INTRODUCTION

The Connaught project hosts an extensive system of silver-lead-gold veins located in the Sixtymile placer gold camp of western Yukon Territory. The project is comprised of 226 CN and NC claims, which are owned by a 50-50 joint venture between ATAC Resources Ltd. and Klondike Silver Corp., and 24 Mag claims, which are under option to ATAC and Klondike Silver from an independent prospector (the Nordling Option). The companies can collectively earn a 100% interest in the Mag claims subject to a Net Smelter Return royalty (NSR) payable to the prospector.

This report describes a program of soil sampling, excavator trenching and excavator stripping performed by Archer Cathro & Associates (1981) Limited on behalf of ATAC and Klondike Silver between June 28 and August 21, 2008. The senior author supervised the program and the junior author participated in the work. Their Statements of Qualifications appears in Appendix I.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The Connaught project consists of 250 contiguous mineral claims located in western Yukon at latitude 63°55' north and longitude 140°48' west on NTS map sheet 115N/15 (Figure 1). The claims are all registered with the Dawson Mining Recorder. The CN and NC claims are filed in the name of Archer Cathro, which holds them in trust for ATAC, the operator of the joint venture. The Mag claims are registered to R. Nordling, the prospector who owns them. Claim data are listed below while the locations of individual claims are shown on Figure 2.

* Expiry dates include 2008 work which has been filed for assessment credit but not yet accepted.

The property lies 65 km due west of Dawson City and can be reached by four wheel drive vehicle via the Sixtymile Road, which runs south from the Top of the World Highway. An extensive system of bush roads and trails exist on the property but to reach them, the Sixtymile River must be forded. During spring runoff and following major storms, this ford is sometimes impassable. The Top of the World Highway extends west from Dawson City into Alaska. It is

open during summer and fall when the ferry across the Yukon River is in service. Dawson City is situated 536 km by road north of Whitehorse, the Yukon's main supply centre, and is reached via the all-season Klondike Highway. Helicopters are based in Dawson City but were not utilized during the 2008 exploration program.

PREVIOUS WORK

This section summarizes pre-2008 exploration activities in the Connaught project area. Figure 3 illustrates the locations of veins and soil geochemical grids described in the following paragraphs.

Although silver-lead-gold veins were likely found in the Sixtymile area in the late 1890s, the first reported discovery was made by J. Lerner and M. Chefkoi in 1965. Their exploration consisted of "cold extraction" soil geochemistry and prospecting, which led to claim staking. Lerner and Chefkoi optioned the claims to A. Moisey, who later transferred them to the Sixtymile Mining Company Ltd.

