Krakatoa Zone mineralization. The DDHs were fitted with 1.25” PVC piezometers, in either the shallow bedrock or overburden, and packer testing was conducted in each borehole during advancement to infer subsurface hydraulic conductivities. A summary of the monitoring well completion details provided by Tetra Tech as of November 2015 is shown in Table 27.

Packer testing was also completed in seven of the ABM resource DDHs as they were being drilled, in an effort to determine the hydraulic conductivity of the fractured bedrock aquifer. Vibrating wire piezometers (VWP) were installed in two DDHs (K15-200, K15-248) to determine *in situ* pore water pressure and temperature, as well as test vertical hydraulic gradients.

Table 27: Summary of groundwater monitoring well completion details

Notes: * "Functional" means that representative groundwater elevation or sample can be obtained from the well.

The 2015 geotechnical drilling program comprised nine DDHs for a total of 955 m (Table 7, Figure 19). The program focussed on gaining a better understanding of the location of the East Fault and surrounding rock mass competency (3 DDHs) as well as characterising and confirming historical geotechnical information in the area of Cominco's designed surface infrastructure and at two alternative sites for the tailings storage facility (6 DDHs). Results from the surface infrastructure DDHs will assist with structural design work and will be used as part of a pre-feasibility study on the KZK Project to be completed by BMC during 2016. At the time of writing this report no results had been received from Knight Piesold characterising the geotechnical conditions of the proposed infrastructure sites.

Drilling that targeted the East Fault plus re-logging of historical Cominco drill core has provided valuable information on the location, nature and orientation of the fault structure. The current interpretation shows that the fault trends at ~50°, dips steeply (~85°) to the south east and is located slightly further north than Cominco's historic interpretation (Baker, 2015b). The fault is characterised by a zone of several-meter thick fault gouge and breccia often with milled and rounded sulphide clasts indicative of low temperature, late, brittle shear planes. The East Fault postdates massive sulphide mineralization, associated alteration and penetrative schistosity that affects the host rocks and it is likely that it formed in relation to slip along the Tintina Fault (Baker, 2015b).

9.0 DISCUSSION

The following sections provide some discussion on the results of the 2015 KZK work program, presented in the same order that they were described in Section 6.0 and Section 8.0. Highlights of the 2015 program were undoubtedly the discovery of the Krakatoa Zone and expansion of the ABM Zone, which together substantially increased the mineral resources of the ABM deposit. The discussion below for each element of the work program includes a brief overview of what was done and potential for future work.

9.1 Historical core re-logging program

The 2015 historical core re-logging program re-logged 87% of the historical DDHs from the KZK Property, for a total of 24952.8 m. The re-logging program was successful in developing a working interpretation of the deposit geology and simplifying the >300 lithological codes present in the Cominco database. This provided a framework for the 2015 data collection and allowed application of the same lithological, mineralization, alteration and veining codes to new and historic core and so provide a uniform core logging database.

Shoulder samples were collected from the historical core to characterize the waste rock adjacent to the ABM lens. In addition, 17% of these samples returned at least one precious (Ag, Au) or base (Cu, Pb, Zn) metal assay exceeding the “mineralized” threshold. The shoulder sampling program was therefore successful in expanding the database for ABM waste rock and adding to the mineral resource inventory.

Another important aspect of the re-logging program was to enable a direct comparison between the historical analytical results and the 2015 results for incorporation into the new resource estimate. This was done by sampling the remaining half-core from all of the mineralized intervals on sections 414750E, 414850E and 415050E and re-drilling each of these sections in their entirety. Comparison of 2015 re-assays to historical assays for Cu, Pb, Zn, Ag and Au indicates generally strong Pearson correlation coefficients (ρ = 0.851–0.972) and a good agreement in Cu up to 3%, positive bias for Pb in the re-assays, positive bias for Zn in the re-assays >2.6%, good agreement for Ag up to 250 ppm and a good agreement for Au up to 3 ppm with a negative bias in the re-assays >3ppm (Arne, 2015).

It is likely that small differences between the historical and 2015 re-assays are at least partly, if not mostly, related to differences and improvements in analytical techniques and detection limits during the 20 year time gap between these two assay programs. Ag results are in good agreement up to 250 ppm when both the historic and re-assay data was obtained using aqua-regia digestion. This agreement breaks down above 250 ppm Ag which is close to the upper detection limit for this method at SGS. The poor agreement and positive bias in historic data for Au above 3 ppm, rather than random scatter, suggests a major difference in the preparation and analysis of samples by fire assay (Arne, 2015). The re-assay program therefore appears to agree well with the historical assay data within the defined grade ranges but the combined dataset should be treated with caution outside of these ranges (Arne, 2015).

There is not much work that remains to be done on the historic core re-logging. The remaining GP4F DDHs that have been archived but were not re-logged in 2015 could be re-logged to further improve modelling and understanding of the GP4F deposit, as could those DDHs falling outside of the ABM and GP4F deposits.

9.2 Geophysical targets

Geophysical surveys carried out during 2015 included 304 line-km of airborne magnetic and VTEM, ground-based gravity and downhole EM. Targets generated from each of these surveys are listed below.

Results of the airborne VTEM survey helped define the geophysical characteristics of several formations in the KZK Property area, delineated the ABM Zone as a well-defined conductive and magnetic anomaly, and identified several anomalies that could be related to massive sulphide mineralization. One of these anomalies, comprising an area of conductivity and magnetic response on the southeast edge of the ABM Zone, is coincident with the newly-discovered Krakatoa Zone which points to the effectiveness of the VTEM data as an exploration tool on the Property. Other untested targets should be modelled using an integrated dataset, these include:

- Tarawera target: a small coincident EM and gravity anomaly with a weak magnetic response located 1.5 km southwest of the ABM deposit that appears to lie along strike of, and within similar host rocks to, ABM;
- The northern edge of the R-15 deposit occurring to the southeast of the GP4F deposit. Here the down dip extension of R-15 appears to extend northwest onto the KZK Property;
- Tambora target: a strong conductor below Jim Lake at the southern edge of the airborne survey. There is no obvious connection between the Tambora conductor and the R-15 or GP4F deposits;
- Lakagigar target: coincident VTEM, magnetic and gravity response located 750 m northwest of the GP4F deposit. Drilling in 2015 (DDH K15-268) intersected gently north to northeast dipping, carbonaceous sedimentary rocks which does not explain the gravity or magnetic response.

Targets identified by the ground-based gravity survey include:

- Tarawera target: a broadly east-west trending gravity high on the north slope of Rhyolite Peak, which coincides with a single-line VTEM response and weak magnetic high;
- Tarumae target: a small coincident magnetic high and residual gravity high occurring just east of the Fault Creek target.

Lastly, targets derived from the downhole EM survey include:

- A possible conductor detected down dip from K15-247, which defines the western-most extent of the GP4F deposit and may correlate with the Lakagigar target;
- A good conductor off-hole to the east and north of K15-261 that could represent the northwest fringe of the R-15 deposit.

9.3 Resource and exploration drilling on the ABM Zone

9.3.1 ABM lens

The 2015 resource confirmation drilling program on the ABM lens of the ABM Zone was successful in corroborating massive sulphide mineralization intersected by Cominco and in supporting the veracity of the historical analytical data. Resource drilling was designed to infill and extend the previous drilling coverage so that a revised resource estimate could be undertaken in accordance with JORC 2012 requirements.

The resource expansion program intersected additional massive sulphide mineralization that indicates the ABM lens remains open to the west, which is also corroborated by the continuation of the EM conductor. However, a thicker zone of proximal and restricted alteration intersected here may represent the beginning of a more distal alteration halo and the bleeding of hydrothermal fluids into the hanging wall, limiting mineralization potential. Nonetheless, further exploration drilling at this western extent is warranted to add any additional easily exploitable mineralization that may be present to the resource inventory, or to test for a new ore lens along the strike trend.

Infill drilling was also successful in expanding the ABM lens to the north at its down dip extents, from section 414800E to 415000E. The intersection of new mineralization in DDHs K15-233, K15-243 and K15-291, as well as a historical intersection in K94-027, also shows that the ABM lens is still open for ~200 m between sections 414800E and 415000E down dip. The down dip limits of the ABM lens are likely constrained by DDH K97-172 on section 414950E but there is some room to close of the ABM lens as suggested by the limits of the EM conductor. In this area the proximal and restricted alteration assemblages occur over a broader zone which could suggest that this down dip area is more distal to mineralization. Additional drilling is recommended here to close off the down dip limits of the ABM lens although this is a lower priority target.

Additional potential to expand the ABM lens east of section 415225E exists in a small triangular shaped panel of un-tested KZK Formation rocks situated between the last ABM lens intersections on section 415225E (K94-029 and K95-114) and the interpreted position of the East Fault now that it is better defined (Baker, 2015b). Drilling is recommended on sections 415250 and 415275E to test the eastern extent although extension in this direction will be limited by the East Fault. This area also shows a strong VTEM response.

Mineralization has been closed off down dip in the northwest area of ABM between sections 414575E and 414750E. No further drilling is recommended here unless required for mine planning purposes or upgrading the resource to indicated or measured category.

9.3.2 Santorini and ABM deep

The Santorini target was tested with two DDHs (K15-327, K15-328), both of which intersected narrow intervals of stringer-style sulphide mineralization within the so-called “Krakatoa Main lens” stratigraphic horizon. This target remains open to the north-northeast where it coalesces with the VTEM anomaly produced by the ABM lens, so further exploration drilling in this direction is warranted if the target size is deemed to be significant for the immediate project development.

The ABM deep target was developed in the ABM Zone west of the East Fault from comparisons to the Krakatoa Main lens, which occurs east of the East Fault within rocks that stratigraphically underlie the ABM lens. As a result, historic drill intercepts piercing the mafic footwall of the ABM lens were reviewed for their potential to host Krakatoa Main lens-style mineralization (Duncan, 2015a). This review identified 13 historical DDHs that may have intersected Krakatoa Main lens-style mineralization west of the East Fault, in addition to several other DDHs that hit muscovite-altered tuffaceous rhyolite on the Main lens horizon (Duncan, 2015a). DDH K15-324 was drilled to test the ABM deep target but did not intersect significant sulphide mineralization. Instead, it hit a thick package of rhyolite (RHYi) that, together with results of the historical DDH review, suggests a crude inverse relationship between the thickness of RHYi and the presence of sulphide mineralization. Hence, the best areas for hosting ABM deep target mineralization are those where RHYi is either absent, thin or located along a different stratigraphic horizon (e.g. sections 414750E to 414950E). This supports the hypothesis that RHYi is peri-contemporaneous with mineralization and not only occupies favourable host stratigraphy within MAFi, but could destroy and remobilize existing ABM deep target mineralization.

It is believed that there is significant potential for the discovery of additional pods of mineralization on the ABM deep horizon. Additional work is recommended around historical DDH K95-053, on section 415000E, and around the four historical drill intersections on section 414950E. Another compelling target is the relatively thick MAFi package between section 415075E and the East Fault.

9.4 Resource and exploration drilling on the Krakatoa Zone

The discovery of the Krakatoa Zone was the highlight of the 2015 KZK Project, with the most recent resource estimate (BMC, 2016) showing that it adds 5.1 Mt of combined Indicated and Inferred resources to the ABM deposit. This discussion provides a brief background on the discovery of the Krakatoa Zone, its features and remaining exploration potential.

The Upper lens of the Krakatoa Zone was intersected by Cominco in DDHs K95-124 and K97-173, which interpreted these narrow intercepts as the up dip edge of the ABM Zone and referred to it as the “KZK-Offset” (Schultze, 2001). BMC recognized this faulted-off part of ABM as a high-priority near-deposit exploration target with subsequent 2015 drilling resulting in the discovery of three stacked massive sulphide lenses; (1) the Upper lens interpreted as the equivalent to the ABM lens, (2) the MAFi-hosted Main lens with a true thickness up to 22 m, and (3) the Lower lens hosted at or near the contact between the MAFi base and underlying felsic rocks (Duncan and Baker, 2015). The Upper lens is hosted in felsic rocks and is the “KZK-Offset” intersected by Cominco. The Main lens sits below this and is hosted either directly within the mafic footwall sill (i.e. MAFi) or within felsic ash tuff units (RHYva) intercalated within MAFi (Duncan and Baker, 2015). Step-out drilling from the discovery DDH demonstrated that Krakatoa Zone mineralization is generally concordant to stratigraphic layering, comprising a dominant ~20 m thick Main lens with areal extends of about 200 by 300 m (Duncan and Baker, 2015) and hosts 5.1 Mt grading 0.6% Cu, 3.2% Pb, 7.5% Zn, 1.7 g/t Au and 213 g/t Ag (Green et al., 2016).

The host rock types and alteration styles of the Krakatoa Zone share similarities with the ABM Zone but also show some important differences. The first of these differences is its relation to the upper contact of the mafic (MAFi) footwall unit, with the Krakatoa Main lens occurring mostly below this horizon and the ABM lens occurring above it (Duncan and Baker, 2015). Mineralization styles are also somewhat different, with the Krakatoa Main lens comprising a combination of OB-style mineralization with higher gangue content than ABM, and OI-style associated with relic lapilli or felsic ash groundmass. This latter feature supports the interpretation that the Krakatoa Zone is a replacement-style deposit and, by extension, adds support to the hypothesis that the ABM Zone is as well (Duncan and Baker, 2015). The Krakatoa Main lens also contains higher grades of

Pb, Zn, Au and Ag than the ABM lens, although the ore mineralogy is broadly similar (Duncan, 2015b), and appears to contain more barite.

The Krakatoa Main lens remains open at depth but is closed off in most other directions. The 2015 work program defined the Main lens from >300 m depth to within 50 m of surface, where it is truncated and buried under 20–30 m of glacial overburden. It's eastern and western extents are truncated by the Sunda and East faults respectively. There is potential that continuations of the Krakatoa Zone are offset by the Sunda and Fault Creek faults and this is a high priority exploration target for future work programs.

9.5 Exploration drilling on ABM-proximal target (Fault Creek)

The Fault Creek target is centered on a geophysical anomaly and a 6.4 m historical intercept of massive sulphide that assayed 5.2% Cu, 1.0% Pb, 5.6% Zn, 141 g/t Ag and 2.4 g/t Au (K97-181). Re-logging of drill core and integration with 2015 VTEM data led to a revision of the stratigraphic interpretation in the area to northwest striking and northeast dipping (Duncan, 2016), as opposed to the east-west striking and north-dipping orientation interpreted by Cominco. Nonetheless, this revised structural interpretation did not meet with exploration success as neither of the 2015 DDHs (K15-329, K15-332) intercepted significant mineralization. Coincident intervals of weakly developed mineralization and moderate chlorite alteration in both DDHs correlate with mineralization in K97-182, located 160 m to the south, which corroborates the newly interpreted strike and dip of the stratigraphy.

9.6 GP4F deposit

Nine of 10 DDHs in the GP4F area intersected the GP4F lens. Drilling has demonstrated that the GP4F lens remains open to the northeast, southeast and southwest. One of the best assay composites from the 2015 program was returned from a massive sulphide interval in K15-306 comprising 4.65 m that grades 7.43% Zn, 2.83% Pb, 0.15% Cu, 122.6 g/t Ag, and 1.04 g/t Au.

The 2015 program also identified thin zones of mineralization and alteration above and below the GP4F lens, referred to as the Upper and Lower targets respectively. The Lower target is the better-developed of these two and returned an assay composite of 5 m grading 6.25% Zn, 1.03% Pb, 0.16% Cu, 18.7 g/t Ag, and 0.023 g/t Au from K15-306. The Upper target is less well-defined and needs more work to determine whether it has any continuity (Jones, 2016).

DDH K15-261 was collared 100 m east-southeast of the GP4F central area and intersected mineralization that may be equivalent in stratigraphic position to the R-15 deposit, located off the KZK property 600 m to the southeast. The R-15 deposit is still considered open in this direction with geophysics suggesting additional potential for the GP4F deposit to continue along strike towards the R-15 deposit (Jones, 2016).

The 2015 drilling has shown that there is still additional exploration potential for expanding the GP4F lens to the northeast, southeast and southwest. The best target direction is to the north-northeast from the well mineralized intersections K15-306. Although the intensity of alteration does wane in this direction, as it does to the west and north-northwest of the central area as well, the GP4F lens can still be identified in DDH K15-247 several hundred metres beyond the central area (Jones, 2016).

9.7 Metallurgical, geotechnical and hydrogeological drill programs

The 2015 metallurgical drilling and sampling program was successful in completing 29 DDHs and collecting 1012 samples that will be split among several composites. No other results for this program were finalized at the time of writing of this report.

The geotechnical drilling and sampling program was successful in completing nine DDHs for 955.4 m and refining the position and nature of the East Fault. No other results for this program were finalized at the time of writing of this report.

The 2015 hydrogeological drilling program was successful in completing 11 shallow monitoring wells at locations of proposed mine infrastructure and above the Krakatoa Zone mineralization as well as completing VWP installations and bore hole packer testing within the area of the proposed open pit. At the time of writing

this report no results characterizing the hydrogeological conditions of the project area had been received from Tetra Tech.

10.0 CONCLUSIONS AND RECOMMENDATIONS

Additional core re-logging should be carried out on the 22 DDHs that are archived but were not re-logged in 2015, especially for improving interpretations of the GP4F deposit and examining additional exploration targets on the Property.

Follow-up work on geophysical surveys should include additional airborne VTEM/magnetic surveys to cover untested ground on the Property, as well as further interpretation/modelling on the 2015 results. Additional work is also recommended for targets identified through the 2015 surveys that include (1) mapping, and if warranted, drilling the EM-gravity Tarawera target, (2) drilling the ground between the R-15 and GP4F deposits, (3) additional gravity to cover the EM Tambora target, and (4) additional modelling of the coincident VTEM-magnetic-gravity Lakagigar target, located 750 m northwest of the GP4F deposit in light of the results from DDH K15-268.

Future work on the ABM lens should include expansion drilling to the west, north (down dip) and the eastern small triangular shaped panel of un-tested KZK Formation between section 415225E and the East Fault. Additional infill drilling could be done on certain sections to further define the local variations in thickness and grade of the ore bodies, and/or to upgrade inferred and/or indicated resources to the indicated and measured categories respectively.

Drill testing of other ABM Zone targets (Santorini, ABM deep) met with limited success in 2015. Perhaps the most promising intercepts were returned from the Santorini target, which remains open to the north-northeast where it appears to underlie the ABM lens so that further exploration drilling is warranted. Similarly, the narrow sulphide intercepts and alteration styles uncovered as part of the ABM deep re-logging and 2015 drilling program suggest there is some potential for discovering small pods of mineralization on this horizon. Additional drilling is recommended around historical DDH K95-053, on section 415000E, around the four historical drill intersections on 414950E and on the relatively thick MAFi package between section 415075E and the East Fault. Further investigation with downhole geophysical techniques (e.g. EM, IP, gravity) is also recommended, although such methods may be limited due to the strong response expected from the overlying ABM lens.

The discovery of the Krakatoa Main lens was the highlight of the 2015 KZK Project. It remains open downdip, although it is closed off towards the surface, by the Sunda Fault to the east and by the East Fault to the west. Down dip extension drilling is recommended and infill drilling should be done to upgrade resource categories and/or further define the spatial and grade variability for this part of the ABM deposit. Additionally there is potential that continuations of the Krakatoa Zone could be offset by the Sunda Fault and/or Fault Creek Fault and this should be a high priority exploration concept.

Further work on the Fault Creek target is not recommended at this time.

The 2015 work program in the GP4F area expanded the GP4F lens and its related alteration and weak mineralization, identified two related lenses (Upper and Lower targets) and possibly intersected the northern margin of the R-15 deposit, which is located 600 m to the southeast. Further work in this area should focus on expanding the GP4F deposit to the north-northeast and drill testing the ground between the GP4F and R-15 deposits.

216.00 hours @ $35/hour	7,560.00	$	2,102,367.06

EQUIPMENT RENTALS:

Field Camp			
6,142.50 days @ $40/manday	$ 245,700.00		
Core Saw (Gas)			
183.00 days @ $60/day	10,980.00		
Field Computers			
1,556.00 days @ $40/day	62,240.00		
First Aid (Level III)			
159.00 days @ $30/day	4,770.00		
Micromine Software			
858.50 hours @ $50/hour	42,925.00		
Magnetic Susceptibility Meter			
86.00 days @ $15/day	1,290.00		

STATEMENT OF EXPENDITURES

Incinerator			
276.00 days @ $25/day	6,900.00		
Chainsaw			
15.00 days @ $30/day	450.00		
Power Soil Auger			
20.00 days @ $30/day	600.00		
Generator	24,915.00	$	400,770.00

EXPENSES:

Licenses	$ 515.62
Customs and Brokerage Fees	160.86
Recording Fees	250.00
Chemical Analyses	312,709.93
Chemical Analyses - Environmental	35,471.50
Field Consumables	7,678.15
Material and Supplies	339,026.42
Plot Charges	2,159.76
Camp Food	195,458.84
Meals	5,823.14
Accommodation	12,168.68
Taxis and Airporters	3,328.71
Parking	69.99
ATV Rental (Non-Equity)	84,330.00
Truck Rental (Non-Equity)	77,280.34
Automotive Fuel	7,538.15
Automotive Expenses	1,449.87
Aircraft Charters	136,337.24
Helicopter Charters	781,941.42
Busfare	5.24
Ferries	216.66
Airfare	101,567.29
Telephone Distance Charges	600.21
Courier	1,003.48
Freight	252,369.15
Bulk Fuel + Tank Rental	473,706.12
Drum Deposit	3,960.00
Airborne Geophysics: Field Work	78,632.44
Ground Geophysics: Field Work	274,368.24
Geophysical Consulting	21,475.00
Pre-Access Drug Testing	36,070.45
Camp Maintenance	53,872.16
Padbuilding	91,107.61
Dump Disposal Fees	31.90
Road Rehabilitation + Maintenance	299,236.46
Contract Camp Construction	68,583.29
Satellite Phone Rental (Non-Equity)	3,578.65
Radio Rental (Non-Equity)	28,926.90
Downhole Survey Tool Rental (Non-Equity)	96,187.17
Generator Rental (Non-Equity)	850.00
Other Equipment Rental (Non-Equity)	4,473.05
Earthworks	400,440.00

STATEMENT OF EXPENDITURES

Excavator	48,010.00	
Drilling: Footage	3,418,751.29	
Drilling: Materials	38,696.03	
Drilling: Coreboxes	128,932.40

1.0 Introduction and Proposed Development

This report presents the results of an investigation completed by Onsite Engineering Ltd. (OEL) for the Access Road to the Kudz Ze Kayah Project northwest of Watson Lake in Yukon Territory, Canada. The Access road is approximately 25 kilometres in length and extends from the Robert Campbell Highway to the project site. See figure 1 for an overview map. The assessment was carried out at the request of Mr. Robin Black on behalf of BMC Minerals (No 1) Ltd.

The access road is an existing, older, unused, single lane gravel road.

2.0 Rationale for the Assessment

The assessment was carried out to ensure that the proposed exploration activities at the Kudz Ze Kayah project site have adequate access and that the use of the road for these purposes would not adversely affect the overall road stability and subgrade integrity. Adequate access, in this case, is defined as safe industrial access for all equipment and personnel without degrading the current condition of the road.

Figure 1 – Location map for the Kudz Ze Kayah Access Road

3.0 Limitations of the Assessment

This report has been prepared in accordance with generally accepted engineering and geotechnical practises in British Columbia and the Yukon Territory. No other warranty, expressed or implied, is made. General observations are made on the existing road prism, slope gradients, shape, morphology and the general stability. Information on the subsurface soil, groundwater and bedrock conditions are gathered from bedrock outcrops and the cutslopes along the road corridor. No subsurface information from deep test pits or drill holes was available.

The classification and identification of the type and condition of the geological units present are judgemental in nature. Variations (even over short distances) are inherent and are a function of natural processes. OEL does not represent or warrant that the conditions listed in the report are exact and the user should recognise that variations may exist. Sub-surface conditions, other than those identified, may be encountered requiring a review of the recommendations contained in this report, with amendments made as needed.

4.0 Background Data and Fieldwork

Prior to fieldwork, Google Earth Imagery was reviewed and the approximate road route was tracked. No other information regarding the site was available prior to the site assessment.

Fieldwork was completed on May 27th by Jeremy Araki, P.Eng of OEL, accompanied by Tim Moon of T. Moon Construction (11808 Yukon Inc.) and Ted Danyluk from Castle Rock Enterprises. Field work involved, vehicle, AVT, and foot traverses of the road alignment and adjacent areas of concern.

5.0 General Site Description

5.1 Terrain Description

The access road generally follows the gentle benches and ridges above the valley bottom leading to the project site. Slopes are gentle with many flat swampy areas dissected by low winding ridges. There is one large bridge crossing in a broad gentle draw. There are a large number of small streams and low, wet swales across the entire project area. The alignment climbs slowly from approximately 1040m asl to 1400m asl at the project site.

Soils are predominantly sand and gravel deposits intersected by areas of silty soils with a large component of gravel to boulder sized material derived from the local Schist outcrops. Areas of low slope and or poor drainage have a heavy organic layer over shallow permafrost. No natural instability was noted in the area near the road or on similar terrain.

5.2 Bedrock and Surficial Materials

Bedrock outcrops noted during field assessment were composed of heavily weathered Schist. Surficial material overlying bedrock in these areas consists of variable thickness silt with some sand and a high component of gravel to small boulder sized material from the local bedrock.

Away from the areas of shallow or exposed bedrock, the sand and gravel deposits are 1 to 3m thick (as observed in the gravel pits) and are generally found on the low gentle ridges between the flat swampy areas.

Materials under the swampy overland construction areas were not visible but can be assumed to be frozen and incompetent if exposed and reworked.

6.0 Access Road - Discussion, Results and Recommendations

The Kudz Ze Kayah Access Road is an existing road that has not been utilized in a number of years and now has two major crossing failures. Further, most of the road shoulders and ditches are grown in with local vegetation.

Table 6.1 contains site descriptions, and maintenance prescriptions for the access road.

6.1 Anticipated Soil and bedrock Conditions

Observations made during the field assessment suggest that the following subsurface conditions are present along the alignment:

1. The majority of the road traverses sand and gravel deposits over gentle terrain. These areas are generally well drained except where flat or near flat.

2. Much of the remaining road alignment rests on the shallow silty soils with high gravel to boulder content derived from the local Schist bedrock. No blasting is expected to be required for the maintenance work.

3. The remaining portions of the alignment fall on the flat swampy terrain likely underlain with shallow permafrost. These areas have been overlanded with either the adjacent sand and gravels or the blocky weathered silt dominated soils from the schist.

Ground types expected to be found at the following chainages: 0+000 – 12+136, sand and gravels. 12+136 – 14+539, schist. 14+539 – 18+490, sand and gravels. 18+490 – 19+993, transition from sand and gravel to schist. 19+993 – 22+497, schist. 22+497 – 24+898, sand and gravels.

6.2 Seepage Conditions

Surficial materials within the study area appear to be generally well to moderately well drained in the sands and gravels, moderately to imperfect drainage in the silts, and poor drainage in the swampy flats. Many of the low areas in the cut slopes have shallow sub surface flows.

6.3 Cutslope Excavation Recommendations

The existing cutslopes are relatively stable and are all low given the gentle gradients surrounding the alignment. Any new excavations along the road or in borrow sites should be sloped similarly to avoid sloughing. Only one area of instability was noted in an overburden pile that had a recently active face. It did not appear to affect the road or the surrounding terrain measurably.

6.4 Road Prism Recommendations

Road maintenance recommendations along the alignment are generally required to reshape the existing prism to crown the road and deepen the ditches to properly drain the road prism. Most of this work is to be completed with a grader. There are a few areas where the ditching may require an excavator. Further, at least half of the cross drain culverts will require their sumps cleaned with an excavator. The two crossings that have washed out will require full road prism rehabilition and re-installation of existing culverts.

6.5 Road Drainage Recommendations

Cross drain culverts are installed in all low seepage areas and in crossings. Only three additional cross drain culverts are prescribed near the end of the alignment. These culverts can be installed when the road is opened for mining activities and need not be installed for the planned exploration activities. One of the failed crossings is dramatically undersized and will require the installation of

an addition culvert. This culvert should be added during the current maintenance work.

6.6 Bridge Crossing Condition and Recommendations

The existing structure is a pair of riveted rails cars with a timber deck resting on sill logs on a bin wall abutment. The riveted rail cars are not the standard Hawker Siddeley type cars that are approved for this type of application. Further, the timber deck is not adequate to spread the loads, without eccentricity, to the two rail cars. There are no guard rails on the structure. The bin walls under the abutments have yielded. This is likely due to inadequate compaction during construction and the subsequent surcharge loading of the bridge and road fill.

This existing structure may be re-used. To re-use the existing structure the superstructure must be removed and the binwalls excavated and backfilled with geosynthetic reinforced soil (GRS). Then, the failed bin walls are only to act as a form for the GRS. However, due to the close proximity of the bridge bearing to the bin wall face, a concrete strip footing must be added as well. The rail cars may be replaced and properly bolted together with a minimum 14' wide timber deck as per BC MoF Standard Drawings for a BCFS L-75 timber deck. Due to the rail cars not being the standard Hawker Siddeley welded type, a reduced load rating would still be applied. This reduction is somewhat judgemental in nature but would likely be half the full load rating, or a 34 tonne GVW five axle truck and trailer.

