INTRODUCTION

The Nikki property is located within the Kluane Ranges of southwestern Yukon. It is owned 100% by ATAC Resources Ltd. and is under option to Kria Resources Inc. It was staked in June 2004 to cover a gold-copper porphyry target marked by an aeromagnetic high and strongly anomalous results from a regional stream sediment geochemical survey.

The 2006 exploration program was managed by Archer, Cathro & Associates (1981) Limited under the author's supervision. Work was completed utilizing two or three person crews in two separate phases. The initial phase entailed grid and contour soil sampling, stream sediment sampling, geological mapping, prospecting, hand trenching and additional claim staking, all conducted between June 24 and July 10. The second phase was done between August 22 and September 13 and involved more grid soil sampling. All of the work was helicopter supported. The author's Statement of Qualifications appears in Appendix I.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The Nikki property consists of 40 contiguous mineral claims located in southwestern Yukon at latitude 62°03'N and longitude 140°58'W on NTS 115 K/02. The general location of the property is shown on Figure 1 while the locations of individual claims are displayed on Figure 2. The claims were staked under the Yukon Quartz Mining Act and are registered with the Whitehorse Mining Recorder in the name of Archer Cathro, which holds them in trust for ATAC. The claims cover an area of approximately 800 hectares. Mineral claim tenure information is summarized as follows.

<u>Claim Name</u>	<u>Grant Number</u>	<u>Expiry Date*</u>

35-40	YC47495-YC47500	August 2, 2007

*Expiry dates do not include 2006 work that has not yet been filed for assessment credit.

The Nikki property is located immediately east of the Canada-United States border, 18 km west-northwest of the White River Lodge which is located 375 km northwest of Whitehorse via the Alaska Highway. Access in 2006 was by Bell 206 B helicopters operated by Trans North Helicopters and Kluane Helicopters from their bases in Haines Junction, 235 km to the southeast.

PREVIOUS WORK

The Nikki property was first staked as a copper target in 1910 and later restaked as the Trudi claims in 1968. In 1971 Quintana Minerals Corp. Ltd. optioned the Trudi claims and conducted grid soil sampling, geological mapping and 290.17 m of diamond drilling in two holes (Deklerk, 2003). Soil sampling identified an 1830 m long by 610 m wide zone of weakly to moderately intense copper response.

One diamond drill hole (DDH 1) reportedly returned an average grade of 0.12% Cu with 0.007% MoS₂ across 140.21 m and the other (DDH 2) 0.15% Cu with 0.003% MoS₂ across 149.96 m. No drill logs or individual assays are available. No assays were reported for gold from core or soil samples.

Government funded, regional stream sediment sampling later returned elevated gold and copper values from a creek draining the property. Both gold and copper values returned results in the 98th percentile range, 134 ppb and 124 ppm, respectively (Hornbrook, et al., 1986). Government regional aeromagnetic surveys had identified a magnetic high in the headwaters of the geochemically anomalous creek on what is now the Nikki property.

ATAC briefly prospected and soil sampled in the vicinity of the old drill holes in 2002. This work confirmed the target but it was not staked until June 2004. Exploration later that year included grid and contour soil sampling, stream sediment sampling, geological mapping, prospecting, and an induced polarization survey (Eaton, 2005).