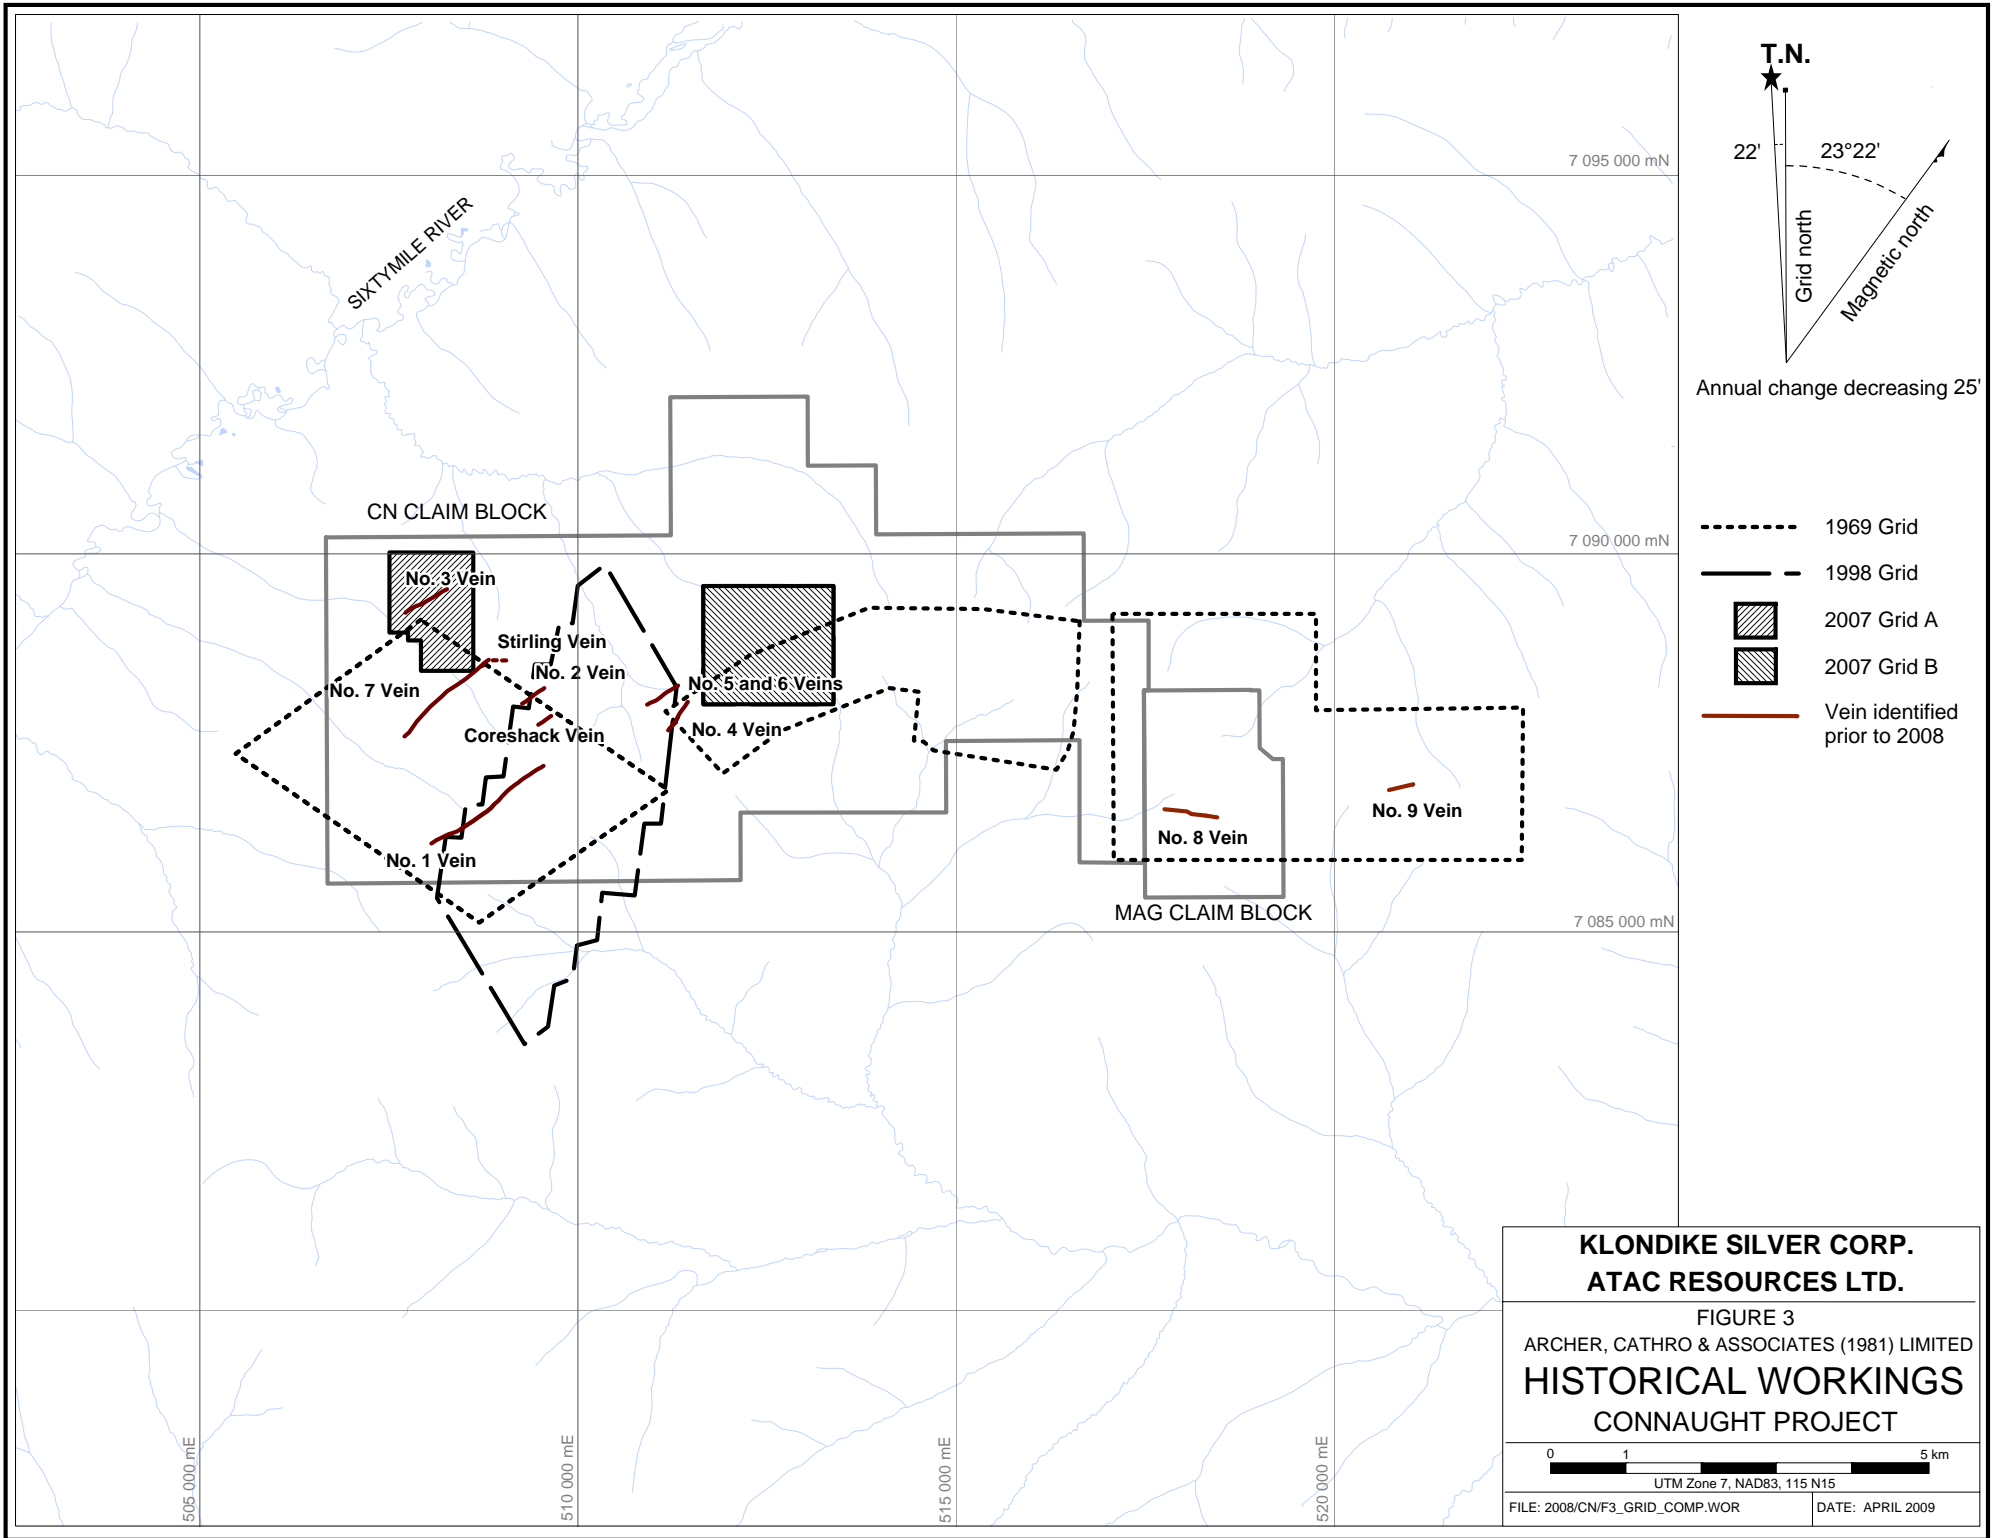

In 1966 and 1967, Sixtymile Mining carried out bulldozer trenching and electromagnetic (EM) surveys. The trenching uncovered substantial lenses of massive galena on the No. 1 and No. 3 veins. In summer 1966, a total of 22.7 tonnes of hand sorted material was collected from open cuts on the No. 1 and No. 3 veins, and shipped to the Cominco smelter at Trail, BC (Harper, 1967). This shipment averaged 2297 g/t Ag, 67.3% Pb and 2.1 g/t Au (Cholach, 1969).

During 1968 and 1969, the property was held under option by Connaught Mines Ltd, which completed geological mapping, geochemical sampling, 35,200 m³ of bulldozer trenching and 431.8 m of diamond drilling in eight holes. The 1969 soil sampling covered much of the property and generated new silver-lead targets. It also identified strong copper response in irregular clusters away from the veins. Bulldozer trenching on the geochemical anomalies led to the discovery or delineation of more vein zones, the best of which were the No. 4, No. 7 and No. 8 (Archer, 1969). Six of the diamond drill holes tested the No. 1 Vein and the other two holes explored the No. 3 Vein. Most of the holes intersected variably mineralized vein structures (Cholach, 1969).

In 1976, Connaught Mines transferred its interest to A. Tottrup, who optioned the property to J. Lerner. That summer J. Lerner extracted an additional 218 tonnes of ore from shallow pits on the No. 1 and No. 3 Veins and shipped it to the Asarco smelter in East Helena, Montana. Combined, the 1966 and 1976 shipments totalled 240.7 tonnes at an average grade of 2228.5 g/t Ag, 60% Pb and 1.0 g/t Au.

In 1979, A. Tottrup re-optioned the claims to Westley Mines Ltd. but there is no record of work by that company and the option was dropped after one year.

In 1981, J. Lerner staked sixteen additional claims. The entire claim block was then sold to Loughheed Resources Ltd., which cut trenches on the No. 1 Vein totalling 4134 m³. These trenches were not mapped or sampled until 1982 due to an early snowstorm. The claims were held in good standing by Loughheed Resources for four years but were allowed to lapse in 1986.

HISTORICAL WORKINGS
CONNAUGHT PROJECT

FILE: 2008/CN/F3_GRID_COMP.WOR

DATE: APRIL 2009

In spring 1987, Walhalla Exploration Ltd. restaked the core of the property and optioned the claims to Croesus Resources Inc., which sub-optioned part of the claim block to Red Fox Minerals Ltd. and Kelan Resources Ltd. Aurum Geological Consultants Inc. was contracted to conduct an exploration program that consisted of geological mapping, geochemical sampling, geophysical surveys and bulldozer trenching (Price, 1988). The following year, Kelan Resources and Croesus Resources completed 315.8 m of diamond drilling in ten holes. Three of the holes tested the No. 9 Vein, which is on claims that adjoin the Connaught project but which are owned by another party (see Figures 2 and 3). Another of the holes tested the No. 8 Vein and the other six holes explored beneath a magnetite skarn. Both the No. 8 Vein and magnetite skarn are now covered the Mag claims, which comprise the Nordling Option. Also in 1988, Red Fox Minerals drilled a total of 296.4 m in eight holes on the No. 4 Vein. Results from the drilling were not considered to be encouraging and all of the claims were allowed to lapse.

In 1998, 17363 Yukon Inc. restaked the main showings and surrounding area. It conducted minor prospecting and geochemical sampling before contracting Equity Engineering Ltd. to perform geological mapping and geochemical sampling across the known veins and showings (Harris, 1998).

In 2005, R. Nordling staked the Mag claims.

In spring 2006, the CN and NC claims were staked by ATAC, which immediately optioned them to Klondike Silver. A property-wide helicopter borne VTEM survey was flown that summer.

In 2007, Klondike Silver performed prospecting, soil sampling, excavator trenching and 556 m of diamond drilling in seven holes (Wengzynowski, 2008). Soil sampling was conducted on two grids (referred to as Grids A and B) to follow up anomalies from earlier soil geochemical surveys and from the VTEM survey. Samples from both grids yielded positive results. Trenching led to the discovery of a new vein (Stirling Vein) and the formal recognition of another, previously identified structure (Core Shack Vein). Diamond drilling confirmed down dip continuity of mineralization at the No. 1, No. 3, and No. 4 veins.

In fall 2007, ATAC and Klondike Silver optioned Mag claims from R. Nordling.

GEOMORPHOLOGY AND VEGETATION

The Connaught project is situated in the northern part of the Dawson Range, about 45 km southwest of the Tintina Trench. The Dawson Range features rounded ridges and low peaks, which represent the top of an ancient peneplane plane that has been deeply incised by dendritic drainages. Continental ice sheets did not cover the area but there is evidence of localized alpine glaciation. The property is drained by creeks that flow into the Sixtymile River, part of the Yukon River watershed.

Local elevations range from about 800 m alongside the Sixtymile River to 1500 m atop a ridge near the centre of the claim block. Terrain is subdued with gentle to moderately steep hillsides flanking broad, rounded hilltops. Outcrop is rare and is mostly confined to ridge crests. In areas where drilling had been done, the rocks are typically weathered to about 30 m below surface

(Cholach, 1969). Soil development is good but there has been considerable solifluction on hillsides.

Vegetation varies from mature spruce and poplar forests on the floor of the Sixtymile River valley to sparse, stunted spruce and buckbrush near ridge tops. North facing slopes are often moss covered and permanently frozen, which presents a significant obstacle to soil sampling, trenching and road construction.

GEOLOGY

Geology in the vicinity of the Connaught project was most recently mapped by Mortensen (1996) and put into broader context by Gordey and Makepeace (1999).

The property lies between the Tintina and Denali Faults (Figure 4) within a part of Yukon that is mostly underlain by Yukon-Tanana Terrane. That tectonic terrane is composed of continental margin sediments, island arc volcanics and coeval intrusions, which were metamorphosed and deformed during accretion to the North American continent during Mesozoic times. In the Sixtymile district, the Yukon-Tanana Terrane is subdivided into two stratigraphic elements (the Nasina and Klondike Schist Assemblages) and a metaplutonic package (the South Fiftymile Batholith). The Yukon-Tanana units are intruded by undeformed, Late Cretaceous plugs and stocks.

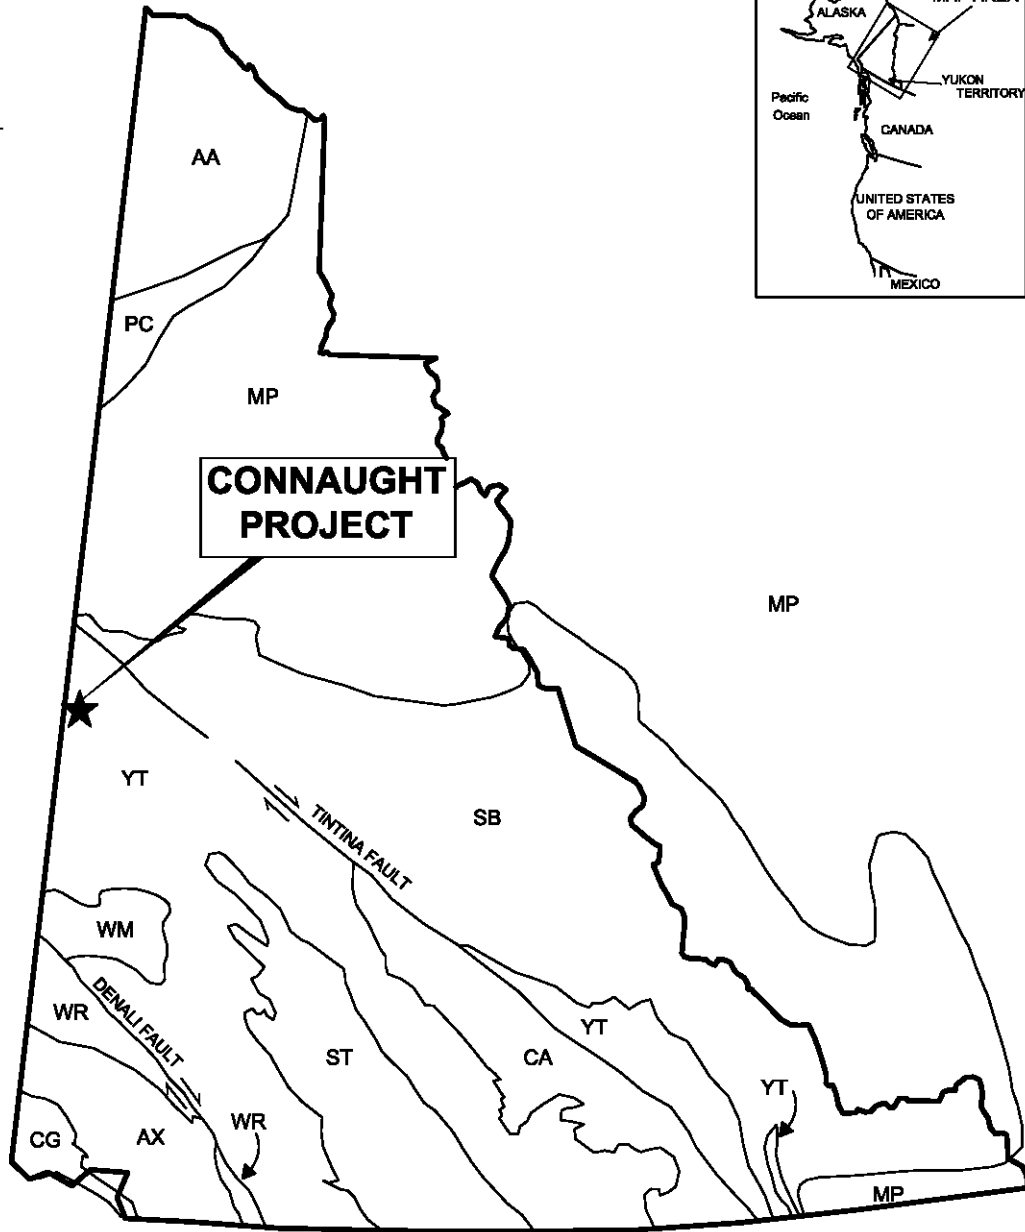

The geology in the vicinity of the Connaught project can be divided into two main domains. The southern domain is mostly underlain by the South Fiftymile Batholith while the northern domain contains supracrustal rocks of the Nasina and Klondike Schist Assemblages (Figure 5). The major lithological units are briefly summarized in the following paragraphs.