A second option for the structure repair is to install a portable all steel two piece bridge over the existing structure that would span the rail cars and the bin abutments. This would require a 60' long bridge. The existing rail cars can either be removed or left in place. If left in place the approach roads would need to be built up to accommodate the higher bridge height.

A permanent solution can be GRS abutments rebuilt with similar forms to the bins and either the portable superstructure or a cheaper dual steel I-beam bridge with a timber or concrete deck. In this case the rail car is to be removed and placed outside the confines of the stream draw. The top few forms from the binwall under the bridge are to be removed to a point where the superstructure can be installed with the deck elevation to match the existing deck elevations (the number of forms to be removed will depend on the type of superstructure supplied but will be between one and three). The two middle bins under the bridge will be excavated down to original ground or at least 2m. The fill will be replaced with sand and gravel compacted to 95% SPMDD in layers no thicker than 8" placed loose. Between each layer of fill non-woven Armtec 855 geotextile or approved equivalent. Sills are to be minimum 8"x16"x20' long treated douglas fir timbers. The wing wall bins are to be left in place to help retain fill. Treated 4x12"x20' long ballast timbers are required; minimum 4 per side.

6.7 Bridge to Other Side of Valley at the Project Site

There is an old structure just off the assessed road at 24+315 that is in very poor condition. The structure accesses the exploration trails on that side of the valley. It is an older rail bulkhead type structure on lock blocks. It is not serviceable and will require a new crossing structure if this road is required.

Table 6.1: Kudz Ze Kayah Access Road: Summary of Observations, Risk Analysis, and Construction Recommendations

Road Section		Terrain Characteristics			Existing Structure	Recommendations	Required Equipment	Estimated Effort
Start Δ[1]	End Δ	Surficial Materials and Slope Morphology	Est. depth to bedrock	Drainage				
0+000		Silty Sands and gravels visible, highly disturbed from development, no issues noted	5+	Well	Intersection with Robert Campbell Highway	None	N/A	N/A
0+281		Sand and Gravel	5+	Well	Security shack and gate	None	N/A	N/A
0+728		Sand and Gravel	5+	Well	Functioning CSP cross drain culvert	None	N/A	N/A
0+830		Sand and Gravel	5+	Well	Functioning CSP cross drain culvert	None	N/A	N/A
1+255		Sand and Gravel	5+	Well	Functioning CSP cross drain culvert	None	N/A	N/A

General Road Recommendations for Maintenance								
0+000	25+000					Entire road requires grading to clear road shoulders, clean ditches, and reshape the road prism. Assume 4 pass grading required. Grade off shoulders and into ditches first. Then cut crown back onto road.	Grader	60 hrs
0+000	25+000				All Functioning CSP cross drain culverts	Assume 50% of these will require sump cleaning or other minor works, assume 0.5 hours per site	Pit Excavator	15 hrs
0+000	25+000					Pit excavator walking between sites along the alignment	Pit Excavator	16 hrs
0+000	25+000					Site excavator walking between sites along the alignment	Site Excavator	16 hrs

8.0 Closure

This report contains information relating to the road stability following the proposed exploration and/or road building activities. Should the proposed development change and/or the soil/bedrock conditions encountered differ from those outlined in this report, OEL should be contacted so that the recommendations contained in this report can be reviewed.

Factual data and interpretation contained within this report were prepared specifically for BMC Minerals (No 1) Ltd. with whom Onsite has entered into a contract. No other party may rely upon this report without the express written permission of Onsite.

We trust that this report satisfies your present requirements. Should you have any questions or comments, please contact our office at your convenience.

Sincerely,

Onsite Engineering Ltd.

Appendix E: Drill logs for re-logged historical core

This appendix contains all of the drill logs generated from the 2015 historical core re-logging program. Drill logs are placed in alpha-numeric order with the first page of each log starting on the page number indicated below in Table E-1.

Table E-1: Table of contents for re-logged historical drill holes in this appendix

0.00 3.60 CASN Casing

3.60 6.30 RHYva Coarse grained to ash tuff

3.6 - 6.3: Ankerite commonly banded along quartz MS bands as well as disseminated and patchy throughout.

<<Min: 3.6 - 23 6% Min: Ankerite>>

<<Min: 4.1 - 99.2 1% Min: Pyrrhotite>> Spotty and commonly elongated paralleling schistosity. Minor PY.

6.30 8.20 RHYcw Curdy textured-flow banded (flows, subvolcanics)

6.3 - 8.2: flow banded

8.20 11.00 MDSt Rhyolite tuff dominant mudstone

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

11.00 20.30 RHYva Coarse grained to ash tuff

<<Min: 12 - 14.5 1% Min: Calcite>>

20.30 23.00 MDSt Rhyolite tuff dominant mudstone

20.3 - 23: Ankerite is present throughout interval as bands and patches. Biotite present in trace amounts, not consistant throughout interval.

23.00 24.30 RHYcw Curdy textured-flow banded (flows, subvolcanics)

23 - 24.3: Thin flow? Weak mottled FS.

<<Min: 23 - 38.3 15% Min: Ankerite>>

24.30 34.00 RHYvl Lapilli tuff

24.3 - 34: Mottled texture predominantly due to appearance of ankerite altered lapilli. Interval contains minor chlorite.

34.00 36.40 RHYcw Curdy textured-flow banded (flows, subvolcanics)

<<Min: 34.5 - 38.4 5% Min: Calcite>>

36.40 40.80 RHYva Coarse grained to ash tuff

36.4 - 40.8: more Mafic tuff, in part banded.

<<Min: 38.3 - 42.5 1% Min: Ankerite>>

<<Min: 38.4 - 42.5 2% Min: Calcite>>

40.80 50.70 RHYvl Lapilli tuff

40.8 - 50.7: Interval contains minor chlorite. Base of interval has pervasive healed fracturing and contact is marked by presence of massive bull quartz.

<<Min: 42.5 - 66 20% Min: Ankerite>>

<<Min: 44.7 - 47.3 3% Min: Calcite>>

50.70 72.10 RHYcw Curdy textured-flow banded (flows, subvolcanics)

50.7 - 72.1: "Curdy" rhyolite. Distinct FS porphyroblasts up to 3mm also FS aggregates as "curds" in pale grey matrix. Minor fragmental sections.

<<Min: 53 - 57 1% Min: Calcite>>

<<Min: 66 - 92.6 10% Min: Ankerite>>

From (m)	To (m)	Rocktype & Description
72.10	**73.90**	**RHYv** **Rhyolite volcaniclastic**
73.90	**88.10**	**RHYvl** **Lapilli tuff**

<<Min: 83.6 - 85 3% Min: Calcite>>

88.10	**99.20**	**MDSt** **Rhyolite tuff dominant mudstone**

88.1 - 99.2: tuff dominant

<<Min: 92.6 - 119.7 1% Min: Ankerite>>

99.20	**113.30**	**RHYcw** **Curdy textured-flow banded (flows, subvolcanics)**

99.2 - 113.3: Weak banding with zones of contorted banding. Minor interval with thin bands of chlorite. Structural zone with contorted bands. Basal contact gradational into stronger hydrothermal alteration.

<<Alt: 99.2 - 113.3 Weak (Alt) Muscovite>>

113.30	**122.30**	**RHYcw** **Curdy textured-flow banded (flows, subvolcanics)**

113.3 - 122.3: Quartz and sericite mineralization dominates this interval and exhibit strong hydrothermal alteration. Bands of quartz and sericite are accompanied by minor muscovite and are usually textured by appearing broken or contorted.

<<Min: 113.7 - 119.6 1% Min: Pyrite>> Commonly fracture controlled and small patchy clusters. Minor 2cm fracture with CP at 119.1m

<<Min: 113.7 - 119.6 1% Min: Pyrrhotite>>

<<Min: 119.6 - 132 1% Min: Pyrrhotite>> isolated mm scale patches of galena, sphalerite, chalcopyrite. Cordierite commonly contain rims associated with chalcopyrite.

<<Min: 119.7 - 130.6 10% Min: Ankerite>>

<<Alt: 113.3 - 122.3 Strong (Alt) Muscovite>>

122.30	**132.00**	**RHYcw** **Curdy textured-flow banded (flows, subvolcanics)**

122.3 - 132: Strongly altered and contorted. Dominantly MS at top with strong QZ or possibly albite near base with minor TO noted. Cordierite commonly along bands and as widely spaced porrphyroblasts up to 5mm. Chlorite after biotite, weak.

<<Min: 129.7 - 130.5 3% Min: Chalcopyrite>> Minor sphalerite.

<<Min: 131.6 - 135.2 3% Min: Ankerite>>

<<Alt: 123.3 - 132 Strong (Alt) Chlorite>> minor cordierite porphyroblasts up to 5mm

0.00 3.70 OVBN Overburden

3.70 8.00 RHYva Coarse grained to ash tuff grey-green

3.7 - 8: strongly oxidized, heterogeneous, minor contorted massive bands(flow?)

<<Min: 3.7 - 11.8 0.2% Min: Sphalerite>> in aggregates of PY

<<Min: 3.7 - 11.8 3% Min: Pyrite>> Po locally

<<Min: 3.7 - 11.8 5% Min: Ankerite>> bands, too, aggregates form lenses, not really in fracs

<<Alt: 3.7 - 45.5 Weak (Alt) Muscovite>> pretty consistent, chlorite not breally present, minor biotite locally

8.00 11.80 RHYcw Curdy textured-flow banded (flows, subvolcanics) green-brown FG

8 - 11.8: contorted flow bands common, darker green-blackmatrix (BI-CL?afetr flowbands? Minor curdy and bx texture

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

11.80 14.30 RHYvl Lapilli tuff grey-green

11.8 - 14.3: ankeritic, FP? Augens and siliceous lapilli, QZ lapilli,

<<Min: 11.8 - 14.3 10% Min: Ankerite>> more conc'd than above

<<Min: 11.8 - 25.9 0.1% Min: Pyrite>> locl conc'ns along fol'n

<<Min: 11.8 - 25.9 0.1% Min: Pyrrhotite>>

14.30 15.30 MDSw Coherent rhyolite flow with carbonaceous content grey-green

14.3 - 15.3: ankeritic, FP? Augens and siliceous lapilli, QZ lapilli,

<<Min: 14.3 - 26.2 5% Min: Ankerite>> as 1st iterval for the most part

15.30 20.20 RHYvl Lapilli tuff

20.20 21.30 RHYcw Curdy textured-flow banded (flows, subvolcanics) grey-green

20.2 - 21.3: ankeritic, FP? Augens and siliceous lapilli, QZ lapilli,

21.30 26.20 RHYvl Lapilli tuff

<<Min: 25.9 - 28.2 2% Min: Pyrite>> mostly frac controlled to vein, stronlgly deformed, mixed with PO

<<Min: 25.9 - 28.2 2% Min: Pyrrhotite>> as PY

<<Min: 25.9 - 28.2 0.01% Min: Galena>> with PY/PO

26.20 27.40 RHYcw Curdy textured-flow banded (flows, subvolcanics) cream

26.2 - 27.4: massive, glassy, bx'd, sx in fractures,

<<Min: 26.2 - 28.5 0.5% Min: Ankerite>>

27.40 34.10 RHYvl Lapilli tuff grey FMG

27.4 - 34.1: fine lapilli, relatively homogeneous, narrow bands with xtals are darker colour, intermediate?, QZ masses locally minor veins

<<Min: 28.2 - 51.1 0.1% Min: Pyrite>> scatered, mx PY up to 3 mm wide, not common

<<Min: 28.2 - 54.4 0.25% Min: Pyrrhotite>> scattered, wispy,locally conc'd along fol'n

<<Min: 28.5 - 38.6 5% Min: Ankerite>>

34.10 46.00 MDSw Coherent rhyolite flow with carbonaceous content grey-brown

34.1 - 46: weakly carbonaceous, BI gives darker colour, replacing flowbanding?, massive to contorted, strongly sheared

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

<<Min: 38.6 - 46 5% Min: Ankerite>> similar conc'n, different habit, because it is in a flow?

<<Alt: 45.5 - 85.3 Weak-Moderate (Alt) Muscovite>> gradually increases especially towards the bottom

46.00 54.40 RHYvl Lapilli tuff grey-green

46 - 54.4: minor ash tuff, possible flow blocks?

<<Min: 46 - 54.4 5% Min: Ankerite>> strongly on fol'n

<<Min: 51.1 - 54.4 1% Min: Pyrite>> spaced veinlets and diss'd blebs

54.40 62.50 RHYcw Curdy textured-flow banded (flows, subvolcanics) grey-green

54.4 - 62.5: abdt sx t/o section, as veins, bx matrix

<<Min: 54.4 - 60.6 5% Min: Pyrite>> some patchyand frac filling

<<Min: 54.4 - 60.6 2% Min: Pyrrhotite>> and patchy, mostly in upper portion of int?

<<Min: 54.4 - 60.6 0.25% Min: Galena>> lensy with PY

<<Min: 54.4 - 60.6 0.1% Min: Chalcopyrite>> scattered in sx veins/patches

<<Min: 54.4 - 61.9 8% Min: Ankerite>> to aggregates, strong contnet in veins, associated with sx

<<Min: 60.6 - 79 0.5% Min: Pyrrhotite>> wispy diss'ns, scattered along fol'n, locally blebs, in veins

<<Min: 61.9 - 75.9 3% Min: Ankerite>> more sparse, poss pblasts, scattered pods,

62.50 79.00 RHYvl Lapilli tuff grey-green

62.5 - 79: minor ash tuff, possible flow blocks?

<<Min: 63.5 - 72.2 1% Min: Pyrite>> highlydeformed, transposed, SI-PY stringers, fairly conc'd, look like lenses when dragged out

<<Min: 72.2 - 79 0.25% Min: Pyrite>> scattered blebs, some veining

<<Min: 75.9 - 79 5% Min: Ankerite>>

79.00 97.80 RHYcw Curdy textured-flow banded (flows, subvolcanics) grey-brown

79 - 97.8: flow banded flow with tuffaceous intervls, qtz eyes present locally, thin flow bands, contorted, alt'n increases dramatically towards bottom of setion. Tuff abovecontains frags of this kind of flow - tops up?

<<Min: 79 - 89 0.5% Min: Pyrite>> scattered blebs but also minor disaggregated siliceous stringers

<<Min: 79 - 95.7 3% Min: Ankerite>> lensy, veins

<<Min: 89 - 97.8 1% Min: Pyrite>> some in veins

<<Min: 89 - 97.8 1% Min: Pyrrhotite>> blebs, aggregates in vein

<<Min: 95.7 - 102.2 1% Min: Ankerite>> local lenses, veins, patches

<<Alt: 85.3 - 92 Moderate (Alt) Muscovite>> MU becoming stronger on foliation surfaces

From (m)	To (m)		Rocktype & Description		From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

0.00	**4.80**	**OVBN**	**Overburden**								
4.80	**9.00**	**RHYcw**	**Curdy textured-flow banded (flows, subvolcanics)**								

4.8 - 9: light grey, fine to medium grained, comprinsing silica bands, milky, deformed,folded and locally dismembered, " curdy" texture. Weakly/moderately MU and AK altered.1-3% of Po (wisps/bands) and Py diss.

<<Min: 4.8 - 10 2% Min: Pyrrhotite>> Small aggregates disseminated, also occuring as thin veinlets/bands.

<<Min: 4.8 - 34 3% Min: Ankerite>>

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

9.00 24.00 RHYvl Lapilli tuff

9 - 24: light grey, fine to medium grained, comprinsing silica fragments, milky, locally AK altered, deformed and stretched/dismembered, lapillis? Possibly RHYcw. Weakly/moderately MU and AK altered.2-3% of Po (wisps/bands) and < 1% Py diss.

<<Min: 10 - 19 3% Min: Pyrrhotite>> Small aggregate disseminated, also occuring as thin veinlets/bands.

<<Min: 19 - 27 1% Min: Pyrite>>

<<Min: 19 - 27 4% Min: Pyrrhotite>> Mainly occuring as thin veinlets/bands, subconcordant.

<<Min: 21 - 33.5 3% Min: Calcite>> Mainly associated with Qtz-+/-Ak veins/veinlets

24.00 34.00 RHYcw Curdy textured-flow banded (flows, subvolcanics)

24 - 34: light grey, fine to medium grained, comprinsing silica bands, milky, deformed,folded and locally dismembered, '' curdy'' texture. Weakly MU and AK altered.2-4% of Po (wisps/bands) and Py diss.

<<Min: 27 - 36 1% Min: Pyrite>> small aggregate.

<<Min: 27 - 36 2% Min: Pyrrhotite>> Small aggregate disseminated, also occuring as thin veinlets/bands.

34.00 34.80 RHYvl Lapilli tuff

34 - 34.8: Bands desappear, trace of leucocratic crystals (0.5 cm), comprinsing stretched fragments, silicified, milky.

<<Min: 34 - 65.5 6% Min: Ankerite>>

34.80 45.30 RHYcw Curdy textured-flow banded (flows, subvolcanics)

34.8 - 45.3: light grey, fine to medium grained, comprinsing silica bands, milky, deformed,folded and locally dismembered, '' curdy'' texture but not strong. Weakly MU and moderate AK altered.1-3% of Po/Sp (wisps/bands) and Py diss.

<<Min: 36 - 40.5 3% Min: Pyrite>> Coarse grained, diss within matrix.

<<Min: 36 - 40.5 0.5% Min: Pyrrhotite>>

<<Min: 40.5 - 66.6 2% Min: Pyrrhotite>> Diss as small aggregats.

<<Vein: 36 - 37.8 20% Quartz>> Interval comprinsing milky qtz veins, strongly deformed, 2-15 cm wide.

<<Struc: 36 - 37.8 Strong (Alt) Foliation>> Irregular foliation, folded interval.

45.30 50.40 MDSt Rhyolite tuff dominant mudstone

45.3 - 50.4: Thin concordant carbonacious mudstone bands within probably tuff.

<<Struc: 45.3 - 46 Moderate (Alt) Fault>> moderately fractured with short gauge interval.

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

50.40 53.40 RHYvl Lapilli tuff

50.4 - 53.4: Interval comprinsing leucocratic fragments, cm, heterogeneous, silicified. Locally occuring as bands.

53.40 54.10 MDSt Rhyolite tuff dominant mudstone

53.4 - 54.1: Thin concordant carbonacious mudstone bands within probably tuff.

54.10 56.70 RHYvl Lapilli tuff

54.1 - 56.7: Interval comprinsing leucocratic fragments, cm, heterogeneous, silicified. Locally occuring as bands. Trace of crystals (Fsp?)

56.70 57.50 MDSc Carbonaceous dominant mudstone

56.7 - 57.5: Dominantly carbonaceous mudstone.

57.50 61.10 MDSt Rhyolite tuff dominant mudstone

57.5 - 61.1: Thin concordant carbonacious mudstone bands within probably tuff.

61.10 62.00 MDSc Carbonaceous dominant mudstone

62.00 63.30 RHYvl Lapilli tuff

62 - 63.3: Interval comprinsing leucocratic fragments, cm, heterogeneous, silicified. Locally occuring as bands. RHYcw?

63.30 66.60 MDSt Rhyolite tuff dominant mudstone

63.3 - 66.6: Thin concordant carbonacious mudstone bands within probably tuff.

<<Min: 65.5 - 75.6 10% Min: Ankerite>>

66.60 75.60 RHYcw Curdy textured-flow banded (flows, subvolcanics)

66.6 - 75.6: light grey, fine to medium grained, comprinsing silica bands, milky, deformed,folded and locally dismembered, '' curdy'' texture. Moderately MU altered and AK altered (weak).

<<Min: 66.6 - 83.6 0.5% Min: Pyrrhotite>>

<<Alt: 67 - 103.3 Moderate-Strong (Alt) Muscovite>> Also occuring as bands (foliation).

<<Struc: 68.9 - 69.5 Strong (Alt) Fault>> gauge fault, strongly fractured and Ser/Mu filling.

From (m)	To (m)	Rocktype & Description

<<Struc: 75 - 79.8 Moderate-Strong (Alt) Fault>> Large interval fractured, regular fracture surface. Comprinsing short gauge interval.

75.60 80.50 MDSt Rhyolite tuff dominant mudstone

75.6 - 80.5: Thin concordant carbonacious mudstone bands within probably tuff.

<<Min: 75.6 - 116.7 3% Min: Ankerite>>

80.50 91.10 RHYcw Curdy textured-flow banded (flows, subvolcanics)

<<Min: 83.6 - 91.1 0.01% Min: Pyrite>>

<<Min: 83.6 - 91.1 2% Min: Pyrrhotite>> Small aggregate disseminated, also occuring as thin veinlets/bands.

<<Vein: 81 - 83.6 15% Quartz>> Group of milky qtz veins, cm, deformed (boudinage), irregular oriented. Trace of Sp within the veins.

91.10 92.50 MDSc Carbonaceous dominant mudstone

91.1 - 92.5: Dominantly carbonaceous mudstone.

<<Min: 91.1 - 100.5 2% Min: Pyrite>>

<<Min: 91.1 - 100.5 0.5% Min: Pyrrhotite>>

92.50 99.30 MDSt Rhyolite tuff dominant mudstone

92.5 - 99.3: Thin concordant carbonacious mudstone bands within probably tuff.

99.30 100.50 MDS Carbonaceous Mudstone & Tuffaceous Mudstone

99.3 - 100.5: Sharp lower contact with RHYcw.

100.50 103.50 RHYcw Curdy textured-flow banded (flows, subvolcanics)

100.5 - 103.5: beige to greenish, strong MU altered. Sharp contact with RHYva

<<Min: 100.5 - 103.5 3% Min: Pyrrhotite>> small aggregates

<<Alt: 103.3 - 116 Weak-Moderate (Alt) Muscovite>>

<<Alt: 103.3 - 119.8 Moderate (Alt) Cordierite>> the crystal size increase close to the MS, locally associated with Cl at the edges.

103.50 119.70 RHY undifferentiated rhyolite

24.10 29.30 RHYva Coarse grained to ash tuff

24.1 - 29.3: Light green, medium to coarse grained, +/- homogeneous, moderate to strongly foliated. < 3 % of fine crystal of qtz/fsp partially Ak distributed within the matrix, ~1mm. Matrix weakly Cl.

<<Min: 24.1 - 35.6 0.5% Min: Pyrite>>

<<Min: 24.1 - 36.7 3% Min: Calcite>> Associated with qtz veins/veinlets and isolated clots.

<<Min: 24.1 - 41.7 3% Min: Ankerite>> Associated with siliceous fragments/veinlets, isolated clots distributed within matrix.

<<Alt: 24.1 - 29.3 Weak (Alt) Chlorite>>

29.30 31.70 RHYi Aphanitic Rhyolite (intrusion)

29.3 - 31.7: Interval comprinsing 40% of Rhy dykes, mostly decimetric, aphanitic to very fine grained, strongly Si, rare trace of very small qtz crystals. Hosted within RHYva or RHYvl, with trace of dismembered silliceous bands, strongly foliated and MU altered.

<<Alt: 29.3 - 31.7 Strong (Alt) Silicification>> Associated with RHYi.

<<Alt: 29.3 - 39.4 Moderate-Strong (Alt) Muscovite>>

31.70 36.70 RHYvl Lapilli tuff

31.7 - 36.7: Beige to light grey,medium to coarse grained, strongly foliated and MU altered. +/- homogeneous. Probably RHYva.

<<Min: 36.1 - 37.4 0.5% Min: Pyrite>>

36.70 39.40 RHYcw Curdy textured-flow banded (flows, subvolcanics)

36.7 - 39.4: beige to light grey, fine to medium grained, comprinsing siliceous bands, milky, deformed,folded and locally dismembered, " curdy" texture. moderately MU and weakly AK altered.

<<Min: 37.4 - 41.5 3% Min: Sphalerite>>

<<Min: 37.4 - 41.5 1% Min: Pyrite>>

39.40 41.50 RHYva Coarse grained to ash tuff

39.4 - 41.5: Light grey, medium to coarse grained, +/- homogeneous, moderate to strongly foliated. < 2 % of fine crystal of qtz/fsp partially Ak distributed within the matrix, ~1mm. Matrix weakly Cl at the bottom of unit.

<<Min: 41 - 41.7 5% Min: Calcite>> Associated with breccia.

<<Alt: 40.2 - 40.8 Intense (Alt) Chlorite>> Associated with mineralisation

<<Alt: 40.8 - 41.7 Weak-Moderate (Alt) Cordierite>> Ocuring as coarse disseminated crystals,

<<Struc: 40.2 - 40.8 Strong (Alt) Fault>> Comprinsing gauge interval and strong fracturation.

From (m)	To (m)	Rocktype & Description
41.50	**42.00**	**OJ** **Heavilly disseminated sulphides in proximal altered rock**
42.00	**42.60**	**OF** **Pyrrhotite rich sulphides**

From (m)	To (m)	Rocktype & Description
0.00	**26.00**	**OVBN** **Overburden**
26.00	**30.80**	**RHYcw** **Curdy textured-flow banded (flows, subvolcanics)**

26 - 30.8: Beige, fine to medium grained, comprinsing siliceous bands, milky, deformed,folded and locally dismembered, " curdy" texture. Moderately MU and AK altered.

29.45-29.55m: Short interval of mudstone.

<<Min: 26 - 34.6 1% Min: Pyrite>>

<<Min: 26.2 - 34.6 6% Min: Ankerite>> Occuring as bands/fragments, associated with veinlets?

<<Alt: 27.7 - 34.6 Strong (Alt) Muscovite>>

30.80	**31.40**	**MDSt** **Rhyolite tuff dominant mudstone**

30.8 - 31.4: Interval intensively foliated (fault), Comprinsing thin carbonaceous bands.

<<Struc: 30.8 - 31.4 Strong (Alt) Fault>> Interval strongly fractured, comprising gauge interval (10cm).

From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %
30.70	32.20	1.50	B00233037	17.8	0.108	0.02	0.2	0.86

From (m)	To (m)	Rocktype & Description		
31.40	**33.70**	**RHYcw**	**Curdy textured-flow banded (flows, subvolcanics)**	

31.4 - 33.7: Beige, fine to medium grained, comprinsing siliceous bands, milky, deformed,folded and locally dismembered, '' curdy'' texture. Moderately MU and AK altered. Locally, short interval of Mdst (~5cm wide).

33.70	**34.60**	**RHYv**	**Rhyolite volcaniclastic**	

33.7 - 34.6: Sharp contact with RHYcw, no evidence of flow texture, +/- homogeneous. Probably volcanoclastic (felsic) sequence, medium to coarse grained, ash tuff?

<<Alt: 33.7 - 34.9 Moderate (Alt) Cordierite>> occuring as disseminated crystals.

34.60	**35.20**	**OJ**	**Heavilly disseminated sulphides in proximal altered rock**	**MG**

<<Min: 34.6 - 34.9 15% Min: Ankerite>>

<<Min: 34.6 - 35.2 3% Min: Pyrite>>

<<Min: 34.6 - 35.2 2% Min: Pyrrhotite>>

<<Min: 34.6 - 35.2 1% Min: Chalcopyrite>>

<<Alt: 34.6 - 35.2 Weak-Moderate (Alt) Chlorite>>

35.20	**40.10**	**OB**	**Wispy laminate, fine buckshot textured, non-magnetite bearing sulphides**	**FMG**

35.2 - 40.1: Comprinsing centimetric coarse grained (Py) bands

<<Min: 35.2 - 40.1 10% Min: Sphalerite>>

<<Min: 35.2 - 40.1 80% Min: Pyrite>>

<<Min: 35.2 - 40.1 2% Min: Pyrrhotite>>

<<Min: 35.2 - 40.1 3% Min: Chalcopyrite>>

40.10	**40.20**	**RHYv**	**Rhyolite volcaniclastic**	
40.20	**40.30**	**OB**	**Wispy laminate, fine buckshot textured, non-magnetite bearing sulphides**	**FG**

<<Min: 40.2 - 40.3 10% Min: Sphalerite>>

<<Min: 40.2 - 40.3 80% Min: Pyrite>>

From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

40.30 40.80 RHYv Rhyolite volcaniclastic

40.3 - 40.8: Beige, no evidence of flow texture, +/- homogeneous. Probably volcanoclastic (felsic) sequence, medium to coarse grained, ash tuff?

<<Min: 40.3 - 40.8 1% Min: Pyrite>>

40.80 40.90 OB Wispy laminate, fine buckshot textured, non-magnetite bearing sulphides MCG

<<Min: 40.8 - 40.9 15% Min: Sphalerite>>

<<Min: 40.8 - 40.9 75% Min: Pyrite>>

<<Min: 40.8 - 40.9 1% Min: Chalcopyrite>>

<<Min: 40.8 - 46.9 3% Min: Calcite>>

<<Min: 40.8 - 49 2% Min: Ankerite>> Occuring as bands/fragments, associated with veinlets?

40.90 42.80 RHYv Rhyolite volcaniclastic

40.9 - 42.8: Beige, no evidence of flow texture, +/- homogeneous. Probably volcanoclastic (felsic) sequence, medium to coarse grained, ash tuff? After 42.8 m, Flow texture appears ("curdy" texture).