GEOMORPHOLOGY AND VEGETATION

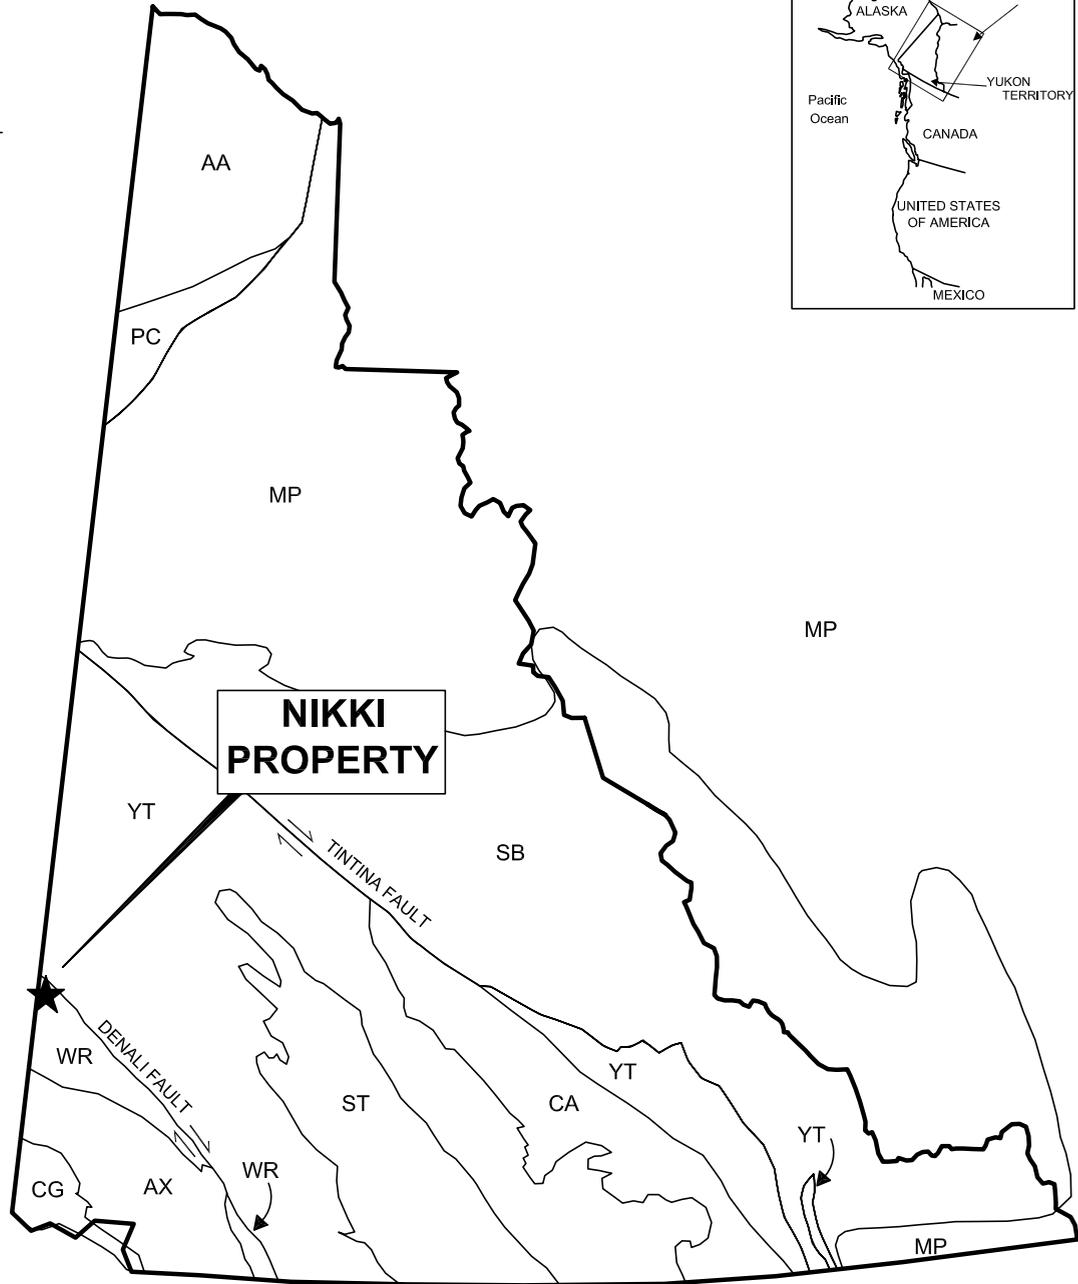

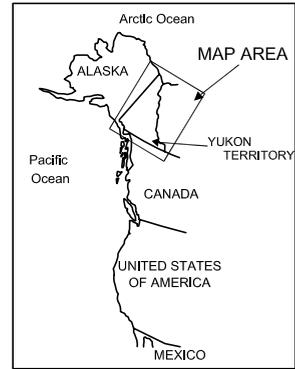

The Nikki property lies within the Nutzotin Range immediately southwest of the Shakwak Trench. It is in an alpine setting and is centred on a major ridge running east-west with series of spurs radiating from it. Local elevations range from about 1950 m atop the central ridge to 1160 m along a creek in the southeastern corner of the property. Recent valley glaciation is marked by lateral moraines, the tops of which are at about 1250 m. Outcrop occurs mostly near ridge crests and along actively eroding creeks. Upper slopes are predominantly talus covered and average about 30°. Gentler slopes in the southern part of the property are typically soil or till covered. The lower areas are vegetated with grass, buckbrush, stunted spruce and dwarf birch.

Creeks draining the property contain enough water to support diamond drilling if necessary, but long waterlines will be required to reach some areas. Streams draining the southern and eastern parts of the property flow into Beaver Creek, a tributary of White River.

REGIONAL GEOLOGY

The Nikki property is located within Wrangellia, a Paleozoic to Early Mesozoic volcanic arc complex that was accreted to North America in Mid-Jurassic times (Figure 3). The property lies between two major, high angle faults: the Denali Fault about 10 km to the northeast; and, a smaller unnamed fault directly south of the property, which is one of a series of secondary structures that approximately parallel the Denali Fault. Movement on the Denali Fault involves hundreds of kilometres of dextral strike-slip. Sense of motion on the smaller fault is uncertain.

The regional stratigraphic section consists of: Pennsylvanian to Lower Permian Skolai Group volcanic and sedimentary rocks; Upper Triassic Nikolai Formation basalt and andesite flows; Upper Triassic Chitistone Formation limestone; and, Lower Cretaceous Dezadeash Formation fine grained clastic sediments (Gordey and Makepeace, 1999). The Skolai Group contains: tuff breccia, argillite, agglomerate and basaltic to andesitic flows belonging to the Station Creek

Formation; and, thin bedded argillite, siltstone, minor greywacke and conglomerate, with local thin basaltic flows, breccias and tuffs of the overlying Hasen Creek Formation.

The stratified units are intruded by Late Cretaceous medium to coarse grained stocks and dykes of predominantly granodiorite to diorite composition and Oligocene plugs and dykes of intermediate to felsic composition.

The Denali fault juxtaposes Wrangellia against units belonging to the Yukon-Tanana Terrane. The unnamed fault immediately south of the property separates predominantly Skolai Group rocks to the north from younger stratigraphy to the south.