The **Nasina Assemblage** comprises Late Devonian to Mid-Mississippian fine grained, moderately to non-carbonaceous, quartz-muscovite-chlorite schist and quartzite with locally abundant interlayered mafic schist and amphibolite. In the Sixtymile River area, some higher grade metamorphic equivalent rocks are also present including coarse grained, locally garnetiferous biotite-quartz-muscovite schist and amphibolite.

The **Klondike Schist Assemblage** comprises a variety of Mid-Permian felsic schists of volcanic affinity. Micaceous quartzite and quartz-feldspar-muscovite-biotite schist are commonly interlayered with the felsic schist. This assemblage forms a klippen that has sits atop the Nasina Assemblage.

The **South Fiftymile Batholith** is an Early Mississippian granitic orthogneiss that contains coarse potassium feldspar augen. These rocks are believed to be separated from Nasina Assemblage strata by a shallow northeasterly dipping normal fault.

A string of **Late Cretaceous Plugs and Stocks** intrude the Nasina Assemblage and South Fiftymile Batholith in the southern and eastern parts of the project area. These plutons consist of fine to medium grained, equigranular biotite-hornblende quartz monzonite and granodiorite.

CONNAUGHT PROJECT

0 1 5 km
UTM Zone 7, NAD83, 115 N15

FILE: 2008/CN/F5_REGIONAL.WOR DATE: APRIL 2009

The dominant foliation in the metamorphic sequences strikes 150° and dips 31° to the northeast (Cholach, 1969).

A number of large-scale, northeasterly trending normal faults are present in the region. The Sixtymile River valley bottom may mark the centre of a graben (Mortensen pers. comm.). Eleven major vein structures have been identified in the vicinity of the property. These veins form two sets: one striking east-northeasterly and the other north-northeasterly.

MINERALIZATION

Connaught project area has mostly been explored as a high-grade silver-lead±gold vein prospect modelled after the highly productive mines in the Keno Hill district, located about 250 km to the east. Some exploration has also been directed to skarn mineralization on ground now covered by the Nordling Option and porphyry copper mineralization on adjoining claims to the east (Grid Capital claims on Figure 2).

Prior to 2008, ten main veins were known on claims held by Connaught project (Figure 3). These vein zones are hosted by dilatant fault structures up to several metres in thickness. Individual veins have been traced for lengths in excess of 260 m and most are open in both directions along strike. Typical vein exposures consist of multiphase quartz that is variable mineralized with blebby to massive arsenopyrite+galena±chalcopyrite ± covellite ± stibnite±sulphosalts. Massive galena±anglesite lenses are intermittently exposed in the core of some veins. The galena is usually coarsely cubic and contains scattered blebs of chalcopyrite. Anglesite weathered surfaces often exhibit botryoidal textures and some show shear textures. The veins and their selvages are usually light coloured compared to the surrounding units and are often tinted green, because of oxidization of arsenopyrite to scorodite and sericitization of mafic minerals. Bleached phyllic- and argillic-altered halos extend up to six metres into adjacent wallrocks.

The No. 1, 3, 8 and Stirling veins strike 050 to 094° and dip subvertically to 070° to the south, while the No. 2, 4, 5, 6, 7 and Core Shack veins strike 020 to 038° and dip steeply toward the west or east (Harris, 1998).

Historical data concerning individual veins are summarized in the following paragraphs.

The **No. 1 Vein** has been delineated by 32 bulldozer trenches for roughly 200 m along strike but it is inferred to continue for an additional 1000 m based on anomalous lead-in-soil geochemistry. The surface trace is marked by a subtle linear gully that is evident intermittently along a talus covered, northwest facing slope. The host rocks are gently northeast dipping orthogneiss of the South Fiftymile Batholith with narrow layers of coarse biotite-muscovite schist. The vein strikes northeast and has a sub-vertical dip.

Mineralization is dominated by pale green- and yellow-stained, sulphosalt bearing quartz. This material is exposed in all trenches excavated across the vein and ranges in width from 30 cm to 4 m. Four semi-massive to massive galena lenses occur in the core of the vein along a 125 m strike length.

The largest and most continuous of the galena lenses is at the northeast end of the vein exposure, on the floor of the historical bulk sample pit. This lens is approximately 67 m long. The galena lens frequently bifurcates from a single wide band into multiple narrow stringers. In 2007, detail sampling was conducted along this lens. The pit from which most of the bulk sample was collected was not re-examined in 2008 because it was filled with water. Table I contains results from the sampling across the No. 1 Vein.

Table I: No. 1 Vein - Historical Chip Sample Results

Two excavator trenches located 55 m northeast along strike of the main lens exposed the vein where it contains manganiferous clay gouge and crushed quartz, but no visible galena or sulphosalt mineralization. The best chip sample from these trenches yielded 51.90 g/t Ag, 0.78 % Pb and 0.016 g/t Au over 0.56 m.

The **No. 2 Vein** has been exposed for a strike length of about 90 m along a 030° trend. It exhibits steep southerly dips averaging 76°. This vein has a composition similar to the No. 1 Vein but it has stronger wallrock alteration, with a bleached halo that extends up to six metres into the footwall rocks. No excavator trenching was done across this vein in 2007 or 2008. Select historical samples documented by Harris, (1998), appear in Table II.

Table II: No. 2 Vein - Select Historical Results

Sample Type	Width (m)	Ag (g/t)	Pb %	Au (g/t)
Chip	0.50	93.0	2.44	1.50
Specimen	n/a	13.8	0.19	3.23
Specimen	n/a	2150	67.20	n/a
Chip	0.68	1365	35.60	0.74
Specimen	n/a	576	n/a	3.59

The **No. 3 Vein** has been outlined by trenching for roughly 100 m along a 067° trend. It has steep southerly dips between 70 and 79°. The best mineralization is exposed at surface along a 10 m strike length where massive galena occurs with subordinate arsenopyrite and pyrite plus traces of covellite, in a multi-episodic quartz-sericite gangue. This portion of the vein is exposed in an approximately 5 m deep pit from which an historical bulk sample was taken. In 2007, the base of the pit was cleared of slough and debris exposing a five metre long massive anglesite and galena lens that is up to 1.25 m wide. The mineralization is hosted within highly fractured, bleached and rusty weathering quartzite and quartz-muscovite schist, tentatively assigned to the Klondike Schist Assemblage.

A series of narrow galena-rich veinlets and stringers bifurcate from the main lens into the footwall strata. Some sulphosalt minerals are also disseminated in quartz rich wallrocks adjacent to this vein. In 2007, four channel samples were sawn at regular intervals across the thickest portion of the galena lens. The results from these samples are shown in Table III.

Table III: No. 3 Vein - Historical Sawn Channel Sample Results

5.00	0.75-1.45	0.70	1100	35.65	1.695

Prospecting approximately 90 m northeast along strike from the of the bulk sample pit discovered massive galena-anglesite and quartz-sulphosalt mineralized float alongside two old bulldozer trenches. Excavator trenches dug in 2007 into the floors of the old trenches exposed broad intervals of multi-coloured gouge but no quartz or metallic minerals. Chip samples collected along the base of the excavator trenches returned low values for silver, lead and gold. The gouge alteration could be an unmineralized portion of the vein but could also mark a thrust fault separating the Klondike Schist from the underlying Nasina Assemblage.

The **No. 4 Vein** lies approximately two kilometres northeast of the No. 1 Vein and is exposed for 260 m along the northwestern side of an alpine knoll. It is hosted by orange weathering hypidiomorphic medium-grained granodiorite that is locally metamorphosed to quartz-feldspar gneiss. The vein strikes 035° and dips steeply south, averaging 77° . It dominantly consists of multi-episodic quartz that is variably mineralized with sulphosalts. The vein is surrounded by strong clay alteration. In 1969, operators reported an “average assay” of 624 g/t Ag and 9.34% Pb across 1.22 m for a series of chip samples collected along the northeastern-most 152.4 m long portion of the exposure (Price, 1989). These samples include peak grades of 2451 g/t Ag and 34.90% Pb across 0.73 m.

Five short excavator trenches were cut in 2007 at equal intervals along an 80 m section at the southwestern end of the vein exposure. Three of those trenches tested the footwall portion of the previously defined vein, which was mostly covered by talus, and the other two were intended to explore the projected trace of the vein to the southwest. The three trenches dug into the footwall of the vein zone discovered new mineralization in a splay off the main structure. The other trenches did not reach bedrock due to permafrost.

The **No. 7 Vein** and the recently discovered **Stirling Vein** are located approximately three kilometres west of the No. 4 Vein. Bulldozer trenching was done prior to 2007 in both of these areas but no significant mineralization was reported.

In 2007, the No. 7 Vein was exposed by deepening an old bulldozer trench where massive galena cobbles were found in the lower part of the soil profile. A vein that is likely the source of the galena cobbles was exposed in that trench and in a second trench situated approximately 120 m to the north. The host stratigraphy consists of flat-lying quartz-feldspar augen gneiss. Alteration envelopes immediately adjacent to the vein are narrow, not exceeding 0.5 m on either side of the mineralized structure.

The northern trench exposed a quartz-sulphosalt vein with massive galena lenses up to 55 cm wide and 23 m long. The vein is hosted within competent orthogneiss and strikes between 020° and 045° with a steep dip to the west at 80° . The northern-most galena lens is open along strike to the northeast where it projects beneath an access road. Approximately two tonnes of massive galena were recovered during the exploration of this lens. Results for all samples collected from this vein are shown in Table VI.

The **Stirling Vein** was discovered in 2007 by deepening an old bulldozer trench situated approximately 400 m northeast of the No. 7 Vein. It is composed of strongly sulphosalt-bearing quartz with intermittent massive galena lenses up to 47 cm wide. The vein is exposed for a strike length of 22 m in tuffaceous quartz-feldspar-biotite-muscovite schist. It strikes 094° and dips steeply south at 70°. The mineralization is open along strike. Table V contains assays for channel samples sawn across the vein, including weighted average grades for intervals where multiple samples were collected across the exposure.

