HALFERDAHL & ASSOCIATES LTD.
SECTION 1.0  INTRODUCTION

Exploration of the Bur property continued in 1982 with the collection of nine panned concentrates from three of the pups tributary to Burwash Creek, not previously sampled. In addition three holes were diamond drilled, and an access trail part of the way to proposed drillsites was constructed. This report deals only with the panned heavy mineral samples; the other exploration is expected to be the subject of a subsequent submission. The geographic setting, previous work, and geology of the property have been fully covered in previous assessment reports, and so are not repeated in this report; information on these aspects is included in the reports listed in the references.

Many of the tributaries of Burwash and Tatamagouche Creeks have not been formally named. For convenience some of these tributaries or pups have been given informal names (Fig. 4.1, 4.2).

The work reported here was conducted by four people who formed part of a larger crew engaged in other work on the Bur property. Accommodation was in a temporary camp in the valley of Burwash Creek. A four-wheel-drive vehicle provided access along the road up Burwash Creek.

SECTION 2.0  RESULTS AND RECOMMENDATIONS

2.1 Results

1. Anomalous concentrations of gold are present in samples from the three creeks sampled: Mullere, Betz, and San.

2. Anomalous concentrations of lead, zinc, and copper are present in samples from Betz and San Creeks. They may be related to a zone near the base of the Hasen Creek Formation.

2.2 Recommendations

1. Collect heavy mineral samples from tributary creeks or pups not yet sampled.

2. Sample those with anomalous concentrations of gold, and possibly lead, zinc, and copper at closer intervals.
SECTION 3.0  PROPERTY

The Bur property now consists of 261 quartz mineral claims along Burwash and Tatamagouche Creeks in the Whitehorse Mining District but only the 151 staked prior to 1982 are shown in Fig. 1.2. Only the six claims to which the work reported herein is to be applied are listed below.

</tbody>
</table>

The recorded holder of these claims is Laurence B. Halferdahl, for whom the work described in this report was conducted. This work is expected to fulfill representation work requirements so that on its approval, the expiry dates for the four JY claims above will be 1984 10 16, and for the two EL claims above, 1985 09 28. No work is to be applied to claims JY 30 and JY 55, grant numbers YA 52568 and YA 52593, so that they lapse on October 16, 1982.

The work reported here was performed in 1982 on the following claims:

JY 17       YA 51133
JY 25-27    YA 52563-65
JY 50       YA 52588
DEN 7-8     YA 23583-84
EL 9        YA 73861

SECTION 4.0  HEAVY MINERAL SAMPLES

4.1 Sampling and Analyses

Samples of heavy minerals were collected from Mullere Creek in the central part of the property (Fig. 4.1) and from Betz and San Creeks in the western part of the property (Fig. 4.2). Unlike that for the heavy mineral sampling in August 1981, in September 1982 water was present and flowing in the creeks sampled only in a few short stretches, so that the distances between sampling points are not uniform. They were dictated in part by the
availability of water at the sample locations. Some samples were carried from the sample location to a place where there was sufficient water for panning. As in 1981, the sample number corresponds to the number of metres up the creek from its confluence with Burwash Creek. Three samples were collected on each of the three creeks sampled.

<table>
<thead>
<tr>
<th>Creek</th>
<th>Sampled Length</th>
<th>Number of Samples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mullere</td>
<td>760 m</td>
<td>3</td>
</tr>
<tr>
<td>Betz</td>
<td>855</td>
<td>3</td>
</tr>
<tr>
<td>San</td>
<td>760</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>2375 m</td>
<td>9</td>
</tr>
</tbody>
</table>

At each sample location gravel from the bed of the creek was shovelled into a five-gallon pail with the larger boulders omitted, so that at most sample locations, the boulders omitted from the samples will compensate for the swell of the disturbed gravel. The gravel in the pail was sieved wet with an 8-inch hand sieve and the -10 mesh material panned to about \(\frac{1}{2}\) kg in the field and subsequently to less than 200 g in the office. These concentrates were later dried and the heavy minerals separated at a specific gravity of 2.96. A representative part of the heavy fraction was analyzed by standard atomic absorption techniques for copper, nickel, lead, and zinc, and by neutron activation techniques for gold.

4.2 Results

The analytical results are in appendix 1 and shown in Fig. 4.1 and 4.2. In addition to the results in appendix 1, visible colors of gold were present in two samples as follows:

<table>
<thead>
<tr>
<th>Sample of Colors</th>
<th>Total Weight of Colors</th>
<th>Revised Gold Concentration in Panned Heavy Minerals</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mullere 65</td>
<td>2.23 mg</td>
<td>66,830 ppb</td>
</tr>
<tr>
<td>Mullere 330</td>
<td>1.03</td>
<td>120,880</td>
</tr>
</tbody>
</table>

Addition of these gold colors to the results in appendix 1 indicates that the gold concentrations in the heavy minerals from the panned concentrates should be revised to the values above.
The nine samples collected in 1982 plus the 25 samples collected in 1981 are too few for statistical analyses, but inspection of the results indicates the following:

Gold is very highly anomalous at two locations along Mullere Creek, highly anomalous at one location along Betz Creek, and slightly anomalous at other locations along all three creeks.

Lead is highly anomalous at one location each along Betz and San Creeks, and slightly anomalous at all but two of the other sample locations.

Zinc is anomalous in Betz Creek, and possibly slightly anomalous in one sample from San Creek.

Copper is anomalous in Betz Creek, and slightly anomalous in San Creek.

Nickel may be slightly anomalous in two samples from Betz Creek.

Inspection of the available geological maps suggests that the anomalous concentrations of lead and zinc in samples from Betz and San creeks may be related to a zone near the base of the Hasen Creek Formation. The great decrease in gold concentrations from Mullere 330 to Mullere 760 may be due to the presence of thick glacial deposits at the location of Mullere 760.

Respectfully submitted,

L.B. Halferdahl, Ph.D., P.Eng.

APPENDIX 3: QUALIFICATIONS

L.B. Halferdahl obtained degrees in geological engineering and
geology from Queen's University and The John Hopkins University. He has had
more than 25 years experience as a practising engineer and geologist in
research and mining exploration, including consulting since 1969. He is a
member of the Canadian Institute of Mining and Metallurgy, and is registered
as P.Eng. and P. Geol. in the Association of Professional Engineers, Geologists,
and Geophysicists of Alberta, and licensed as P.Eng. in the Association of
Professional Engineers of British Columbia.