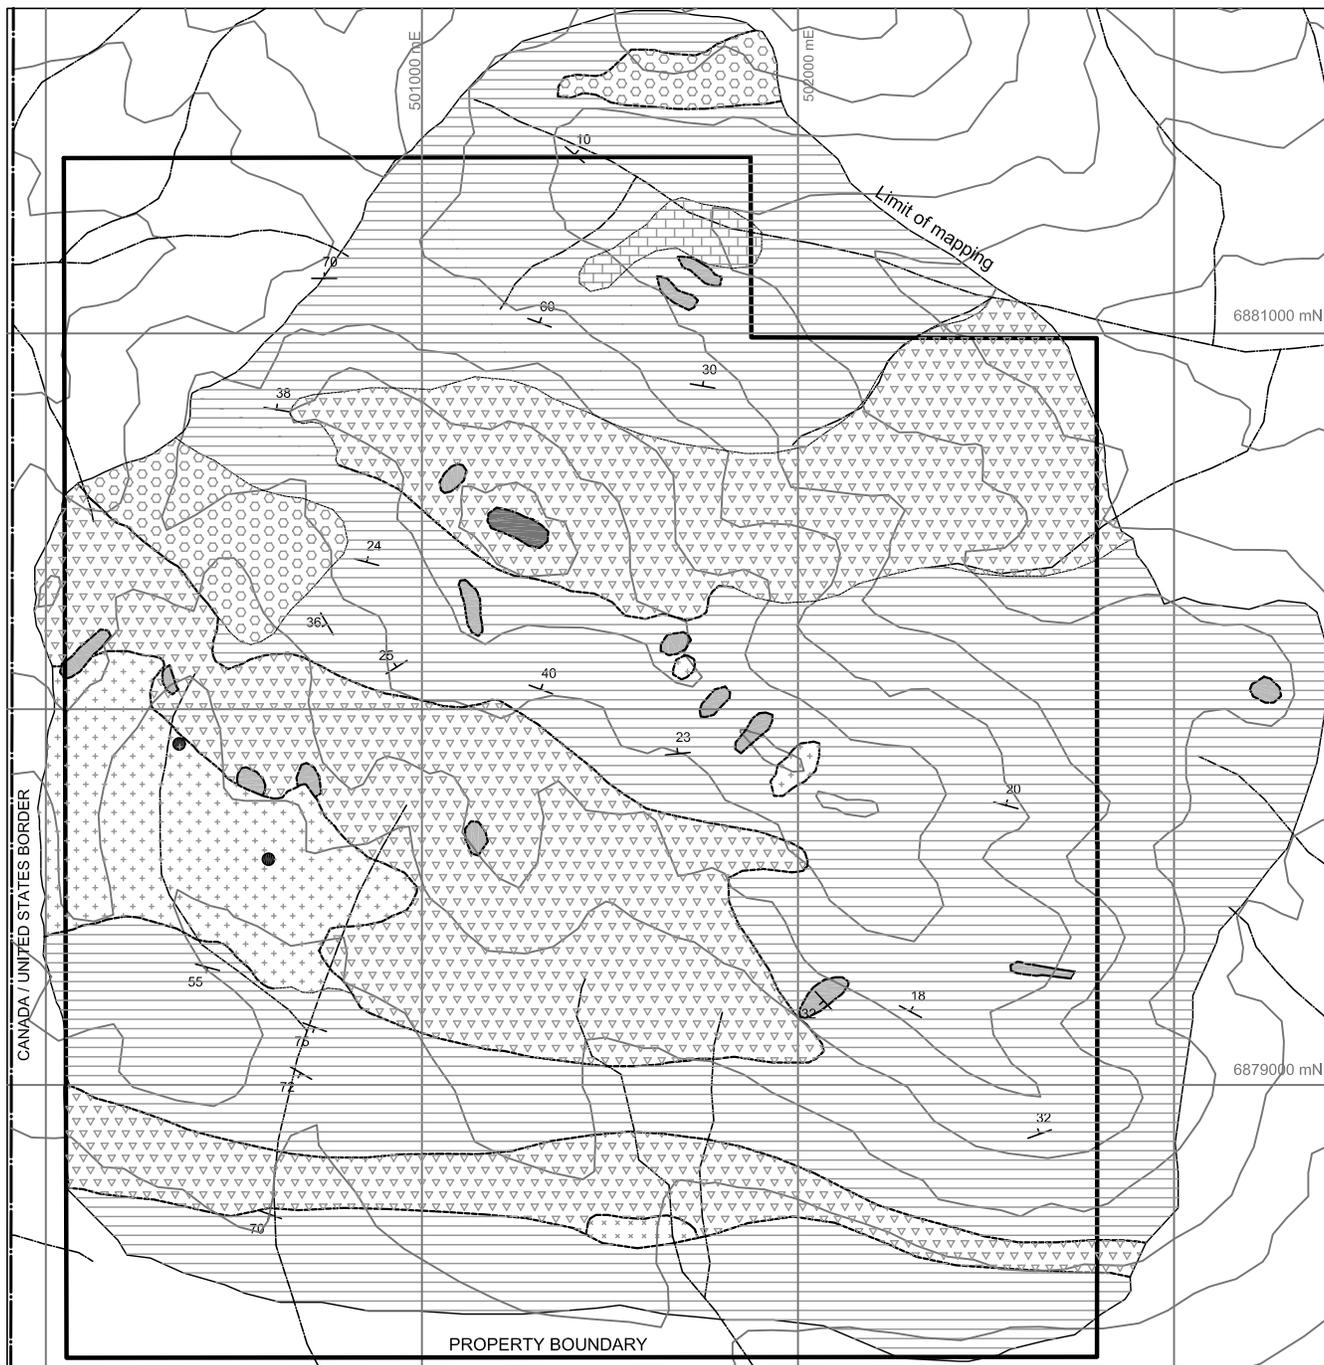

PROPERTY GEOLOGY

The geology of the Nikki property was mapped by Archer Cathro crews working on behalf of ATAC in 2004 and Kria in 2006. The porphyry style mineralization is hosted in a high level system of dykes and plugs belonging to the Kluane Range Plutonic Suite and in adjacent variably metamorphosed sedimentary rocks. Property geology is illustrated on Figure 4 while the main features are discussed in the following paragraphs.

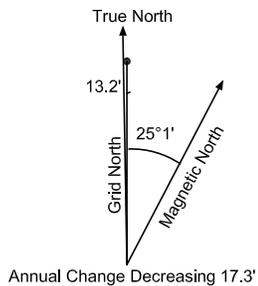

The oldest rocks on the Nikki property belong to the Hasen Creek Formation which forms the upper part of the Pennsylvanian to Lower Permian Skolai Group. This unit consists primarily of siliceous argillite with interbedded mudstone and rare lenses of limestone, the largest of which is a 375 by 150 m lens that outcrops in the northern part of the property. A 150 by 50 m area of skarn capping the highest peak on the property is likely a xenolith of limestone that is strongly altered to a coarse grained mixture of epidote, chlorite, and tremolite. Non-limy sections of the Hasen Creek Formation are extensively altered to rusty weathering hornfels.

The most abundant and earliest intrusive unit is medium grained diorite consisting of 10 to 40% hornblende and 55 to 68% plagioclase. The diorite forms three easterly trending dykes. The most northerly dyke is up to 500 m wide and was traced for 2200 m along strike before continuing further to the east off the property. The centre dyke reaches a maximum width of 900 m and was traced about 2300 m along strike before extending westward into Alaska. The southernmost dyke is only exposed intermittently in outcrop but is projected to extend across the entire property. It is up to 300 m thick and at least 3000 m long.

