KF, DF and Flip Group Mineral Claims

105-H-2, 61°8'N, 128°40'W

Watson Lake M.D., Yukon Territory

1. INTRODUCTION

Montana Mines Ltd. (NPL), during the year August 1968 to August 1969, has carried out an evaluation program consisting of an airborne geophysical survey, ground magnetometer and electromagnetic surveys, geochemical survey and linecutting on their Hyland River Area, Yukon Territory property.

The ground surveys were directed by the writer who is the Company Geologist and Exploration Manager.

The text of this Report comprises a review of the results of the above surveys.

Two additional Summary Geophysical Reports are also included within this Report.

2. PROPERTY AND LOCATION

The claims held by the Company are located in the Watson Lake, Yukon Territory, Mining District, on the east side of Dolly Varden Creek, a south flowing tributary of the Hyland River. They are approximately 12 miles north of the Cantung Road and 72 air-miles north of Watson Lake, Yukon.

Claims currently held in good standing by the Company are as follows:

<table>
<thead>
<tr>
<th>Claim Name</th>
<th>Grant Number</th>
<th>Date of Record</th>
</tr>
</thead>
<tbody>
<tr>
<td>KF 1 to 8 incl.</td>

<td>August 22, 1968</td>
</tr>
<tr>
<td>Flip 1 to 16 incl.</td>
<td>Y 27887 - Y 27904</td>
<td>August 22, 1968</td>
</tr>
</tbody>
</table>
3. GEOLOGY

Regional geologic mapping has been carried out by the Geologic Survey of Canada and is published as Map 6 - 1966.

The area covered by the claim block is believed to be largely underlain by argillites, hornfels and schists indicated as Unit 14 on the above publication.

Towards the eastern edge of the claim group a contact is found and the rock is noted to be granitic, shown as Unit 15.

Disseminated sulphides are found in many locations on the property, both in outcrop and in float occurrences.

The main interest lies in a group of massive sulphide boulders located roughly in the center of the claim block, and having potentially good economic values.

The Company is presently engaged in a more detailed study of the geologic setting.

The area presumably underlain by the Devonian and Mississippian sediments and their metamorphic equivalents appears to have a very complex structure. The general trend appears to have a northerly strike with a varying easterly dip, although this is by no means a consistent factor.

The attitudes of the sediments are difficult to determine because of the extensive overburden cover in most areas, and the severe alteration by faulting and folding in areas of outcrop.

4. GEOCHEMISTRY

Soil samples were taken over an area predominantly north and east of the sulphide float boulders. This would be the logical direction of migration of the float by either gravity or glacial action.

A limited number of samples were taken the previous year and the reader is referred to a Report by P.H. Sevensma, Ph.D., P. Eng., dated January 28th, 1969, for a discussion of these results.

The present survey carries out the first stage of the recommendations of Dr. Sevensma's Report.
A total of 223 samples were taken and the analytical results are shown on the attached maps. Field procedure involved the preparation of a grid by chain and picket surveys along cut lines. The grid is oriented with a N-S baseline and E-W survey lines. Sample pits were dug at 100 foot intervals along the survey lines and samples were collected from the soil horizon below the Yukon volcanic ash layer. Detailed notes on topography, vegetation, drainage and soil type were prepared as an aid in correlation of the results.

Analytical work was done by the Whitehorse Assay Office, Whitehorse, Yukon using a hot acid (HNO₃-HCl) extraction process and Atomic Absorption analysis.

The analytical results exhibit low background values which is believed by the writer to be attributed to extensive overburden depths in the majority of the sample area.

Areas of anomalous values are shown on the attached maps. The anomalous area west of the sulphide float location (0+00 NS - 0+00 EW) is probably attributed to ground water leaching of the float combined with down slope migration of the ions.

An area of above background values is found to coincide with a magnetometer high and a weak electromagnetometer conductor at 20+00 N between stations 4+00 E and 8+00 E. This area warrants careful examination but due to extensive overburden depth the use of further geochemical means of investigation may be limited.

An area to the east, upslope of the mineralized float, shows anomalous values in the region of the creek flowing westward into Dolly Varden Creek. This anomaly may be due to a thinner coating of migration hampering overburden, but cannot be discounted as a possible source area of the float.

A chip sample from one of the mineralized float boulders was taken and assayed by the Whitehorse Assay Office, Whitehorse, Yukon and the following results were obtained:

<table>

5. **GEOPHYSICA**

The reader is referred to the attached Geophysical Reports by Peter E. Walcott, P. Eng., and R.A. Hillman for a summary of the data obtained on both airborne and ground geophysical surveys.