* All reported intervals are true widths.

The **Core Shack** is exposed in old bulldozer trenches that were deepened with an excavator in 2007. This vein is one of a series of sulphosalt-bearing quartz veins that are marked by lead-in-soil geochemical anomalies in the area between the No. 1 and No. 2 veins. The excavator trenches encountered an up to 1.30 m wide quartz vein that is variably mineralized with yellow-green arsenic-antimony secondary minerals, sulphosalts and minor coarse cubic galena. Chip samples collected across the vein zone returned peak values of 1230 g/t Ag, 15.0 % Pb and 1.96 g/t Au. Significant results from samples collected across the mineralized zone are presented in Table VI.

Table VI: Core Shack Vein - Historical Chip Sample Results

	31.70	0.00-0.29	0.29	1230	15.00	1.96

The **No. 8 Vein** is situated on the claims comprising the Nordling Option, roughly seven kilometres east of the No. 4 Vein. It is similar to the veins exposed on the CN property but has a slightly higher silver to lead ratio. Historical grades, from select galena-dominant rock samples collected intermittently along a 275 m strike length are shown in Table VII.

Table VII: No. 8 Vein - Historical Rock Sample Results

275	723	22.30

2008 EXPLORATION PROGRAM

The 2008 exploration program was conducted between June 28 and August 22 and consisted of grid soil sampling, prospecting, excavator trenching and excavator stripping. This work was conducted from a tent frame camp in the central part of the property. The camp was left standing at the end of the program, ready for use in 2009.

Soil Geochemistry

The 2008 soil sampling built on earlier grid sampling that was conducted in 1969, 1987, 1998 and 2007 (Figure 6).

CONNAUGHT PROJECT

0 1 4 km
UTM Zone 7, NAD83, 115 N15

FILE: 2008/CN/F6_GRID_COMP.WOR DATE: APRIL 2009

The 1969 survey consisted of three grids that cover a 26 km² area. Samples were taken either at 25 m spacing along lines spaced 25 m apart or at 100 m spacing along lines spaced 100 m apart. The samples that were taken at 25 m centres were from an 8 km² grid while the samples collected at 100 m centres were from two grids that collectively covered a 16 km² area. All three grids were orientated to sample topographic highs, leaving significant gaps in the coverage. The 1969 samples were only analyzed for copper, lead and silver.

The 1987 soil sampling was performed over a 9 km² area at 25 intervals on lines spaced 200 m apart. All of these samples were taken with the areas of previous coverage. They were analyzed for 30 elements by an ICP technique.

The 1998 soil sampling was performed at 50 m intervals on four traverse lines that were run along ridge tops in the vicinity of the No. 2 and No. 6 Veins. These samples were analyzed for gold and 32 other elements.

The following table of anomalous thresholds was compiled from historical data from the Connaught project area plus data obtained by Archer Cathro from other nonglaciaded areas in Yukon.

Table VIII: Anomalous Thresholds - Soil Geochemistry

Element	Threshold Value (ppm)		
	Weak	Moderate	Strong
Ag	1	2	5
Pb	50	100	200
As	50	100	200
Sb	5	10	25
Cu	50	100	200
W	20	50	100

Results from the pre-2007 grids identified numerous northeasterly trending clusters of anomalous lead response, with peak values up to 6600 ppm. Where silver data is available, the results closely coincide with lead-in-soil values. Silver-in-soil results peaked at 24.9 ppm.

In 2007, soil sampling was done at 50 m intervals on lines spaced 50 m apart on Grids A and B, which are located in the western and central parts of the CN property. Together these grids covered an area of 3.9 km².

The 2008 soil sampling program was completed on three more grids, referred to as Grids C, D and E (Figure 6). Grid C covers an 8.6 km² area in a gap between the earlier grids in the northwestern and central parts of the CN property. It adjoins Grid A to the west and slightly overlaps the 1969 grid to the south. Grid D encompasses a 2.6 km² area that starts in the southwest corner of the MAG claim block and extends westward onto open ground. This grid was intended to test along the projected extension of the No. 8 Vein. Grid E is another infill sample grid that covers approximately 1 km² in the south-central part of the CN property. It is contiguous with Grid C to the northwest and the 1969 sample grid to the east.

The 2007 and 2008 soil samples were located using compass and hip-chain surveys that were constrained and slope corrected with handheld GPS units. The sites are marked by aluminium tags inscribed with the sample numbers, which are affixed to 0.5 m wooden lath that were driven into the ground. Soil samples were collected using soil augers. They were placed into individually pre-numbered Kraft paper bags.

A total of 4000 soil samples were collected from Grids C, D and E (3364, 266, and 370 samples, respectively). All of the 2007 and 2008 samples were sent to ALS Chemex in North Vancouver where they were dried and sieved to -180 microns. A portion of each sample was digested in aqua regia and then analysed for 34 elements by the inductively coupled plasma-atomic emission spectroscopy technique (ME-ICP41). Sample locations for Grids C and E are shown on Figure 7 while those for Grid D are illustrated on Figure 8. Certificates of Analysis are in Appendix II. Thematic plots for silver, lead, arsenic, antimony, copper and tungsten are illustrated on Figures 9, 10, 11, 12, 13 and 14 respectively, along with the known and projected traces of the main vein zones.

Soil sampling within Grid C outlined strong anomalies in the vicinity of several known veins. The most intense of these anomalies is located in the southeastern part of the grid near the trenches on the No. 4 Vein. This anomaly is an irregularly shaped cluster of high values, which peak at 22.9 ppm silver, 4010 ppm lead, 3200 ppm arsenic, and 156 ppm antimony. Although these values are significant, they are likely amplified by inclusion of mineralized material from bulldozer and excavator disturbances on the No. 4 Vein. The largest anomaly is a 500 m wide and 1000 m long band of discontinuous moderately to strongly anomalous values, which trends northeasterly. Peak values from this band are 5.3 ppm silver, 1270 ppm lead, 13,600 ppm arsenic and 411 ppm antimony. No trenching has been done in this anomaly, but it appears to mark the extension of the No. 7 Vein or Stirling Vein.

Soil sampling within Grid D was widely spaced, but it did outline two small, relatively strong anomalies. The more intense and larger of the anomalies, located in the east-central part of the grid, has peak values of 9.3 ppm silver and 623 ppm lead. The other anomaly is on the western side of the grid.

The southern half of Grid E contains widespread moderately to strongly anomalous values. Peak values are 27.1 ppm silver, 3670 ppm lead, 804 ppm arsenic and 17 ppm antimony. The highest values form two bands that trend easterly to northeasterly across the grid. Both bands are open to extension along trend. No veins are known in the vicinity of either anomalous band.

All of the 2008 soil geochemical results were received after the program was completed, therefore, none of them received any follow up work.

Prospecting and Excavator Trenching

Prospecting focussed mainly on lead-in-soil anomalies that were outlined by the 2007 soil geochemical surveys, while trenching tested the most prospective of those anomalies and areas where previous trenching had exposed well mineralized veins. Most of the trenching was done with a Hitachi EX 200 excavator owned and operated by 15317 Yukon Ltd. of Whitehorse.

Some trenching was also done with a Hitachi EX 300 excavator contracted from Nordling Mining and Mechanical of Dawson City. In total, 41 trenches were excavated across ten targets, only 36 of which reached bedrock. Extensive permafrost was encountered in most trenches, which significantly reduced productivity. The trenches were aligned approximate northwest to intersect the general east-northeasterly to northeasterly trends of the veins.

A total of 254 chip, channel, and specimen rock samples were collected from bedrock exposed in trenches or from mineralization discovered during prospecting traverses. Chip samples were collected from either the floors or ribs of trenches, and channel samples were sawn across massive galena lenses. Specimen rock samples were taken from selected high grade exposures in trenches to characterize hand-sortable material or from road cuts and float occurrences where previously undocumented mineralization was discovered. All samples were transported to Whitehorse and forwarded to ALS Chemex in North Vancouver, where they were dried and fine crushed to better than 70% passing 2 mm. A 250 g split of the crushed material was pulverized to better than 85% passing 75 micron. A split was then subjected to aqua regia digestion and analyzed for 34 elements using the ME-ICP41 technique. If a sample exceeded the detection limit for lead or silver it was further analyzed for total metal content using standard assay procedures. Samples exceeding upper detection limits for standard assay procedures were subject to bullion assay methods. All pulps were analyzed for gold using fire assay and atomic absorption finish. Certificates of Analysis are contained in Appendix II. Individual trench maps are in Appendix III. These maps show sample locations. Specific gravity data for trench samples appears in Appendix IV.