The second oldest and second most abundant intrusive unit is granodiorite. It is strongly porphyritic and contains: 20% to 40% subhedral, 1.5 to 3 mm plagioclase phenocrysts; up to 5%, 3 mm diameter quartz phenocrysts; and, about 3%, 2 mm hornblende phenocrysts, all in a fine pale grey-green matrix. Rounded, up to 1 cm fragments of bleached and strongly pyritic diorite are observed to comprise up to 5% of the rock on sawn faces but they are difficult to recognize on weathered surfaces or broken faces. The granodiorite is often clay altered along fractures and weathers to a yellow-orange colour. Calcite-pyrite veinlets are abundant, ranging from 1-8 mm wide. The main granodiorite exposures are part of a plug situated between the central diorite sill and adjacent argillite wallrock. This plug is approximately 850 m wide and extends for a length of 1000 m before continuing westward into Alaska. Smaller satellite plugs are located on the margin of the southern dyke and along the ridge crest near the centre of the property.

NIKKI PROPERTY

Dark green to black, fine to medium grained gabbro plugs and dykes are scattered across the property. They commonly cut diorite and argillite, and at one location are seen intruding granodiorite. The gabbro bodies are all less than 100 m wide and do not exceed 200 m in length.

The youngest unit on the property is probably quartz-feldspar porphyry. This unit forms two plugs near the eastern and northern edges of the property. The largest plug is about 400 m wide and is more than 500 m long. The quartz-feldspar porphyry typically contains about 20% quartz and feldspar phenocrysts in a very fine grained, greenish blue-grey matrix. The phenocrysts are up to 1 cm across.

Bedding within the northern half of the property dips shallowly to the north and in the southern half dips moderately to the south. This suggests that the centre diorite dyke and largest granodiorite plug have intruded along an anticlinal axis that trends northwesterly across the property.

Although no large scale faults have been mapped on the property, up to 2 m wide shear zones have been reported. These structures trend northerly, dip steeply and characteristically contain gouge. Quartz-sulphide vein float is common. When observed in bedrock, the veins are about 10 cm wide, strike northeasterly and dip steeply.

MINERALIZATION

A total of 55 grab and chip samples were collected in 2006. All were sent to ALS Chemex in North Vancouver where they were fine crushed to better than 70% passing -2mm, then a 250 g split was pulverized so that better than 85% passed 75 microns. Splits of the pulverized material were analyzed for gold using fire assay and atomic absorption spectroscopy, and for 34 other elements by aqua regia digestion followed by inductively coupled plasma- atomic emission spectroscopy. Sample locations and results are shown on Figure 5. Certificates of Analysis are in Appendix II while rock sample descriptions are in Appendix III.

The porphyry style mineralization exposed at the Nikki property is associated with a relatively high level intrusive complex of Late Cretaceous age. Fracture filling pyrite, chalcopyrite and their oxidized equivalents (limonite, malachite and azurite) occur in a northwesterly elongated zone that is about 800 m long by 300 m wide. This zone is flanked on the northeast side by a few small skarn zones and by precious metal enriched veins and shears (Figure 5). The southwestern side of the zone is mostly covered by talus or glacial material.

There are relatively few outcrop exposures of the fracture filling, porphyry style mineralization. Where observed, the host rocks exhibit pervasive propylitic alteration with localized areas of argillic alteration. Fractures are typically limonitic and less frequently copper stained. Residual sulphide grains are common in some exposures, especially along rapidly eroding creek banks.

Little rock sampling has been done within the area of porphyry style mineralization. In 2006, two hand trenches were dug to bedrock on a grassy ridge about midway between the reported locations of the two 1971 diamond drill holes. Three chip samples along the length of one trench

averaged 0.38% copper, 0.364 g/t gold and 1.6 g/t silver over 6 m. Five chip samples from the other trench graded 0.47% copper, 0.194 g/t gold and 3.0 g/t silver over 8 m.

Prospecting and hand trenching along the ridge top 500 to 1000 m north and east of the above mentioned trenches identified scattered vein and shear hosted mineralization. Grab samples and chip samples from this type of material typically grade between 0.1 and 1 g/t gold with 1 to 10 g/t silver. Two chip samples across the best vein exposed by hand trenching averaged 0.898 g/t gold and 3.8 g/t silver over 2 m. The vein and shear mineralization generally contains less copper than the porphyry style fracture filling mineralization but has more lead, zinc, arsenic and bismuth.

Prospecting along the ridge top also identified one area of chalcopyrite bearing skarn. A hand trench dug across this target in 2006 exposed an area of highly fractured bedrock, from which a 2 m long chip sample returned 11.95 g/t gold and 7.0 g/t silver.