6. **SUMMARY AND RECOMMENDATIONS**

The highly mineralized float occurrences combined with the favourable results obtained in the above surveys would indicate a high degree of assurance in finding a mineralized source area within the claim block.

The presumed overburden depth would tend to make further examinations a geophysical problem, with wide-spread geochemistry and prospecting being used to investigate the area regionally.

It is recommended that the grid be extended to give a more detailed picture of the area between 16+00 N and 24+00 N and the southern end be extended to both the east and west.

The recommendations contained in the attached Report by Peter E. Walcott, P. Eng. should be followed in the near future in the hope that a favourable diamond drill target will be located.

Respectfully submitted,

B.C. Fulcher, B.Sc.

INTRODUCTION

During July and August 1969, Montana Mines Limited carried out linecutting, geochemical soil sampling, and magnetic and electromagnetic surveys on part of their property located in the Hyland River area, Yukon Territory.

The soil sampling and surveys were carried out over handcut lines which were turned off at right angles every 200 or 400 foot from a north-south baseline, and which were chained and picketed at 100 foot intervals.

Soil samples were collected every 100 feet along the picket lines where possible, while readings were made every 100 feet using a Sabre Mk II magnetometer and a Ronka E.M. 16 electromagnetic unit.

The results are shown on plan maps of the line grid, Maps No's H-1 to -5, that accompany this report, with the data being plotted in contoured form in the case of the soil determinations for copper, lead and zinc content and the magnetometer survey, and in profile form in the case of the E.M. survey.

The following is a report on the above mentioned magnetic and electromagnetic surveys with reference to the soil sampling results on data made available to the writer by Montana Mines Limited.
PROPERTY, LOCATION AND ACCESS

The property consists of the following claims recorded in Watson Lake recording office as follows:

<table>
<thead>
<tr>
<th>Claim Name</th>
<th>Grant No.</th>
<th>Recorded Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>KF 1 to 8</td>

</tr>
<tr>
<td>Kee 1 to 16</td>
<td>Y27702 - Y27717</td>
<td>Jul. 2nd, 68</td>
</tr>
</tbody>
</table>

The property is situated in the Watson Lake Mining District of the Yukon Territory, and is located on the east side of Dolly Varden Creek, a southward flowing tributary of the Hyland River, some 12 miles north of the Cantung road.

Access is obtained by means of helicopter from Watson Lake, a distance of some 72 airmiles.
PURPOSE

The purpose of the surveys was to (1) try and locate by ground geophysical methods the presence of electromagnetic conductors that could correspond to sulphide mineralization as indicated by previously flown airborne magnetic and electromagnetic surveys and (2) trace by geochemical and geophysical means the source of heavily mineralized boulders found on the property.
GEOLOGY

The reader is referred to two reports to Montana Mines Limited by P.H. Sevensma, Ph.D., P.Eng., and to Map 6-1966 by the Geological Survey of Canada.
SURVEY SPECIFICATIONS

The basic principle of any electromagnetic survey is that when conductors are subjected to primary alternating fields secondary magnetic fields are induced in them. Measurements of these secondary fields give indication as to the size, shape and conductivity of conductors. In the absence of conductors no secondary fields are obtained.

The electromagnetic survey was carried out using a Ronka E.M. 16 unit. This unit utilizes the U.L.F. radio stations that exist for submarine communications as its transmitter source. Their vertical antennae create concentric horizontal primary magnetic fields, and the receiver, i.e. the E.M. 16 unit, measures the vertical components of secondary fields that might be induced by the primary ones.

The magnetic survey was carried out using a Sabre Mk II magnetometer. This instrument makes measurements of the vertical component of the earth's magnetic field to an accuracy of plus or minus 50 gammas. Corrections for diurnal variations of the earth's field were made by tying-in to previously established base stations.
DISCUSSION OF RESULTS

The magnetometer survey (Map H-1) showed that part of the property surveyed to exhibit moderate magnetic relief with an area of lower magnetic intensity discernible in the northeast corner.

This is in direct contrast to the airborne magnetic survey (Waterton Aeronautics Ltd, report by R.A. Hillman, June 1969) where magnetic gradients of 600 gammas were recorded over 500 feet at a mean terrain clearance of 500 feet, as gradients of at least 1200 to 1800 gammas in 500 feet would be expected on ground traverses.

This lack of correlation suggests either (a) a discrepancy in the location of the ground grid with respect to the airborne positioning or (b) a malfunction in one of the two magnetic units.

The E.M. 16 survey (Map H-2) gave relatively smooth in and out of phase profiles suggestive of deep and/or conductive overburden.