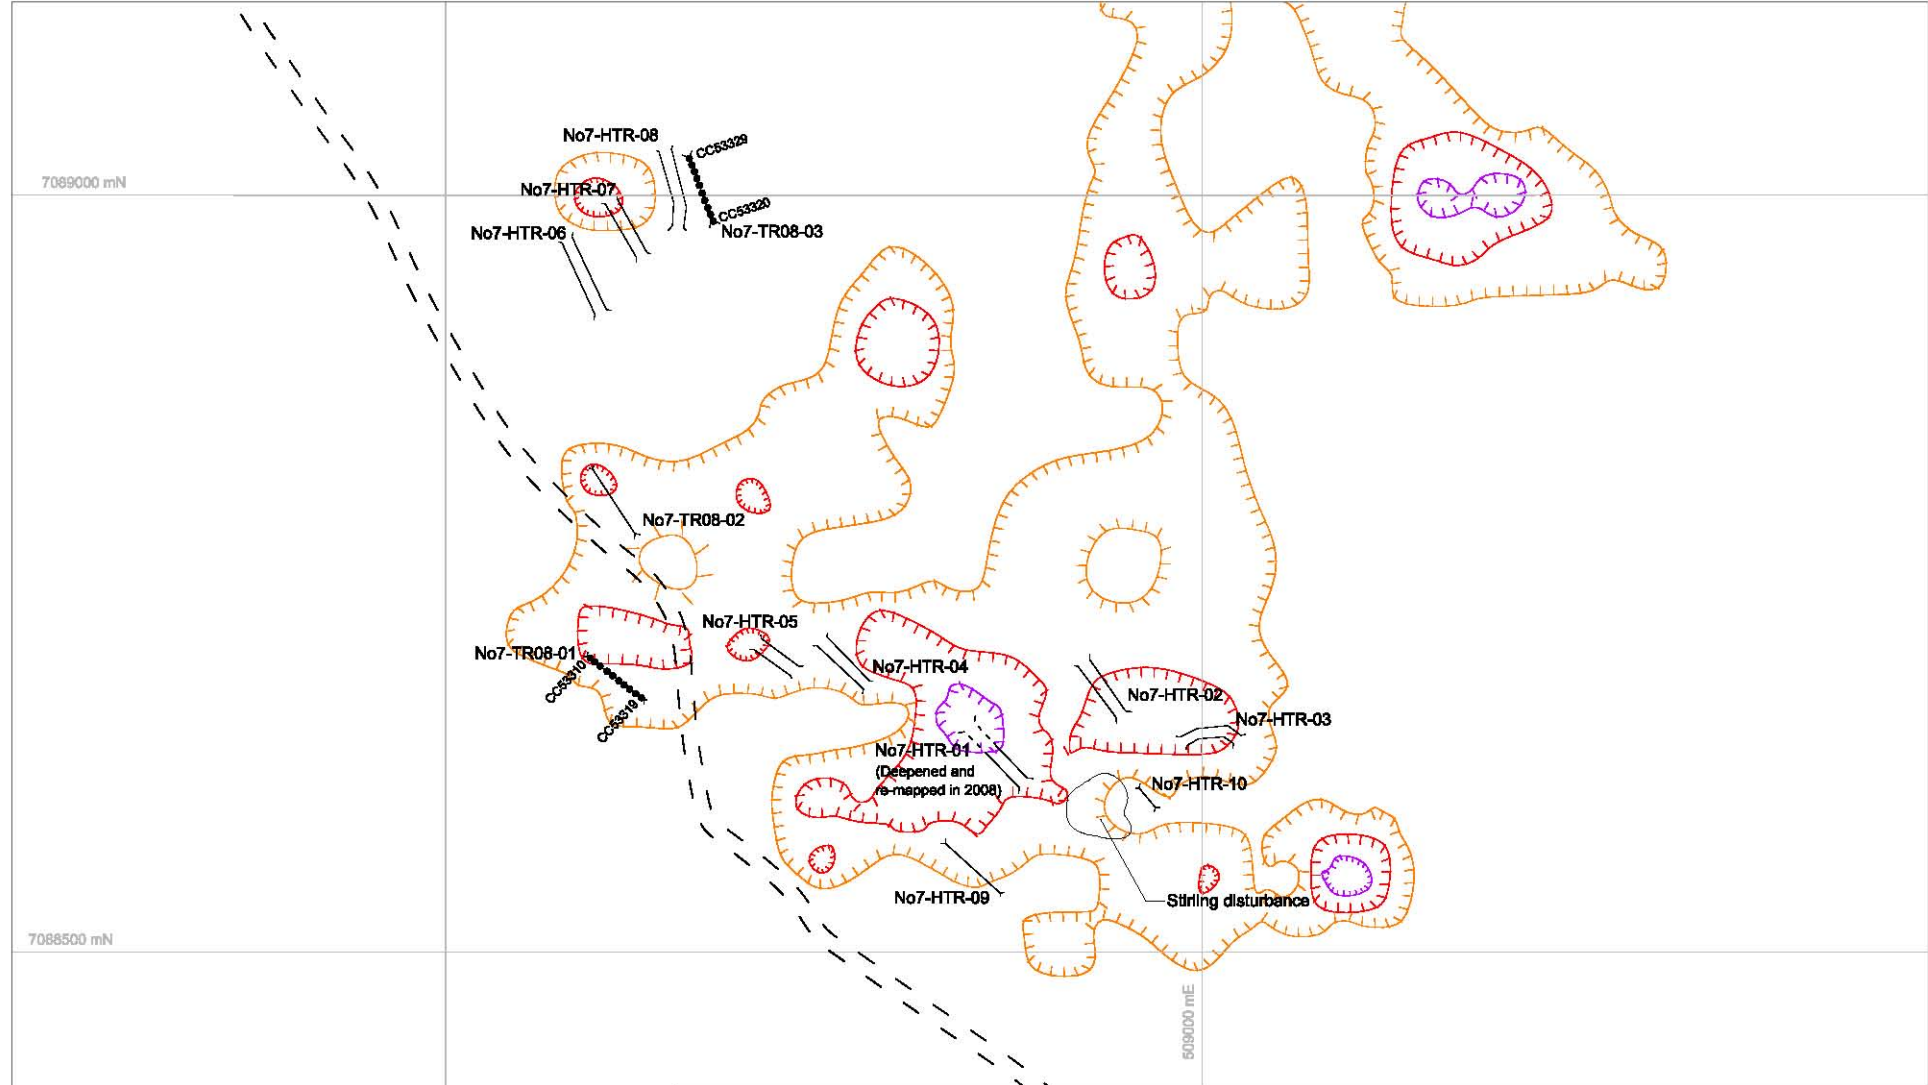

Excavator trenching had two main purposes: 1) to follow up 2007 soil geochemical anomalies, particularly those on Grid B; and, 2) to explore along strike from known vein exposures.

A total of 21 trenches were cut on or immediately adjacent to **Grid B**. Of these, seventeen tested the strongest geochemical anomalies and the other four were cut across quartz-arsenopyrite float found during a prospecting traverse along the main access road.

Four new vein zones (AC/DC, Ice, PP and Rain) were discovered in the Grid B area in 2008 (Figure 15). Trenching of soil geochemical anomalies identified the Ice, PP, and Rain veins while the AC/DC vein was discovered by prospecting along the road cut.

The **AC/DC vein** is located alongside the main access road, approximately 1000 m east of the No. 4 Vein. Three of the four trenches dug in the area exposed the vein, delineating it for a strike length of roughly 70 m (Figure 16). Most of the bedrock is poorly exposed. The vein is up to 1 m thick and contains comb quartz with small irregular masses of sulphosalts and weak to moderate, blebby and disseminated arsenopyrite. It is hosted in grey quartz-feldspar-biotite gneiss grading to quartzite. A selected rock sample of well mineralized material assayed 12 g/t Ag, 2.2% Pb, and 0.374 g/t Au. All chip samples returned sub-economic values for all metals.

The **Ice Vein** lies about 1000 m northeast of the No. 4 Vein on a northwest facing hillside. Five trenches were excavated but only three reached bedrock (Figure 17). Trenches, or portions of trenches, that did not reach bedrock were soil sampled. Chip samples were taken at five metre intervals from the ribs or floors of the trenches where the vein was exposed. The vein is well

exposed in GB-TR08-05 and 06 and poorly exposed in GB-TR08-09. Mineralization consists of coarse cubic galena weathering to botryoidal anglesite or dense dark red limonite containing relict galena and/or crushed quartz. Yellow-green clay gouge is also present. The Ice Vein is hosted in grey quartz-feldspar-biotite gneiss. The approximate altitude of the vein is 049°/80° SE. Its apparent width is 70 cm but the mineralized portion is only 20 to 25 cm wide. Significant chip samples from these trenches are compiled in Table IX.

