INTRODUCTION

The Rosy property covers a gold-silver prospect located five kilometres south of the Red Mountain porphyry molybdenum deposit in southern Yukon. The property consists of 90 claims that are owned 100% by ATAC Resources Ltd. subject to an option agreement with Valere Mining Ltd.

This report describes an exploration program that was conducted between July 8 and 23, 2008, as well as two day visits on September 11 and 27. All of this work was done by Archer, Cathro & Associates (1981) Limited on behalf of ATAC and Valere. The main program consisted of geochemical sampling, prospecting and geological mapping. After receiving positive results from this program, the property was significantly enlarged by staking an additional 60 claims. The day visits involved follow up prospecting in the vicinity of the best soil geochemical anomalies. The author participated in and directed the main program, and her Statement of Qualifications is in Appendix I.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The Rosy property comprises 90 contiguous mineral claims located 77 km east-northeast of Whitehorse in southern Yukon at latitude 60°56'N and longitude 133°45'W on NTS 105C/13, as shown on Figure 1. The claims are registered with the Whitehorse Mining Recorder in the name of Archer Cathro, which holds them in trust for ATAC. Claim data are listed below while the locations of individual claims are illustrated on Figure 2.

<u>Claim Name</u>	<u>Grant Number</u>	<u>Expiry Date*</u>

21-30	YC18159-YC18168	March 21, 2014
31-90	YC83534-YC83593	September 26, 2009

*Expiry date does not include 2008 work that has not yet been filed for assessment credit.

In 2008, the main program was done from two fly camps, located in different valleys on the property. The day trips were done from Whitehorse with daily helicopter setouts and pick-ups. All access was provided by Bell 206B helicopters owned by Capital Helicopters (1995) Inc. of Whitehorse.

The closest road access to the property is the Sydney Creek trail, which services placer workings about 25 km southeast of the property. An abandoned winter road extends northwest from the Sydney Creek trail to the Red Mountain Deposit, passing through the east side of the Rosy property. That trail would be the logical access route if heavy equipment were required on the property.

HISTORY

The first recorded activity in the vicinity of the Rosy property occurred in 1935 when silver-lead-zinc veins on the edge of the Red Mountain porphyry molybdenum deposit were staked. These

occurrences consist of galena and sphalerite in quartz-carbonate veins cutting metasedimentary rocks. They have been staked and explored by a number of operators over the years and are currently owned by another party.

The Red Mountain Deposit is marked by a prominent red gossan and comprises quartz stockwork veining associated with a Late Cretaceous quartz monzonite stock. It was first drilled in 1967 but the main exploration program was conducted in the late 1970s by Amoco Canada, which earned a 50% interest from the owner Tintina Mines. Drill indicated reserves are reported to be 170 million tonnes grading 0.167% MoS₂, including 19.3 million tonnes averaging 0.293% MoS₂ (Deklerk and Traynor, 2005). Gold content is low in the porphyry deposit and is inversely proportional to molybdenum content.

Recent prospecting on the Rosy property discovered numerous very old claim posts that likely date from the 1930s or 1940s. There is no record of this staking or any exploration related to it.

The first reported staking on what is now the Rosy property occurred in July 1986 immediately following the release of geochemical results from a reconnaissance stream sediment sampling program conducted by the Geological Survey of Canada (Open File 517). All-North Resources staked the Was 1-6 claims in the headwaters of a creek, samples from which returned 95th percentile values for gold (36 ppb), arsenic (121 ppm) and antimony (2.8 ppm). Concurrently, Noranda Exploration Company Limited staked the Saw 1-6 claims on a north-facing slope further downstream to cover another part of the anomalous drainage.

Both All-North and Noranda conducted reconnaissance mapping and soil sampling in 1987. All-North reported quartz vein float that assayed up to 1.3 g/t gold and 102 g/t silver associated with a soil anomaly containing values up to 145 ppb gold and 9 ppm silver (Garagan, 1987). Noranda found quartz-carbonate alteration zones, samples of which returned low values. No further work was done on either property and the claims were allowed to lapse.

ATAC restaked the property in summer 1999 and explored later that year with prospecting and soil geochemistry (Eaton, 1999). That work outlined several veins marked by recessive linears and strongly anomalous gold, silver and arsenic soil geochemical results. ATAC conducted further prospecting and soil geochemistry in 2004, discovering additional veins and expanding the area of anomalous geochemistry (Eaton, 2004).

In September 2007, a property wide helicopter-borne total field magnetic and versatile time domain electromagnetic (VTEM) survey was conducted on behalf of ATAC. Neither geophysical survey defined specific targets. Total field magnetics showed a strong correlation to geological units. VTEM response was only elevated in the area of a major fault (Wengzynowski, 2008).

Valere optioned the property in Spring 2008.

GEOMORPHOLOGY

The claims cover a series of ridges and glacial valleys, most of which are above tree line. The highest point is a prominent, 2094 m peak located in the northern part of the property. Elevations elsewhere range between 1300 and 1900 m. North facing slopes are characterized by cliffs and unstable talus. South facing slopes are steep but relatively accessible, featuring outcrops separated by grass- or buckbrush-stabilized talus.