<<Alt: 41.3 - 43.9 Moderate-Strong (Alt) Muscovite>>

42.80 43.90 RHYcw Curdy textured-flow banded (flows, subvolcanics)

42.8 - 43.9: Beige, fine to medium grained, comprinsing siliceous bands, milky, deformed,folded and locally dismembered, " curdy" texture. Moderately MU and weakly AK altered.

43.90 44.30 OB Wispy laminate, fine buckshot textured, non-magnetite bearing sulphides FCG

43.9 - 44.3: Comprinsing centimetric coarse grained (Py) bands

<<Min: 43.9 - 44.3 10% Min: Sphalerite>>

<<Min: 43.9 - 44.3 80% Min: Pyrite>>

<<Min: 43.9 - 44.3 2% Min: Chalcopyrite>>

44.30 47.50 OJ Heavilly disseminated sulphides in proximal altered rock MCG

<<Min: 46.9 - 47.5 5% Min: Pyrite>>

<<Min: 46.9 - 47.5 5% Min: Pyrrhotite>>

From (m)	To (m)	Rocktype & Description
		<<Min: 46.9 - 47.5 2% Min: Chalcopyrite>>
		<<Alt: 44.3 - 51.6 Strong (Alt) Muscovite>>
47.50	**51.60**	**RHYc** **Rhyolite coherant volcanics**
		47.5 - 51.6: Beige, fine to medium grained, comprinsing siliceous bands, milky, deformed,folded and mostly dismembered, no evidence of "curdy" texture. Moderately MU and AK altered.
		<<Min: 47.5 - 51.6 1% Min: Calcite>>
		<<Min: 47.5 - 51.7 1% Min: Pyrite>>
		<<Min: 49 - 51.6 4% Min: Ankerite>> Occuring as bands/fragments, associated with veinlets?
51.60	**59.70**	**MAFi** **Mafic Intrusions (primarily footwall mafic intrusion)**
		51.6 - 59.7: Green, fine to medium grained, large interval of mafic intrusive, strongly sheared/foliated. Mainly chlorite altered (pervasive, moderate/strong). Centimetric chlorite clots, flattered, mafic crystals altered? > 15% of Qtz-Cal veinlets/bands, concordant.
		<<Min: 51.6 - 59.7 18% Min: Calcite>> Associated with qtz veinlets, and also patchy/blebs.
		<<Alt: 51.6 - 59.7 Moderate-Strong (Alt) Chlorite>>

0.00 11.30 OVBN Overburden

11.30 20.60 RHYvl Lapilli tuff

11.3 - 20.6: Light grey, moderately sheared, > 15% of siliceous fragments/dismembered bands, deformed and folded, flattered within the foliation, mostly Ak altered. Matrix Mu altered. Probably felsic lapilli tuff.

<<Min: 11.3 - 17 2% Min: Calcite>> Associated with veinlets and diseminated as small fragments/clots

<<Min: 11.3 - 23.5 0.5% Min: Sphalerite>>

<<Min: 11.3 - 23.5 1.5% Min: Pyrite>>

<<Min: 11.3 - 23.5 2% Min: Pyrrhotite>>

<<Min: 11.3 - 27.5 8% Min: Ankerite>> Mainly associated with siliceous bands/fragments.

20.60 23.50 RHYcw Curdy textured-flow banded (flows, subvolcanics)

20.6 - 23.5: light grey, fine to medium grained, comprinsing siliceous bands , milky, deformed,folded and locally dismembered, '' curdy'' texture. Weakly/moderately MU and AK altered.

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

23.50 26.00 MDS Carbonaceous Mudstone & Tuffaceous Mudstone

23.5 - 26: Thin concordant carbonacious mudstone bands within probably RHY.

<<Min: 23.5 - 24.5 1% Min: Pyrite>>

<<Min: 23.5 - 24.5 2% Min: Pyrrhotite>>

<<Min: 24.5 - 29.6 1.5% Min: Pyrite>>

<<Min: 24.5 - 29.6 6.5% Min: Pyrrhotite>>

26.00 29.60 RHYcw Curdy textured-flow banded (flows, subvolcanics)

26 - 29.6: light grey, fine to medium grained, comprinsing siliceous bands , milky, deformed,folded and locally dismembered, '' curdy'' texture. Weakly/moderately MU and AK altered.

<<Min: 27.5 - 35.7 5% Min: Ankerite>>

<<Min: 29 - 35 3% Min: Calcite>> Associated with veinlets and diseminated as small fragments/clots. Locally more concentrated (pervasive).

29.60 33.00 MDSc Carbonaceous dominant mudstone

29.6 - 33: Alternation of thin carbonaceous mudstone bands with siliceous bands.

<<Min: 29.6 - 33 1% Min: Pyrite>>

<<Min: 29.6 - 33 2% Min: Pyrrhotite>>

33.00 34.50 RHYvl Lapilli tuff

33 - 34.5: Light grey, moderately sheared, > 15% of siliceous fragments/dismembered bands, deformed and folded, flattered within the foliation, mostly Ak altered. Matrix Mu altered. Probably felsic lapilli tuff.

<<Min: 33 - 42.5 2% Min: Pyrite>>

<<Min: 33 - 42.5 3% Min: Pyrrhotite>>

34.50 47.60 RHYcw Curdy textured-flow banded (flows, subvolcanics)

34.5 - 47.6: light grey, fine to medium grained, comprinsing siliceous bands , milky, deformed,folded and locally dismembered, '' curdy'' texture. Weakly/moderately MU and AK altered.

<<Min: 35.7 - 47.5 10% Min: Ankerite>> Mainly associated with siliceous bands/fragments.

<<Min: 43.3 - 47.6 2% Min: Pyrite>>

<<Min: 43.3 - 47.6 3% Min: Pyrrhotite>>

<<Min: 47.5 - 75.3 3% Min: Ankerite>> Mainly associated with siliceous bands/fragments.

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

<<Alt: 45 - 75.2 Moderate-Strong (Alt) Muscovite>> Pervasive and associated with fracture surface.

47.60 49.20 MDSt Rhyolite tuff dominant mudstone

47.6 - 49.2: The top of the unit (first 10 cm is mudstone dominant) and follows by MDScw.

<<Struc: 48.9 - 49.2 Strong (Alt) Fault>> gauge fault.

49.20 77.20 RHYcw Curdy textured-flow banded (flows, subvolcanics)

49.2 - 77.2: light grey, fine to medium grained, comprinsing siliceous bands , milky, deformed,folded and locally dismembered, '' curdy'' texture. Weakly/moderately MU and AK altered.

<<Min: 50.9 - 74.7 2% Min: Pyrite>>

<<Min: 50.9 - 74.7 3% Min: Pyrrhotite>>

<<Min: 75.3 - 78.5 8% Min: Ankerite>> Mainly associated with siliceous bands/fragments.

77.20 78.00 RHYvl Lapilli tuff

77.2 - 78: Short interval of felsic lapilli tuff.

<<Min: 77.9 - 84.4 0.8% Min: Sphalerite>>

<<Min: 77.9 - 84.4 1.5% Min: Pyrite>>

<<Min: 77.9 - 84.4 3.5% Min: Pyrrhotite>>

<<Min: 77.9 - 84.4 0.5% Min: Chalcopyrite>>

78.00 81.10 MDSt Rhyolite tuff dominant mudstone

78 - 81.1: Thin concordant carbonacious mudstone bands within probably RHYva. >5% of cordierite crystals, phenocrystals, distributed within coarse grained matrix.

<<Min: 78.5 - 89.5 3% Min: Ankerite>>

<<Alt: 78.2 - 89.5 Moderate-Strong (Alt) Cordierite>> Phenocrystal of cordierite distributed within the matrix, 0.5-1cm, partially altered. Become bigger after 85m, associated with massive qtz vein.

81.10	**89.50**	**RHYva**	**Coarse grained to ash tuff**	83.50	85.00	1.50	B00233027	6.9	0.006	0.05	0.05	2.2

81.1 - 89.5: Light grey, coarse grained ash tuff, moderate to strongly foliated. 5-10% of phenocrystals of cordierite distributed within the matrix. After 85 m, large interval of massive qtz veins, milky, associated with TL and mineralisation.

<<Min: 84.4 - 89.5 4% Min: Pyrrhotite>>				85.00	86.50	1.50	B00233028	36.8	0.074	1.77	0.02	1.18

<<Min: 84.4 - 89.5 0.8% Min: Chalcopyrite>>

<<Min: 85 - 89.5 8% Min: Calcite>> Associated with veining interval brecciated.

<<Alt: 84.5 - 85 Strong (Alt) Chlorite>> Occuring as bands, centimetric, subconcordant associated with mineralisation.

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

<<Vein: 84.4 - 89.5 60% Quartz-Tourmaline>> Large interval of massive qtz veins, decimetric, deformed, milky, associated with strong TL at the margins and mineralised with Cp and Po

89.50 91.00 OJ Heavilly disseminated sulphides in proximal altered rock

<<Min: 89.5 - 91 1.5% Min: Sphalerite>>

<<Min: 89.5 - 91 30% Min: Pyrrhotite>>

<<Min: 89.5 - 91 0.8% Min: Chalcopyrite>>

91.00 91.60 OA Magnetite bearing sulphides

<<Min: 91 - 91.6 4.5% Min: Sphalerite>>

<<Min: 91 - 91.6 5% Min: Pyrite>>

<<Min: 91 - 91.6 27.5% Min: Pyrrhotite>>

<<Min: 91 - 91.6 5% Min: Magnetite>> Occuring as thin massive bands/aggregates.

<<Min: 91 - 91.6 1.3% Min: Chalcopyrite>>

91.60 92.30 OG Chalcopyrite rich sulphides

<<Min: 91.6 - 92.3 5% Min: Sphalerite>>

<<Min: 15.2 - 23.1 5% Min: Calcite>> and veinlets

<<Min: 15.2 - 23.2 10% Min: Ankerite>>

<<Vein: 15.2 - 82 5% Quartz-Carbonate>> Entire drill hole is in a fault zone, qtz-carbonate veinlets in as filling inb brecciated and fractured schist are ubiquitous.

<<Struc: 15.2 - 56.1 Strong (Alt) Fault>> Entire drill hole is in a fault zone of variable intensity. Phyllites - argillites are sheared, brecciated and locally crushed to zones of rock flour. The MAFi are more competent but still strongly sheared.

<<Struc: 15.2 - 84.2 Moderate (Alt) >> bedding defined by lamination - compositional banding; mostly parallel to foliation but locally foliation crosscuts laminations resulting inb crenulations

<<Struc: 15.2 - 84.2 Strong (Alt) Foliation>> foliation is parrallel to shearing - faulting which is at low angles to CA, 00-30 degrees for most part.

<<Min: 165.6 - 170 10% Min: Calcite>>

<<Min: 170 - 182.2 1% Min: Calcite>>

171.30 178.10 RHYvl Lapilli tuff

<<Min: 172.4 - 198.8 5% Min: Ankerite>>

<<Struc: 171.8 - 188 Moderate-Strong (Alt) Shear>> protomylonite to healed cataclastic txt pervasive throughout. Milled coherent qtz fragments and pervasive (discrete) gouge zones subparallel TCA.

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

178.10 194.20 RHY undifferentiated rhyolite

178.1 - 194.2: strong cataclastic txt overprint, consolidated clay fault gouge with milled pebble sz clasts, flt bx

<<Vein: 183.6 - 184 Quartz-Carbonate>>

<<Struc: 188 - 196.4 Strong (Alt) Fault>> Pervasive cataclastic (fault bx) mortar txt throughout. Weakly consolidated to mod. Healed. Late stage overprinting cataclastic txt on protomylonite developed.

194.20 201.70 RHYcw Curdy textured-flow banded (flows, subvolcanics)

194.2 - 201.7: FP overprinted by ankerite, possibly mixed with RHYvl within fault bx.

<<Min: 198.8 - 206.6 10% Min: Ankerite>>

<<Min: 201.1 - 206 10% Min: Calcite>>

<<Struc: 201 - 209.1 Intense (Alt) Fault>> Pervasive consolidated fault gouge with intensely comminutated clay to sand size matrix and pebble size bx clasts. Rock type changes discernable by color of gouge zone.

201.70 206.10 RHY undifferentiated rhyolite

201.7 - 206.1: healed clay gouge dominant, minor intervals of strongly comminutated rock, milled pebble sz clasts in fault bx

<<Vein: 204.2 - 205 Quartz-Carbonate>>

206.10 213.80 MDSc Carbonaceous dominant mudstone

206.1 - 213.8: strngly graphitic, appears heterolitic with interstitial qtz banding towards end of interval (grad. LCT). Broken throughout, flt bx.

<<Min: 206.1 - 213.8 2% Min: Pyrite>>

<<Min: 206.6 - 212.9 5% Min: Ankerite>>

<<Min: 212.9 - 221.3 2% Min: Ankerite>>

<<Struc: 209.1 - 221.3 Moderate-Strong (Alt) Shear>> pervasively broken core, no gouge. Protomylonite to mylonite developed throughout. Contrasting rock types of MDSc/MDSt and RHY - deformation highlighted by heterolithic appearing MDSt and MDSc. RHY is more massive but does have fabric developed at high angle TCA.

213.80 215.80 RHY undifferentiated rhyolite

213.8 - 215.8: siliceous RHY, possibly RHYcw, cataclastic overprint

215.80 219.40 MDSc Carbonaceous dominant mudstone

215.8 - 219.4: strongly graphitic. Foliation sub parallel to core axis.

<<Min: 215.8 - 219.4 2% Min: Pyrite>>

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %
219.40	**221.30**	**RHYvl** **Lapilli tuff** 219.4 - 221.3: strongly silicified <<Min: 219.4 - 221.3 2% Min: Calcite>>

<<Alt: 35.5 - 92 Weak (Alt) Muscovite>>

38.60 42.00 RHYcw Curdy textured-flow banded (flows, subvolcanics)

38.6 - 42: Excellent contorted flow foliation, Tightly spaced folded quartz-rich bands fold axes paralell to foliation. Sericite and muscovite, minor Fe-carb

<<Min: 38.6 - 40.7 5% Min: Calcite>>

42.00 44.40 RHYvl Lapilli tuff

42 - 44.4: Top of interval contains larage brecciated clasts replaced by Fe-carb.

44.40 45.20 RHYcw Curdy textured-flow banded (flows, subvolcanics)

<<Min: 45 - 50.6 0.5% Min: Calcite>>

45.20 64.90 RHYvl Lapilli tuff

45.2 - 64.9: Interval contains a mix of textures. Long Fe-carbonate altered feldspar/quartz ribbons, Porphyroblasts in fine grained quartz,sericite,muscovite groundmass (resembles curdy Rhy flow texture, and flattened lapilli. Could be a flow/tuff mixture interval.

<<Min: 47.5 - 82 10% Min: Ankerite>>

<<Min: 50.6 - 104.9 0.25% Min: Calcite>>

64.90 66.50 RHYcw Curdy textured-flow banded (flows, subvolcanics)

66.50 72.80 RHYvl Lapilli tuff

66.5 - 72.8: texture of coarse-grain to lapilli sized fragments. Dominantly coarse grained. Contains biotite rich flattened lithics and dark, regularly spaced bands

72.80 73.90 RHYcw Curdy textured-flow banded (flows, subvolcanics)

73.90 87.30 RHYvl Lapilli tuff

73.9 - 87.3: Contains 40cm rhyolite flow at 89.9m. Quartz-pyrite rich stringers at 103.8 to 104.6

<<Min: 82 - 111 15% Min: Ankerite>>

87.30 90.10 RHYcw Curdy textured-flow banded (flows, subvolcanics)

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

90.10 108.50 RHYvl Lapilli tuff

90.1 - 108.5: Contains 40cm rhyolite flow at 89.9m. Quartz-pyrite rich stringers at 103.8 to 104.6; strong deformation, isoclinal folds, kink banding, contorted veinlets

<<Alt: 92 - 122 Moderate (Alt) Muscovite>>

108.50 109.60 RHYcw Curdy textured-flow banded (flows, subvolcanics)

108.5 - 109.6: curdy to flow banded texture

109.60 116.10 RHYva Coarse grained to ash tuff

109.6 - 116.1: Dominantly coarse grained tuff. Contains some flattened lapilli fragments intermittantly, as well as flattened lenses of quartz-pyrite-biotite-chlorite (mafic lapilli?)

<<Min: 111 - 169 5% Min: Ankerite>>

116.10 118.00 MDSt Rhyolite tuff dominant mudstone

116.1 - 118: Very weakly carbonaceous, Main minerals include quartz, muscovite, sericite, biotite, Fe-carbonate. Textures range from contorted, thin banded, lapilli fragments, and foliation parallel sheared contortions. Possible argillaceous component.

118.00 120.40 MDSc Carbonaceous dominant mudstone

120.40 123.00 MDSt Rhyolite tuff dominant mudstone

120.4 - 123: Contains mix of lapilli and coarse grained fragments. Minor biotite component

<<Alt: 122 - 142 Weak (Alt) Muscovite>>

123.00 132.00 MDSw Coherent rhyolite flow with carbonaceous content FG

123 - 132: Mineralogy: Quartz,muscovite,biotite,sericite. Very fissile rock, broken surfaces of core are greasy. Texture is mostly wavy mica dominated foliations.

132.00 142.00 RHYcw Curdy textured-flow banded (flows, subvolcanics)

132 - 142: Quartz rich interval with pervasive sericite and minor carbonate. Thin dark bands of quartz+/- sulphide (Py, Cpy) present.

<<Min: 132 - 158 0.5% Min: Pyrrhotite>>

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

0.00 5.50 OVBN Overburden

5.50 8.30 MDSc Carbonaceous dominant mudstone

5.5 - 8.3: Dark grey, fine grained, strongly foliated/sheared (intervals with crenulation). Alternation with thin carbonacious bands (mudstone), very fine grained, and tuffaceous bands. Banded texture. The foliation is folded and irregular. Moderate to strong calcite (clots/ thin veinlets) within mudstone/tuff intervals.

<<Min: 5.5 - 11 15% Min: Ankerite>>

<<Min: 5.5 - 17.5 10% Min: Calcite>> Also occuring as thin pervasive bands

8.30 10.30 MAFta Coarse grained to ash tuff

8.3 - 10.3: Mafic ash tuff or intrusive unit, fine to medium grained, +/- homogeneous, light green. Weakly chlorite altered (pervasive), moderate to strongly CA altered (Thin vesicular veinlets, concordant, and also locally pervasive).

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

10.30 37.00 MDSc Carbonaceous dominant mudstone

10.3 - 37: Dark grey, fine grained, strongly foliated/sheared (intervals with crenulation and fault gauge). Alternation with thin carbonacious bands (mudstone), very fine grained, and tuffaceous bands. Banded texture. The foliation is folded and irregular. Moderate to strong calcite (clots/ thin veinlets) within mudstone/tuff intervals. Locally comprising short intervals of MAFta/MAFi.

20.6-24m: Large interval dominated by carbonaceous mudstone, >70%, Brecciated.

<<Min: 10.4 - 12.7 0% Min: Pyrrhotite>>

<<Min: 11 - 37 3% Min: Ankerite>> Mainly associated with MAFi.

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

0.00 3.00 OVBN Overburden

3.00 18.30 MAFi Mafic Intrusions (primarily green-brown FG footwall mafic intrusion)

3 - 18.3: massive, relatively homogeneous, intermediate?, BI from weak sedimentary component?, abdt CA veinlets, not strongly schistose so possibly a sill?

<<Min: 3 - 32.6 5% Min: Calcite>> in veinlets, patches in groundmass

<<Min: 13.1 - 14.8 3% Min: Pyrite>> strongly gossanous, PY in seams and blebs on fol'n, in veinlets -sheared zone?

18.30 19.90 RHYif feldspar and quartz porphyry buff intrusions

18.3 - 19.9: not really a RHY, probably intermediate rock, spotty due to Felsic phenos or augens, in soft micaceous groundmass, no CA, minor BI pblasts

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

19.90 31.20 MAFi Mafic Intrusions (primarily footwall mafic intrusion) green-brown

19.9 - 31.2: same unit as 3-18.3, fg homogeneous groundmass, CA in veinets, minor blebs, small mafic looking dykelets cut through and have gossanous envelopes

<<Min: 20.6 - 24 0.01% Min: Pyrite>> blotchy JA best evidence

<<Struc: 20.2 - 20.21 Strong (Alt) dominant foliation>>

31.20 31.60 MDS Carbonaceous Mudstone & Tuffaceous Mudstone black

31.2 - 31.6: narrow bed, CB in lenses, black pblasts-TO or BI?

31.60 43.30 MAFta Coarse grained to ash tuff green

31.6 - 43.3: Intermediate tuff? With sedimentary component represented by BI partings that increase towards bottom of interval, Abundant AK-CA veinlets throughout, almost dominant, highly deformed, transposed layers and veinlets, interbedded at bottom with underlying unit.

Could this be MDSt, as below, with CL alteration associated with the veining?

<<Min: 31.6 - 43.3 0.01% Min: Pyrite>> associated with AK-QZ veining, rare

<<Min: 31.6 - 47.1 5% Min: Ankerite>> contorted veinlets, with CA, QZ

<<Min: 32.6 - 43.3 3% Min: Calcite>> in AK veinlets

<<Alt: 31.6 - 43.3 Moderate (Alt) Chlorite>> related to intense AK-CA-QZ veining in section, could be an alt'n lithology i.e. should be part of MDSt below

<<Vein: 35.5 - 35.7 90% Quartz-Chalcopyrite 20 deg. >> 10 cm QZ-CA-AK-minor PY vein

43.30 47.10 MDSt Rhyolite tuff dominant mudstone dark grey

43.3 - 47.1: interlayered quartzose and BI-rich layers, gradational from MAFta above, contorted

<<Min: 43.3 - 70 5% Min: Calcite>>

47.10 80.80 SEDc calcareous Sediment black

47.1 - 80.8: interlayered black MDS with lighter, QZ-CA-AK lenses/bands, segregated components, Originally a turbiditic unit?-argillite with silty layers?, contorted, maybe weakly carbonaceous locally, particulalry in fault/shear zones, overall would this form a conductive unit?

<<Min: 47.1 - 49 1% Min: Pyrite>> heavy oxidation-JA- in shear?, PY in fracs, on fol'n, sporadic

<<Min: 55.9 - 64 0.5% Min: Pyrite>> scattered and in narrow lenses or bands

<<Min: 70 - 70.7 3% Min: Pyrrhotite>> diss'd along fol'n in alt'n zone

<<Min: 70 - 70.7 10% Min: Calcite>> pervasive

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

<<Min: 70.7 - 86.9 5% Min: Calcite>> seems stronger below 70 m

<<Alt: 70 - 70.7 Moderate (Alt) Chlorite>> weak zone in SED

<<Vein: 49 - 86.9 15% Quartz-Carbonate>> abundant QZ-CA-DO veins, spaced and vein zones

<<Struc: 53.6 - 55.8 Moderate (Alt) Fault>> broken core, gouge

<<Struc: 55.3 - 55.31 Strong (Alt) dominant foliation>>

<<Struc: 64 - 69.8 Intense (Alt) Fault>> measured on edge of gouge zone, very broken, lots of gouge, reasonable recovery

<<Struc: 76.2 - 76.3 Moderate (Alt) Fault>> slip plane

80.80 82.10 MAFi Mafic Intrusions (primarily footwall mafic intrusion)

<<Min: 80.8 - 82.1 3% Min: Pyrrhotite>> diss'd along fol'n

<<Alt: 80.8 - 82.1 Moderate (Alt) Chlorite>> looks like QE present as in unit below but possibly remnant QZ from SED

<<Alt: 81.2 - 81.8 Weak (Alt) Silicification>>

82.10 86.90 MDSt Rhyolite tuff dominant mudstone dark grey

82.1 - 86.9: tuffaceous component dominant, picks up possibly in alt'n zone from 80.8-82.1 where QE's occur

<<Min: 82.1 - 86.9 1% Min: Pyrrhotite>> blebs in QZ-AK domains, and in fractures locally

<<Min: 82.1 - 86.9 10% Min: Ankerite>> in groundmass, lensy

<<Struc: 86.5 - 86.9 Moderate (Alt) Fault>> broken core

86.90 94.10 RHYif feldspar and quartz porphyry intrusions green FG

86.9 - 94.1: sill?, trace slightly bluish QE's scattered trhough unit but distinct - felsic? With CL alt'n?

<<Min: 86.9 - 92.4 3% Min: Pyrrhotite>>

<<Min: 86.9 - 94.1 15% Min: Calcite>> to pervasive, in veins

<<Min: 86.9 - 94.3 5% Min: Ankerite>> lenses

<<Min: 92.4 - 94.3 5% Min: Pyrrhotite>> and wisps

<<Alt: 86.9 - 94.3 Moderate (Alt) Chlorite>> wx'd out around fault

94.10 106.50 SEDc calcareous Sediment black

94.1 - 106.5: slight variation from MDSt, CA in lenses, contorted, AK locally in groundmass, several small RHYif dykelets cutting through

<<Min: 94.1 - 106.5 10% Min: Calcite>> occurs in lenses with QZ, veinlets

<<Min: 94.3 - 104.7 0.5% Min: Pyrrhotite>> small lenses, scattered

From (m)	To (m)	Rocktype & Description	From (m)	To (m)	Width	Sample	Ag PPM	Au PPM	Cu %	Pb %	Zn %

<<Min: 100.1 - 104.7 10% Min: Ankerite>> in groundmass, lenses

106.50 110.30 MDSc Carbonaceous dominant mudstone black

106.5 - 110.3: laminated appearance, contorted, possibly carbonaceous, intruded by QE RHYi

110.30 113.50 SEDc calcareous Sediment black

110.3 - 113.5: bedded, CA in patches, lenses, possibly carbonaceous, extremely deformed QZ-CA veinlets t/o, broken core

<<Min: 110.3 - 113.5 0.5% Min: Pyrrhotite>> scattered

<<Min: 110.3 - 113.5 5% Min: Calcite>>

<<Min: 110.3 - 117.5 0.5% Min: Pyrite>> and in QZ vn

113.50 115.00 RHYif feldspar and quartz porphyry intrusions green MG

113.5 - 115: relatively homogeneous, poorly fol'd, bluish QE, numerous dykelets in proximity to this interval

<<Min: 113.5 - 115 10% Min: Calcite>> t/o dyke

<<Alt: 113.5 - 115 Weak (Alt) Chlorite>> not as strong, because CA prevalent?

115.00 129.10 SEDc calcareous Sediment black

115 - 129.1: highly contorted, variable CA/AK, cut by numerous felsic dykelets, QV's minor

<<Min: 115 - 125.9 5% Min: Calcite>>

<<Min: 117.5 - 125.9 0.5% Min: Pyrrhotite>> and wisps, scattered

<<Min: 125.9 - 129.1 0.5% Min: Pyrite>>

<<Min: 127 - 132.8 3% Min: Ankerite>> scattered in SED and strong in dykes

<<Alt: 126.4 - 127 Weak (Alt) Silicification>> related to fault? Or nearby dyke?

<<Vein: 116.3 - 116.7 100% Quartz 60 deg. >> qz-cl-py

<<Struc: 126.5 - 126.53 Moderate (Alt) Fault>> drags fol'n, filled by PY, SI alt'n around

129.10 140.20 SED undifferentiated Sediment black

129.1 - 140.2: much less CB veining but CA pervasive locally, graphitic coatings on fol'n and in fault, several MAFi dykes included

<<Min: 129.1 - 139.9 0.5% Min: Pyrrhotite>> in fractures

<<Min: 129.1 - 139.9 10% Min: Calcite>> absent locally

<<Struc: 129.8 - 133.6 Strong (Alt) Fault>> measured on gouge contact, several dykes and minor QV's in interval

<<Struc: 132.1 - 132.11 Strong (Alt) Contact>> upper contact of dyke

Presence of wacke sediment and blue qe bearing white augen gneiss RHYVX below seems to correlate with SED in K97-181 in Fw to the massive sulphide. This suggests it pinches out here naturally not from faulting and our best hope is that it strikes NW SE. However only weak -mod mu alteration here.