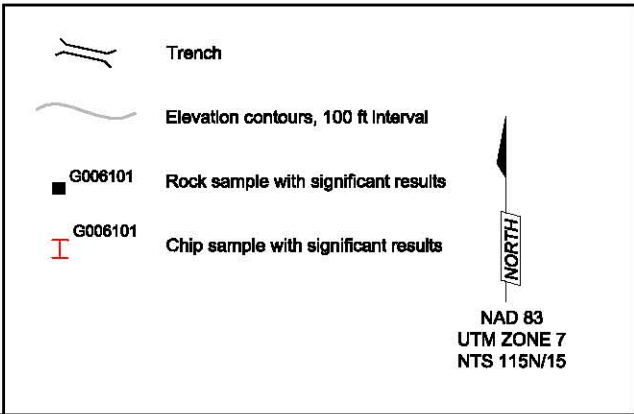

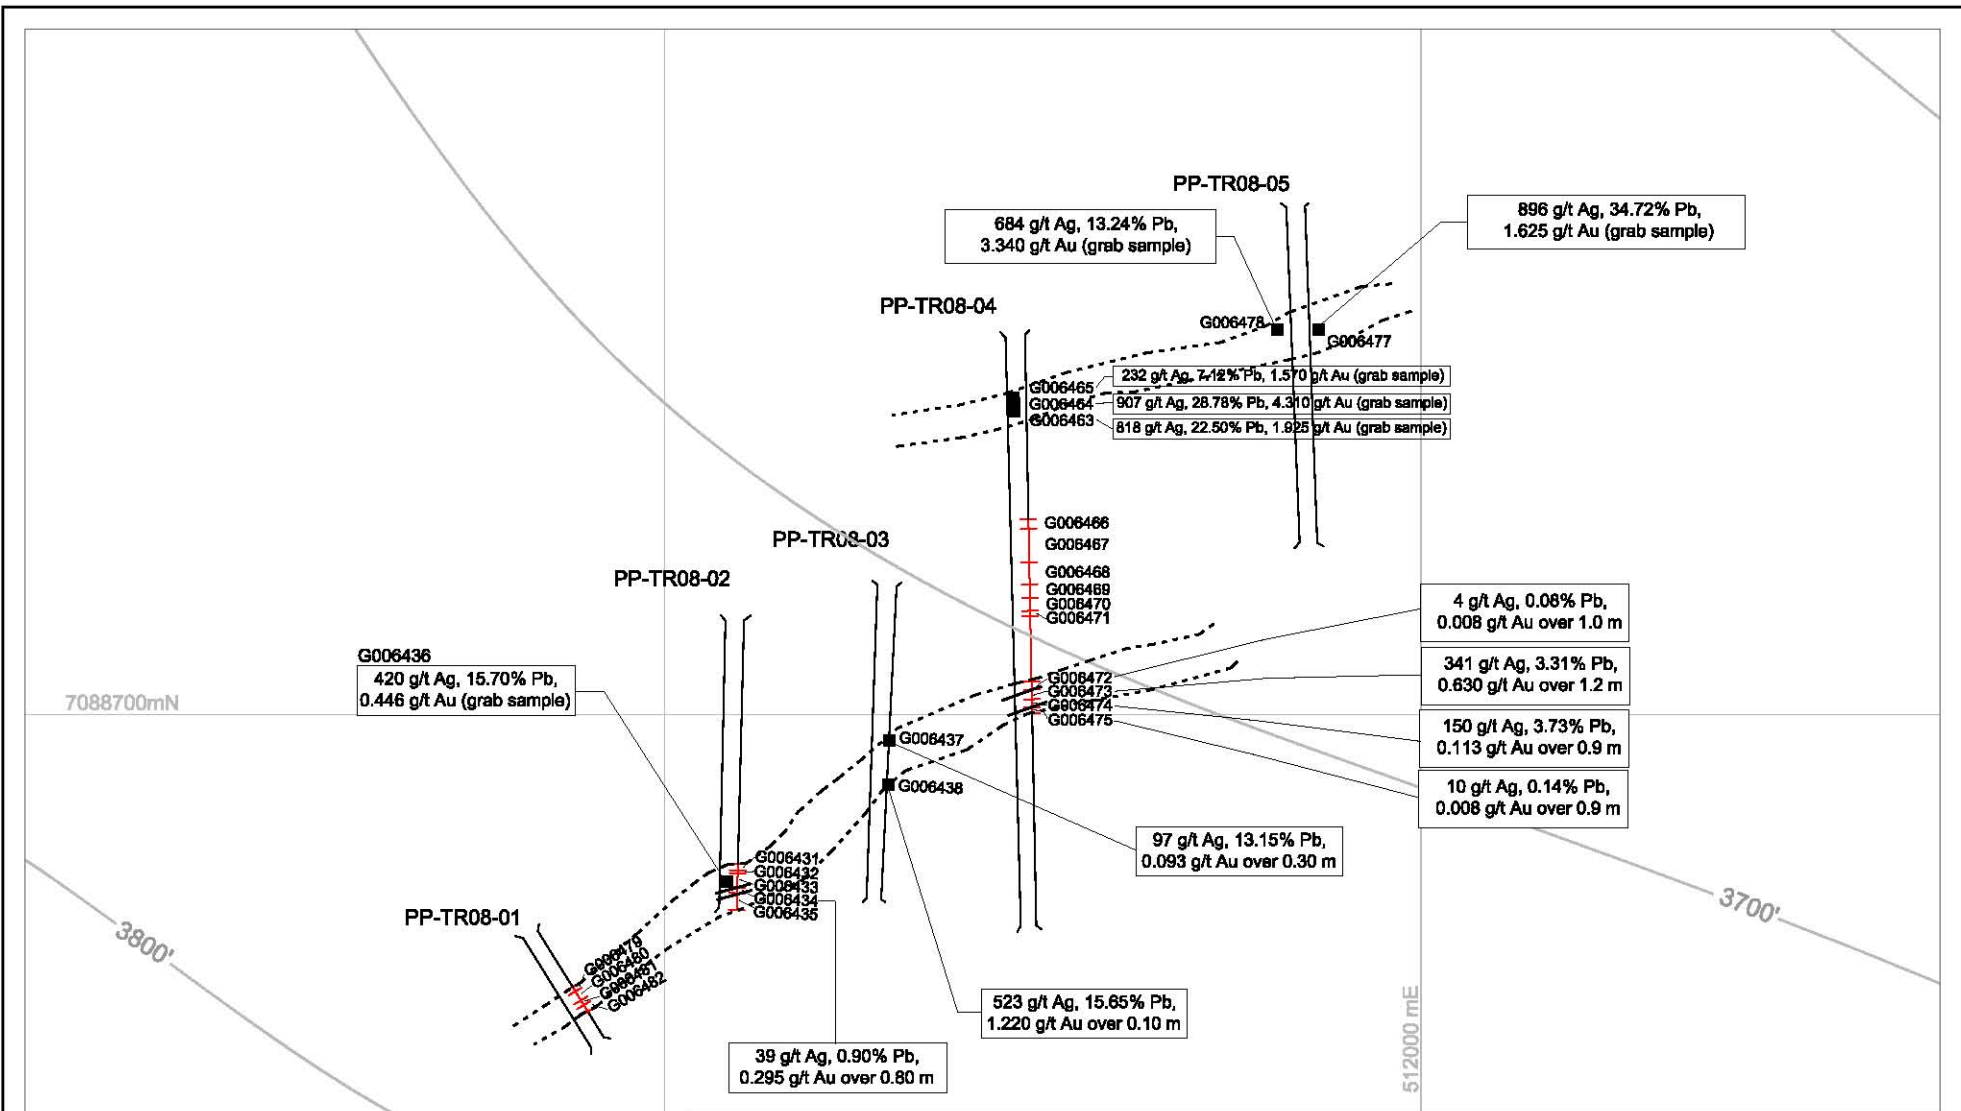

Table IX: Grid B Trenches - Significant 2008 Chip Sample Results*

Vein	Trench	From-To (m W)	Width (m)	Ag (g/t)	Pb (%)	Au (g/t)
Ice	GB-TR08-01	65.00-65.50	0.50	253	8.19	0.403
	GB-TR08-05	32.70-33.89	1.19	142	1.08	0.453

		including	1.20	406	4.04	2.880
Rain	GR-TR08-16	34.65-36.50	1.85	24	0.95	0.032
		including	0.85	31	1.22	0.027
PP	PP-TR08-03	20.50-20.80	0.30	97	3.15	0.093
		26.00-26.10	0.10	523	15.65	1.220
	PP-TR08-04	46.60-48.70	2.10	259	3.49	0.408

*Assay values in this table are generally low, compared with rock sample assays from the same area (Table X). This contrast may be due in part to sample quality due to poor bedrock exposure caused by patchy permafrost and varying depths of overburden. The chip samples were often diluted by foreign soil and rock fragments.

The **PP Vein** is located 1200 m north-northeast of the Ice Vein on a northeast facing hillside. Vein float containing galena and anglesite was discovered during a prospecting traverse that followed up soil geochemical anomalies. Five trenches were cut to locate the source of the float (Figure 18). A narrow quartz-sulphosalt-galena vein up to 15 cm wide was located in trenches PP-TR08-01 through -04. This vein is hosted in pale yellow quartzite and grey quartz-feldspar-biotite gneiss. Chip samples collected from this vein returned weak lead and silver values (Table IX). However, grab samples of anglesite weathered galena float collected from the spoil piles of PP-TR08-04 and -05 at the end of the field season suggest that another, unexposed vein exists north of the trenches.

The **Rain Vein** is situated 1600 m northeast of the No. 4 Vein. It lies northwest downslope from the main access road. Trenches were cut across two strong geochemical anomalies (Figure 15). The Rain Vein is well exposed in only one trench, (GB-TR08-01 on Figure 19), and is poorly exposed in two adjacent trenches (GB-TR08-15 and -16). High values obtained from rock and soil samples taken from GB-TR08-02 and -10 suggest the vein continues to the east. Where exposed in GB-TR08-01, the vein is composed of quartz-poor sulphide bands with antimony-arsenic sulphosalts and galena in their cores and pyrite, arsenopyrite and possible stibnite on their margins. The sulphide-rich material is hosted in bright yellow clay gouge. The galena is coarsely cubic and weathers to anglesite on rims, with scorodite stains on some faces. The Rain Vein is hosted in quartz-feldspar-biotite gneiss, but schists were found nearby, which often contain much more muscovite than biotite. Chip samples returned low values (Table IX) but this

maybe due to contamination by fragments of unmineralized soil and bedrock, caused by the poor vein exposure. Rock samples of well mineralized vein yielded much higher values for lead and silver.

Nineteen trenches were dug in 2008 in the vicinity of previously identified veins. These trenches are described in the following paragraphs.

A total of seven trenches were dug near the **No. 3 and No. 7 veins** (Figures 20 and 21). Six new trenches were excavated and one historic trench was deepened. All of these trenches either bottomed in overburden or barely reached bedrock. Vein exposures were poor so no chip samples were taken. Trenches that bottomed in overburden were soil sampled. Some of these samples yielded positive results, particularly those from No. 7-TR08-03 which included peak values of 732 ppm lead and 31 ppm silver. Samples from No. 3-TR08-02 also yielded encouraging results with peak values of 2260 ppm lead, 6 ppm silver and 150 ppm copper.

Trenching in the vicinity of the **No. 4 Vein** involved extension of two 2007 trenches and excavation of one new trench. All of these trenches are located near an area that was stripped to bedrock (see 2008 Excavator Stripping sub-section). Only trench No. 4-TR07-20 EXT was sampled. It yielded 186 g/t Ag, 2.44% Pb and 0.115 g/t Au across 1.0 m of strongly clay altered granodiorite mineralized with disseminated sulphosalts. The adjacent trench, No. 4-TR08-21 EXT, showed similar but weaker clay alteration without the sulphosalt mineralization. The new trench was dug southwest of the vein trend to test for the source of mineralization float found in disturbed soil on an old access road. No evidence of veining was seen in this trench and it was not sampled.

Nine trenches were excavated on the **No. 8 Vein** (Figure 22). Seven of these trenches either deepened or extended historical trenches and two were dug at new sites. Many of the trenches were excavated to better establish the location of galena-rich lenses prior to stripping while the others explored for possible extensions along strike. The vein was closed off to the west but is

still open to the east. It was exposed for 75 m along strike (see 2008 Excavator Stripping subsection). The mineralization is less continuous than indicated by previous workers, but chip sampling done prior to stripping confirmed historical reports of high-grade lead and silver mineralization (Table XI). The best mineralized part of the vein was stripped continuously to bedrock and was tested by closely spaced channel samples (see 2008 Excavator Stripping subsection).

2008 Excavator Stripping

Excavator stripping on the Connaught project was designed to evaluate bulk sampling potential of the best mineralized veins and, where appropriate, to prepare certain exposures for future bulk sampling. The work was mostly performed with a Hitachi EX300 excavator contracted from Nordling Mining and Mechanical. Although overall stripping results were positive, progress was often slow due to hard rock, permafrost and frequent mechanical failure of the equipment. After the veins were stripped into bedrock they were geologically mapped, surveyed (either with a transit or Leica Total Station) and chip or channel sampled. Sawn channel samples were collected where massive galena lenses more than 10 cm thick were exposed or where bedrock was too competent to chip sample.

Areas on four of the ten known veins in the project area are considered to be suitable for bulk sampling. These areas are on the No. 1, No. 7, No. 8 and Stirling Veins. Some parts of other veins were also stripped (most notably the No. 4 Vein) but these areas have little potential for bulk sampling.

Delineating the extent of mineralization at the **No. 1 Vein** proved to be difficult because of frozen soil, poor drainage and very competent wallrocks. However, preparing the exposed mineralization for bulk sampling was successful. Approximately 50 m of the vein was exposed up to 3 m down the dip. The tops of the vein exposures were well sampled in 2007, but few additional chip and channel samples were collected in areas that were missed in 2007 (Figure 23). Assays for those samples are compiled in Table XII.

The **No. 4 Vein** was stripped approximately 240 m along strike. As described in the mineralization section, the exposed part of the vein is up to 2 m wide and consists of multi-episodal bands of sulphosalt bearing quartz surrounded by yellow, green or dark brown gouge (Figure 24). This vein material is intermittently enriched with small lenses of coarse cubic galena up to 10 cm wide. Although this vein has historically been shown to have higher silver to lead ratios than most others on the property, comparatively low grades and limited continuity of higher grade lenses suggest little potential for bulk sampling. Results of 2008 chip sampling are illustrated on Table XIII.

The No. 7 Vein is located in the west-central part of the property. It has been exposed along a strike length of approximately 50 m and remains open at both ends. Lenses of massive coarse grained, cubic galena pinch and swell to widths of 35 cm. The longest lens has a strike length of about 10 m at an average 20 cm width (Figure 25). Channel and rock samples taken at various points along this vein are compiled in Table XIV. Rock samples were taken from high-grade galena lenses and are intended to represent grades attainable by hand-sorting.

The No. 8 Vein is located on the Nordling Option. It has been stripped along strike for 75 m and remains open at its east end (Figure 26). Bands, pods and lenses of massive galena up to 4.5 m long and 35 cm thick occur within an envelope of quartz and rusty clay altered, gouge and wallrock. Stripping showed that while the mineralization was locally strong it was less continuous than previous workers had reported. Results from channel samples and well mineralized character samples are compiled in Table XV.