It also showed the portion surveyed to be underlain by two different "conductive" units, units A and B, as indicated by characteristic changes in the in and out of phase readings (Map H-2). These characteristic changes could be due to changes in the underlying rock type and/or to deepening or shallowing of overburden.

A weak conductor can also be seen on Map H-2. This conductor is indicated only by changes in the in-phase readings and is considered to be most probably caused by a change in bedrock topography beneath the overburden cover, and not by sulphide mineralization.

The results of the soil sampling survey are shown on maps H-3, -4 and -5 as contours of their copper, lead and zinc content respectively. All show an anomalous east northeast trend upslope from the location of several mineralized boulders near the baseline. In general, however, the overall readings in parts per million are low, and could be reflecting deep overburden conditions.
SUMMARY, CONCLUSIONS AND RECOMMENDATIONS

During July and August 1969, Montana Mines Limited carried out linecutting, soil sampling and magnetic and electromagnetic surveys on part of their Hyland property.

This property is located in the Watson Lake Mining District of the Yukon, some 70 miles north of the town of Watson Lake.

The surveys were designed to locate the source of heavily mineralized boulders found on the property, and to investigate the cause of magnetic and electromagnetic anomalies detected on previously flown airborne surveys.

The ground magnetic survey showed the part surveyed to exhibit moderate magnetic relief in direct contrast to the strong relief obtained on the airborne survey, thereby suggesting improper ground location or instrument malfunction.

The E.M. survey suggested reasonably deep overburden cover with a possible contact trending north-east through the line grid, but failed to locate the presence of any conductors that might be indicative of sulphide mineralization.

The geochemical survey indicated reasonably strong anomalous conditions trending east north-east from the location of the mineralized boulders, but in general the overall parts per million contents were low possibly indicating deep overburden conditions.

As a result of the forementioned surveys the writer concludes that (a) the validity of the magnetometer work is questionable, and (b) the overburden is reasonably deep. He, therefore, recommends that in view of the above and the favourable geochemical indications that the grid be resurveyed using the Turam electromagnetic system, a deep penetration E.M. technique (contrary to popular belief the penetration of the E.M. 16 unit is severely limited by attenuation in areas of conductive rock and/or overburden and is
probably not more than 30 or so feet), and a Sharpe fluxgate magnetometer.

The cost of this programme is estimated as follows:

<table>

1. INTRODUCTION

Montana Mines Ltd., has acquired by purchase and staking, a total of 48 mineral claims located in the "Cantung" road area of South-eastern Yukon. A previous aerial survey was flown for Montana Mines by Waterton Aeronautics Ltd., 4210 Almondeel, West Vancouver, B. C. The following is an account of the second Waterton aerial survey.

2. HISTORY

The decision to perform the first aerial survey was made after an examination of the property by R.G. Gifford, P. Eng. The survey consisted of a fixed wing aircraft monitoring magnetic, electromagnetic and radioactive data. Results of the survey showed an E.M. conductor in an area of relatively sharp magnetic relief located upslope from the mineralized float occurrence. (Float occurrence at location posts KF 1, 2, 3 and 4.)

3. LOCATION AND ACCESS

The property is located on the East side of Dolly Varden Creek, a South flowing tributary of the Hyland River. Claims extend from the valley floor at 3,500 feet to an elevation of 5,000 feet across a moderately timbered, West facing
slope. The Cantung road crosses this valley some 12 miles to the South.

A camp site and helicopter pad on the property are 72 airmiles North of Watson Lake.

4. REGIONAL GEOLOGY

Geological mapping of the area on a scale of 4 miles to the inch was published as Map 6 - 1966 by the Geological Survey of Canada. The area is shown to be underlain by pelitic rocks and limestone of Devonian-Mississippian age along a North-South trending embayment in the enclosing crystalline rocks. Limestones, argillite and chert, together with their schistose and contact-metamorphic equivalents comprise the host formation.

5. DESCRIPTION - GEOPHYSICAL SURVEY

The fixed wing aircraft, employed by Waterton Aeronautics, monitors magnetic, electromagnetic and radioactive data in flight. The data is recorded on film strips and later plotted on appropriate grids. Ground checks provide the needed information as to the flight position of the aircraft.

The magnetometer is of the fluxgate-element type. It is extremely sensitive to changes in the earth's vertical magnetic field, which then gives a measure of subsurface magnetic anomalies.

The electromagnetic unit consists principally of a transmitting coil and a receiving coil ideally at right angles.
The receiving coil, in the trailing "bird" of the aircraft, detects the horizontal component of induced secondary magnetic field in the conductor. A good conductor, even in the shape of a vertical dike and sub-parallel to the flight lines, will have a substantial, secondary, horizontal component. No difficulty is envisioned in receiving this horizontal component from a vertical conductor.