Project Information

Project Name:	Finlayson - High Density Area
Project Number:	13214
Client:	Challenger Geomatics

Project Type:	Local Area
Project Location:	Watson Lk, YT, Canada
Project Size:	33 sq km

Acquisition Projects

Project Name	Project Number	Vintage
1571	Finlayson	Sept. 2015

Acquisition Parameters

Date (MM/DD/YY)	Mission	Flying Height (m)	Flying Speed (knots)	Pulse Rate Rep (kHz)	Scan Freq (Hz)	Scan Angle (degree)	Side Lap %	Point Density (pts/m²)	LiDAR System
09/27/15	7915270a	1300	160	410	53	50	50	9.50	Leica ALS70
Multiple Return Capabilities:			YES		**Number of returns recorded:**				Maximum 4

Geodetic Control

Horizontal Datum:	Nad83 CSRS	**Vertical Datum:**	CGVD28
Geoid Model:	HT2.0	**UTM Zone:**	9

Note: We established a local geodetic network fixed to the following control:

Station ID	Lat	Long	Orthometric Height
72Y023	N60deg 21' 02.83600"	W129deg 03' 17.44660"	839.473m
77Y011	N60deg 04' 56.82910"	W129deg 22' 07.22160"	858.916m

Calibration Methodology

Airborne Imaging performs a complete calibration on every LiDAR acquisition flight, data is acquired over a calibration site flown with at least two passes in opposite directions before and after the flight. Any error in the attitude of the aircraft (roll, pitch and heading) can be observed and corrected for within system specifications. To statistically quantify the accuracy, we compare the LiDAR elevations with independently surveyed ground points. A GPS mounted truck collects data while driving on an open road. The kinematic positions on the road are post-processed from a nearby base station (common to the aerial survey)

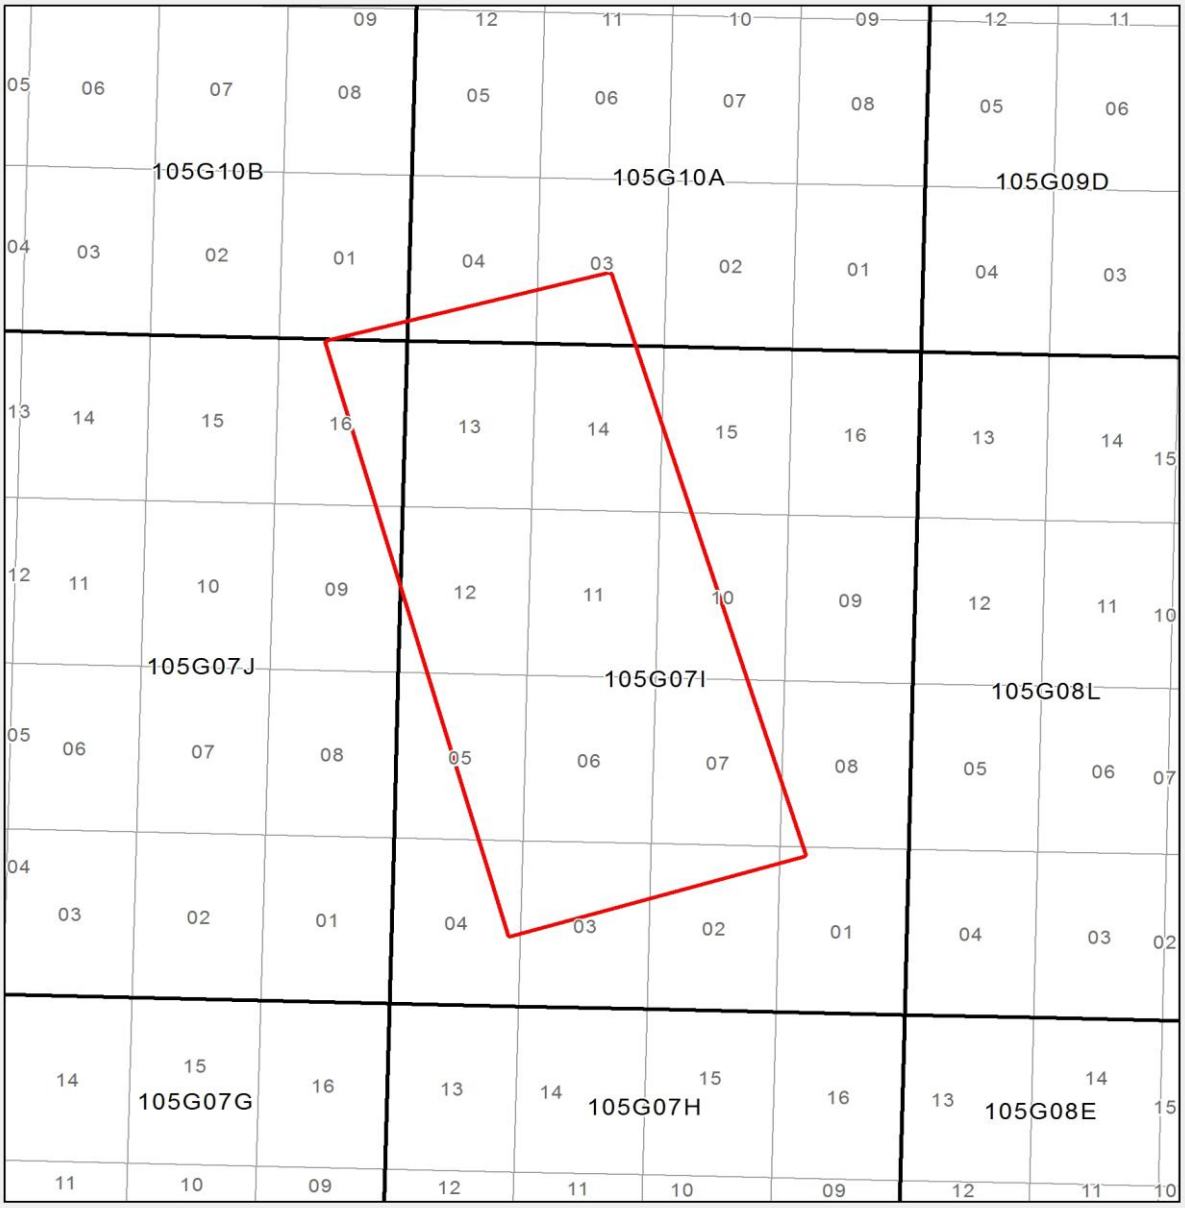
Accuracy

Horizontal Accuracy, 95% or 2σ:	35 cm
Fundamental Vertical Accuracy (on flat hard surfaces), 95% or 2σ:	15 cm

Deliverables

Hillshade Images (Geotiffs), Bare Earth, Full Feature
1m Grids (XYZ ASCII), Bare Earth and Full Feature
Point Cloud (LAS v1.2, ASPRS Classes)

Projected in UTM 9 NAD 83 Summary Produced: October 9, 2015



13214 - Finlayson 2015 - Challenger Geomatics

The Red outline represents the extent of the new data delivered.
Data is tiled following the National Topographic System (NTS).

The NTS system is separated into four tiling levels for example: 93 L 10 D.
These blocks are further divided into 16ths for a manageable tile size of approx. 2km X 2km.
The final tile names appear as follows: 093L10D15

AIRBORNE IMAGING
A Clean Harbors Company

End User LiDAR Data License Agreement

Airborne Imaging, a Clean Harbors Company, is a body corporate duly incorporated pursuant to the laws of the Province of Alberta

By downloading, installing or using **Airborne Imaging** supplied LiDAR**,** you acknowledge that you have read this agreement and agree to be bound by its terms and conditions.

Whereas **Airborne Imaging, a Clean Harbors Company** has collected and processed certain data, known as LiDAR data, and is the **Owner** of said data, and you as **Licensee (Customer)** is desirous of using said data for purposes to be determined solely by Licensee, in consideration of the mutual covenants contained herein, **Airborne Imaging** hereby grants to the Licensee a non-exclusive, non-transferable, royalty free license, subject to the following terms and conditions:

1. For the purpose of this license agreement, the word "Data" with respect to each LiDAR data shall have the following meaning:

    a. point derived data from the LiDAR survey, which data describes the location and height of the ground or of vegetation or other structures above the ground, in a digital format;

    b. graphic files derived from the point data, showing the area in a shaded form, in a digital format

2. Licensee recognizes that **Airborne Imaging** does not guarantee the accuracy or quality of the Data for a particular purpose and Licensee shall use the Data at its own risk. Owner shall not be liable to the Licensee for any loss or damage arising from the use of the Data whether arising from any defects, inaccuracies or incompleteness regardless of the reason or cause of any such defects, inaccuracies or incompleteness.

3. Licensee understands and agrees that **Airborne Imaging** has and retains ownership rights in the data and Owner shall continue to have the exclusive right to license, sell, trade, loan and use the Data for any purpose.

4. No part of the LiDAR or products derived there from, or any right granted under this Agreement may be copied, sold, rented, leased, lent, sub-licensed, disclosed, or transferred to any other person or entity. In the event the Licensee is purchasing the LiDAR data as a sub-contractor to a Final End User Licensee, the Licensee must make the final end user aware the data is licensed from Airborne Imaging and agree to the terms of this agreement. In this type of arrangement, it is the obligation of the Licensee to insure a copy of this agreement is delivered to their end client (end user licensee).

5. Licensee agrees that the Data and copies shall be for its own internal use and it will not sell, trade, and otherwise make available to any third parties any of the Data received by it under this agreement without the written consent of **Airborne Imaging**. This prohibition shall not preclude the Licensee from giving the Data to its parent or any subsidiary, a subsidiary of its parent company, any contractors or sub-contractors working for the Licensee in the area covered by the Data, providing such parent, subsidiary, contractor, or sub-contractor agrees to abide by the terms of this agreement.

6. Licensee agrees that if or when any additional partners desire to share the Data, it will require consent from **Airborne Imaging**, and an additional license fee for each partner will be charged by Owner, to be paid by each additional partner, and the use of the data by each additional partner shall be subject to the terms set out in this License Agreement.

7. If required by applicable Laws, Licensee may disclose the Data to appropriate governmental agencies having jurisdiction, provided that Owner consents in writing prior to the disclosure, which consent shall not be unreasonably withheld, and provided further that Licensee promptly informs Owner in writing of full details of each request for the Data, to whom the disclosure is to be made and the reason for such disclosure.

8. This Agreement is the complete and exclusive statement of the understanding between the Licensee and Airborne Imaging with respect to the LiDAR data and may be amended or modified only in a written instrument signed by a duly authorized representative of both parties. If any provision is determined to be invalid or unenforceable, the remaining provisions of this Agreement shall continue to be valid and enforceable. Without the prior written consent of Airborne Imaging, neither this Agreement nor any of the rights granted by it may be assigned or transferred by the Licensee. This restriction on assignments or transfers shall apply to assignments or transfers by operation of law, as well as by contract, merger or consolidation.

9. It is THE LICENSEE'S RESPONSIBILITY to ensure that its use of the LiDAR data complies with these terms and to seek prior written permission from Airborne Imaging for any uses not expressly permitted or not specified in this Agreement.

Dear Mr. Black;

Re: Survey Methodology and Equipment; Kudz Ze Kayah (KZK), Yukon

Thank you for the opportunity to work on this interesting project. The following outlines our general survey methodology and the technical equipment we use at KZK.

Challenger uses exclusively Leica Geomatics Ltd. survey grade technical equipment. In open areas (almost all of KZK) we use Leica Viva Global Navigation Satellite Systems (GNSS). GNSS includes GPS and other satellites and is more robust than GPS alone. We have used differentially corrected Real Time Kinematic (RTK) GNSS for most measurements at KZK. These measurements are possible when we have radio contact with our base receiver. When we do not have radio contact (ie in GP4F) we post process the GNSS vectors. We have survey control that will reach the GP4F area with radio however the cost to move the GNSS base station with the helicopter is too high unless we are measuring many locations in GP4F.

Challenger also has several total stations available in case GNSS techniques are not appropriate (heavy trees). Thus far we have not used anything other than GNSS on the KZK site. Please find attached a fact sheet for the Leica Viva GS15 GNSS receiver.
Coordinates for our control have been derived using Natural Resources Canada's Precise Point Positioning (PPP) service which uses precise GNSS orbit information to compute the absolute position of a measured point. Uncertainty statistics are provided and are primarily a function of observation time and satellite constellation. Once a PPP solution for our primary control point was obtained we processed static GNSS vectors within our control network to determine the coordinates of all other control. These values were compared against PPP values for these points as a check. Several control stations are located in various areas to allow for checks (performed each day to ensure equipment is performing correctly) and are available in case of destruction of other control points. All check measurements are recorded in hard copy and digitally.

CHALLENGER GEOMATICS LTD.

Leica Viva GS15
Data sheet

Engaging software

The Leica Viva GS15 GNSS smart antenna is accompanied with the revolutionary Captivate software, turning complex data into the most realistic and workable 3D models. With easy-to-use apps and familiar touch technology, all forms of measured and design data can be viewed in all dimensions. Leica Captivate spans industries and applications with little more than a simple swipe, regardless of whether you work with GNSS, total stations or both.

Seamlessly share data among all your instruments

Leica Geo Office imports and combines data from your GNSS, total station and level instruments for one final and accurate result. Processing has never been made easier when all your instruments work in tandem to produce precise and actionable information.

ACC»

Customer care is only a click away

Through Active Customer Care (ACC), a global network of experienced professionals is only a click away to expertly guide you through any problem. Eliminate delays with superior technical service, finish jobs faster with excellent consultancy support, and avoid costly site revisits with online service to send and receive data directly from the field. Control your costs with a tailored Customer Care Package, giving you peace of mind you're covered anywhere, anytime.

[1] The Unlimited series includes a future upgrade to 500+ channels.
[2] Support of QZSS is incorporated and will be provided through future firmware upgrade.

[3] Measurement precision, accuracy, reliability and time for initialisation are dependent upon various factors including number of satellites, observation time, atmospheric conditions, multipath etc. Figures quoted assume normal to favourable conditions. A full BeiDou and Galileo constellation will further increase measurement performance and accuracy.
[4] Might vary with temperature, age of battery, transmit power of data link device.

Appendix H: Drill collar coordinates and orientations

This appendix contains the most up-to-date collar coordinates for all 2015 drill holes (Table H-1) and all of those historical drill holes that were re-surveyed in 2015 (Table H-2). The survey used to located the collar is indicated as either differential GPS ("RTK DGPS") or as done by the integration of LiDAR elevation data with eastings and northings from a handheld GPS ("GPS-LiDAR") or azimuth pointing system ("APS-LiDAR").

Table H-1: Survey collar information for 2015 diamond drill holes

Hole ID	Easting[1]	Northing[1]	Elevation (m)	Length (m)	Azimuth (°)	Dip (°)	Survey Type

EXECUTIVE SUMMARY

KUDZ ZE KAYAH, PELLY AND LIMY - WOLVERINE LAKE, YUKON

During August 28th to September 7th 2015 Geotech Ltd. carried out a helicopter-borne geophysical survey over Kudz Ze Kayah, Pelly and Limy situated near Wolverine Lake, Yukon.

Principal geophysical sensors included a versatile time domain electromagnetic (VTEMplus) system and horizontal magnetic gradiometer with two caesium sensors. Ancillary equipment included a GPS navigation system and a radar altimeter. A total of 557 line-kilometres of geophysical data were acquired during the survey.

In-field data quality assurance and preliminary processing were carried out on a daily basis during the acquisition phase. Preliminary and final data processing, including generation of final digital data and map products were undertaken from the office of Geotech Ltd. in Aurora, Ontario.

The processed survey results are presented as the following maps:

- Electromagnetic stacked profiles of the B-field Z Component,
- Electromagnetic stacked profiles of dB/dt Z Component,
- B-Field Z Component Channel grids,
- dB/dt X Component Fraser Filtered Channel grid,
- Total Magnetic Intensity (TMI),
- Magnetic Total Horizontal Gradient,
- Magnetic Tilt-Angle Derivative of TMI,
- Calculated Time Constant (Tau) with Calculated Vertical Derivative contours and
- Resistivity Depth Images (RDI) sections are presented.

Digital data includes all electromagnetic and magnetic products, plus ancillary data including the waveform.

The survey report describes the procedures for data acquisition, processing, final image presentation and the specifications for the digital data set.

1. INTRODUCTION

1.1 GENERAL CONSIDERATIONS

Geotech Ltd. performed a helicopter-borne geophysical survey over Kudz Ze Kayah, Pelly and Limy situated near Wolverine Lake, Yukon (Figure 1 & Figure 2).

Robin Black represented BMC Minerals (No. 1) Ltd during the data acquisition and data processing phases of this project.

The geophysical surveys consisted of helicopter borne EM using the versatile time-domain electromagnetic (VTEMplus) system with Full-Waveform processing. Measurements consisted of Vertical (Z) and In-line Horizontal (X) components of the EM fields using induction coils and the aeromagnetic total field using a magnetic gradiometer. A total of 557 line-km of geophysical data were acquired during the survey.

The crew was based out of Inconnu Lodge (Figure 2) in Yukon for the acquisition phase of the survey. Survey flying started on August 28th and was completed on September 7th, 2015.

Data quality control and quality assurance, and preliminary data processing were carried out on a daily basis during the acquisition phase of the project. Final data processing followed immediately after the end of the survey. Final reporting, data presentation and archiving were completed from the Aurora office of Geotech Ltd. in November, 2015.

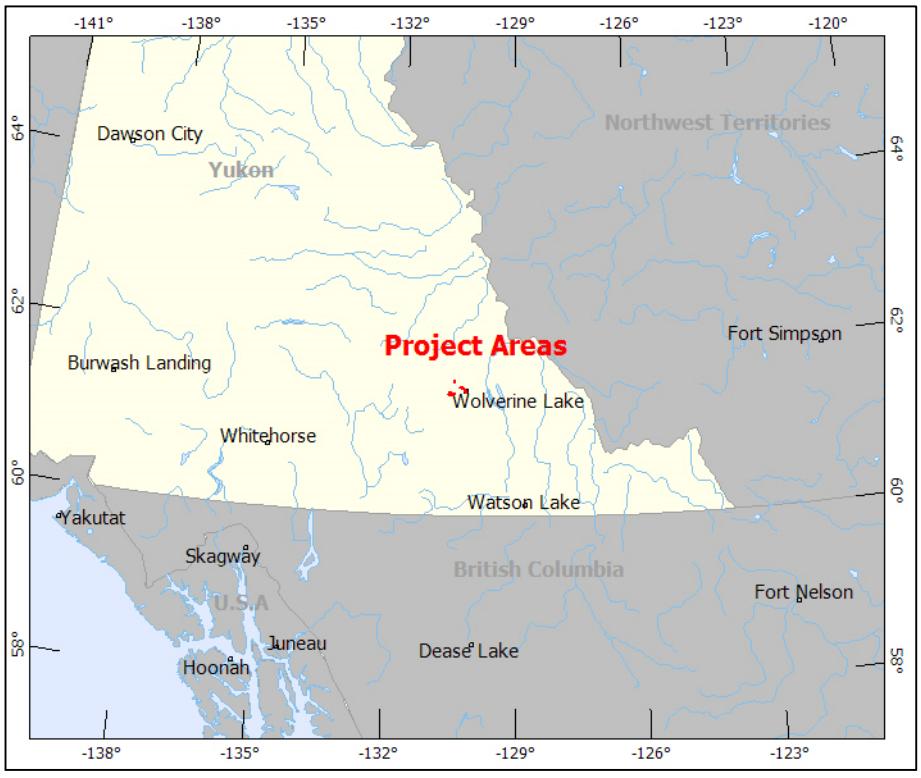

Figure 1: Survey location

1.2 SURVEY AND SYSTEM SPECIFICATIONS

The survey areas, Kudz Ze Kayah, Pelly and Limy are located approximately 13 kilometres west, 1.5 kilometres north and 19 kilometres northwest of Wolverine Lake, Yukon respectively (Figure 2).

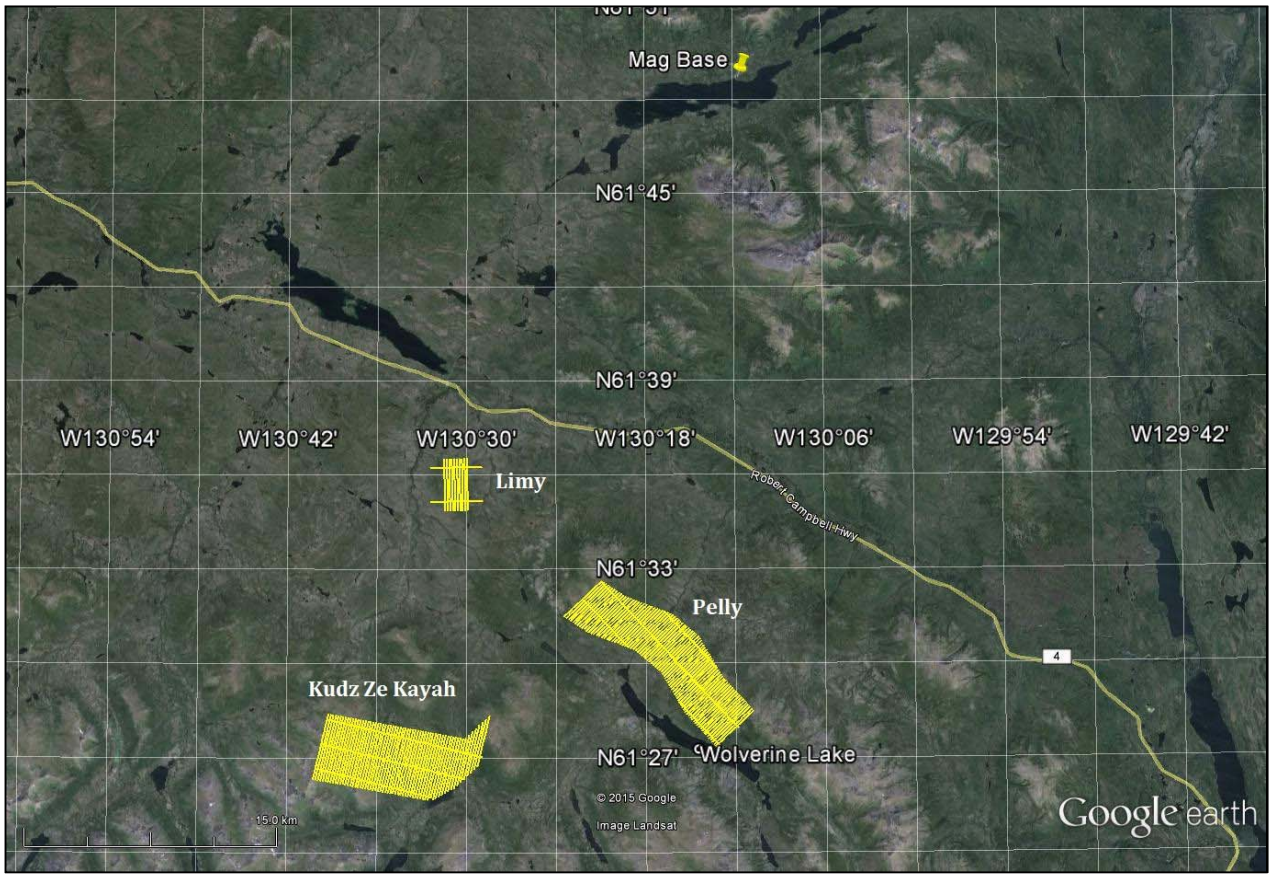

Figure 2: Survey area location on Google Earth.

The block, Kudz Ze Kayah was flown in a northeast to southwest (N 15° E azimuth) direction, Pelly was flown in a southwest to northeast (N48° E azimuth) direction, and Limy were flown in a north to south (N 0° E azimuth) with traverse line spacing of 150 metres as depicted in Figure 3 to 5. Tie lines were flown perpendicular to the traverse lines at a spacing of 1500 and 2000 metres respectively. For more detailed information on the flight spacing and direction see Table 1.

1.3 TOPOGRAPHIC RELIEF AND CULTURAL FEATURES

Topographically, the survey areas exhibits a highly rugged relief with an elevation ranging from 1091 to 2038 metres above mean sea level over an area of 73 square kilometres (Figure 3 to 5).

There are various rivers and streams running through the survey areas which connect various lakes. There are no visible signs of culture such as roads, transmission lines, mining areas and settlements located in the survey areas (Figure 3 to 5).

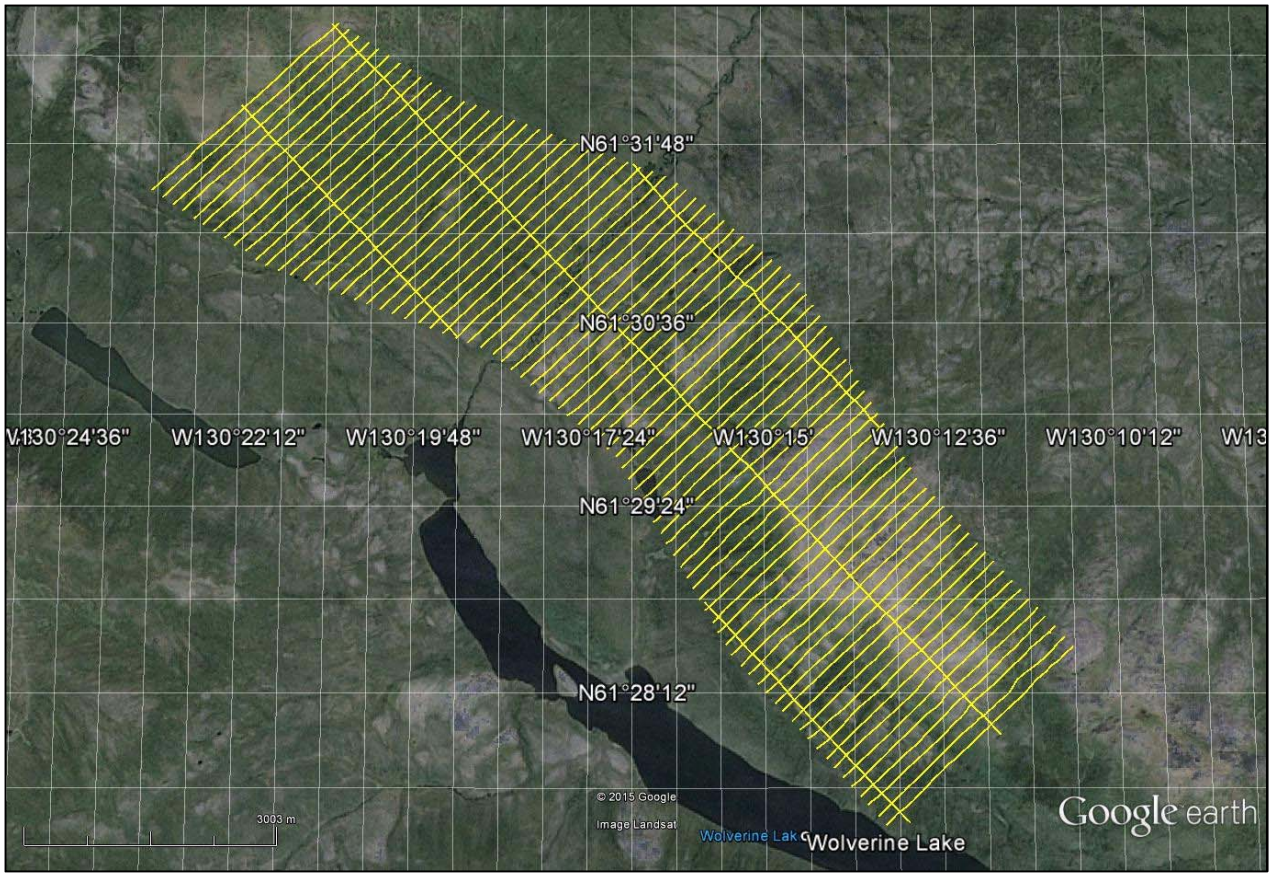

Figure 4: Flight path of Pelly over a Google Earth Image.

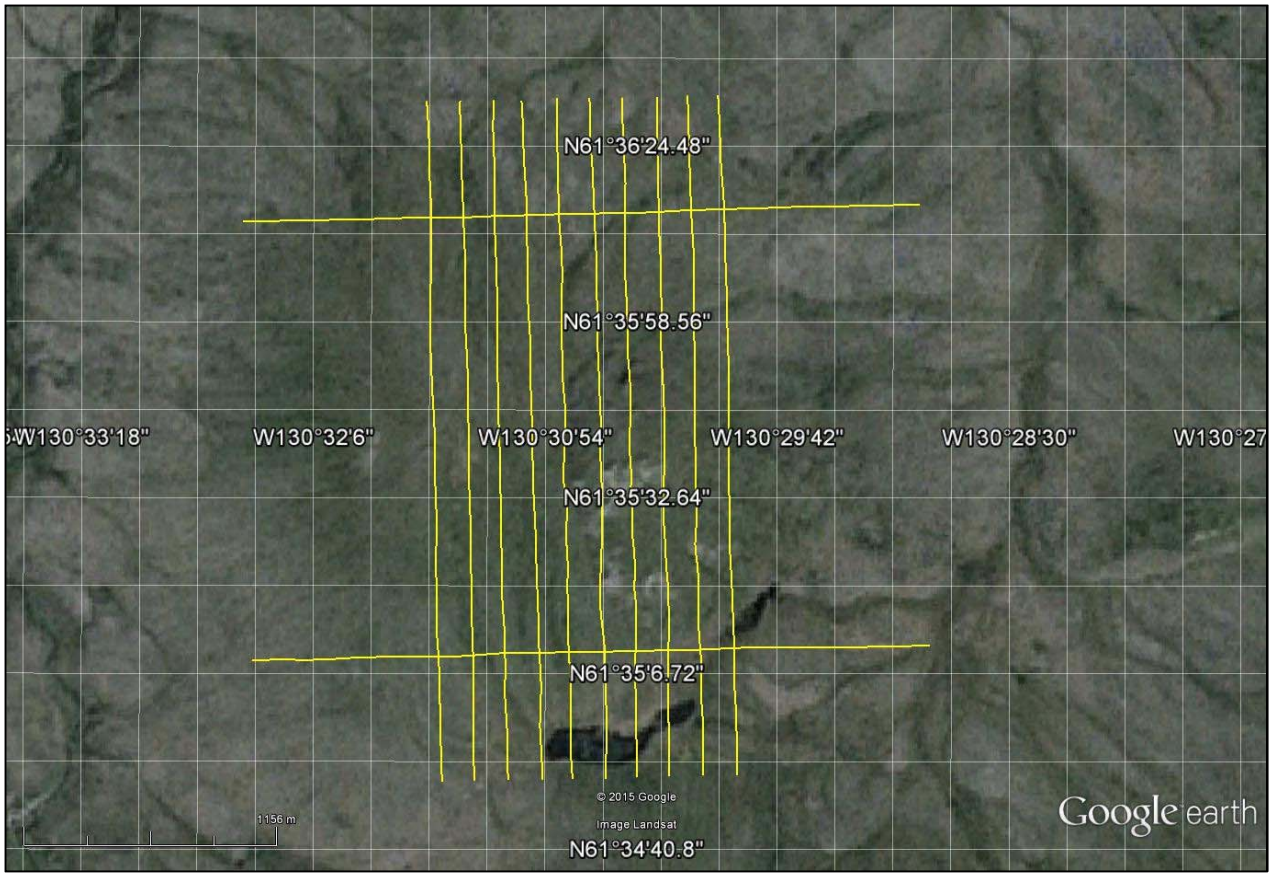

Figure 5: Flight path of Limy over a Google Earth Image.