GEOCHEMISTRY

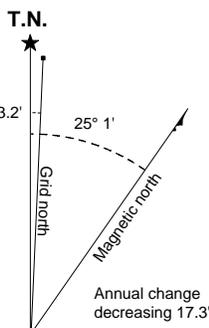

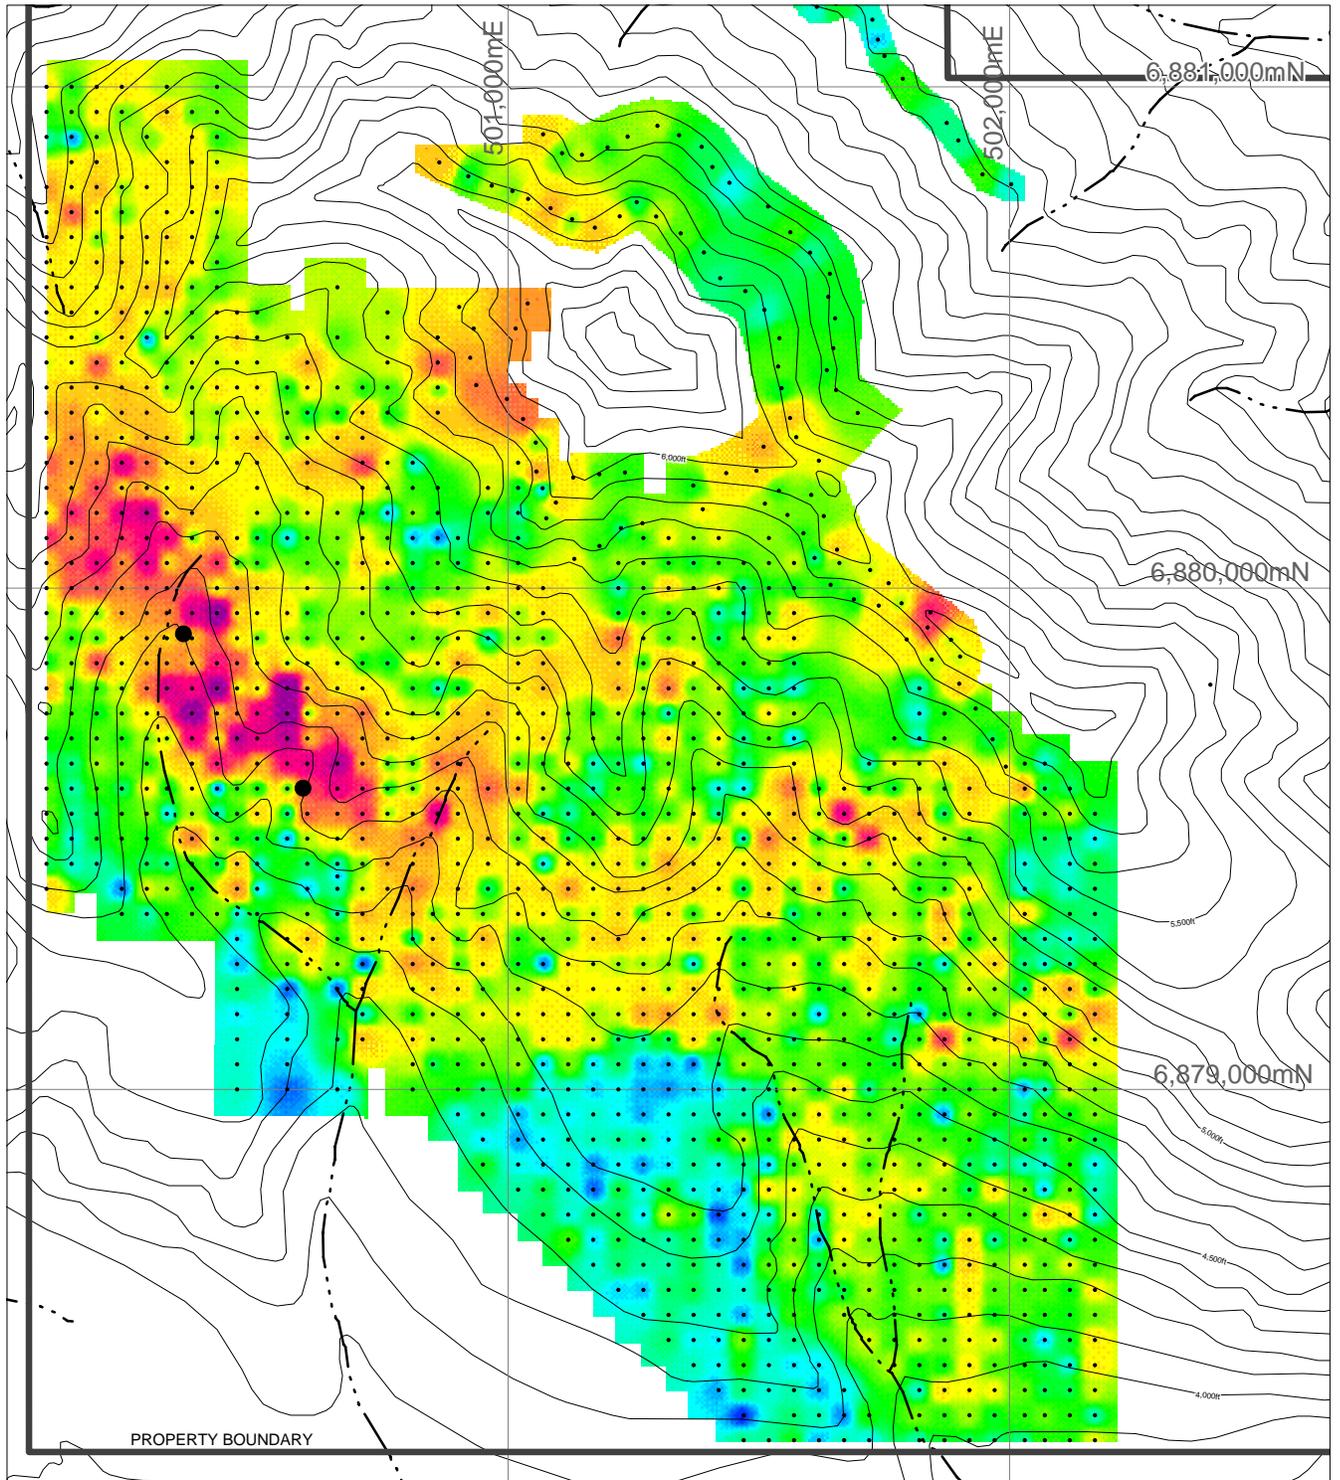

A total of 1309 soil and 14 stream sediment samples were collected in 2006. The samples were sent to ALS Chemex in North Vancouver. Soils and stream sediments were dried and screened to -180 microns. Splits were then analyzed for gold using fire assay and atomic absorption spectroscopy, and for 34 other elements by aqua regia digestion followed by inductively coupled plasma-atomic emission spectroscopy. Stream sediment sample locations appear on Figure 5. Soil sample locations are shown on Figure 6 while copper, molybdenum, gold, lead and zinc results are illustrated on Figures 7 to 11, respectively. Certificates of Analysis are contained in Appendix II.