Both the **No. 3 Vein** and **Stirling Vein** received minor stripping in 2008. The depth of the historical pit at the No. 3 Vein limited the amount of time-efficient excavation that was possible with the available equipment. Work at the Stirling Vein encountered pervasive permafrost at a shallow depth, which made for very slow progress. Stripping on both of these veins was quickly abandoned in favour of other targets. No new sampling or mapping was done and descriptions are unchanged from those that appear in the Mineralization section of this report.

DISCUSSION AND CONCLUSIONS

The Connaught project hosts an extensive system of silver-lead-gold veins, which are located at the head of the Sixtymile placer gold camp. Mineralized veins are associated with east-northeasterly to north-northeasterly trending structural zones that cut all pre-Cretaceous units. The source of mineralization has not yet been determined, but it was likely deposited by a hydrothermal system related to Late Cretaceous plutonism. Porphyry copper and skarn occurrences in the area are probably associated with the same hydrothermal system.

Vein mineralogy is complex and consists of multiple episodes of quartz and sulphide emplacement. Correlation coefficients show close relationships between silver-lead-antimony and gold-arsenic-bismuth metal assemblages, which can be broadly characterized as Type I and II mineralization, respectively.

Type I mineralization is galena dominant and is usually confined to intermittent lenses within the veins. It resembles the ores mined in the highly productive Keno Hill district about 250 km to the east. Silver:lead ratios for most samples collected from the Connaught project area are roughly 1:1 (1 oz/ton silver per 1% lead) but ratios up to 2.5:1 are reported from samples collected from the No. 8 Vein. Gold values associated with this type of mineralization are low (usually less than 1 g/t), especially when compared to the high lead and silver values. Due to its high silver and lead contents, this type of mineralization is the often suitable for direct shipping and smelting, without on-site concentration.

Type II mineralization is quartz dominant with variable concentrations of sulphides, sulphosalts and secondary oxides. Volumetrically it is much more abundant than Type I mineralization. Silver:lead ratios in this type of mineralization also average about 1:1, but absolute values are usually much lower than are characteristic of Type I mineralization. Gold values are significantly elevated relative to silver and lead. This type of mineralization is too low grade to warrant direct shipping and smelting and would require concentration on-site by milling before it could be economically shipped and smelted.

Despite the presence of deep weathering, strong solifluction and permafrost, soil geochemistry has proven to be an excellent tool for identifying veins that have been buried by overburden. The size and shape of soil anomalies suggest some of the veins have strike length of 1000 m or more. Many of the anomalies have received little or no follow up prospecting and trenching. In 2008, a new anomaly was partially defined on the south side of the main ridge, about 800 m from the closest known vein. This discovery suggests that the limits of the vein system are not yet established and that there is a good potential for additional discoveries.

Excavator trenching is considered to be the most effective tool for evaluating the soil geochemical anomalies and delineating the veins. Many soil anomalies remain untested and most veins are open along strike. Permafrost and deep overburden are significant impediments to effective trenching in some areas. Overburden drilling is a possible alternative; however, it provides relatively little visual information regarding the nature of the veins. Presently, there is a limited understanding of the structural and hydrothermal controls associated with the development of the veins in the Connaught area. Data suggest there may be significant

metal zoning within the vein camp and that its ultimate limits have not yet been established. Additional exploration is definitely warranted and should be implemented with three objectives in mind. The first objective should focus on the discovery of new vein zones utilizing continued property-wide close spaced grid soil geochemical surveys and excavator trenching across prospective geochemical trends. The second objective should focus on establishing controls responsible for development of Type I and II mineralization, particularly as those controls relate to lateral or vertical zonation within the system. Bulk sampling of selected areas of Type I mineralization would contribute to this objective by providing detailed three dimensional assessments of the ore shoots and by identifying geological settings that are especially favourable for the development of ore shoots. The third objective should be to gradually build up a resource of Type I and Type II mineralization that is too low grade to warrant bulk sampling and direct shipping. Data regarding this lower grade mineralization should be carefully documented so that it can later be used to design a comprehensive diamond drill program. That type of drill program would be needed to establish a reserve that is large enough to warrant detailed studies on the viability of a large-scale mining and on-site milling operation.

Future exploration should also include detail geological mapping to delineating areas underlain by favourable host rocks such as the granitic orthogneiss of the South Fiftymile Batholith and quartzite of Nasina Assemblage. These units are particularly prospective hosts because they are brittle, and therefore were better able to form broad, continuous dilatant zones where rich veins could have precipitated from circulating hydrothermal fluids.

Finally, the next phase of work should include claim staking along the southern boundary of the project to cover projected extensions of soil geochemical anomalies on Grids D and E. This staking should be done in conjunction with reconnaissance-scale prospecting and soil sampling traverses along ridges radiating out from the core of the project area. The off-property work should be designed to establish the limit of the vein system and to explore for metal zoning within the system.

Respectfully submitted,

ARCHER, CATHRO & ASSOCIATES (1981) LIMITED

W. Douglas Eaton, B.Sc.

Justin J. Mundhenk, B.Sc.

APPENDIX I
STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

I, W. Douglas Eaton, geologist, with business address in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in North Vancouver, British Columbia, hereby declare that:

1. I graduated from the University of British Columbia in 1980 with a B.Sc. majoring in Geological Sciences.
2. From 1971 to present, I have been actively engaged in mineral exploration in British Columbia and Yukon Territory and on June 1, 1981, became a partner in Archer, Cathro & Associates (1981) Limited.
3. In 1983, 1984 and 1989, I participated in and supervised profitable small-scale, high grade mining operations on mineral claims leased from United Keno Hill Mines Ltd. in central Yukon, and in 1999. I supervised a similar operation on behalf of Nordac Resources Ltd. at its Blue Heaven property in southern Yukon.
4. I have personally participated in or supervised the field work reported herein and have interpreted all data resulting from this work.

W. Douglas Eaton, B.Sc. Geology

STATEMENT OF QUALIFICATIONS

I, Justin Mundhenk, with business addresses in Vancouver, British Columbia and Whitehorse, Yukon Territory and residential address at 7681 Westsyde Road, Kamloops, British Columbia, V2B 8S1 do hereby certify that:

1. I am an employee of Archer, Cathro & Associates (1981) Limited.
2. I graduated from the University of British Columbia in 2008 with a B.Sc. in Geological Sciences.
3. From 2005 to present, I have been actively engaged in mineral exploration in the Yukon Territory, and northern British Columbia.
4. I have personally participated in and supervised the fieldwork reported herein.

Justin J. Mundhenk, B.Sc.

CERTIFICATE VA08121237

Project: CN

P.O. No.:

This report is for 188 Soil samples submitted to our lab in Vancouver, BC, Canada on 27-AUG-2008.

The following have access to data associated with this certificate:

AL ARCHER
BILL WENGZYNOWSKI

DOUG EATON

JOAN MARIACHER

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Pb-OG46	Ore Grade Pb - Aqua Regia	VARIABLE
ME-ICP41	35 Element Aqua Regia ICP-AES	ICP-AES
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES

CERTIFICATE VA08112831

Project: CN

P.O. No.:

This report is for 25 Rock samples submitted to our lab in Vancouver, BC, Canada on 12-AUG-2008.

The following have access to data associated with this certificate:

AL ARCHER
BILL WENGZYNOWSKI

DOUG EATON

JOAN MARIACHER

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-31	Fine crushing - 70% <2mm
PUL-QC	Pulverizing QC Test
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

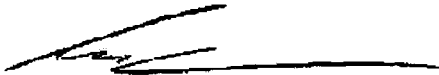

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Pb-OG62	Ore Grade Pb - Four Acid	VARIABLE
Ag-OG62	Ore Grade Ag - Four Acid	VARIABLE
Au-ICP22	Au 50g FA ICP-AES finish	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM
Pb-OG46	Ore Grade Pb - Aqua Regia	VARIABLE
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES
Pb-VOL70	Pb by Titration	
ME-ICP61a	High Grade Four Acid ICP-AES	ICP-AES
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES

CERTIFICATE VA08110712

Project: CN

P.O. No.:

This report is for 7 Rock samples submitted to our lab in Vancouver, BC, Canada on 6-AUG-2008.

The following have access to data associated with this certificate:

AL ARCHER
BILL WENGZYNOWSKI

DOUG EATON

JOAN MARIACHER

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Pb-OG62	Ore Grade Pb - Four Acid	VARIABLE
Ag-OG62	Ore Grade Ag - Four Acid	VARIABLE
Au-ICP22	Au 50g FA ICP-AES finish	ICP-AES
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES
Pb-VOL70	Pb by Titration	
Ag-OG46	Ore Grade Ag - Aqua Regia	VARIABLE
ME-ICP61a	High Grade Four Acid ICP-AES	ICP-AES
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES

CERTIFICATE VA08110711

Project: CN

P.O. No.:

This report is for 40 Rock samples submitted to our lab in Vancouver, BC, Canada on 6-AUG-2008.

The following have access to data associated with this certificate:

AL ARCHER
BILL WENGZYNOWSKI

DOUG EATON

JOAN MARIACHER

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

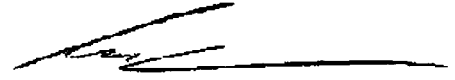

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Pb-OG62	Ore Grade Pb - Four Acid	VARIABLE
Ag-OG62	Ore Grade Ag - Four Acid	VARIABLE
Au-ICP22	Au 50g FA ICP-AES finish	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM
Pb-OG46	Ore Grade Pb - Aqua Regia	VARIABLE
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES
Pb-VOL70	Pb by Titration	
Ag-OG46	Ore Grade Ag - Aqua Regia	VARIABLE
ME-ICP61a	High Grade Four Acid ICP-AES	ICP-AES
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES

CERTIFICATE VA08110710

Project: CN

P.O. No.:

This report is for 28 Rock samples submitted to our lab in Vancouver, BC, Canada on 6-AUG-2008.

The following have access to data associated with this certificate:

AL ARCHER
BILL WENGZYNOWSKI

DOUG EATON

JOAN MARIACHER

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

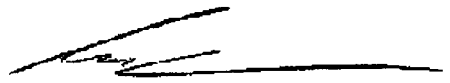

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Pb-OG62	Ore Grade Pb - Four Acid	VARIABLE
Ag-OG62	Ore Grade Ag - Four Acid	VARIABLE
Au-ICP22	Au 50g FA ICP-AES finish	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM
Pb-OG46	Ore Grade Pb - Aqua Regia	VARIABLE
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES
Pb-VOL70	Pb by Titration	
Ag-OG46	Ore Grade Ag - Aqua Regia	VARIABLE
ME-ICP61a	High Grade Four Acid ICP-AES	ICP-AES
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES

P.O. No.:

This report is for 24 Rock samples submitted to our lab in Vancouver, BC, Canada on 18-JUL-2008.