2. DATA ACQUISITION

2.1 SURVEY AREA

The survey areas (see Figure 3, Figure 4, Figure 5, and Appendix A) and general flight specifications are as follows:

Table 1: Survey Specifications

Survey block	Line spacing (m)	Area (Km^2)	Planned[1] Line-km	Actual Line-km	Flight direction	Line numbers
Kudz Ze Kayah	Traverse: 150	35	260	241.1	N 15° E / N 195° E	L1000 - L1620
	Tie: 1500			26.3	N 105° E / N 285° E	T2001 - T2020
Pelly	Traverse: 150	36	261	245.3	N 48° E / N 228° E	L3000 - L3780
	Tie: 1500			24.1	N 138° E / N 318° E	T4000 - T4021
Limy	Traverse: 150	2	36	31.0	N 0° E / N 180° E	L5000 - L5090
	Tie: 2000			6.2	N 90° E / N 270° E	T6000 - T6010
TOTAL		73	557	574		

Survey area boundaries co-ordinates are provided in Appendix B.

2.2 SURVEY OPERATIONS

Survey operations were based out of Inconnu Lodge in Yukon from August 22nd until September 7th 2015. The following table shows the timing of the flying.

Table 2: Survey schedule

Date	Flight #	Flown km	Block	Crew location	Comments
22-Aug-2015				Watson Lake, Yukon	Crew arrived
23-Aug-2015				Watson Lake, Yukon	System Assembly
24-Aug-2015				Watson Lake, Yukon	System Assembly
25-Aug-2015				Watson Lake, Yukon	System testing
26-Aug-2015				Watson Lake, Yukon	Test completed
27-Aug-2015				Inconnu Lodge, Yukon	System ferry - no production due to weather
28-Aug-2015	1,2,3	103	Kudz Ze Kayah	Inconnu Lodge, Yukon	103km flown
29-Aug-2015	4	9	Pelly	Inconnu Lodge, Yukon	9km flown - limited due to weather
30-Aug-2015	5,6	144	Kudz Ze Kayah, Pelly	Inconnu Lodge, Yukon	144km flown
31-Aug-2015				Inconnu Lodge, Yukon	No production due to weather
1-Sep-2015				Inconnu Lodge, Yukon	No production due to weather
2-Sep-2015	7	69	Limy, Pelly	Inconnu Lodge, Yukon	69km flown limited due to weather
3-Sep-2015	8,9,10	139	Pelly	Inconnu Lodge, Yukon	139km flown
4-Sep-2015	11,12	84	Kudz Ze Kayah, Pelly	Inconnu Lodge, Yukon	84km flown
5-Sep-2015	13	16	Kudz Ze	Inconnu Lodge, Yukon	reflights

[1] Note: Actual Line kilometres represent the total line kilometres in the final database. These line-km normally exceed the Planned Line-km, as indicated in the survey NAV files.

Date	Flight #	Flown km	Block	Crew location	Comments
			Kayah		
6-Sep-2015				Inconnu Lodge, Yukon	Reflights not done due to weather
7-Sep-2015	14	15	Kudz Ze Kayah, Pelly	Inconnu Lodge, Yukon	Remaining kms were flown – flying complete

2.3 FLIGHT SPECIFICATIONS

During the survey the helicopter was maintained at a mean altitude of 77 metres above the ground with an average survey speed of 80 km/hour. This allowed for an actual average Transmitter-receiver loop terrain clearance of 44 metres and a magnetic sensor clearance of 54 metres.

The on board operator was responsible for monitoring the system integrity. He also maintained a detailed flight log during the survey, tracking the times of the flight as well as any unusual geophysical or topographic features.

On return of the aircrew to the base camp the survey data was transferred from a compact flash card (PCMCIA) to the data processing computer. The data were then uploaded via ftp to the Geotech office in Aurora for daily quality assurance and quality control by qualified personnel.

2.4 AIRCRAFT AND EQUIPMENT

2.4.1 SURVEY AIRCRAFT

The survey was flown using a Eurocopter Aerospatiale (Astar) 350 B3 helicopter, registration C-GAKF. The helicopter is owned and operated by Access Helicopters. Installation of the geophysical and ancillary equipment was carried out by a Geotech Ltd crew.

2.4.2 ELECTROMAGNETIC SYSTEM

The electromagnetic system was a Geotech Time Domain EM (VTEM™Plus) full receiver-waveform streamed data recorded system. The "full waveform VTEM system" uses the streamed half-cycle recording of transmitter and receiver waveforms to obtain a complete system response calibration throughout the entire survey flight. The VTEM™ transmitter current waveform is shown diagrammatically in Figure 6. VTEM with the Serial number 19 had been used for the survey.

The VTEM™ Receiver and transmitter coils were in concentric-coplanar and Z-direction oriented configuration. The receiver system for the project also included a coincident-coaxial X-direction coil to measure the in-line dB/dt and calculate B-Field responses. The Transmitter-receiver loop was towed at a mean distance of 31 metres below the aircraft as shown in Figure 7.

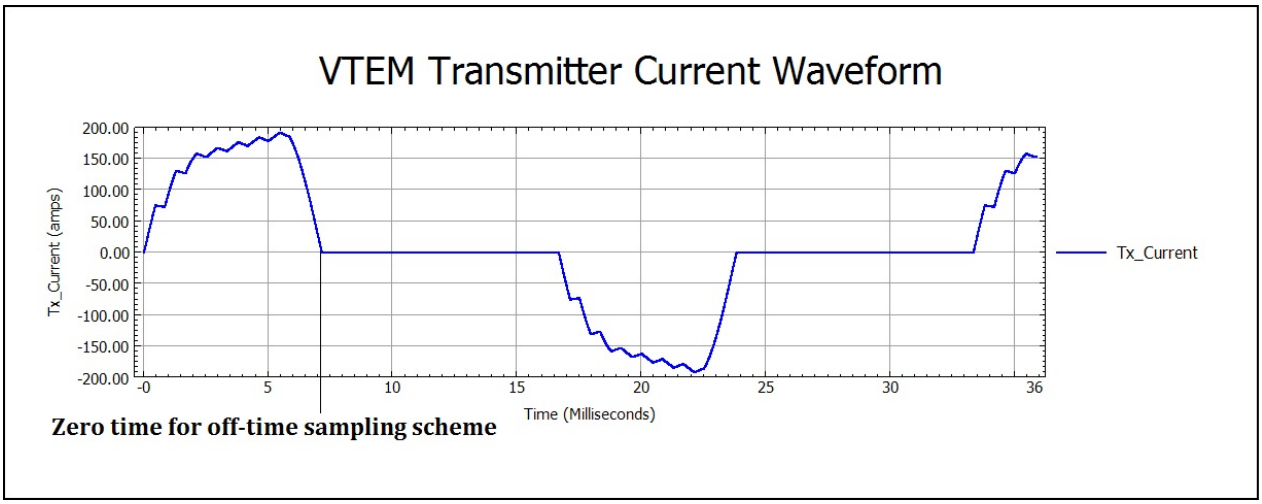

Figure 6: VTEM™ Transmitter Current Waveform

The VTEM™ decay sampling scheme is shown in Table 3 below. Forty-three time measurement gates were used for the final data processing in the range from 0.021 to 8.083 msec. Zero time for the off-time sampling scheme is equal to the current pulse width and is defined as the time near the end of the turn-off ramp where the dI/dt waveform falls to 1/2 of its peak value.

Table 3: Off-Time Decay Sampling Scheme

Z Component: 4 - 46 time gates
X Component: 20 - 46 time gates

VTEM™ system specifications:

Transmitter	Receiver
• Transmitter loop diameter: 26 m • Number of turns: 4 • Effective Transmitter loop area: 2123.7 m^2 • Transmitter base frequency: 30 Hz • Peak current: 191 A • Pulse width: 7.17 ms • Waveform shape: Bi-polar trapezoid • Peak dipole moment: 405,630 nIA • Actual average Transmitter-receiver loop terrain clearance: 44 metres above the ground	• X Coil diameter: 0.32 m • Number of turns: 245 • Effective coil area: 19.69 m^2 • Z-Coil diameter: 1.2 m • Number of turns: 100 • Effective coil area: 113.04 m^2

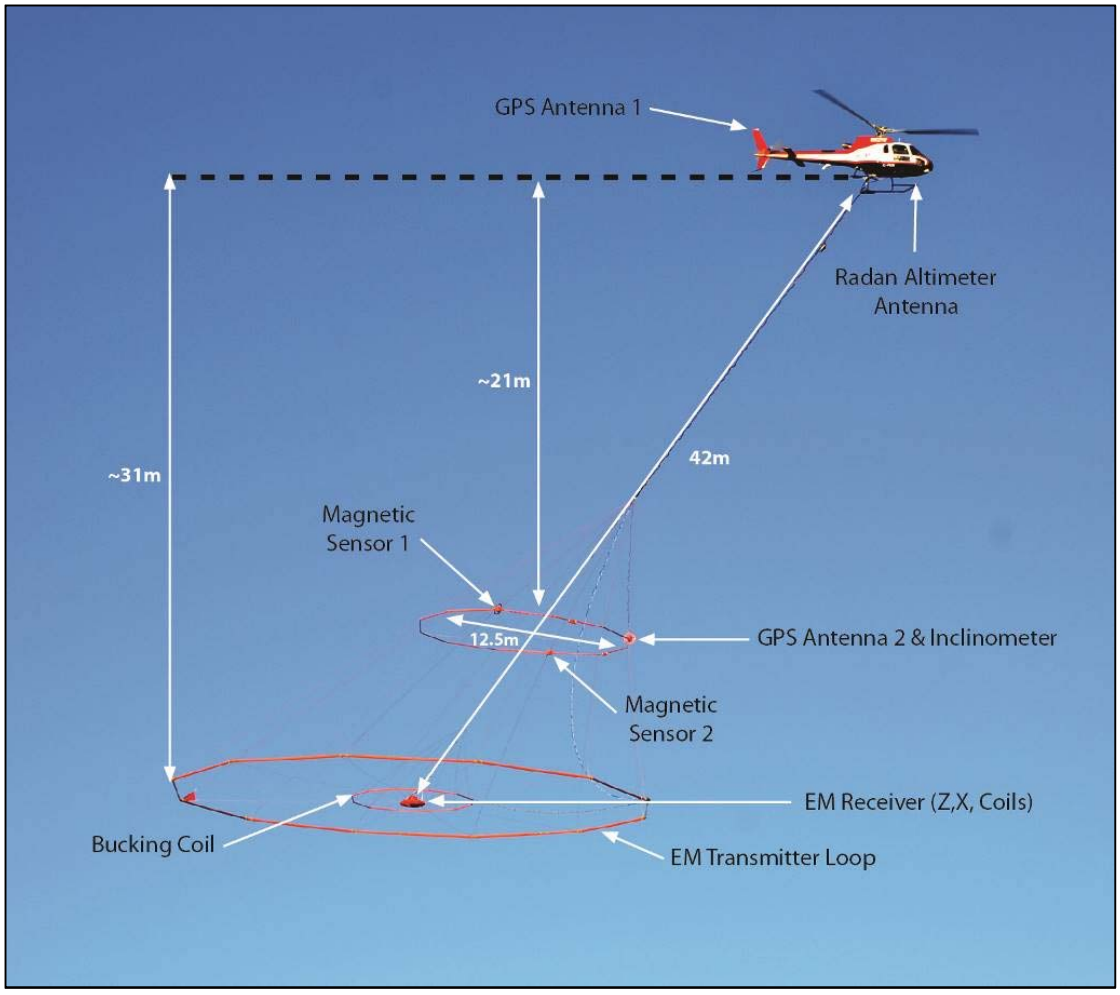

Figure 7: VTEM™Plus System Configuration.

2.4.3 FULL WAVEFORM VTEM™ SENSOR CALIBRATION

The calibration is performed on the complete VTEM™ system installed in and connected to the helicopter, using special calibration equipment.

The procedure takes half-cycle files acquired and calculates a calibration file consisting of a single stacked half-cycle waveform. The purpose of the stacking is to attenuate natural and man-made magnetic signals, leaving only the response to the calibration signal.

2.4.4 HORIZONTAL MAGNETIC GRADIOMETER

The horizontal magnetic gradiometer consists of two Geometrics split-beam field magnetic sensors with a sampling interval of 0.1 seconds. These sensors are mounted 12.5 metres apart on a separate loop, 10 metres above the Transmitter-receiver loop. A GPS antenna and Gyro Inclinometer is installed on the separate loop to accurately record the tilt and position of the magnetic gradiomag bird.

2.4.5 RADAR ALTIMETER

A Terra TRA 3000/TRI 40 radar altimeter was used to record terrain clearance. The antenna was mounted beneath the bubble of the helicopter cockpit (Figure 7).

2.4.6 GPS NAVIGATION SYSTEM

The navigation system used was a Geotech PC104 based navigation system utilizing a NovAtel's WAAS (Wide Area Augmentation System) enabled GPS receiver, Geotech navigate software, a full screen display with controls in front of the pilot to direct the flight and a NovAtel GPS antenna mounted on the helicopter tail (Figure 7). As many as 11 GPS and two WAAS satellites may be monitored at any one time. The positional accuracy or circular error probability (CEP) is 1.8 m, with WAAS active, it is 1.0 m. The co-ordinates of the survey area were set-up prior to the survey and the information was fed into the airborne navigation system. The second GPS antenna is installed on the additional magnetic loop together with Gyro Inclinometer.

2.4.7 DIGITAL ACQUISITION SYSTEM

A Geotech data acquisition system recorded the digital survey data on an internal compact flash card. Data is displayed on an LCD screen as traces to allow the operator to monitor the integrity of the system. The data type and sampling interval as provided in Table 4.

Table 4: Acquisition Sampling Rates

Data Type	Sampling
TDEM	0.1 sec
Magnetometer	0.1 sec
GPS Position	0.2 sec
Radar Altimeter	0.2 sec
Inclinometer	0.1 sec

2.5 BASE STATION

A combined magnetometer/GPS base station was utilized on this project. A Geometrics Caesium vapour magnetometer was used as a magnetic sensor with a sensitivity of 0.001 nT. The base station was recording the magnetic field together with the GPS time at 1 Hz on a base station computer.

The base station magnetometer sensor was installed at 130° 11.6730' W, 61° 48.7029' N; away from electric transmission lines and moving ferrous objects such as motor vehicles. The base station data were backed-up to the data processing computer at the end of each survey day.

3. PERSONNEL

The following Geotech Ltd. personnel were involved in the project.

FIELD:

Project Manager:	Darren Tuck (Office)
Data QC:	Neil Fiset (Office)
Crew chief:	Roger Leblanc
Operator:	n/a

The survey pilot and the mechanical engineer were employed directly by the helicopter operator – Access Helicopters.

Pilot:	Michael Holcroft
Mechanical Engineer:	n/a

OFFICE:

Preliminary Data Processing:	Neil Fiset
Final Data Processing:	TaiChyi Shei
Final Data QA/QC:	Geoffrey Plastow
Reporting/Mapping:	Liz Mathew

Data acquisition phase was carried out under the supervision of Andrei Bagrianski, P. Geo, and Chief Operating Officer. Processing and Interpretation phases were carried out under the supervision of Geoffrey Plastow, P. Geo, and Data Processing Manager. The customer relations were looked after by David Hitz.

4. DATA PROCESSING AND PRESENTATION

Data compilation and processing were carried out by the application of Geosoft OASIS Montaj and programs proprietary to Geotech Ltd.

4.1 FLIGHT PATH

The flight path, recorded by the acquisition program as WGS 84 latitude/longitude, was converted into the NAD83 Datum, UTM Zone 9 North coordinate system in Oasis Montaj.

The flight path was drawn using linear interpolation between x, y positions from the navigation system. Positions are updated every second and expressed as UTM easting's (x) and UTM northing's (y).

4.2 ELECTROMAGNETIC DATA

The Full Waveform EM specific data processing operations included:

- Half cycle stacking (performed at time of acquisition);
- System response correction;
- Parasitic and drift removal by deconvolution.

A three stage digital filtering process was used to reject major sferic events and to reduce noise levels. Local sferic activity can produce sharp, large amplitude events that cannot be removed by conventional filtering procedures. Smoothing or stacking will reduce their amplitude but leave a broader residual response that can be confused with geological phenomena. To avoid this possibility, a computer algorithm searches out and rejects the major sferic events.

The signal to noise ratio was further improved by the application of a low pass linear digital filter. This filter has zero phase shift which prevents any lag or peak displacement from occurring, and it suppresses only variations with a wavelength less than about 1 second or 15 metres. This filter is a symmetrical 1 sec linear filter.

The results are presented as stacked profiles of EM voltages for the time gates, in linear - logarithmic scale for the B-field Z component and dB/dt responses in the Z and X components. B-field Z component time channel recorded at 2.021 milliseconds (Kudz Ze Kayah) and at 4.641 milliseconds (Limy and Pelly) after the termination of the impulse is also presented as a colour image. Calculated Time Constant (TAU) with Calculated Vertical Derivative contours is presented in Appendix C and E. Resistivity Depth Image (RDI) is also presented in Appendix F and G.

VTEM has two receiver coil orientations. Z-axis coil is oriented parallel to the transmitter coil axis and both are horizontal to the ground. The X-axis coil is oriented parallel to the ground and along the line-of-flight. This combined two coil configuration provides information on the position, depth, dip and thickness of a conductor. Generalized modeling results of VTEM max data are shown in Appendix D.

In general X-component data produce cross-over type anomalies: from "+ to – "in flight direction of flight for "thin" sub vertical targets and from "- to +" in direction of flight for "thick" targets. Z component data produce double peak type anomalies for "thin" sub vertical targets and single peak for "thick" targets.

The limits and change-over of "thin-thick" depends on dimensions of a TEM system (Appendix D, Figure D-16).

Because of X component polarity is under line-of-flight, convolution Fraser Filter (Figure 8) is applied to X component data to represent axes of conductors in the form of grid map. In this case positive FF anomalies always correspond to "plus-to-minus" X data crossovers independent of the flight direction.

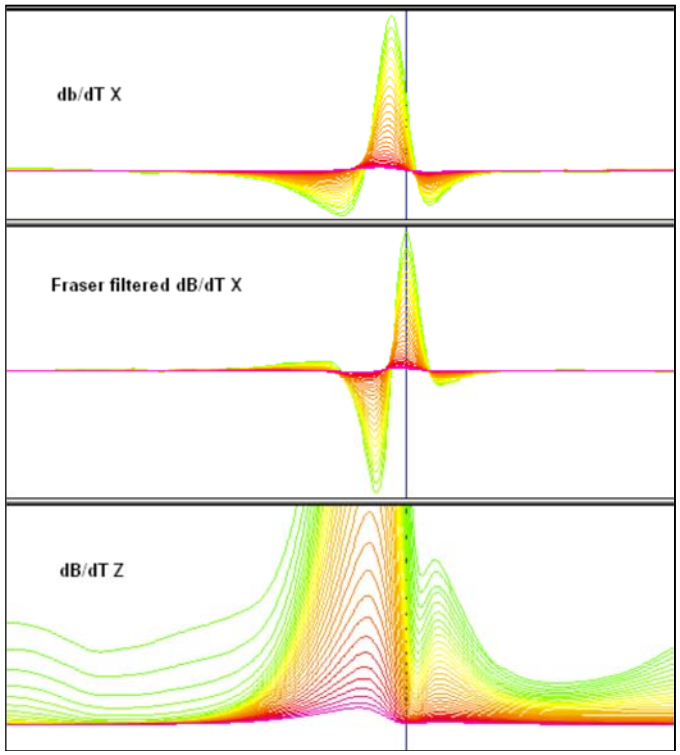

Figure 8: Z, X and Fraser filtered X (FFx) components for "thin" target.

4.3 HORIZONTAL MAGNETIC GRADIOMETER DATA

The horizontal gradients data from the VTEM™Plus are measured by two magnetometers 12.5 m apart on an independent bird mounted10m above the VTEM™ loop. A GPS and a Gyro Inclinometer help to determine the positions and orientations of the magnetometers. The data from the two magnetometers are corrected for position and orientation variations, as well as for the diurnal variations using the base station data.

The position of the centre of the horizontal magnetic gradiometer bird is calculated form the GPS utilizing in-house processing tool in Geosoft. Following that total magnetic intensity is calculated at the center of the bird by calculating the mean values from both sensors. In addition to the total intensity advanced processing is done to calculate the in-line and cross-line (or lateral) horizontal gradient which enhance the understanding of magnetic targets. The in-line (longitudinal) horizontal gradient is calculated from the difference of two consecutive total magnetic field readings divided by the distance along the flight line direction, while the cross-line (lateral) horizontal magnetic gradient is calculated from the difference in the magnetic readings from both magnetic sensors divided by their horizontal separation.

Two advanced magnetic derivative products, the total horizontal derivative (THDR), and tilt angle derivative and are also created. The total horizontal derivative or gradient is defined as:

THDR = sqrt(Hx*Hx+Hy*Hy), where Hx and Hy are cross-line and in-line horizontal gradients.

The tilt angle derivative (TDR) is defined as:

TDR = arctan(Vz/THDR), where THDR is the total horizontal derivative, and Vz is the vertical derivative.

Measured cross-line gradients can help to enhance cross-line linear features during gridding.

5. DELIVERABLES

5.1 SURVEY REPORT

The survey report describes the data acquisition, processing, and final presentation of the survey results. The survey report is provided in two paper copies and digitally in PDF format.

5.2 MAPS

Final maps were produced at scale of 1:10,000 for best representation of the survey size and line spacing. The coordinate/projection system used was NAD83 Datum, UTM Zone 9 North. All maps show the flight path trace and topographic data; latitude and longitude are also noted on maps.

The preliminary and final results of the survey are presented as EM profiles, a late-time gate gridded EM channel, and a colour magnetic TMI contour map.

- Maps at 1:10,000 in Geosoft MAP format, as follows:

GL150055_10k_bb_dBdtz:	dB/dt profiles Z Component, Time Gates 0.220 – 7.036 ms in linear – logarithmic scale.

A Geosoft .GRD file has a .GI metadata file associated with it, containing grid projection information. A grid cell size of 37.5 metres was used.

6. CONCLUSIONS AND RECOMMENDATIONS

A helicopter-borne versatile time domain electromagnetic (VTEMplus) and horizontal magnetic gradiometer geophysical survey has been completed over Kudz Ze Kayah, Pelly and Limy situated near Wolverine Lake, Yukon.

The total area coverage is 73 km². Total survey line coverage 557 line kilometres. The principal sensors included a Time Domain EM system and a horizontal magnetic gradiometer using two caesium magnetometers. Results have been presented as stacked profiles, and contour colour images at a scale of 1:10,000. A formal Interpretation has not been included or requested.

Based on the geophysical results obtained, a number of TEM anomalous zones are identified across the properties. They can be seen overlapping the TAU decay parameter image presented with the calculated vertical magnetic gradient (CVG) contours (see Appendix C).

If the conductors correspond to an exploration model on the area it is recommended picking EM anomalies with conductance grading and center localization of the targets, detail resistivity depth imaging and plate modeling with test drill hole parameters planning prior to ground follow up and drill testing.

GENERALIZED MODELING RESULTS OF THE VTEM SYSTEM
INTRODUCTION

The VTEM system is based on a concentric or central loop design, whereby, the receiver is positioned at the centre of a transmitter loop that produces a primary field. The wave form is a bi-polar, modified square wave with a turn-on and turn-off at each end.

During turn-on and turn-off, a time varying field is produced (dB/dt) and an electro-motive force (emf) is created as a finite impulse response. A current ring around the transmitter loop moves outward and downward as time progresses. When conductive rocks and mineralization are encountered, a secondary field is created by mutual induction and measured by the receiver at the centre of the transmitter loop.

Efficient modeling of the results can be carried out on regularly shaped geometries, thus yielding close approximations to the parameters of the measured targets. The following is a description of a series of common models made for the purpose of promoting a general understanding of the measured results.

A set of models has been produced for the Geotech VTEM® system dB/dT Z and X components (see models D1 to D15). The Maxwell ™ modeling program (EMIT Technology Pty. Ltd. Midland, WA, AU) used to generate the following responses assumes a resistive half-space. The reader is encouraged to review these models, so as to get a general understanding of the responses as they apply to survey results. While these models do not begin to cover all possibilities, they give a general perspective on the simple and most commonly encountered anomalies.

As the plate dips and departs from the vertical position, the peaks become asymmetrical.

As the dip increases, the aspect ratio (Min/Max) decreases and this aspect ratio can be used as an empirical guide to dip angles from near 90º to about 30º. The method is not sensitive enough where dips are less than about 30º.

APPENDIX E

EM TIME CONSTANT (TAU) ANALYSIS

Estimation of time constant parameter[1] in transient electromagnetic method is one of the steps toward the extraction of the information about conductances beneath the surface from TEM measurements.

The most reliable method to discriminate or rank conductors from overburden, background or one and other is by calculating the EM field decay time constant (TAU parameter), which directly depends on conductance despite their depth and accordingly amplitude of the response.

THEORY

As established in electromagnetic theory, the magnitude of the electro-motive force (emf) induced is proportional to the time rate of change of primary magnetic field at the conductor. This emf causes eddy currents to flow in the conductor with a characteristic transient decay, whose Time Constant (Tau) is a function of the conductance of the survey target or conductivity and geometry (including dimensions) of the target. The decaying currents generate a proportional secondary magnetic field, the time rate of change of which is measured by the receiver coil as induced voltage during the Off time.

The receiver coil output voltage ($\mathbf{e_0}$) is proportional to the time rate of change of the secondary magnetic field and has the form,

$$e_0 \, \alpha \, (1 / \tau) \, e^{-(t/\tau)}$$

Where,
τ = L/R is the characteristic time constant of the target (TAU)
R = resistance
L = inductance

From the expression, conductive targets that have small value of resistance and hence large value of τ yield signals with small initial amplitude that decays relatively slowly with progress of time. Conversely, signals from poorly conducting targets that have large resistance value and smallτ, have high initial amplitude but decay rapidly with time[1] (Fig. E1).

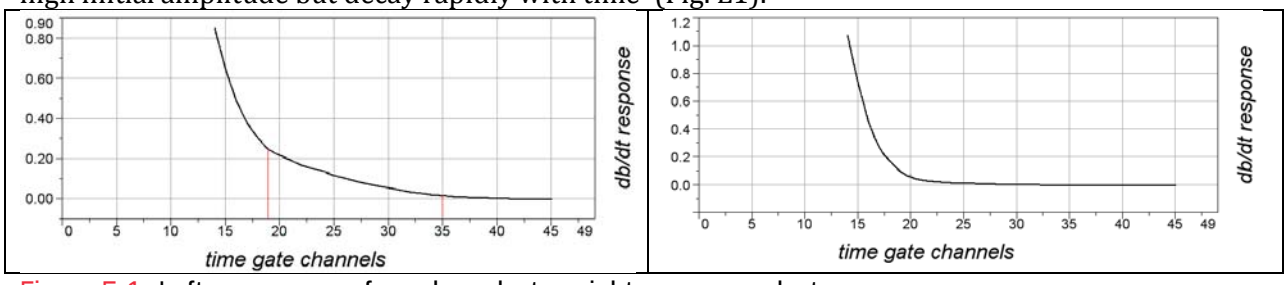

Figure E-1: Left – presence of good conductor, right – poor conductor.

[1] McNeill, JD, 1980, "Applications of Transient Electromagnetic Techniques", Technical Note TN-7 page 5, Geonics Limited, Mississauga, Ontario.

EM Time Constant (Tau) Calculation

The EM Time-Constant (TAU) is a general measure of the speed of decay of the electromagnetic response and indicates the presence of eddy currents in conductive sources as well as reflecting the "conductance quality" of a source. Although TAU can be calculated using either the measured dB/dt decay or the calculated B-field decay, dB/dt is commonly preferred due to better stability (S/N) relating to signal noise. Generally, TAU calculated on base of early time response reflects both near surface overburden and poor conductors whereas, in the late ranges of time, deep and more conductive sources, respectively. For example early time TAU distribution in an area that indicates conductive overburden is shown in Figure 2.