In 2004 and 2006, stream sediment samples were collected from small creeks draining different parts of the property. Most of these samples returned anomalous copper values when compared to regional backgrounds (>150 ppm vs. backgrounds of 35 ppm or less). The highest values (414 to 564 ppm Cu) were obtained from sediments collected within the area of porphyry style mineralization or up to 1000 m downstream from it. Gold values are well correlated with copper values.

The 2006 soil sampling expanded the area of grid coverage and tightened the density of samples. Grid sampling in 2006 was done at 50 m intervals on lines spaced 50 m apart. Some additional contour sampling was also done peripheral to the grid. These samples taken at 50 to 100 m intervals on lines spaced 150 to 800 m apart. Sample locations are marked with 0.5 m lath bearing aluminium tags inscribed with the sample number. Soil development is immature and samples largely consist of C horizon soil and talus fines.

The combined 2004 and 2006 soil sampling outlined moderately to strongly anomalous values for various metals in different parts of the property.

Copper values are highest (500 to 2750 ppm) in an 1100 m long by approximately 250 m wide zone that encompasses the area of porphyry style mineralization (Figure 7). The zone is elongated in a northwesterly direction and is open to extension further to the northwest into

Alaska. At its southeast end the main zone of anomalous values appear to arc toward the northeast; however, this could be due to mixing of anomalous soils related to veins with those derived from porphyry style mineralization. Other smaller areas of elevated values can mostly be attributed to vein or skarn mineralization.

Molybdenum values are highest (10 to 204 ppm) and most tightly clustered toward the southeastern end of the main copper anomaly; however, they also show the same, arcuate extension trailing off to the northeast (Figure 8).

The most consistently high gold values (50 to 1590 ppb) generally follow the main copper zone but are offset slightly to the north or uphill side (Figure 9). Scattered high values (up to 611 ppb) are located to the north and east of the copper zone in the vicinity of precious metal bearing veins and skarn mineralization.

Silver, lead and zinc values are closely correlated. All three returned background to weakly anomalous values in the area of the porphyry style mineralization but produced clusters of high values to the north and east (Figures 10 and 11). Moderately to strongly anomalous values (200 to 5830 ppm Pb, 200 to 6010 ppm Zn and 5 to 83.7 ppm Ag) are most abundant near precious metal vein and skarn occurrences.

GEOPHYSICS

High level aeromagnetic surveys conducted over the Kluane Ranges on behalf of the Geological Survey of Canada identified a 3 km diameter area of high magnetic susceptibility, centred directly on the Nikki property. This anomaly shows sharp contrast with the relatively uniform low susceptibility associated with the surrounding sediments. The positive magnetic response is likely due to disseminated magnetite, which comprises up to 5% of some diorite specimens.

Induced polarization and resistivity surveys were completed over a total of 15.1 line km between August 24 and September 7, 2004 (Power, 2004). The following paragraphs summarize results.

A band of low resistivity approximately coincides with the granodiorite. This band is approximately 400 to 500 m wide near the western property boundary and pinches to approximately 100 m wide toward the east. A chargeability high follows the northeastern boundary of the low in the west and passes under it in the east.

The main gold geochemical anomaly lies on the southwestern (downhill) edge of the main chargeability high. The core of that copper anomaly is displaced slightly downhill into the resistivity low where Quintana's drill holes are located.

CONCLUSION AND RECOMENDATIONS

The Nikki property hosts porphyry style gold-copper mineralization associated with Cretaceous or younger intrusions cutting a Permo-Triassic island arc assemblage. The associated intrusions were emplaced in an extensional environment that followed accretion of Wrangellia to North America. They contain little free quartz. Thus, mineralization and alteration are more likely to

follow the “diorite or alkalic” porphyry model rather than the more common “calc-alkaline” model. Figure 12 is a schematic diagram showing alteration zonation and metal distribution in an idealized alkalic porphyry system.

The widespread propylitic alteration that has been observed at Nikki is consistent with the alkalic porphyry model, as is the absence of pervasive argillic or phyllic alteration zones. The lack of an outcropping, strongly potassic altered core is explained by the high level nature of the system. The current level of erosion exposes only the propylitic shell and hornfels halo. Deeper erosion would be required to expose the potassic core. The high level nature of the system is further indicated by the geochemical response which includes elevated lead and zinc as well as copper and gold. If the core of the porphyry body were exposed, the lead and zinc values would be expected to form a more distal halo surrounding the copper-gold mineralization.

The presence of a magnetic high is also consistent with the alkalic exploration model while the chargeability and resistivity results support the geochemical data, indicating a large hydrothermal system.

Most of the area of interest is talus or soil covered. Although Quintana’s 1971 drill holes returned subeconomic grades for copper, they explored to a relatively shallow depth and were located downhill from the main gold-in-soil anomaly in a zone of low chargeability. The importance of the holes is difficult to assess because no detailed assay or geological information is available and the core could not be located.