The radioactive measuring device employed is a scintillation counter with high gamma-ray detection efficiency. Due to the absence of continuous radioactive readings, the radioactive data is considered of little value and is not dealt with in this report.

6. RESULTS

AEROMAGNETIC SURVEY

The results of the aeromagnetic survey are shown in Drawings 1 and 3. Claim boundaries, flight lines and magnetic contours are shown.

In correlation with aerial Survey 1, two magnetic "highs" are located up slope from the mineralized float occurrence. (Read 15 on Drawing No. 1 but interpreted as 1500 gammas, the ground expression would be higher due to the height of reconnaissance aircraft.) Similar occurrences of magnetic "highs" occur in Drawings 1 and 3.

A possible explanation of these anomalous highs can be derived from information obtained from mineralized float. Galena, Sphalerite and Chalcopyrite from the chief ore minerals present. These minerals are weak magnetically
and would be difficult to locate using aerial or ground magnetometer units. The ore minerals Galena, Sphalerite and Chalcopyrite do however, become susceptible to magnetic methods due to their association with highly ferromagnetic Pyrrhotite. Numerous rock samples gathered during the 1968 season did, in fact, possess significant amounts of Pyrrhotite associated with the valuable sulfides. Whether the sulfide zones are disseminated or massive will have, due to the presence of pyrrhotite, little overall effect on the magnetic expression. In Drawing No. 3 there are, along with magnetically high areas, areas of negative magnetic relief. (Shown as minus 5's on Drawing No. 3, these areas can be interpreted as negative magnetic relief of magnitude -500 gammas.)

The most obvious explanation is that the underlying rock formations have a strong reversed remanent magnetization which overrides the induced component due to the earth's magnetic field.

A second explanation is that intensely, deep-seated, magnetized dipoles have been overturned since acquiring remanent magnetization. This viewpoint would have to be supported by evidence of intense geological folding. Chip samples taken at random display moderate to intense polarity yielding support in part, for the presence of magnetic dipoles.

ELECTROMAGNETIC SURVEY

Collectively Sphalerite, Chalcopyrite, Galena and Pyrrhotite make a good conductor. Being a good conductor, the
sulfide body (if massive) is highly susceptible to aerial or ground E.M. techniques.

If the sulfide zones are disseminated, then E.M. techniques become less useful.

Many areas of relatively high conductivity, in relation to background, exist. The most conductive areas are shown in Drawings 2 and 4 as areas of increasing numerical procession from as low as 1 to as high as 10 (not numerically denoted, but shown).

An area of relatively high response is located up slope from the KF Group, Claim posts 1, 2, 3 and 4 (position of float). As illustrated, numerous other E.M. highs exist throughout the KF, DF, Flip and Kee Groups. These "highs" closely resemble spheres which electrically conduct more effectively than geological "background" units. The conducting spheres should not, however, be immediately interpreted as sulfide zones.

7. SUMMARY

Mineralized rock samples taken from the claim group area exhibited a range of magnetic susceptibilities. The percent pyrrhotite-content probably fixes the magnetic strengths of the various samples. In view of this criteria, further evidence to define areas of interest is needed.

The aerial E.M. as stated, shows numerous areas of conductivity above "background" levels. Massive to near massive sulfide zones would display this same characteristic. The aerial E.M. and magnetometer transparent overlays help to
... 6

distinguish areas of relatively sharp magnetic relief and
electrical conductivity.

Some rock samples from the claim-group area showed
disseminated mineralization. Geophysical data, with the ex-
ception of magnetic methods, become less valuable in this
instance. Geochemistry and geology are the more valuable
instruments in the search for disseminated sulfides.

8. **RECOMMENDATIONS**

Areas exhibiting anomalous geochem. values,
favourable geologic structure, electromagnetic conductivity
and relatively high magnetic relief should be areas of more
intense study.

The area of geochem. anomaly defined by present
work should be given first priority. Other areas can then
be explored as further information is gathered.

The present grid should be extended along the geochem.
anomaly already defined. Lines 200 feet apart with 100 foot
stations would accommodate soil sampling, vertical or hori-
zontal loop E.M. and Sabre-magnetometer work. This grid will
provide more control over the area defined and will supplement
findings to date. The information gathered from this area will
be extremely valuable in locating secondary targets.
**APPENDIX "C"**

Statement of costs incurred in Geochemical and Geophysical surveys of Montana Mines Ltd., Hyland River area, Yukon Territory mineral claims.