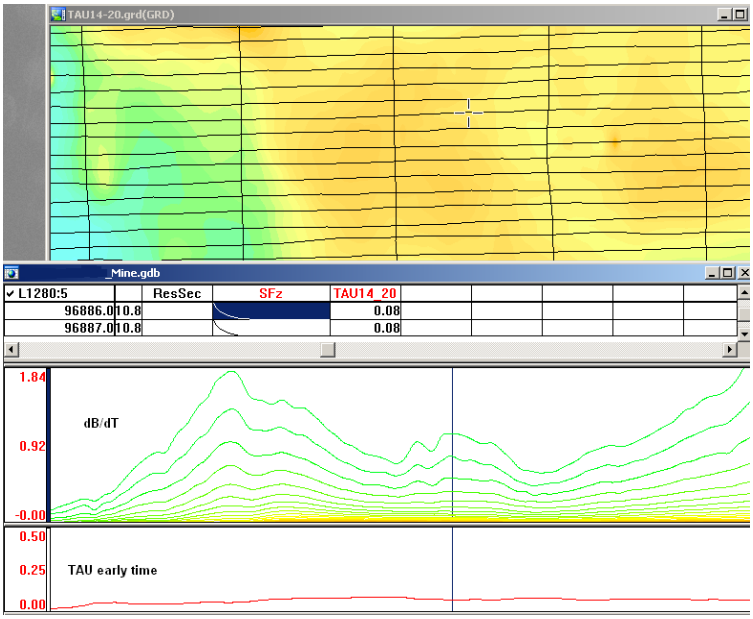

Figure E-2: Map of early time TAU. Area with overburden conductive layer and local sources.

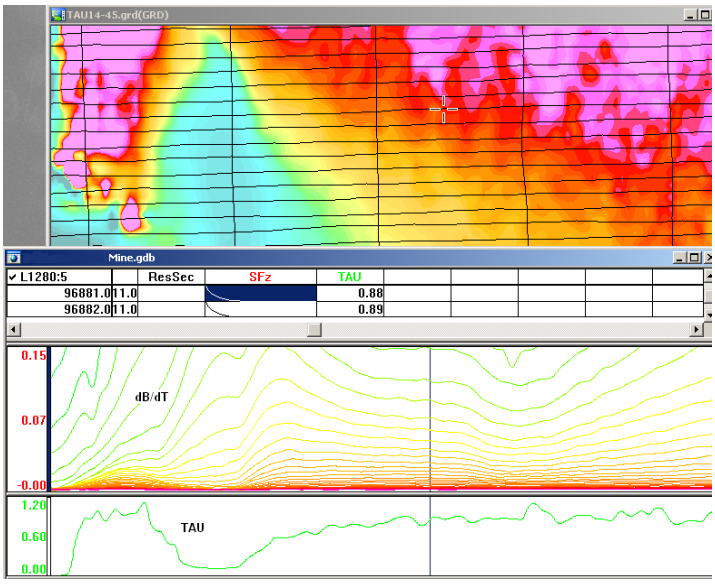

Figure E-3: Map of full time range TAU with EM anomaly due to deep highly conductive target.

There are many advantages of TAU maps:

- TAU depends only on one parameter (conductance) in contrast to response magnitude;
- TAU is integral parameter, which covers time range and all conductive zones and targets are displayed independently of their depth and conductivity on a single map.
- Very good differential resolution in complex conductive places with many sources with different conductivity.
- Signs of the presence of good conductive targets are amplified and emphasized independently of their depth and level of response accordingly.

In the example shown in Figure 4 and 5, three local targets are defined, each of them with a different depth of burial, as indicated on the resistivity depth image (RDI). All are very good conductors but the deeper target (number 2) has a relatively weak dB/dt signal yet also features the strongest total TAU (Figure 4). This example highlights the benefit of TAU analysis in terms of an additional target discrimination tool.

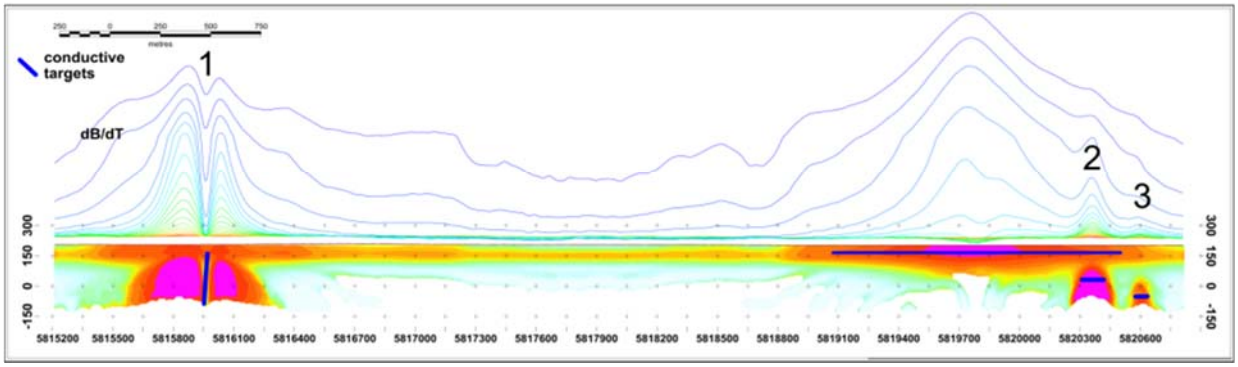

Figure E-4: dB/dt profile and RDI with different depths of targets.

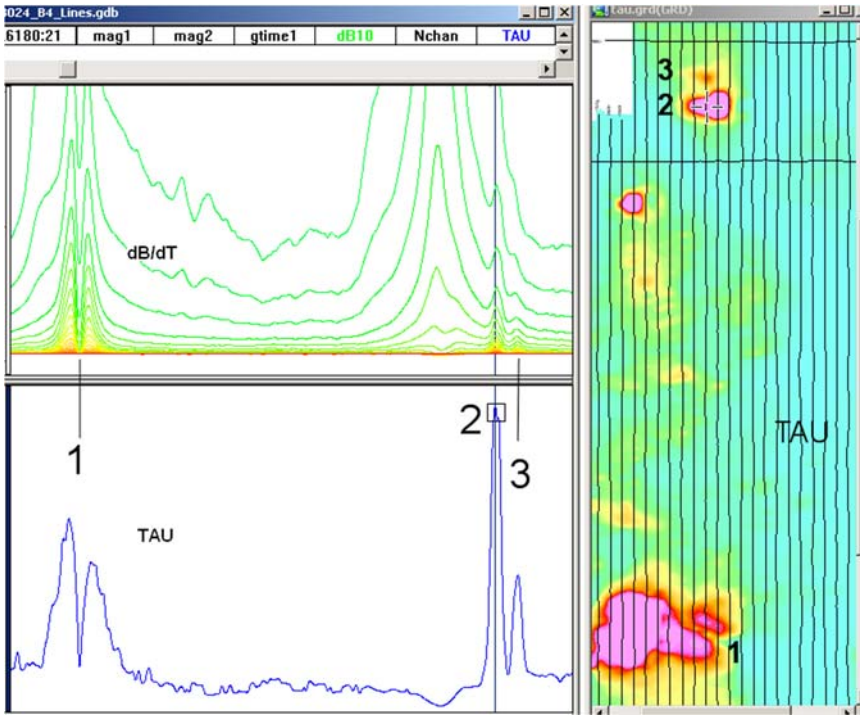

Figure E-5: Map of total TAU and dB/dt profile.

The EM Time Constants for dB/dt and B-field were calculated using the "sliding Tau" in-house program developed at Geotech2. The principle of the calculation is based on using of time window (4 time channels) which is sliding along the curve decay and looking for latest time channels which have a response above the level of noise and decay. The EM decays are obtained from all available decay channels, starting at the latest channel. Time constants are taken from a least square fit of a straight-line (log/linear space) over the last 4 gates above a pre-set signal threshold level (Figure F6). Threshold settings are pointed in the "label" property of TAU database channels. The sliding Tau method determines that, as the amplitudes increase, the time-constant is taken at progressively later times in the EM decay. Conversely, as the amplitudes decrease, Tau is taken at progressively earlier times in the decay. If the maximum signal amplitude falls below the threshold, or becomes negative for any of the 4 time gates, then Tau is not calculated and is assigned a value of "dummy" by default.

APPENDIX F

TEM RESISTIVITY DEPTH IMAGING (RDI)

Resistivity depth imaging (RDI) is technique used to rapidly convert EM profile decay data into an equivalent resistivity versus depth cross-section, by deconvolving the measured TEM data.
The used RDI algorithm of Resistivity-Depth transformation is based on scheme of the apparent resistivity transform of Maxwell A.Meju (1998)[1] and TEM response from conductive half-space. The program is developed by Alexander Prikhodko and depth calibrated based on forward plate modeling for VTEM system configuration (Fig. 1-10).

RDIs provide reasonable indications of conductor relative depth and vertical extent, as well as accurate 1D layered-earth apparent conductivity/resistivity structure across VTEM flight lines. Approximate depth of investigation of a TEM system, image of secondary field distribution in half space, effective resistivity, initial geometry and position of conductive targets is the information obtained on base of the RDIs.

1 SUMMARY

This geophysical report describes a gravity survey conducted for BMC minerals on the Kudz Ze Kayah (KZK) project, Yukon to assist in locating VMS ore deposits within the survey area. The survey was conducted in a 6 km X 2 km area located within NTS map sheets 105 G/07 and 105 G/08 with a station separation of 50 m and a line separation of 200 to 300 m. In total 1734 data points were collected in the 2015 program.

The crew was on-site at the KZK camp operated by BMC Minerals. The geophysics project extended from Aug 9th – Oct 16th, 2015 with the crew simultaneously conducting a DHEM survey (not described in this report). The survey was conducted by one or two gravity crews transported to and from to the survey grid by truck/side by side ATV or helicopter depending on the proximity of the lines to the access road. Travel between points was on foot. Aurora personnel rotations used scheduled flights to and from camp. The crew was prevented from working due to non-flyable weather one day through the course of the survey. Heavy snowfall in the highest part of the survey area made it temporarily unsafe for travel, but the crew concentrated on lower areas until the snow melted and completed all planned gravity points. A crew log describing daily operations and production is included with this report.

No interpretation or modelling of the data are included in this report.

2 CREW AND EQUIPMENT

The following personnel conducted the survey:

Andre Lebel	Geophysicist (Gravity Operator)	Aug. 9 – Aug 22, Aug 26-Aug 31, Sept 4 - Sept 11, Sept 18, Sept 21 - Sept 24, Sept 28 – Oct 2, Oct 6 – Oct 9, 2015
Dave Hildes	Geophysicist (Gravity Operator)	Sept. 11–Sept. 18, 2015
Darrel Epp	Geophysicist (Gravity Operator)	Aug 26 - Aug 31, Sept 4 - Sept 11, Sept 13 - Sept 18, Sept 21 - Sept 24, Sept 28 – Oct 2, Oct 6 – Oct 9, 2015
Franz Dzuiba	Geophysicist (Gravity Operator)	Aug. 25 – Aug 30, 2015
Heiko Mueller	Field Technician (GPS Operator)	Aug. 9 – Aug. 16, Aug. 21 – Aug. 22, Aug. 9 – Aug. 16, Aug. 24 – Aug. 30, and Sept. 4 – Sept. 14 2015
Darren Dawson	Field Technician (GPS Operator)	Sept. 4 – Sept. 11, and Sept. 13 – Sept. 14 2015
Terry Ollie	Field Technician (GPS Operator)	Aug. 10 – Aug. 21, 2015

The crew was equipped with the following instruments and equipment:

Gravity:	Gravity meter - Scintrex CG-5 Gravimeter s/n: 1368
	Gravity meter - Scintrex CG-5 Gravimeter s/n: 349
	Gravity accessories
RTK DGPS:	Leica CS 15 controller s/n: 2907999

	Leica GS14 Antenna s/n: 2810411
	Leica GS14 Antenna s/n: 2805723
	Pacific Crest Radio s/n: 10301949
	Pacific Crest Radio-Repeater s/n: 13086191
	GPS accessories
Other:	2 - Laptops with Geosoft, Gravity & GPS processing software
	1 - Repair tools
	1 - Iridium satellite phone
	4 - Garmin handheld GPS
	4 - Bear spray and bear bangers

3 SURVEY LOCATION

The gravity survey consisted of three areas: ABM, GP4F and Rhyolite Peak. ABM comprises a single line (Line 7) which extends over the ABM deposit. The GP4F area consists of Lines 8 – 32 (lines running NNE at a line spacing of 200 m) and Lines 37 and 38 (short lines running ESE) over the GP4F deposit and the area west of GP4F. Rhyolite Peak area consists of Lines 1 – 6 and Lines 33 – 36 on the mountain and plateau in the western portion of the survey grid. Lines 1 – 6 have a line spacing of 300 m while Lines 33 – 36 are over a VTEM anomaly to the west of the ABM deposit and have a line spacing of 200 m. Figure 1 shows the locations of the all lines surveyed in 2015. All coordinates in this report are in the NAD83 (CSRS) datum, UTM Zone 9N projection, and the elevations are recorded as orthometric heights using the CGVD 2013 Geoid (meters above sea level).

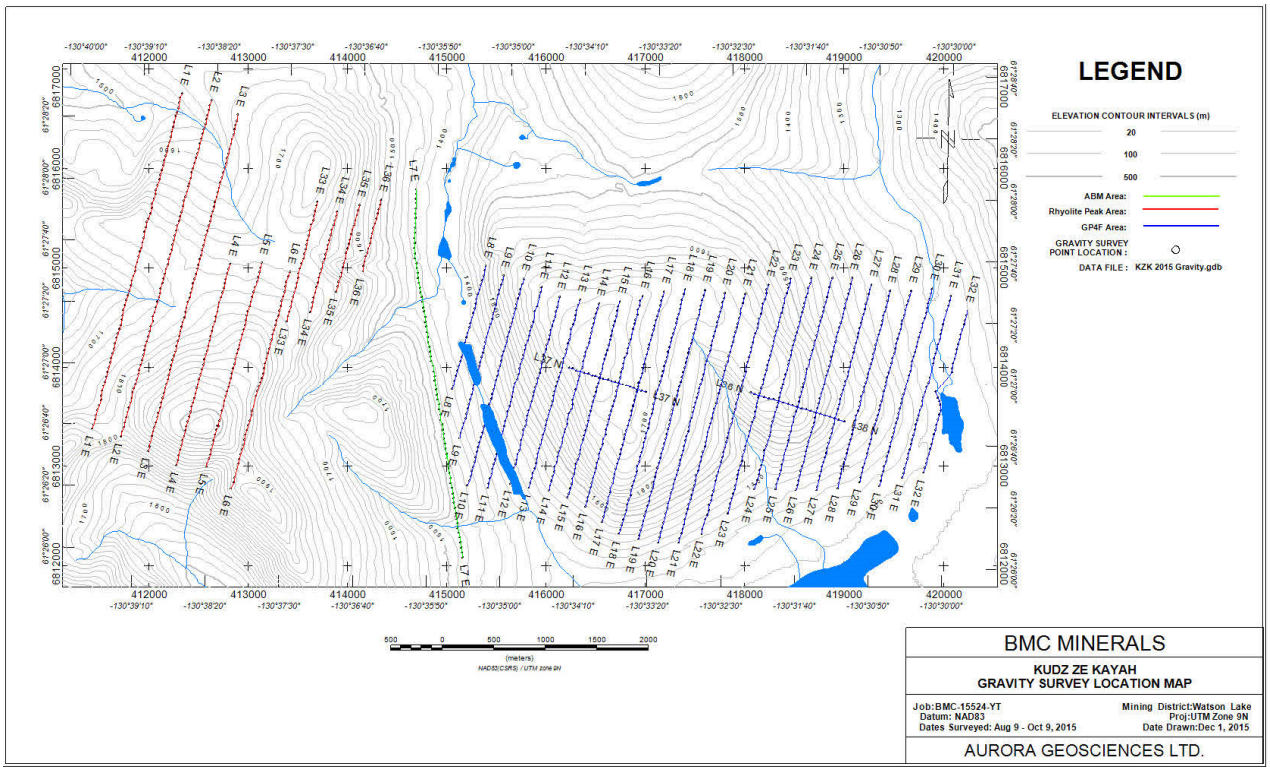

Figure 1: Gravity survey location map

4 SURVEY SPECIFICATIONS

4.1 Gravity Survey Specifications

Each gravity station was located using a handheld Garmin GPS. The site was cleared of soft moss and organics or preferentially located on a low boulder if available. A total of 1792 gravity stations were occupied on the grid, 1602 planned stations, 21 unplanned stations and 169 repeat stations. 20 planned stations were not surveyed due to inaccessibility or due to the presence of a body of water. Figure 2 : Distance between actual to planned location histogram.plots the distance between planned and actual station location; 94% of the points are within 8 m of the planned location.

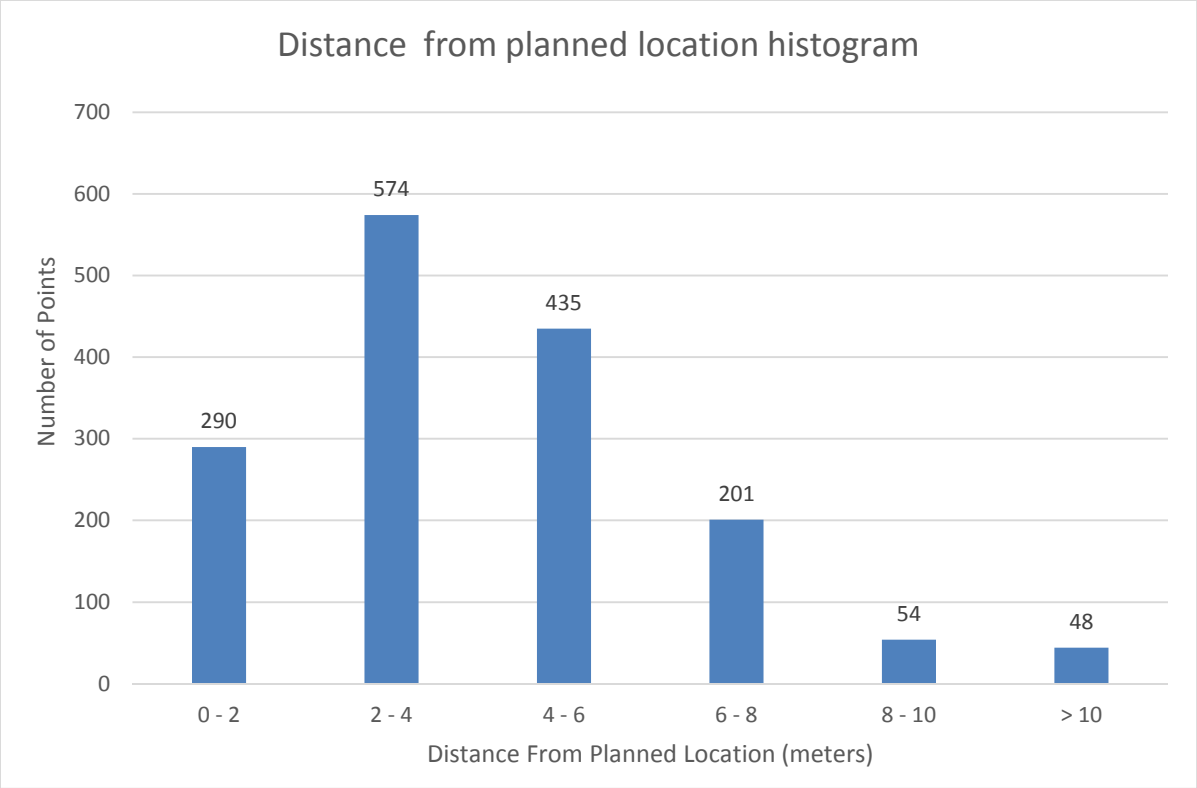

Figure 2 : Distance between actual to planned location histogram.

Station locations: Stations were located with non-differential GPS receivers.

Gravimeter preparation: Both gravimeters were warmed up and levelled on a cement block. The instruments were cycled for up to 24 hours taking 60 seconds readings continuously to determine the remnant instrument drift and to reset instrument drift constants. The instruments remained under power at all times throughout the survey operation.

Walk tests to simulate actual survey conditions were performed. The gravity meter is repeatedly picked up, walked for a minute then returned to exactly the same location and allowed to settle for a pre-determined time before taking the reading. Both gravity meters had a spread less than 0.02 mGal after tie corrections for these tests. The walk tests confirmed that gravity meter s/n: 349 required a longer settling period (5 minutes). A 90 second setting period was sufficient for gravity meter s/n 1368.

Gravity readings: A minimum of two readings that were stacked for a minimum of 20 s were taken at each station and the standard deviation in individual 5Hz readings (after seismic filtering) was kept to less than 0.03 mGal if possible. When this was not possible, readings were repeated at least 3 times to ensure that

the data were repeatable within 0.03 mGal. The gravity meters were leveled and then allowed to settle for a minimum of 90 seconds for gravity meter s/n: 1368 and a minimum of five minutes for gravity meter s/n: 349. Seismic filters were engaged to remove seismic noise and wind noise. Physical wind blocks were also used to reduce wind noise.

Gravity tie readings: Prior and post daily surveying, readings were taken at a control station. Control stations were established at four locations as detailed in Section 4.4. Readings were stacked for a minimum of 60 s. The tie readings were repeated until three readings repeated within 0.01 mGal.

Gravity repeat readings: A minimum of 3 % of the readings were repeated daily in a series of closed loops where the first reading of the loop was repeated in the exact same location. The criterion of a successful repeat reading is that the gravity values are within 0.06 mGal or the loop is redone. Details of the repeat readings are in Section 4.5.

4.2 GPS Survey Specifications

Accompanying the gravity survey was a GPS survey to provide vertical control for the gravity reductions described in Section 5; GPS readings were taken in identical locations as the gravity readings. The specifications for the GPS survey are:

Geographic datum & projection	NAD83 (CSRS) datum, UTM Zone 9N projection.
Elevation datum:	Orthometric Height (CGVD 2013 Geoid) or Meters above Sea Level
Satellites used:	GPS and Glonass
GPS base:	The base stations were established in conjunction with the gravity control stations as detailed in Section 4.4. The daily measured height of the GPS antenna above the control point is detailed in Table 1. The base Leica GPS antenna logged data continuously at one second epochs, recording the data to disk as well as broadcasting over a RTK radio link.

GPS rover: The GPS antenna was placed on the gravity survey station and elevations corrected for a rover antenna height of 2 m. If an RTK link was established, a minimum of 10 coincidental epochs with the base were measured. For stations with no RTK link (post-processed), the greater of 300 or 60 coincidental epochs with the base per kilometer from the base were measured. Regardless of whether the solution is RTK or post-processed, only phase corrected solutions are accepted in the final data set.

GPS repeat readings: A minimum of 3 % of the readings were repeated daily in a series of closed loops where the first reading of the loop was repeated in the exact same location. The criterion of a successful repeat reading is that the horizontal and vertical locations are within 0.01 m or the loop is redone. Details of the repeat readings are in Section 4.5. There were cases where daily loops were not closed because of pressing helicopter scheduling or lack of a phase-corrected GPS solution; in these cases the GPS loops were closed successfully on a subsequent day.

Table 1 : Measured antenna height above control.

Date	Control Station	Height above control(m)

Oct 9, 2015	GP4F (9998)	0.817

4.3 Gravity Meter Pre-survey Cycling

Prior to the survey each gravity meter was cycled for a period of up to 24 hours to check instrument calibration and the spring drift constant. Figure 3 and Figure 4 show the linear trend for each instrument through a period starting on Aug 8th, 2015 for gravity meter s/n: 1368 and Aug 23rd, 2015 for gravity meter s/n: 349. The gravity meter s/n: 349 cycled at the Rhyolite Peak base and is subject to wind noise. A linear trend can still be seen in Figure 4**Error! Reference source not found.** once the wind subsided. The gravity measurement is shown on the y-axis in mGal vs decimal days on the x-axis. An adjustment was made to the drift constant prior to the start of the survey of - 0.29 mGal/day for gravity meter s/n 1368; no adjustment was made for gravity meter s/n 349.

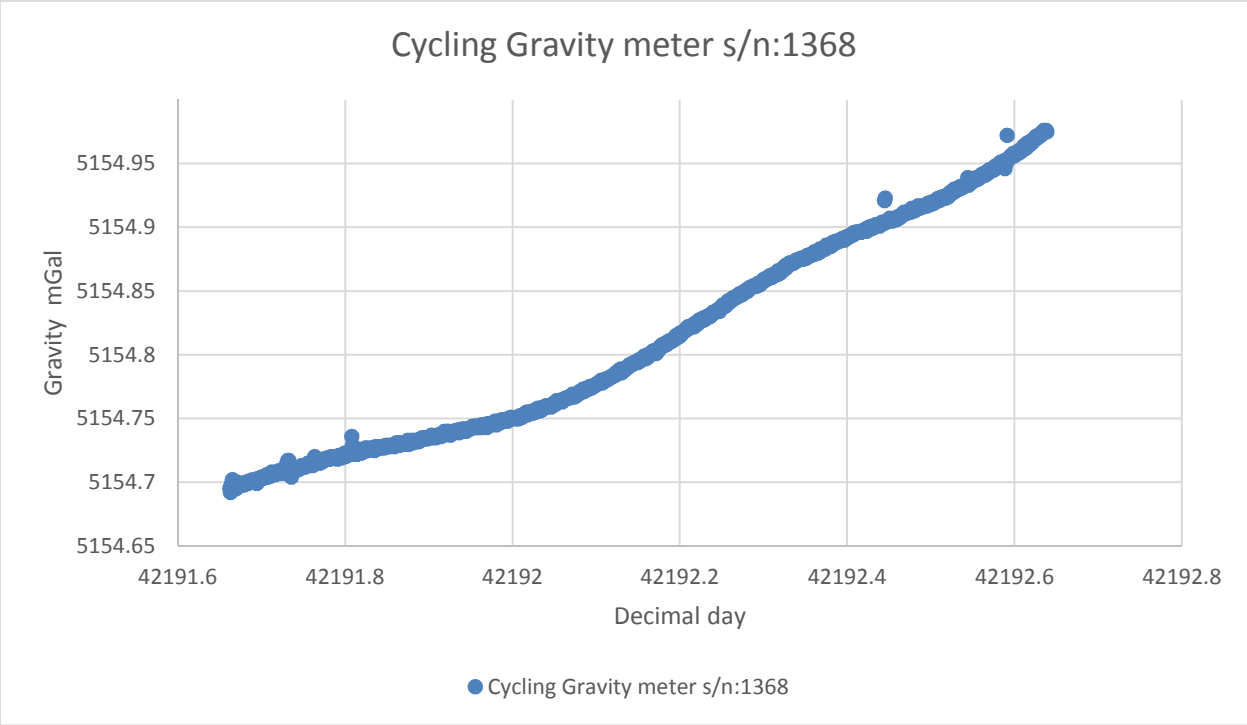

Figure 3 - Gravity meter s/n 1368 cycling results.

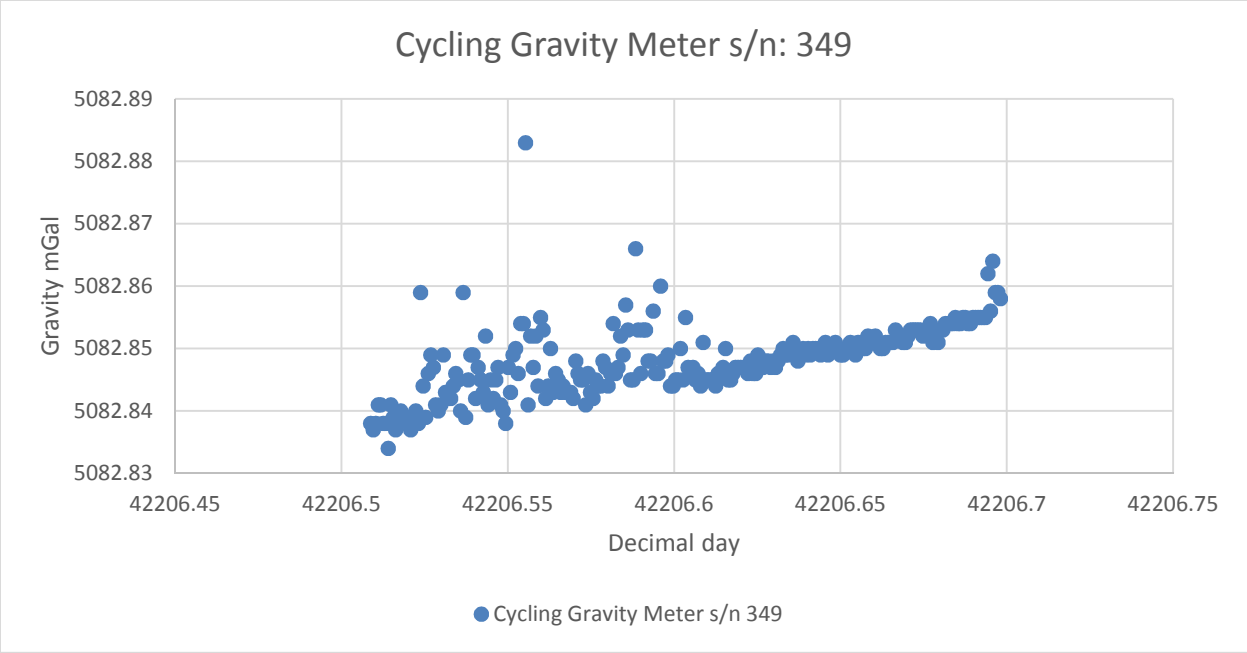

Figure 4 - Gravity meter s/n 349 cycling results.