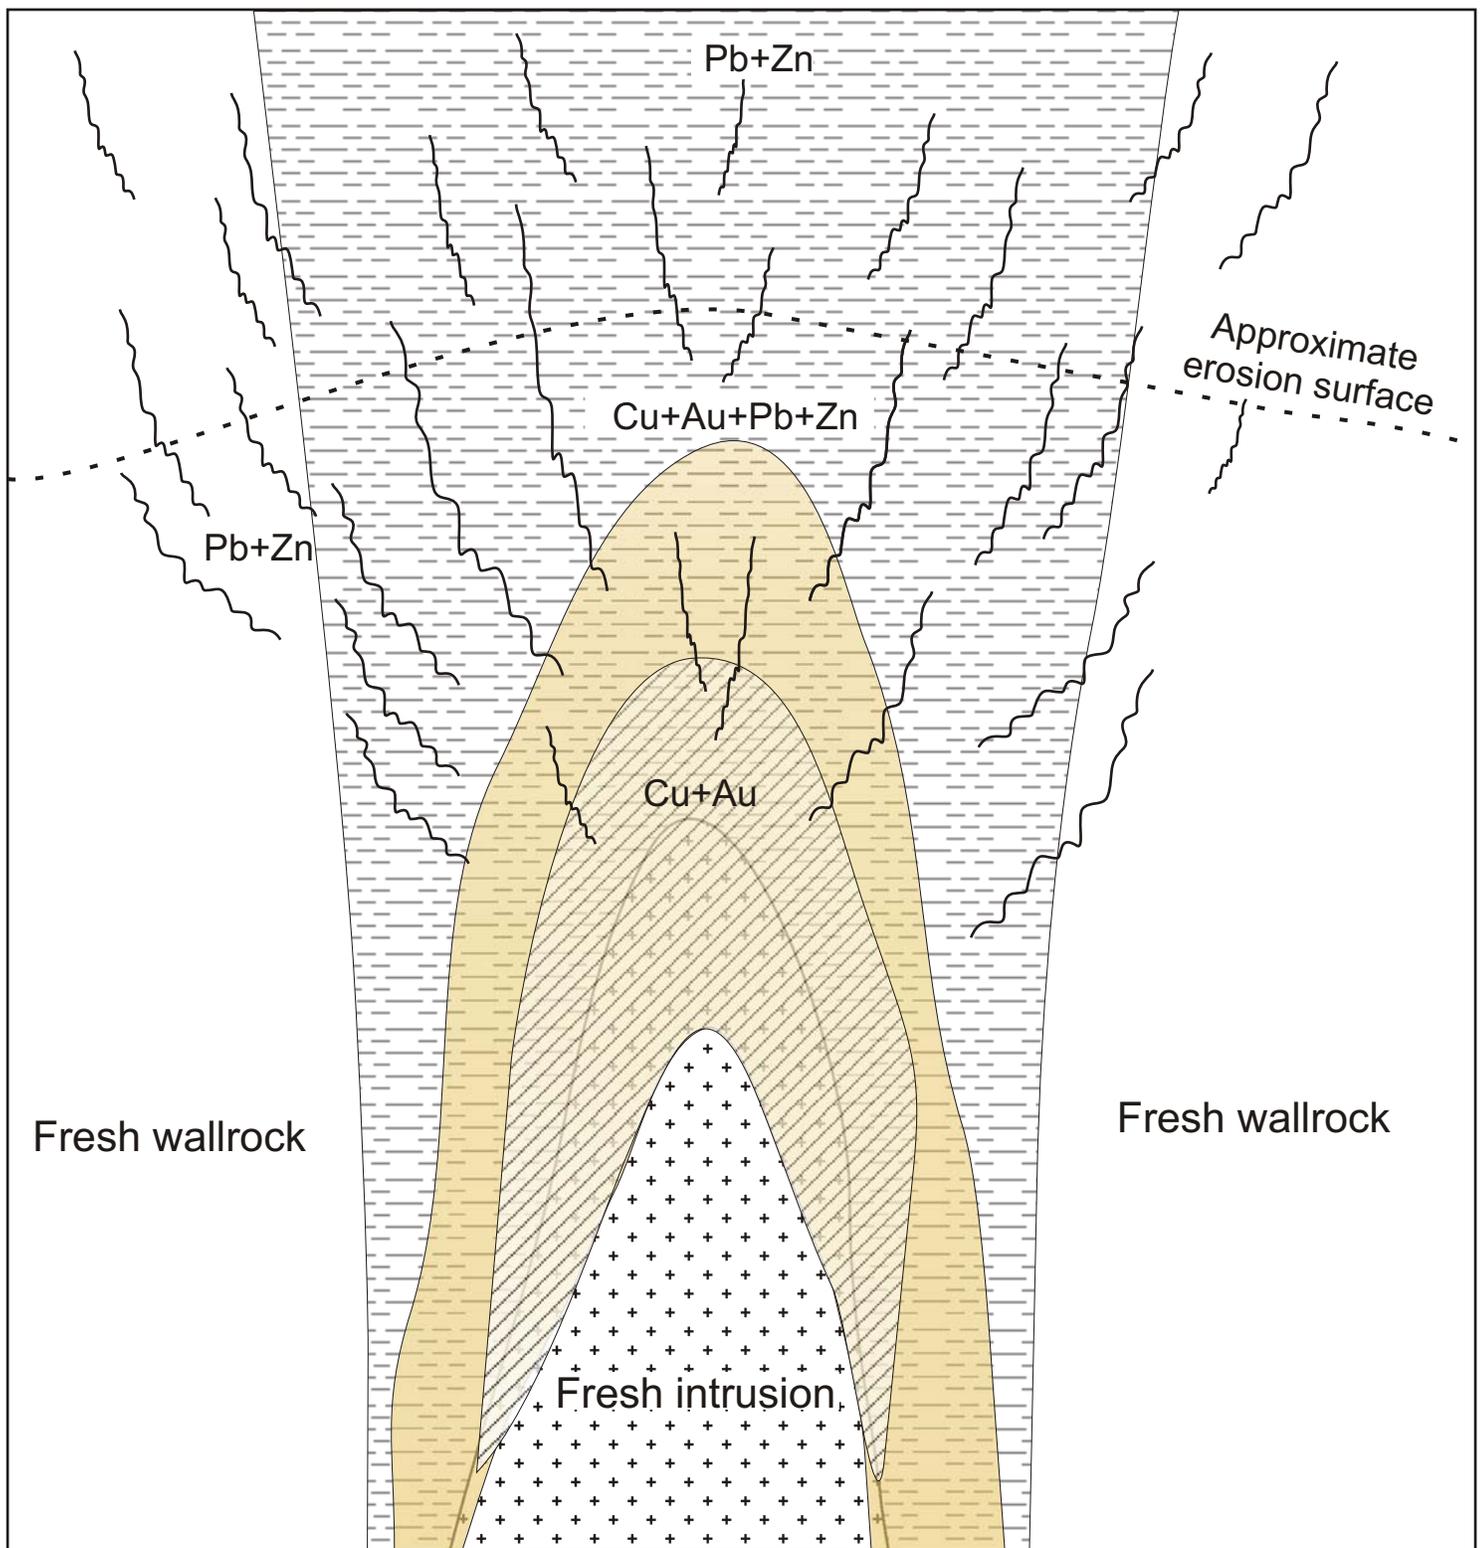

The porphyry system at Nikki clearly extends northwesterly into Alaska. Unfortunately, the adjacent area is a game preserve where no staking is allowed. Proximity to the border is a concern but there is ample room to develop a porphyry size deposit on Canadian soil. Relatively easy access to Nikki is possible from the Alaska Highway and creeks draining the area of interest flow into Canada.