The following have access to data associated with this certificate:

AL ARCHER
BILL WENGZYNOWSKI

DOUG EATON

JOAN MARIACHER

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM
ME-ICP61a	High Grade Four Acid ICP-AES	ICP-AES
Ag-OG62	Ore Grade Ag - Four Acid	VARIABLE
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES
Pb-OG62	Ore Grade Pb - Four Acid	VARIABLE
Pb-VOL70	Pb by Titration	
Ag-OG46	Ore Grade Ag - Aqua Regia	VARIABLE
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES

Poddy galena - qtz - scorodite
clay vein up to 8cm wide.
Barren portions consist of yellow
qtz - scorodite vein material
to weak pyrite in blebs and
disseminations

5-7cm (or less) galena
vein. Galena is generally
coarse grained, massive
and euhedral. Clots of
quartz and calc py blebs and trace tetrahedrite
occur in galena. Narrow
(5cm or less) clay alteration selvage
occur on both footwall and
hanging wall sides. Vein is cut
by gougy structure and offset
by less than 1m.

VERY BRONZE GNEISSIC
QUARTZITE

Dark, quartz poor sulphide bands with Sb+As sulphasalts and weathered galena (to anglesite) in core of bands, and pyrite and arsenopyrite (or stibnite?) on margins. G006485 bands of vein material and in altered wallrock as described above. G006486 semi-massive galena in the core of vein bands.

Rusty orange clay alteration

Bright yellow gouge

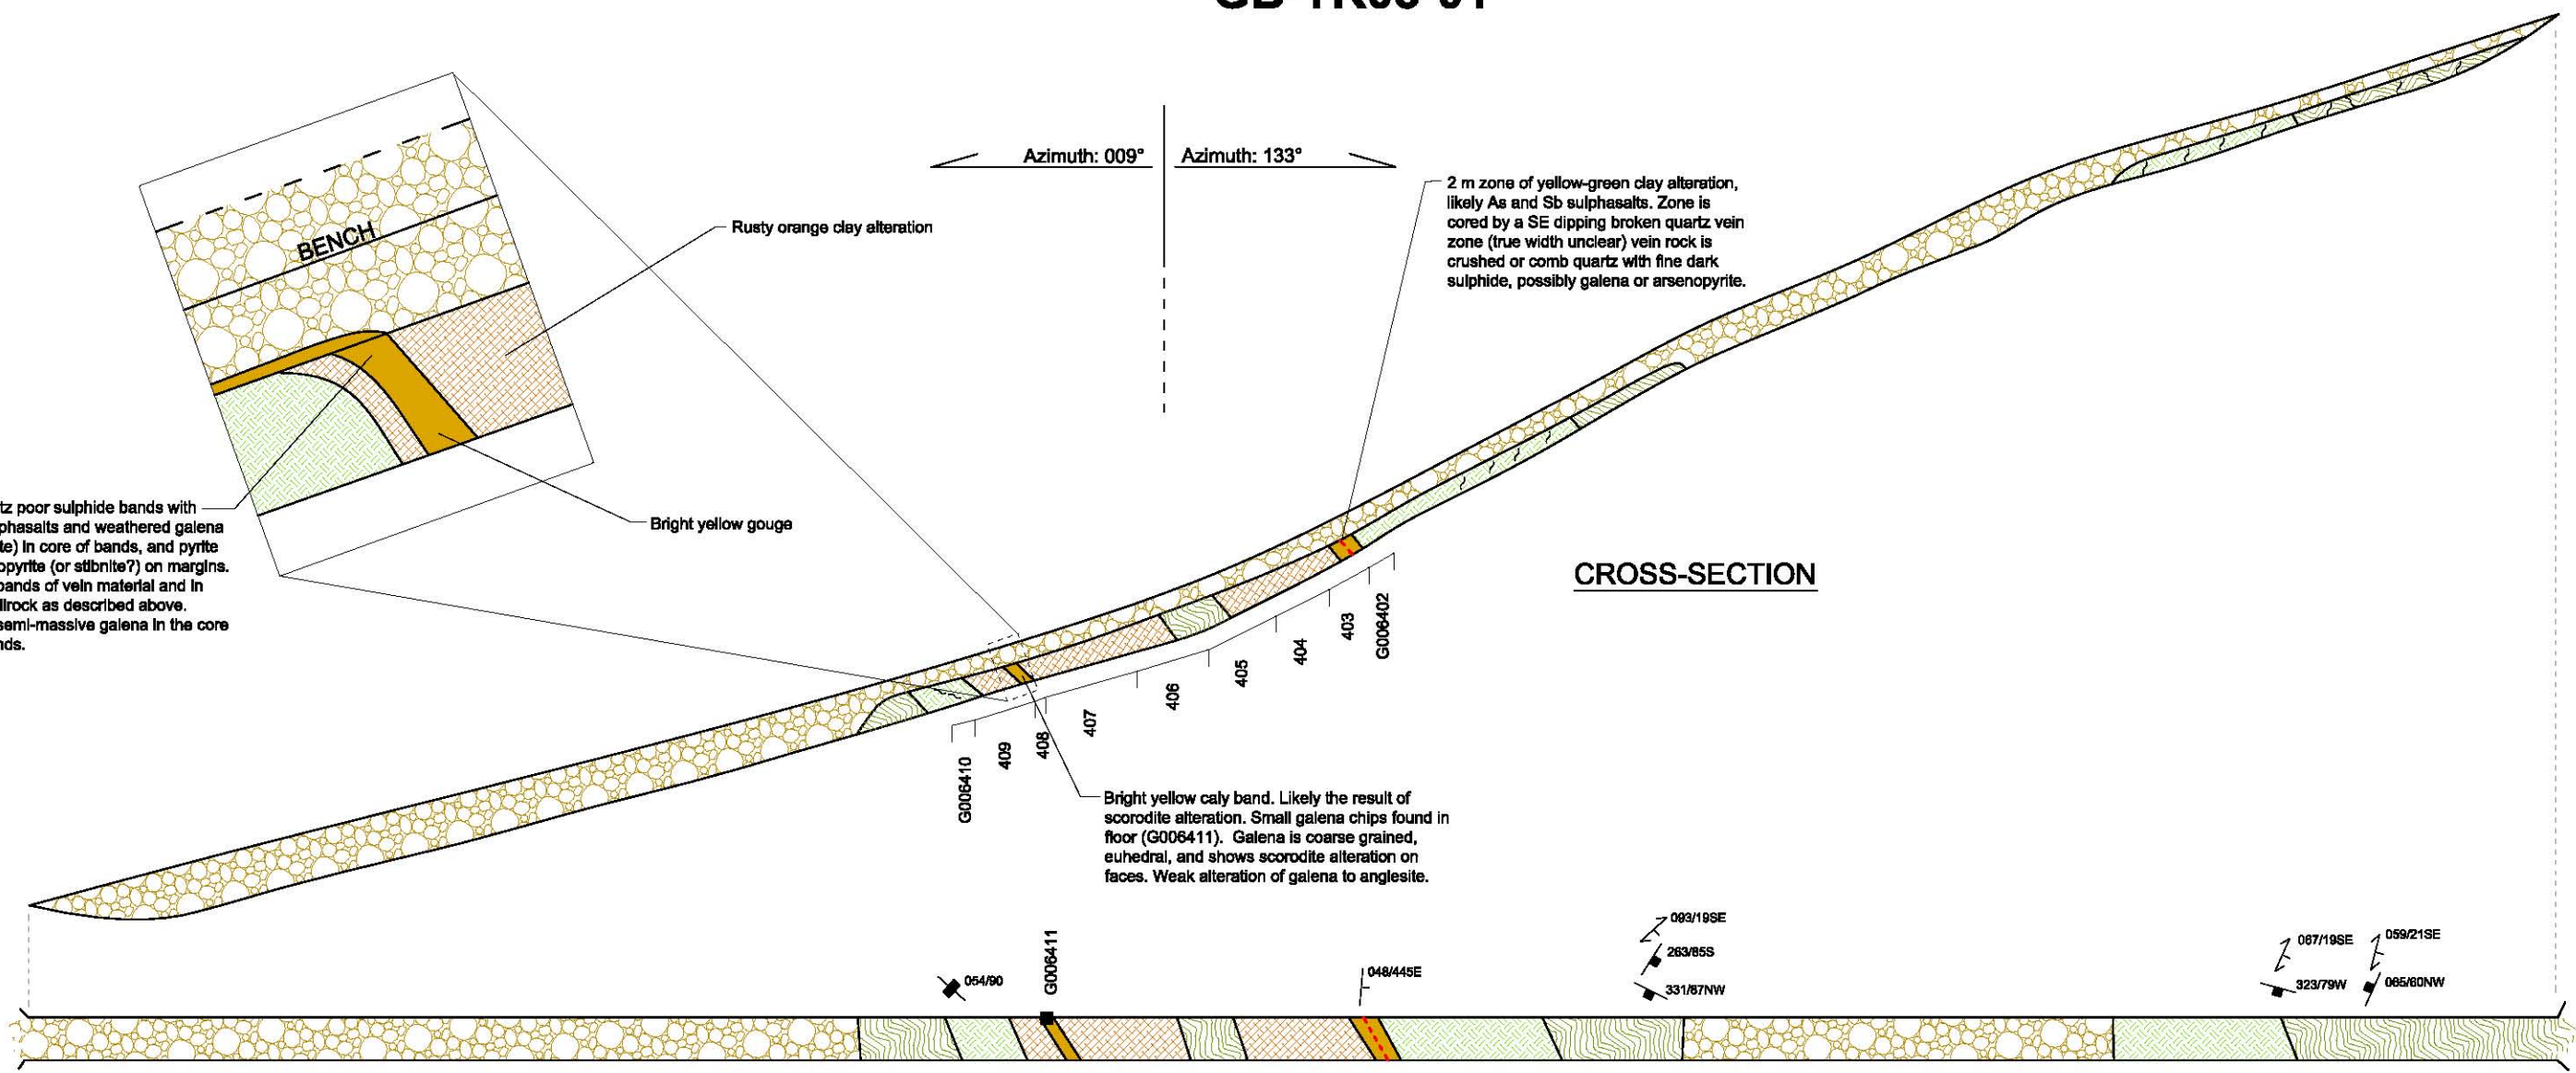

Azimuth: 009°

Azimuth: 133°

2 m zone of yellow-green clay alteration, likely As and Sb sulphasalts. Zone is cored by a SE dipping broken quartz vein zone (true width unclear) vein rock is crushed or comb quartz with fine dark sulphide, possibly galena or arsenopyrite.

CROSS-SECTION

Bright yellow clay band. Likely the result of scorodite alteration. Small galena chips found in floor (G006411). Galena is coarse grained, euhedral, and shows scorodite alteration on faces. Weak alteration of galena to anglesite.