4.4 Control Points

Control points were established at four locations in 2015 as detailed in Table 2. A concrete pad and two reference posts are installed at each control station; a short T-post protrudes approximately 10 cm above the ground and defines the positional location and a long reference post protrudes at least 30 cm above the ground within a metre of the short post and is labeled with a metal tag. Figure 5, Figure 6, Figure 7 and Figure 8 are pictures of the control stations. The concrete pad defines the gravity control station using a standard Scintrex CG5 tripod with the legs at their minimum extension.

Table 2: Gravity bases locations and dates used.

Base	UTM East (m)	UTM North (m)	Orthometric Height (m)	Dates used (2015)	Gravity Reference Value (mGal)
ABM (9999)	414838.290	6814779.579	1410.286	Aug 10 – 13 Aug 20 – 21 Sept 23 – Oct 1 Oct 08	5023.6
GP4F (9998)	419113.358	6813563.075	1432.621	Aug 13 – 20 Oct 9	5017.554l
Rhyolite Peak (9997)	41224.783	6814019.985	1896.343	Aug 22 – 30 Oct 7	4951.495
GP4F-W (9996)	416569.254	6814021.222	1758.742	Aug 31 – Sept 22 Oct 2 – Oct 6	4923.730

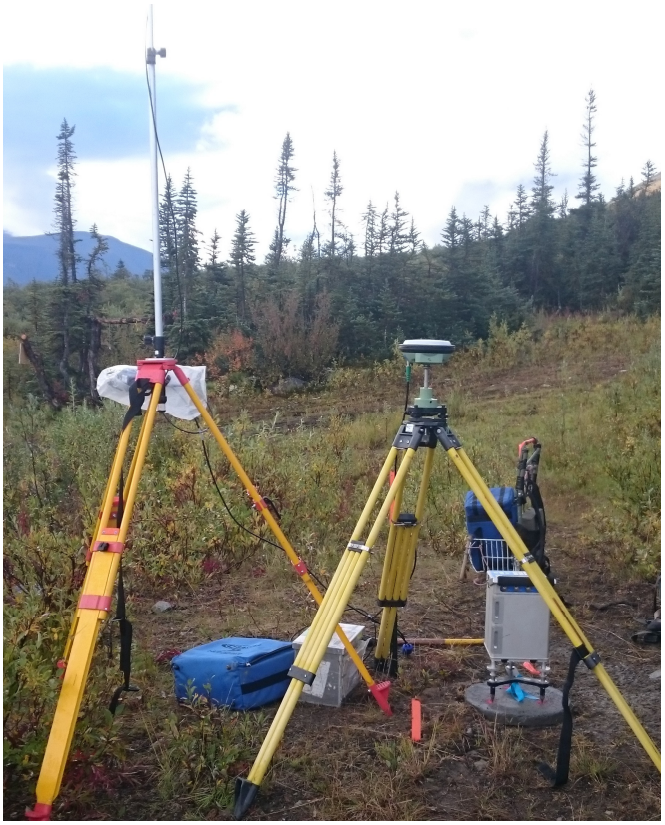

Figure 5: The ABM control station (9999).

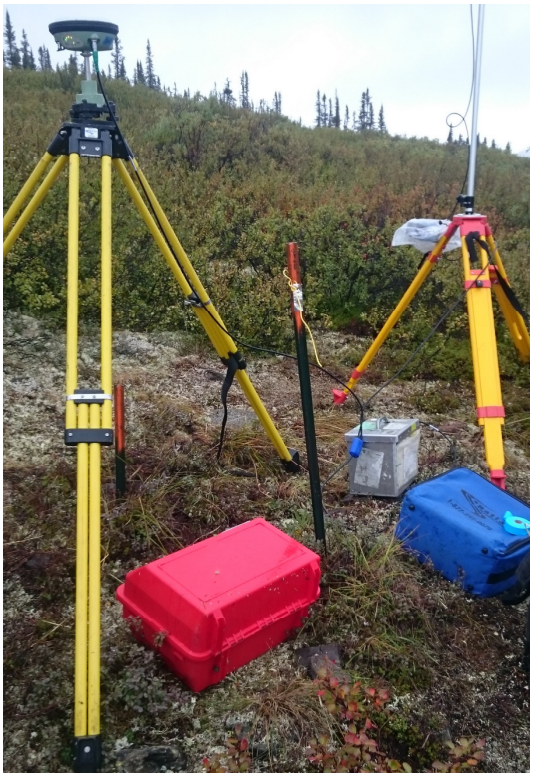

Figure 6: The GP4F control station (9998).

Figure 7: The Rhyolite Peak control station (9997).

Figure 8: The GP4F-W control station (9996).

The gravity reference value of 5023.600 mGal is arbitrarily set (at the value of the first drift reading on Aug 9th 2015) at the ABM control station. The other three gravity control stations were levelled to the ABM control station by an ABABABA tie survey which consisted of a reading at the "A" control station followed by the reading at the "B" control station repeated three times and finishing with a final reading at the "A" control station. After drift corrections for station A, the reference value for control station B is calculated by averaging the three readings. These control tie surveys were done on Aug 13, 2015 for the GP4F base and on Sept 4, 2015 for the GP4F-W and Rhyolite Peak control stations. The details of the tie surveys are appended to this report in *tie surveys.xls*.

Selected GPS base data were decimated to 30 s, converted to RINEX format and sent to the Canadian Spatial Reference System Precise Point Positioning (CSRS-PPP) tool to obtain a corrected position for the control station. Data were not sent to CSRS-PPP until more than 13 days had passed to ensure the best available ephemerides (+/- 2 cm) from the International Terrestrial Reference Frame (ITRF) were used in the correction. Four days of base station data for control point 9999, five days for control points 9998 and 9996 and eight days for control point 9998 were send the CSRS-PPP and the results averaged to obtain the final position as detailed in Table 2 using NAD83 (CSRS) datum, UTM Zone 9N projected coordinates and orthometric Height referenced to the CGVD 2013 Geoid**Error! Reference source not found.**. Reports from CSRS-PPP are appended to this report.

During the survey drift measurements were made at a control point prior to and after each day's survey. Figure 9, Figure 10, Figure 11, Figure 12, Figure 13 and Figure 14**Error! Reference source not found. Error! Reference source not found.** show the drift for each instrument at each control station used for the survey from Aug 10 to Oct 9, 2015. The gravity measurement is shown on the y-axis in mGal vs hours on the x-axis. Datum shifts are caused by memory clearing which is done episodically during the survey to keep the file size of raw data dumps low. A list of the control point locations and dates used is in Table 2.

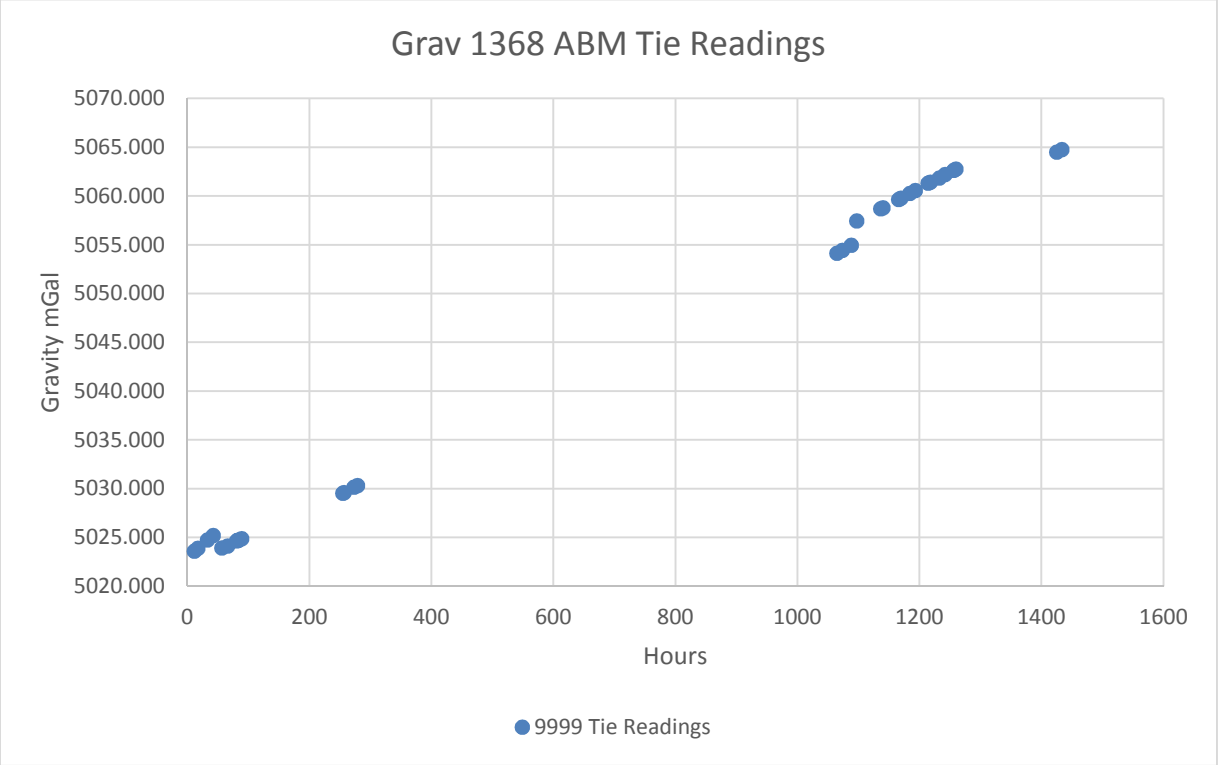

Figure 13: Gravity Meter (s/n 1368) ABM control station readings.

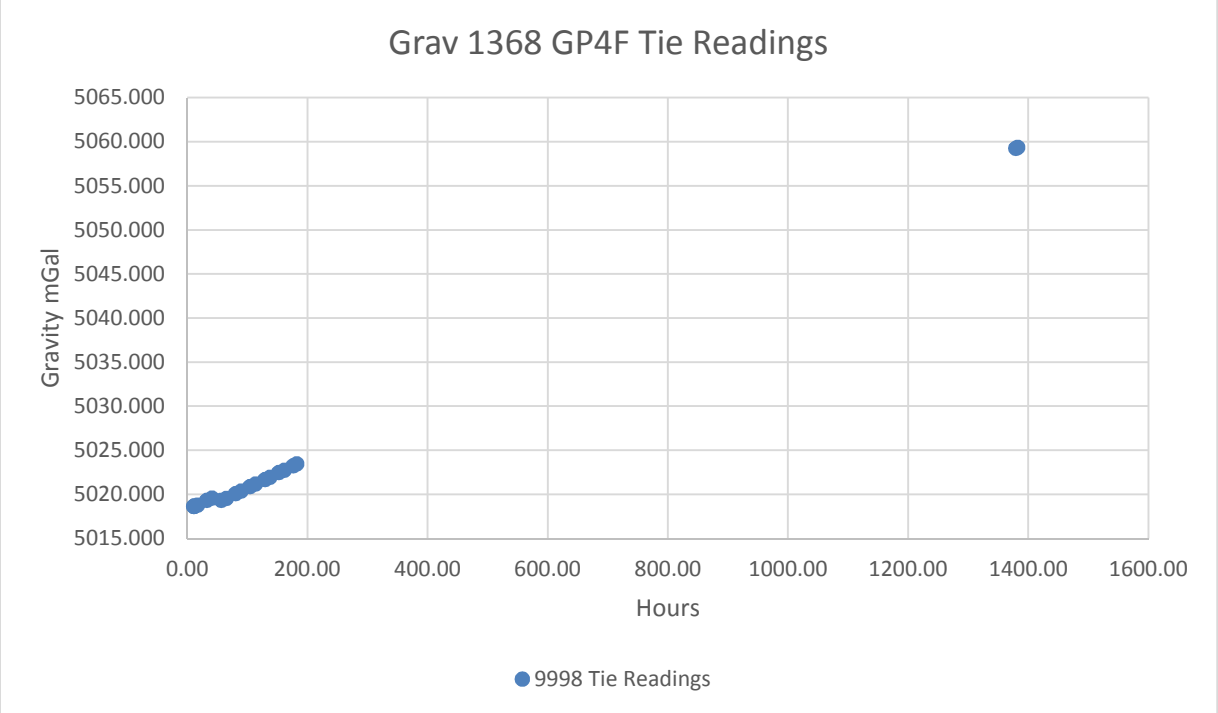

Figure 14: Gravity meter (s/n 1368) GP4F control station readings.

4.5 Repeat Stations

As described in Sections 4.1 and 4.2 a minimum of 3 % of the readings were repeated daily in a series of closed loops where the first reading of the loop was repeated in the exact same location. If the repeated readings did not satisfy the criteria then the loop was redone. The excel sheet *repeats.xlsx* containing all the repeated reading is included with this report.

A histogram of the difference in 169 gravity repeated station is shown in Figure 15. Nine repeat stations were beyond specification and the loops were redone. Excluding these, the average difference in gravity repeats is 0.013 mGal.

Details for the nine repeat stations that were beyond specifications are:

- A gravity meter malfunction on September 4th, 2015 caused an incorrect reading for the loop with repeat reading L17 station 1450.
- A tare of approximately 0.2 mGal on September 13th, 2015 which caused three repeat readings of L18 station 950, L18 station 500 and L17 station 500 to be beyond specifications. The cause of the tare is unknown.
- There was a tare of 2.2 mGal on September 24th, 2015 that caused the gravity values on the three repeat locations on L9 station 1550, L9 station 1550 and L12 station 1050 to not repeat within specifications. The gravimeter suffered a physical knock which caused the tare.
- Repeat readings at L5 station 800 on August 25, 2015 and L5 station 1650 &L6 station 1600 on August 27, 2015 exceeded specification. No reasons could be determined.

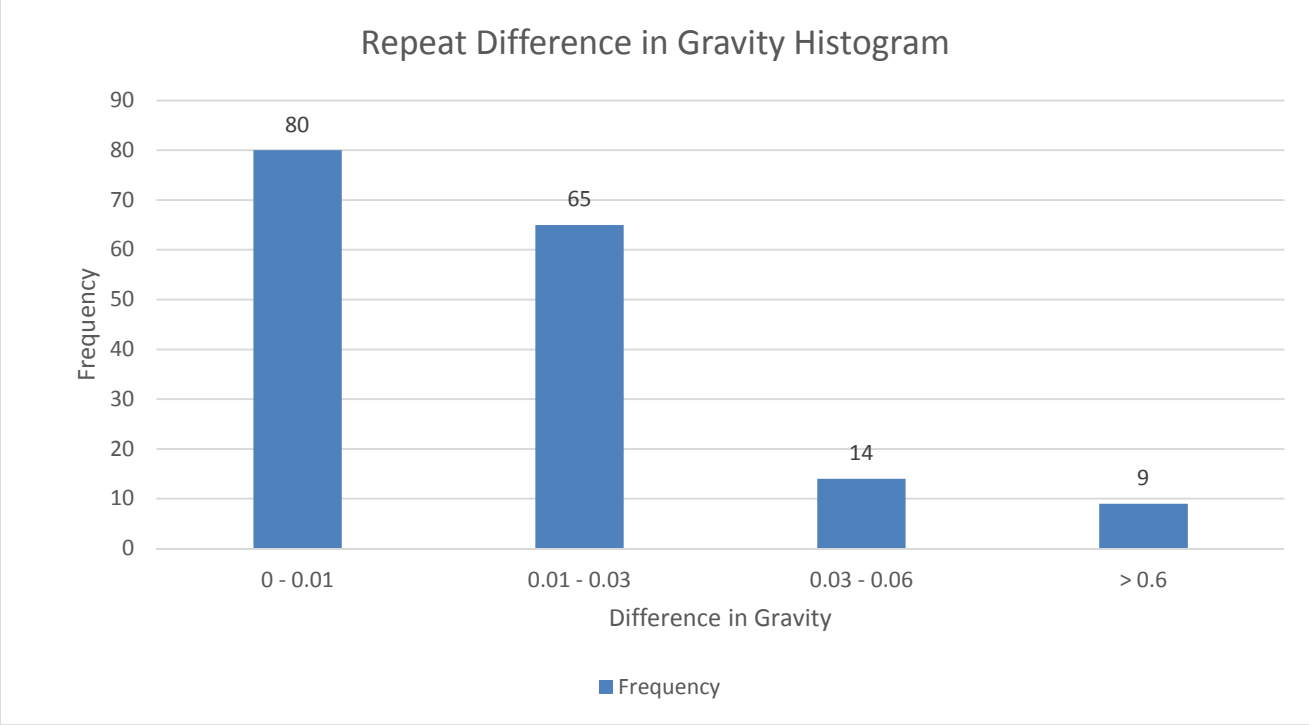

Figure 15: Difference in gravity readings at repeated stations.

A histogram showing the differences in GPS elevation is shown in Figure 16**Error! Reference source not found.**. Five of the elevation repeats were beyond the GPS specification criteria and details are:

- The repeat readings on Aug 15 and 18th, 2015 did not achieve a phase-corrected solution in post-processing and were successfully repeated on a later date.
- The point L2 station 350 collected on August 26th, 2015 was out of specifications by a few millimeters and was rounded to the exact specification in the field. This loop was not redone.
- The point at L18 station 1700 collected on September 5th, 2015 was beyond specification and the loop was later redone.

The elevation repeatability is better than the horizontal repeatability; the proposed explanation is operator error in returning to the identical point in a flat gravity location, particularly where a flat boulder is used as the station. The repeat readings that had a difference of greater than 0.1 m horizontally were either post-processed solutions that later repeated well or were within specification when considering easting and northing separately and no loops were redone due to these repeated values.

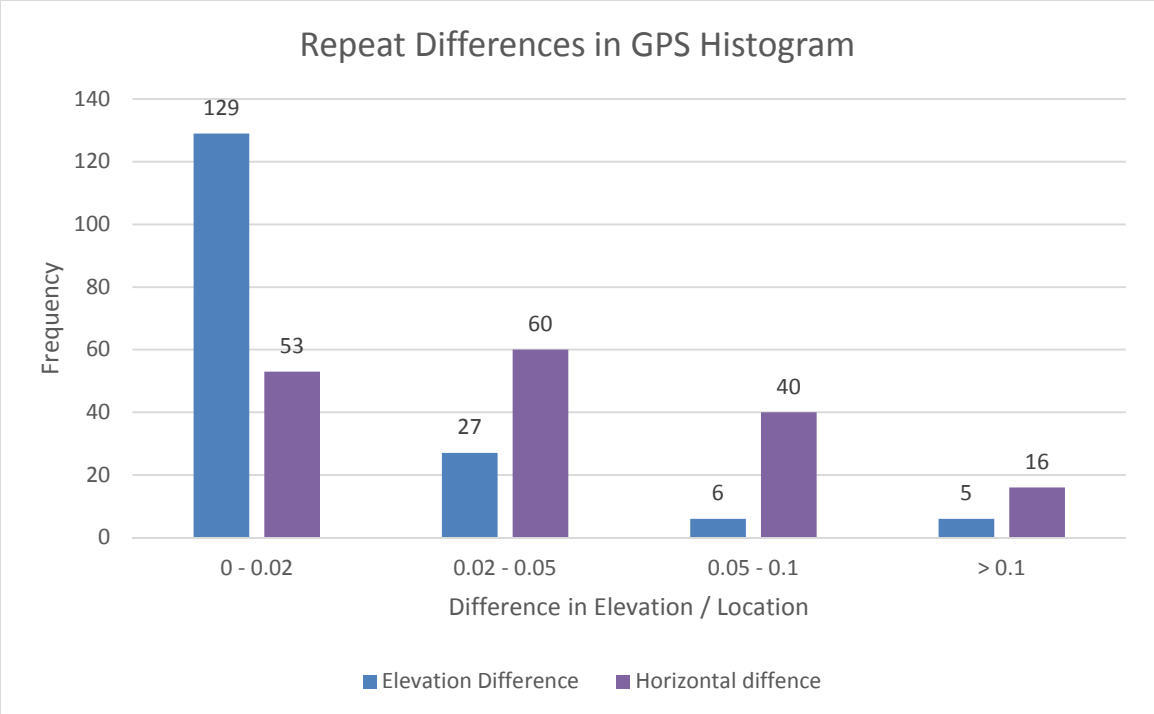

Figure 16: Difference in horizontal location and elevation at GPS repeat stations.

5 DATA PROCESSING

5.1 GPS Processing

The GPS data were downloaded daily in field from the Leica GPS antennae and controllers. Data were post-processed using the algorithm in the Leica Geo-office software based on the same location that was broadcast via RTK to the rover during data collection. Data were checked and unique line-station coordinates attached matching the gravity measurements. Station labels increment typically by 50, the same as the station spacing. Repeat stations are denoted by a station increment of 1.

RTK and post-processed solutions are compiled daily into a spreadsheet that includes both the position and height quality of the solution.

All GPS data are compiled into a single database where a datum shift is applied to each individual day of data to correct both RTK and post-processed solutions to the final corrected location of the control station. This final GPS database, in which all non-phase corrected GPS solution have been discarded, is used for the gravity corrections and is appended to this report.

5.2 Gravity Processing

The gravity data were downloaded daily in the field using Scintrex software and processed using the propriety software package 'Gravred2'. The program merges the gravity data with location and elevation data and corrects for drift, latitude, free-air, Bouguer slab, Bullard–B and a suite of terrain corrections. All corrections were performed daily in the field but final corrections required the corrected GPS control point positions and the final DEM so and so were not completed until after the field program was complete.

5.2.1 Drift

The drift correction removes the linear drift of the gravity meter between the readings at the control stations at the start and end of every survey day. The datum was set arbitrarily on the first day of surveying to 5023.6 mGal, the first reading at the ABM control station (9999) on August 9th. Through the ABABABA survey of each other control station, the appropriate datum for each control station was determined as 5017.554 mGal for the GP4F control station (9998) is, 4923.729 mGal for the Rhyolite Peak control station (9997), and is 4951.495 mGal for GP4F-W control station (9996).

5.2.2 Latitude

The latitude correction is to remove the effects of latitude from the gravity data. A centre latitude is arbitrarily set to 61.5 N and a centre UTME of 416000E, a centre UTMN of 6814000N and UTM declination of -1.4^{o} used to calculate latitude correction from the positional coordinates of each station.

5.2.3 Free-Air, Bouguer Slab and Bullard-B

The free-air correction corrects for the change in distance from the centre of the Earth. A datum of 0 m is used (sea level) and the correction brings the gravity value down to that datum.

The Bouguer slab corrects the gravity for a uniform slab, the thickness of which is equal to the elevation. A uniform density of 2.67 g/cm^3 is used – no other values were experimented with as specific gravity measurements of the core at the project indicated this was an appropriate choice.

The Bouguer slab assumption of an infinite slab is not correct and the Bullard-B correction accounts for the curvature of the earth in the slab. The same density as the Bouguer slab correction of 2.67 g/cm^3 is used.

5.2.4 Terrain corrections

Two styles of terrain corrections are applied to the gravity data: a near-station correction within 20 metres of the station and a far-station correction for terrain further than 20 metres form the station. All terrain corrections use a density of 2.67 g/cm^3.

5.2.4.1 Near-terrain correction (NTC)

The near station correction is a correction that accounts for local differences in topography. The government supplied digital elevation models usually have a cells on the order of 20 m and therefore details close to the station where they have the greatest effect on the gravity reading can be too fine to capture with a 20 m DEM. To compensate for this the gravity operators collect near-station correction measurements at each station that consist of 6 slope readings representing an average slope within the 20 metre radius of the station for each 60° sector. The slopes are converted to an elevation difference and near-station terrain corrections are calculated from the sector equation for the gravitational effect of a vertical cylinder equal to elevation difference and added to the gravity reading.

However BMC Minerals collected LIDAR data on Lines 7 - 22, 35 – 37 and portions of Lines 21 - 25, 33, 34 and 38 resulting in a very high resolution DEM. An algorithm was developed to parse the detailed DEM and calculate the average elevation difference in each of the 60° sectors within 20 metres from the station to mimic the data set collected by slope measurements. The new calculated slopes are used instead of the measured values where the detailed DEM is available.

By comparing the measured slopes against the calculated slopes it was determined that the operators slightly but systematically underestimated the slopes in steep terrain. The effect is no more than 0.19 mGal, but does over-estimate the gravity particularly in steep terrain.

Outside of the LIDAR DEM the points, the original data collected by the operators is used for the NTC corrections. The excel sheet with all the NTC measurements collected is *NTC.xlsx,* either measured or calculated from the LIDAR data. It has the line and station and the slope readings on the left and the elevation differences for the zones on the right.

5.2.4.2 Far-station correction

The far-station corrections compensate for terrain effects from 20 m to 10 km outside the survey area. A combined DEM using the LIDAR data where available and the NRCAN data elsewhere is developed using a cell size of 10 m. The flat top prism algorithm is used to calculate the correction. The effect of correcting for a DEM beyond 10 km results in a differential of less than 0.010 mGal on the scale of this survey and therefore no further corrections were applied to this dataset.

5.2.5 QA/QC

Field data were reduced by the above corrections using whatever data were available to the field crew with final corrections applied once the final GPS control station locations and LIDAR DEM became available.

The gravity data were then manually examined for outliers, high error or high tilt readings. These are masked from the database and an average calculated from the remaining readings.

Maps are created in Geosoft Oasis Montaj. The gravity data after the above corrections is the Bouguer anomaly and is gridded using a minimum curvature gridding algorithm then displayed using a linear colour distribution in Figure 17. Trends are removed using all the points from the Bouguer anomaly map to accentuate property-scale anomalies; the Bouguer anomaly with the first-order trend removed is shown in Figure 18, with the second-order trend removed in Figure 19, and with the third-order trend removed in Figure 20.

Leica GS14 2805723	Aurora	1
Leica CS 2907999	Aurora	1

Notes (production comments, incidents, other)

Moved over to the GP4F area. No RTK link, needed to post process and had to take 10 min GPS readings because we were so far away . The GPS base died before the end of the day and we lost the repeat reading. There were many of the GPS data that didn't phase-correct and will have to redone.

Leica GS14 2810411	Aurora	1
Leica GS14 2805723	Aurora	1
Leica CS 2907999	Aurora	1

Notes (production comments, incidents, other)

Started by redoing the GPS repeats using a 15min reading at the same location as the day before to make sure we got a phase-corrected reading. Did a gravity and GPS base move which involved a tie survey to correct for the movement of the base. Afterwards in the afternoon continued on lines 27,28 and 29 right around the new base.

Digi-Atlantis system	Aurora	1
Geonics PROTEM transmitters	Aurora	1
Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Andre, Heiko and Franz all went on the Digi- Atlantis to start the survey off. Expanded the loop and set up the transmitter. Had to wait until about 5 before we started the dummy probe. It went down all the way to the bottom. Started surveying at the bottom, but there were signal errors and the curves didn't look quite right, so entire crew decided to come in and not try to trouble shoot through the night.

Digi-Atlantis system	Aurora	1
Geonics PROTEM transmitters	Aurora	1
Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Nice day. Decided to get to the top of Rhyolite Peak. Heiko had trouble getting reception to the base with repeater. Tried a few spots on top of the hill found the point where it was previously set up worked the best. Had fairly good connectivity until approximately 4 pm. Heiko couldn't keep ahead of both Andre and Franz, so Andre started to do GPS and gravity at the same time.

Digi-Atlantis system	Aurora	1
Geonics PROTEM transmitters	Aurora	1
Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

The drillers finished pulling the rods around 11pm. Dummied the hole it was good right down to the bottom. Started Digi-Atlantis surveying the hole at around 12am. The generator died around 3:00 am. Ran up and started it back up. Finshed the survey around 6:00 am. Took the rest of the day off after pulling a double shift.

Geonics PROTEM transmitters	Aurora	1
Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Dave flew in from Whitehorse and went through camp orientation, Andre flew to Whitehorse. Darrell worked on the loop in preparation for the next hole as the drilling is almost to the expected depth. Many, many moose (& caribou?) breaks and dragged wires, so could not get it completed. Darrin and Heiko worked on cleaning up points in the GP4F area that did get a phase corrected position.

Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Darrell and Darrin worked on the loop in the morning, set up and surveyed hole 247 on GP4F Pad 55. Did not have access to the pad until 1300 and survey went long - had to cut it short and did not survey the upper 65 metres of the hole so that the crew could return to camp before nightfall with the data from the bottom of the hole. Had a generator problem at the start of the day which appeared to surge voltage to the transmitter. TEM transmitter equipment was not damaged but the generator quit and the crew used the spare. Dave and Heiko gravity surveyed lines 19, 20 and 21.

Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Geophysics surveying reduced to a single 2-person gravity crew to be better time coincident with completion of GP4F downhole EM and the gravity survey. Heiko and Darrin will help around camp until they demobilize Friday. Sent one of the rental Leica GPS units out but kept the radio and repeater as this has increased the production of the gravity crew. Darrell and Dave worked on lines 15, 16, 17 - repeated some stations on line 17 from September 13 as a check on the Sept 13 drift. Cleaned the base on Rhyolite Mountain.

Notes (production comments, incidents, other)

Checked the loop first thing in the morning. It was good, so waited for the drillers to put the PVC down and pull the rods. It was taking a while so moved some spools to pads so that they could be picked up. A rock got jammed in the shoe and the rods brought up the PVC as well. Went back to camp while the drillers cleared the rock from the shoe. Came back out at shift change (7pm). The loop was broken, so we walked the loop and fixed it. Waited for the drillers to finish pulling the rods.

Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Andre and Darrell surveyed approximately 15 historical drill hole collars in the morning. In the afternoon, redid the north ends of L8, L9and L10 when that tare occurred on Sept 23rd.

Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Digi Atlantis downhole survey throughout the night. Started at 8pm, finished at 4am. Could only survey hole down to a depth of 365m because there was insufficient PVC to reach below 365m. The probe ran out of batteries with only 25m left of the hole. There was also a system error with the transmitter GPS between 140m to 150m, causing a large false anomaly. Returned to camp and rested for the day.

1 SUMMARY

This report describes the downhole time domain electro-magnetic survey (DHEM) conducted for BMC minerals on the Kudz Ze Kayah (KZK) project Yukon to assist in locating VMS ore deposits in the near proximity of select diamond drill holes.

The survey consisted of 8 DHEM surveys using 4 loops. The crew stayed on site at the BMC Minerals Inc. KZK camp. The duration of the geophysics project extended from Aug 21st – Oct 16th, 2015, with the crew conducting a gravity survey while during the drilling time of the holes (not described in this report).

On August 21th, 2015 a two person crew drove to KZK from Whitehorse, YT. The survey drill holes and loops were accessed by either side by side or helicopter depending on the proximity of the loops and the survey holes to the access road. The transmitter loops were tested and repaired as required prior to each hole being surveyed. Aurora personnel rotations used scheduled flights to and from camp. The crew demobilized to Whitehorse on Oct 16th, 2015 and the equipment followed shortly after via ground cargo. A crew log describing daily operations and production is included with this report.

Surface EM equipment was on-site as a secondary option to survey during DHEM down-time while drilling was underway. However at the direction of BMC the crew focused exclusively on gravity and DHEM and no surface EM lines were surveyed.

2 CREW AND EQUIPMENT

The following personnel conducted the survey:

Andre Lebel	Geophysicist	Aug. 23, Aug 25, Sept 2 – 3, Sept 19 - 20, Sept 25 - 27, Oct 1, Oct 3 - Oct 5, Oct 9 – 13, 2015	K15-GP4F21-224 K15-GP4F56-234, K15-GP4F59-261, K15-GP4F57-280, K15-GP4F58-285, K15–GP4F63-268
Darrel Epp	Geophysicist	Sept 2 - 3, Sept 12, Sept 16, Sept 19 - 20, Sept 25 – 27, Oct 1, Oct 3 - Oct 5, Oct 9 – 16, 2015	K15-GP4F56-234, K15-GP4F55-247, K15-GP4F59-261, K15-GP4F57-280, K15-GP4F58-285, K15–GP4F63-268, K15-016-292
Franz Dzuiba	Senior Geophysicist	Aug 21 – 25, Aug 31 – Sept 2, 2015	K15-GP4F21-224
Heiko Mueler	Field Technician	Aug 23, Aug 25, Aug 31 – Sept 3, Oct 13 – 16, 2015	K15-GP4F21-224, K15-016-292

Darren Dawson	Field Technician	Sept 12, 2015	K15-GP4F55-247

The crew was equipped with the following instruments and equipment

Digi-Atlantis:	2 – SMARTem24 Receivers s/n: 1175 and 1252
	1 – Panasonic Toughbook
	1 – Digi-Atlantis downhole EM probe s/n:146
Geonics Transmitter:	2 - Geonics TEM-67 Transmitters s/n:71202, 111207
	2 - Geonics TEM-67 Power Modules s/n: 60807,70901
Other DH-EM Gear:	1 - 1000m Downhole Signal Cable and Drum
	1 - Geonics DH-EM winch and Counter s/n: 134
	1 – Dummy Probe with dummy cable and drum
Other:	1 – 1 ton Truck (when required)
	1 – Laptop with Geosoft
	2 – Honda 5Kw Generators
	12 – Large spools of 10 – 14 gauge wire
	1 – Iridium Satellite Phone
	3 – handheld Garmin GPS
	4 – Bear spray and Bear Bangers
	1 – PROTEM receiver and surface coil

3 SURVEY LOCATION

The drill holes and DHEM parameters are described in Table 1. Figure 1 and Figure 2 are location maps showing the drill hole and loop locations of the GP4F area and the Krakatoa area. The transmitter loops were located so that the surveyed drill holes were inside the loop and positioned to have good coupling with expected conductor geometry. The size of the initial GP4F loop (loop 1) was 400 m square which was increased to approximately 1000 m square (loop 2) to surround all the planned holes in the GP4F

area. The GP4F loop was further increased in size (loop 3) to incorporate drill hole K15-GP4F63-268. The size of the ABM loop was 400 m square with its edges approximately parallel to the azimuth of K15-016-292. The crew stayed on site at BMC's KZK camp and accessed the survey holes and loops either by side by side or helicopter. All coordinates in this report are in the NAD83 (CSRS) datum, UTM Zone 9N projection, elevations are height above ellipsoid.

Table 1: DHEM drill holes surveyed.

DDH ID	DDH Location	DDH Dip and Azimuth	Surveyed meters out of a total	TX Loop, Current and TO Time	Date Surveyed

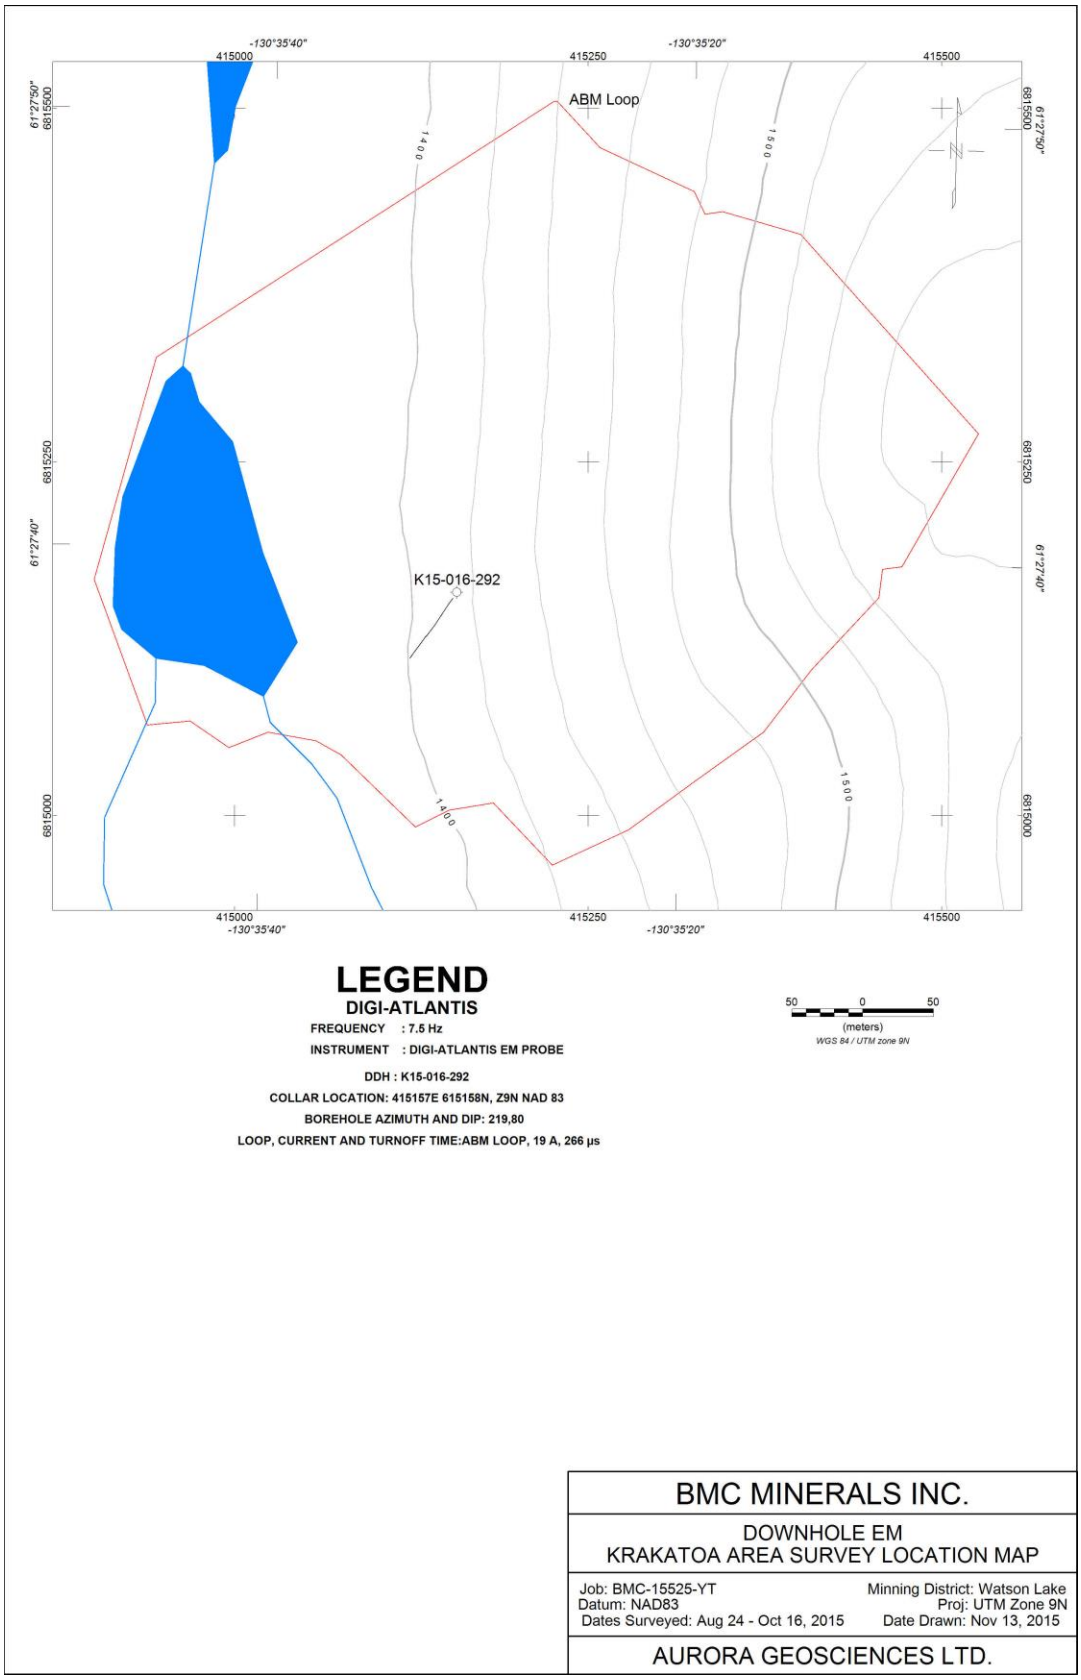

Figure 2: Krakatoa area survey location map.

4 SURVEY SPECIFICATIONS

Each station was determined by the winch counter which was set to zero when the top of the Digi-Atlantis tool was at the top of the drill hole collar. Coordinates of the drill hole collars are supplied by BMC Minerals and were measured by an RTK DGPS system or an APS system. Station spacing was 5 m for all holes with 2.5 m intervals for anomalous areas noticed by the operators. A total of 2569.5 m were surveyed out of the total of 2841 m drilled in the eight holes. Survey gaps of note include the upper 60 m on K15-GP4F55-247 due to time constraints and the lower 43 m on K15-GP4F57-280 because a shortage of PVC and subsequent blockage. **Error! Reference source not found.** lists the DHEM surveyed intervals of the holes.

The survey was performed with the following specifications:

Geographic datum & projection:	NAD83(CSRS) datum, UTM Zone 9N projection
Elevation datum:	Height Above Ellipsoid
Station locations:	Stations were located via the winch counter, generally at 5m intervals
Frequency:	7.5 Hz
Components:	A (down hole), U (cross hole parallel to dip), V (cross hole perpendicular to dip)
Stacks and Repeats:	Readings were stacked for a minimum of 512 stacks and repeated minimum 3 times, except K15-GP4F21-224 where each station was survey with a single stack of 512.
Channels:	SMARTem 24 format, 27 channels for each component. Channel 1 is early time and channel 27 is late time as detailed in Table 2.

Table 2: Channel number, start time (from end of ramp), end time (from end of ramp) and width.

Channel	Start (ms)	End (ms)	Width (ms)
CH 01	0.087	0.112	0.025
CH 02	0.109	0.140	0.031
CH 03	0.135	0.173	0.038
CH 04	0.167	0.215	0.042
CH 05	0.208	0.267	0.059
CH 06	0.258	0.332	0.074
CH 07	0.320	0.412	0.092
CH 08	0.398	0.511	0.113

CH 09	0.494	0.635	0.141
CH 10	0.613	0.788	0.175
CH 11	0.761	0.978	0.217
CH 12	0.945	1.215	0.27
CH 13	1.173	1.508	0.335
CH 14	1.456	1.872	0.416
CH 15	1.808	2.324	0.516
CH 16	2.244	2.885	0.641
CH 17	2.786	3.582	0.796
CH 18	3.459	4.447	0.988
CH 19	4.294	5.521	1.227
CH 20	5.331	6.854	1.523
CH 21	6.618	8.509	1.891
CH 22	8.217	10.564	2.348
CH 23	10.201	13.115	2.91
CH 24	12.664	16.282	3.62
CH 25	15.722	20.214	4.49
CH 26	19.519	25.095	5.58
CH 27	24.232	31.155	6.92

Synchronisation: Transmitter and receiver were synchronized via GPS.

5 DATA PROCESSING

The DH-EM data were downloaded and exported from the EMIT's SMARTem24 data logging software, and raw data converted to ASCII data file (*.dat) and ASCII survey files (*.sur). These raw data are edited with EMIT's Maxwell software where each decay curve was examined and the ones that did not repeat or were suspect are marked for rejection. Polarity reversals were corrected for drill hole K15-GP4F58-285. The headers of the *.dat files were standardized and final coordinates inserted. Data are averaged to one reading for each component at every station and exported as *.tem files. Downhole EM profile plots were created using EMIT's Maxwell software.

6 INTERPRETATION

This section is the results of correspondence between consulting geophysicist Jules Lajoie and geologist Murray Jones. Interpretations are from qualitative examination of profiles only and no detail modelling has been undertaken.

6.1 Hole GP4F21-224

6.1.1 Station 90

A negative crossover in the early-time U component implies a conductor to the south but between channels 3 and 4 the response migrates to a positive crossover in the U component implying a conductor to the north. The response extends to channel 13. This is accompanied by a weak negative dip in the A component indicating an off-hole conductor for both early and middle times. The V component shows a negative crossover at both early and mid-times indicating the causative conductor is to the east of the drill hole. The GP4F mineralized horizon is at 96 to 99 m which is faulted and includes semi-massive sulfides to narrow bands of sulfides (10-15 cm); it is likely not a good continuous conductor.

The bulk of the conductor is interpreted to be off-hole, to the north and east. The anomalous signal decays by channel 10-15, indicative of a weak conductor.

6.1.2 Station 150

An early-time positive crossover at station 150 m in the V component with very weak associated responses in the A and U components indicates an off-hole conductor to the north and west. A small mineralized horizon around 155 m was drilled consisting of 8-10% sulfide (sphalerite-pyrite) in two 1 m intervals on either side of a dyke (4 m wide); the alteration is typical proximal alteration associated with the ABM and GP4F deposits. The weak early-time only response is indicative of a very weak conductor.

6.1.3 Station 220

This anomaly is an early to middle time broad positive response in the A component associated by weak positive crossovers in the U and V components suggesting an in-hole weak conductor. There is a strong fault from approximately 220 – 240 m partially in a black, meta-sediment that is likely the cause of this feature, although the core did not conduct when checked with a hand multi-meter.

6.2 Hole GP4F56-234

There are very sharp (localized) responses at 240 m and 325 m. Both are early to middle-time responses suggesting a weak conductor.

6.2.1 Station 240

A positive in the A component and associated positive crossovers in both the U and V components indicate an in-hole that is mostly to the north and west.

6.2.2 Station 325

This response is in the mineralized GP4F horizon; it has a negative response in the A component with an associated negative crossover in the U component, changing to a positive crossover at channel 13 and disappearing shortly thereafter. This indicates an off-hole conductor to the south (up-dip). The V component response is a sharp positive rather than a crossover of either sign and whether the conductor is to the east or west is therefore ambiguous. This could be a result of a single plate solution being inappropriate, or of under-sampling with 5 m stations as this response is sharp.

6.3 Hole GP4F55-247

There are two anomalies within the hole, a pronounced one at 125 m and a subtle one at 160 m. Both of these are within a bigger unit logged as carbonaceous sediment from 118 m to 166 m presumed to be dipping north. In the early channels there is a broader scale in-hole response in the A component, so the two responses at 125 and 160 could represent smaller more graphitic horizons within the larger carbonaceous unit. The same carbonaceous sediment is presumed to be intersected to the north in drill hole K15-GP4F63-268 at a depth of 330m.

At the very end of the hole, there is the suggestion (at stations 380 to 390) of a response starting in the U component indicating a deeper body down-dip, but this is an incomplete response with no associated response on the A component.

6.3.1 Station 125

The downhole component has a positive anomaly showing an in-hole conductor. In the early-time there are negative crossovers in U and V components that change to positive crossovers after channel 5, suggesting the current filament has passed by the hole and most of the conductor is to the north (down-dip) and to the west as indicated by the later-time channels. The response, particularly the U component, persists into the late-time indicating this is a relatively good conductor.

6.3.2 Station 160

The anomaly at 160 m has a weak positive A component with associated negative crossovers in both the U and V components in the early-time. The A component changes to a negative anomaly and the U component changes to a positive crossover after channel 5. The response is much weaker than that at Station 125 and does not extend into channels later than channel 10. This indicates a weak conductor that is mostly to the north and east.

6.4 Hole GP4F57-280

6.4.1 Station 365

The only anomalous area is an incomplete response the end of the survey (last station is 365 m). This is not the end of the drill hole as there was a shortage of PVC and consequently the hole was blocked preventing a full DHEM survey. Strongly carbonaceous sediment is intersected at 393 m, but this is too far down-hole to explain the DHEM response noted at 360 m.

The response is mostly an early-time (channels 1-10) negative A component anomaly with a negative U crossover and a positive V crossover indicating a weak conductor off-hole, to the south (up-dip) and to the west. Towards mid-time, the U response switches to a very weak positive crossover.

There are several proximal holes; a historic Cominco N-S fence (holes 188-189-193-196) and a BMC N-S fence (drill holes K15-GP4F59-261, K15-GP4F58-285, K15-GP4F-57-280) limit the maximum size of this conductor.

There is an interval of semi-massive to massive sphalerite-pyrrhotite-pyrite from 364.25-365m, albeit with lost core in the middle of the zone. This zone is correlative with a lower zone of mineralization seen in a number of the holes in this area (e.g. to the south at 280 m in K15-GP4F58-285).

6.5 Hole GP4F58-285

The dominant response is a middle-time anomaly centered at 275 m or 280 m which is visible until channel 15. A weaker conductor, only visible in the V component is seen at 225 m.

6.5.1 Station 225

There is a response at station 225 m coincident with a mineralized zone primarily between 225 m and 233 m. Similarly to the anomaly lower down at 275 m – 280 m, it has a clear positive V component crossover indicating the conductor is to the west. There are only very weak A and U component responses.

6.5.2 Station 275

There is a negative A component anomaly and a positive V component crossover indicating the causative conductor is off-hole and to the west. There is only a weak U component response which is a (noisy) negative crossover in the early-time migrating to a positive crossover in the middle-time channels. This indicates the current center is in the shallower up-dip part of the zone to the south at early time, migrating down-dip to the north by mid time, all very much on the west side of the drill hole.

There is a narrow, semi-massive sulfide intercept in-hole at 280 m (pyrrhotite with sphalerite-chalcopyrite) and known massive sulfide mineralization up-dip to the southwest (~200-230 m) and to the west, more or less on strike (~150 m). Disseminated to semi-massive sulfide mineralization was intersected 210 m to the northwest by Cominco in 1998, but no significant massive sulfide. There is weakly carbonaceous sediment below 290 m in the drill hole GP4F58-285. The zone at a depth of 365 to the north on hole GP4F57-280 is roughly correlative based on lithology and alteration.

6.6 Hole GP4F59-261

6.6.1 Station 95

The anomaly at station 95 m is a slight negative early-time A component anomaly with a positive crossover in the V component indicating an off-hole weak conductor to the west. There is no associated response on the U component.

6.6.2 Stations 180, 210 & 240

These anomalies are slight early-time positive A component anomalies with positive crossovers in both U and V components indicating in-hole weak conductors that are primarily to the west and north (down-dip).

There is some ambiguity in the interpretation of whether the anomalies at 210 and 240 are positive (in-hole) or negative (off-hole) but viewing them as positive anomalies matches well with the zones logged in the core that are expected to be weak conductors and therefore the in-hole interpretation is preferred.

6.6.3 Station 285

At the bottom of the surveyed hole is an anomaly in the U and V components which appear to be the start of more significant response coincident with the A component starting to rise. The readings at the bottom of the hole at station 295 m are very noisy and have been discarded but the anomalous responses at 285 and 290 are of good quality. The conductor is interpreted to be to the east and north. The response extends to later channels indicating that it is a better conductor than those further up the hole.

6.7 Hole GP4F63-268

Both of the anomalies at 310 m and 332.5 m extend into the late-time channels, indicative of good conductors but are presumed to be caused by conductive carbonaceous sediments logged around both of these stations.

6.7.1 Station 310

In the early-time, this is a negative A component anomaly indicating an off-hole conductor with no significant U or V response. The response then changes to a positive A component anomaly with weak positive crossovers in the U and V components indicating an in-hole conductor that is to the north (down-dip) and to the west in the late-time.

6.7.2 Station 332.5

In the early-time, this is a negative A component anomaly indicating an off-hole conductor with negative crossovers in U and V indicating a conductor that is south (up-dip) and to the east. The response then changes to a positive A component anomaly with weak positive crossovers in the U and V components indicating an in-hole conductor that is to the north (down-dip) and to the west in the late-time.

There are shoulders in the response at 337.5 m or 340 m indicating a more complicated geometry.

6.8 Hole K15-016-292

6.8.1 Station 175

This is an early-time anomaly with a negative response in the A component and positive crossovers in the U and V components indicating a weak conductor that is off-hole, to the northeast (down-dip) and slightly to the right of the hole (northwest).

Sulfide mineralization is intersected close to this station.

6.8.2 Station 220

At station 220, there is a late-time off-hole response, indicating a good conductor, but not as strong as the one below at station 237.5. There is a negative A component response, very little U component response, and a positive crossover in the V component indicating the conductor is off-hole and to the right of the hole (northwest).

6.8.3 Station 237.5

This is the dominant feature in this hole with a large late-time response indicative of a very good conductor. The late-time A component shows a negative response at 237.5 m with positive crossovers in the U and V components indicating that the conductor is off-hole, down-dip (northeast) and to the right (northwest) of the drill hole. Complexity in the response around station 237.5 is interpreted to reflect heterogeneous geology which cannot be modelled as a single thin conductor; this is consistent with what is logged in the core.

Leica GS14 2810411	Aurora	1
Leica GS14 2805723	Aurora	1
Leica CS 2907999	Aurora	1

Notes (production comments, incidents, other)

Moved over to the GP4F area. No RTK link, needed to post process and had to take 10 min GPS readings because we were so far away . The GPS base died before the end of the day and we lost the repeat reading. There were many of the GPS data that didn't phase-correct and will have to redone.

Leica GS14 2810411	Aurora	1
Leica GS14 2805723	Aurora	1
Leica CS 2907999	Aurora	1

Notes (production comments, incidents, other)

Started by redoing the GPS repeats using a 15min reading at the same location as the day before to make sure we got a phase-corrected reading. Did a gravity and GPS base move which involved a tie survey to correct for the movement of the base. Afterwards in the afternoon continued on lines 27,28 and 29 right around the new base.

Digi-Atlantis system	Aurora	1
Geonics PROTEM transmitters	Aurora	1
Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Andre, Heiko and Franz all went on the Digi- Atlantis to start the survey off. Expanded the loop and set up the transmitter. Had to wait until about 5 before we started the dummy probe. It went down all the way to the bottom. Started surveying at the bottom, but there were signal errors and the curves didn't look quite right, so entire crew decided to come in and not try to trouble shoot through the night.

Geonics PROTEM transmitters	Aurora	1
Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Had to pick up the loop in the morning because of VTEM survey over the GP4f area in the afternoon. Finished cleaning up the wire around 11:00 but had to wait until 2pm to get bumped over to area we were working on top of the hill because of a drill move and the mining inspector was flying around the site. Did a few gravity points with both gravity meters running in the afternoon.

Notes (production comments, incidents, other)

Nice day. Decided to get to the top of Rhyolite Peak. Heiko had trouble getting reception to the base with repeater. Tried a few spots on top of the hill found the point where it was previously set up worked the best. Had fairly good connectivity until approximately 4 pm. Heiko couldn't keep ahead of both Andre and Franz, so Andre started to do GPS and gravity at the same time.

It was raining, the top of the mountain was all socked in, decided to work on a lower down area. The base died part way through the day. Franz went up and switched out the battery. Heiko tried switching the settings on the repeater and the base to get better connectivity but it was already low. Andre repeated Franz's readings from the day before that did not repeat in the morning then continued on doing readings

Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Darrell and Darrin worked on the loop in the morning, set up and surveyed hole 247 on GP4F Pad 55. Did not have access to the pad until 1300 and survey went long - had to cut it short and did not survey the upper 65 metres of the hole so that the crew could return to camp before nightfall with the data from the bottom of the hole. Had a generator problem at the start of the day which appeared to surge voltage to the transmitter. TEM transmitter equipment was not damaged but the generator quit and the crew used the spare. Dave and Heiko gravity surveyed lines 19, 20 and 21.

Geonics surface TEM	Aurora	1
Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Geophysics surveying reduced to a single 2-person gravity crew to be better time coincident with completion of GP4F downhole EM and the gravity survey. Heiko and Darrin will help around camp until they demobilize Friday. Sent one of the rental Leica GPS units out but kept the radio and repeater as this has increased the production of the gravity crew. Darrell and Dave worked on lines 15, 16, 17 - repeated some stations on line 17 from September 13 as a check on the Sept 13 drift. Cleaned the base on Rhyolite Mountain.

Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Checked the loop first thing in the morning. It was good, so waited for the drillers to put the PVC down and pull the rods. It was taking a while so moved some spools to pads so that they could be picked up. A rock got jammed in the shoe and the rods brought up the PVC as well. Went back to camp while the drillers cleared the rock from the shoe. Came back out at shift change (7pm). The loop was broken, so we walked the loop and fixed it. Waited for the drillers to finish pulling the rods.

Notes (production comments, incidents, other)

Andre and Darrell did gravity on L8 and L9 near the south end of the lines in the morning. Came back to camp and rested up in the afternoon for the borehole survey later that day. Went out at 6pm when the drillers finished putting the PVC down the hole. The loop was energized and the hole was dummy probed before the driller shift change. Continued surveying the hole until past midnight.

Geonics winches and cables	Aurora	1

Notes (production comments, incidents, other)

Digi Atlantis downhole survey throughout the night. Started at 8pm, finished at 4am. Could only survey hole down to a depth of 365m because there was insufficient PVC to reach below 365m. The probe ran out of batteries with only 25m left of the hole. There was also a system error with the transmitter GPS between 140m to 150m, causing a large false anomaly. Returned to camp and rested for the day.

SURVEY PARAMETERS

Configuration	: Downhole
Station Spacing	: 2.5-5.0 m

RECEIVER

Receiver	: DigiAtlantis
Frequency	: 7.5
Component	: A,U,V

TRANSMITTER

Transmitter	: Geonics
Loop	: GP4F_loop3
Tx Current	: 15 A
Turn Off	: 0.482 ms

Scale 1:1250

Appendix L: 2015 drilling logs

This appendix contains all of the drill logs generated from the 2015 drilling program, which includes resource definition, exploration, metallurgical, hydrogeological and geotechnical holes. Drill logs are placed in alpha-numeric order with the first page of each log starting on the page number indicated below in Table L-1.

Table L-1: Table of contents for 2015 diamond drill hole logs in this appendix

Hole Number	Length (m)	Target	Purpose	Core Storage Location	Page Number
K15-200	211.5	ABM	Resource/hydrogeological	KZK Camp	1
K15-201	35	ABM	Metallurgical twin	KZK Camp	15
K15-202	71	ABM	Resource/metallurgical/hydrogeological	KZK Camp	18