The Nikki property definitely deserves more exploration to test for a porphyry gold-copper deposit. The next stage of exploration should consist of diamond drill holes extending to depths of at least 300 m to establish alteration zonation, metal distribution and grade variability.

SAMPLE PREPARATION	
ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

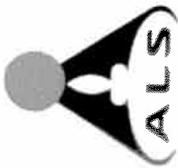

ANALYTICAL PROCEDURES		
ALS CODE	DESCRIPTION	INSTRUMENT
ME-ICP41	34 Element Aqua Regia ICP-AES	ICP-AES
Ag-OG46	Ore Grade Ag - Aqua Regia	VARIABLE
ME-OG46	Ore Grade Elements - Aqua Regia	ICP-AES
Zn-OG46	Ore Grade Zn - Aqua Regia	VARIABLE
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM

APPENDIX III
ROCK SAMPLE DESCRIPTIONS

Rock Sample Descriptions

Project: Nikki

Property: Nikki

Sample Number: C103424
 Grid East: 500065 E
 UTM: 6880215 N
 Elevation: m
 Grid North: N
 Type: Chip
 Sample Width: 2m
 Dimension: moderately
 Abundance: moderately

Comments: Chip sample over 2m of a cpy and py rich (disseminations) in an altered diorite rock. Coarse grained.

Sample Number: C103425
 Grid East: 500060 E
 UTM: 6880210 N
 Elevation: m
 Grid North: N
 Type: Rock
 Sample Width: 1 foot
 Dimension: 2.5 m
 Abundance: moderately

Comments: Sample of magnetite skarn with very coarse crystalline texture. Chalcopyrite is disseminated throughout. Actinolite-magnetite skarn with minor epidote.

Sample Number: C103426
 Grid East: 500082 E
 UTM: 6880544 N
 Elevation: m
 Grid North: N
 Type: Chip
 Sample Width: 1.5 feet
 Dimension: 6m
 Abundance: o/c

Comments: Sample of light green siliceous rock, (chert?, clac-silicate...) with abundant cpy and py disseminated.

Sample Number: C103427
 Grid East: 500089 E
 UTM: 6880537 N
 Elevation: m
 Grid North: N
 Type: Float
 Sample Width:
 Dimension: sparse
 Abundance: sparse

Comments: Rock sample thought to be very close to source. No others in vicinity i.e upslope. Fracture controlled and disseminated cpy and py. Host is a very fine grained silicate rock (poss diorite?)

Sample Number: C103428
 Grid East: 500360 E

Comments: 2m chip sample from TR-06-06, sample of very fine grained propylitic altered diorite with few 2mm hbl crystals that have been extremely altered. Up to 3mm blebs of cpy disseminated and concentrated along green alteration fractures. Rock is dominant type in this end of the trench.

Sample Number: B395957 Grid East: E Grid North: N Type: Chip Dimension: Abundance: UTM: UTM: Sample Width: 2m

Comments: 2m chip also from TR-06-06, to the east of 956 in trench. Rock type is very fine grained green-grey siliceous rock with fine cpy disseminated throughout with fine cpy and pyrite concentrated on fracture surfaces. Orange-red oxidized staining on some surfaces, penetrating in as far as 3mm.

Sample Number: 3395958 Grid East: E Grid North: N Type: Chip Dimension: Abundance: UTM: UTM: Sample Width: 2m

Comments: Final 2m chip sample from TR-06-06. Thought to be very close to in situ. Red-orange altered fracture surfaces, cpy mzn disseminated and py and cpy on fracture surfaces. nature as 956 except they were barren.

Sample Number: 3395959 Grid East: E Grid North: N Type: Float Dimension: Abundance: UTM: UTM: Sample Width: 1 foot

Comments: Rock found in talus train, 1 foot by 1 foot. Dark green groundmass with very coarse cpy and py mineralization throughout. Boxworking present in tarnish on the rock freshly broken surface.

Sample Number: 3395960 Grid East: E Grid North: N Type: Chip Dimension: Abundance: UTM: UTM: Sample Width: 2M

Comments: TR-06-07. 2m chip combo of unmineralized fine grained propylitic altered diorite, minor quartz rich mineralized material with small areas of almost black boxwork, fine grained siliceous rock with lots of cpy mineralization disseminated throughout.

Sample Number: 395961 Grid East: E Grid North: N Type: Chip Dimension: Abundance: UTM: UTM: Sample Width: 2m

Comments: chip sample adjacent to 960, same material with cpy being the main mineralization. Some yellow fault gauge material found in this chip sample area was sampled also.

Sample Number: 395962 Grid East: E Grid North: N Type: Chip Dimension: Abundance: UTM: UTM: Sample Width: 3m

Comments: Final chip sample from TR-06-07, end of trench is a 3m grab sample of felsenmeener in pit bottom. Cpy mineralization in fine grained porphyry rock, disseminated mineralization in siliceous rock, fine grained intrusive rocks mineralized also. Mixed grab sample from trench bottom.

Sample Number: 395963 Grid East: 501017 E UTM: 6880706 N Grid North: 6880706 N Type: Chip Dimension: Abundance: Sample Width: 1m

Comments: Very fine grained propylitic diorite with fine disseminations of cpy. No apparent fracture control on mineralization.

Sample Number: 395964 Grid East: 501019 E UTM: 6880696 N Grid North: 6880696 N Type: Chip Dimension: Abundance: Sample Width: 2m

Comments: 2m chip sample over perpendicular direction to beds. Most of the outcrop is mineralized, some areas have a higher concentration of mineralization than others. beds. Could be a skarn horizon??? Very mineralized with py and cpy, some fracture controlled mineralization.