Valley floors are generally narrow in their headwaters, where talus encroaches from surrounding slopes, but become broad and relatively flat bottomed further downstream, where they are blanketed by glacial and fluvial material. In the southeast part of the property, there is an extensive upland marsh that appears to have formed where an old tarn lake has completely filled with silt. Creeks draining the property all ultimately drain into the Teslin River, which is part of the Yukon River watershed.

REGIONAL GEOLOGY

The Rosy property lies in a structurally complex area where large faults have juxtaposed various metamorphosed volcanic, sedimentary and intrusive rocks, belonging to the Yukon-Tanana, Slide Mountain, Cassiar, and Stikinia terranes (Figures 3 and 4). Previous mappers have interpreted this area to be a steeply dipping suture zone marking accretion of an island arc to North America during Jurassic times (Tempelman-Kluit, 1979). Recent detailed structural mapping led to reinterpretation, which indicates that the steep dips are the result of a large-scale fold (de Keijzer, et al., 1999). Units observed on the Rosy property are assigned to the Nasina Subterrane of the Yukon-Tanana Terrane, an unnamed amphibolite subterrane of the Slide Mountain Terrane and a suite of post-accretion plutons (Gordey and Makepeace, 1999).

The metamorphic rocks are schist, gneiss, quartzite and marble that are believed to be Devonian or earlier in age (Gordey and Stevens, 1994). They are intruded by Early Jurassic and Cretaceous plutons. The youngest rocks are a Late Cretaceous quartz monzonite stock and related miarolitic quartz-feldspar porphyry dykes. The stock hosts the Red Mountain Deposit. The main lithologies are briefly described in the following table.

The main structural trend in the area is northerly to northwesterly. The Teslin Fault, a regional-scale, post-accretionary, high angle structure is located about five kilometres southwest of the property (Figures 3 and 4). Rocks on the southwest side of the Teslin Fault are quite different from those on the northeast side. They belong to the Whitehorse Trough, part of the Stikinia Terrane.

PROPERTY GEOLOGY AND MINERALIZATION

The property is predominantly underlain by weakly foliated metadiorite (EJgA) with lesser quartz-hornblende and quartz-feldspar-hornblende gneiss (DMN), as shown on Figure 5. A fault-bounded package of coarse grained, unfoliated, amphibolite (PPa) outcrops on the ridge in the northeastern part of the property. The southern fault contact of PPa juxtaposes it against a wedge of massive marble belonging to the Nasina Assemblage (DMN2).

The primary structural features on the property are a series of strong north-south trending linears and a less obvious, secondary set of northeast-southwest trending linears that cuts orthogonally across the main structural trend. Individual linears in both sets range from 1 to 10 m thick and exhibit moderate to steep dips to the southeast. Sharp breaks separate unaltered, resistant weathering wallrocks from altered recessive weathering rocks in the linears. The linear features are most evident on ridge crests and cliffs because blocky, unaltered wallrock talus tends to obscure them on normal hillsides.

Numerous cream to pink weathering, quartz-feldspar porphyry dykes (LKP) have been identified on the property. These dykes are generally less than 10 m thick and can be traced along strike for tens to a few hundred metres. They exhibit a variety of strikes but all dip steeply. Many of the dykes have strong recessive linears associated with them and are flanked by quartz-carbonate veins and/or carbonate altered wallrocks.

More than 25 quartz-carbonate veins have been mapped on the property. They occur with gouge zones, quartz-feldspar porphyry dykes and carbonate altered wallrocks, usually within the recessive linears. They are rarely seen in outcrop. Where the veins are exposed in bedrock, they are typically less than 80 cm wide and contain milky white to light grey, often chalcedonic, quartz. Carbonate normally occurs with the quartz. It weathers orange to red-brown and is likely a mixture of ankerite and dolomite. The veins often exhibit differential weathering that highlights delicate interbanding of quartz and carbonate. Most of the quartz-carbonate veins are hosted by EJgA and are surrounded by one to three metre wide alteration envelopes. These envelopes exhibit rusty weathering surfaces and pervasive yellow to green clay alteration. Angular fragments of altered wallrock are occasionally seen within vein zones.

A number of late-stage, barren, white quartz veins crosscut all units on the property.

The Rosy property hosts two main types of mineralization. The first occurs within quartz-carbonate veins and the second is found in altered intrusive rocks.

Primary mineralization within the veins consists of pyrite, lesser arsenopyrite, and rare chalcopyrite. These sulphides typically total 1 to 10 % of the veins. They occur as fine disseminations, blebs and stringers hosted in medium grey quartz. There is a weak positive correlation between the abundance of pyrite and that of arsenopyrite. Arsenopyrite and chalcopyrite abundance is strongly correlated but there is little apparent correlation between pyrite and chalcopyrite. On weathered surfaces, the primary sulphide minerals have been oxidized and leached to produce limonitic pits. Alteration envelopes peripheral to veins are generally riddled with white quartz veinlets. These quartz veinlets contain 1 to 5 % sulphides, consisting of finely disseminated pyrite and arsenopyrite.

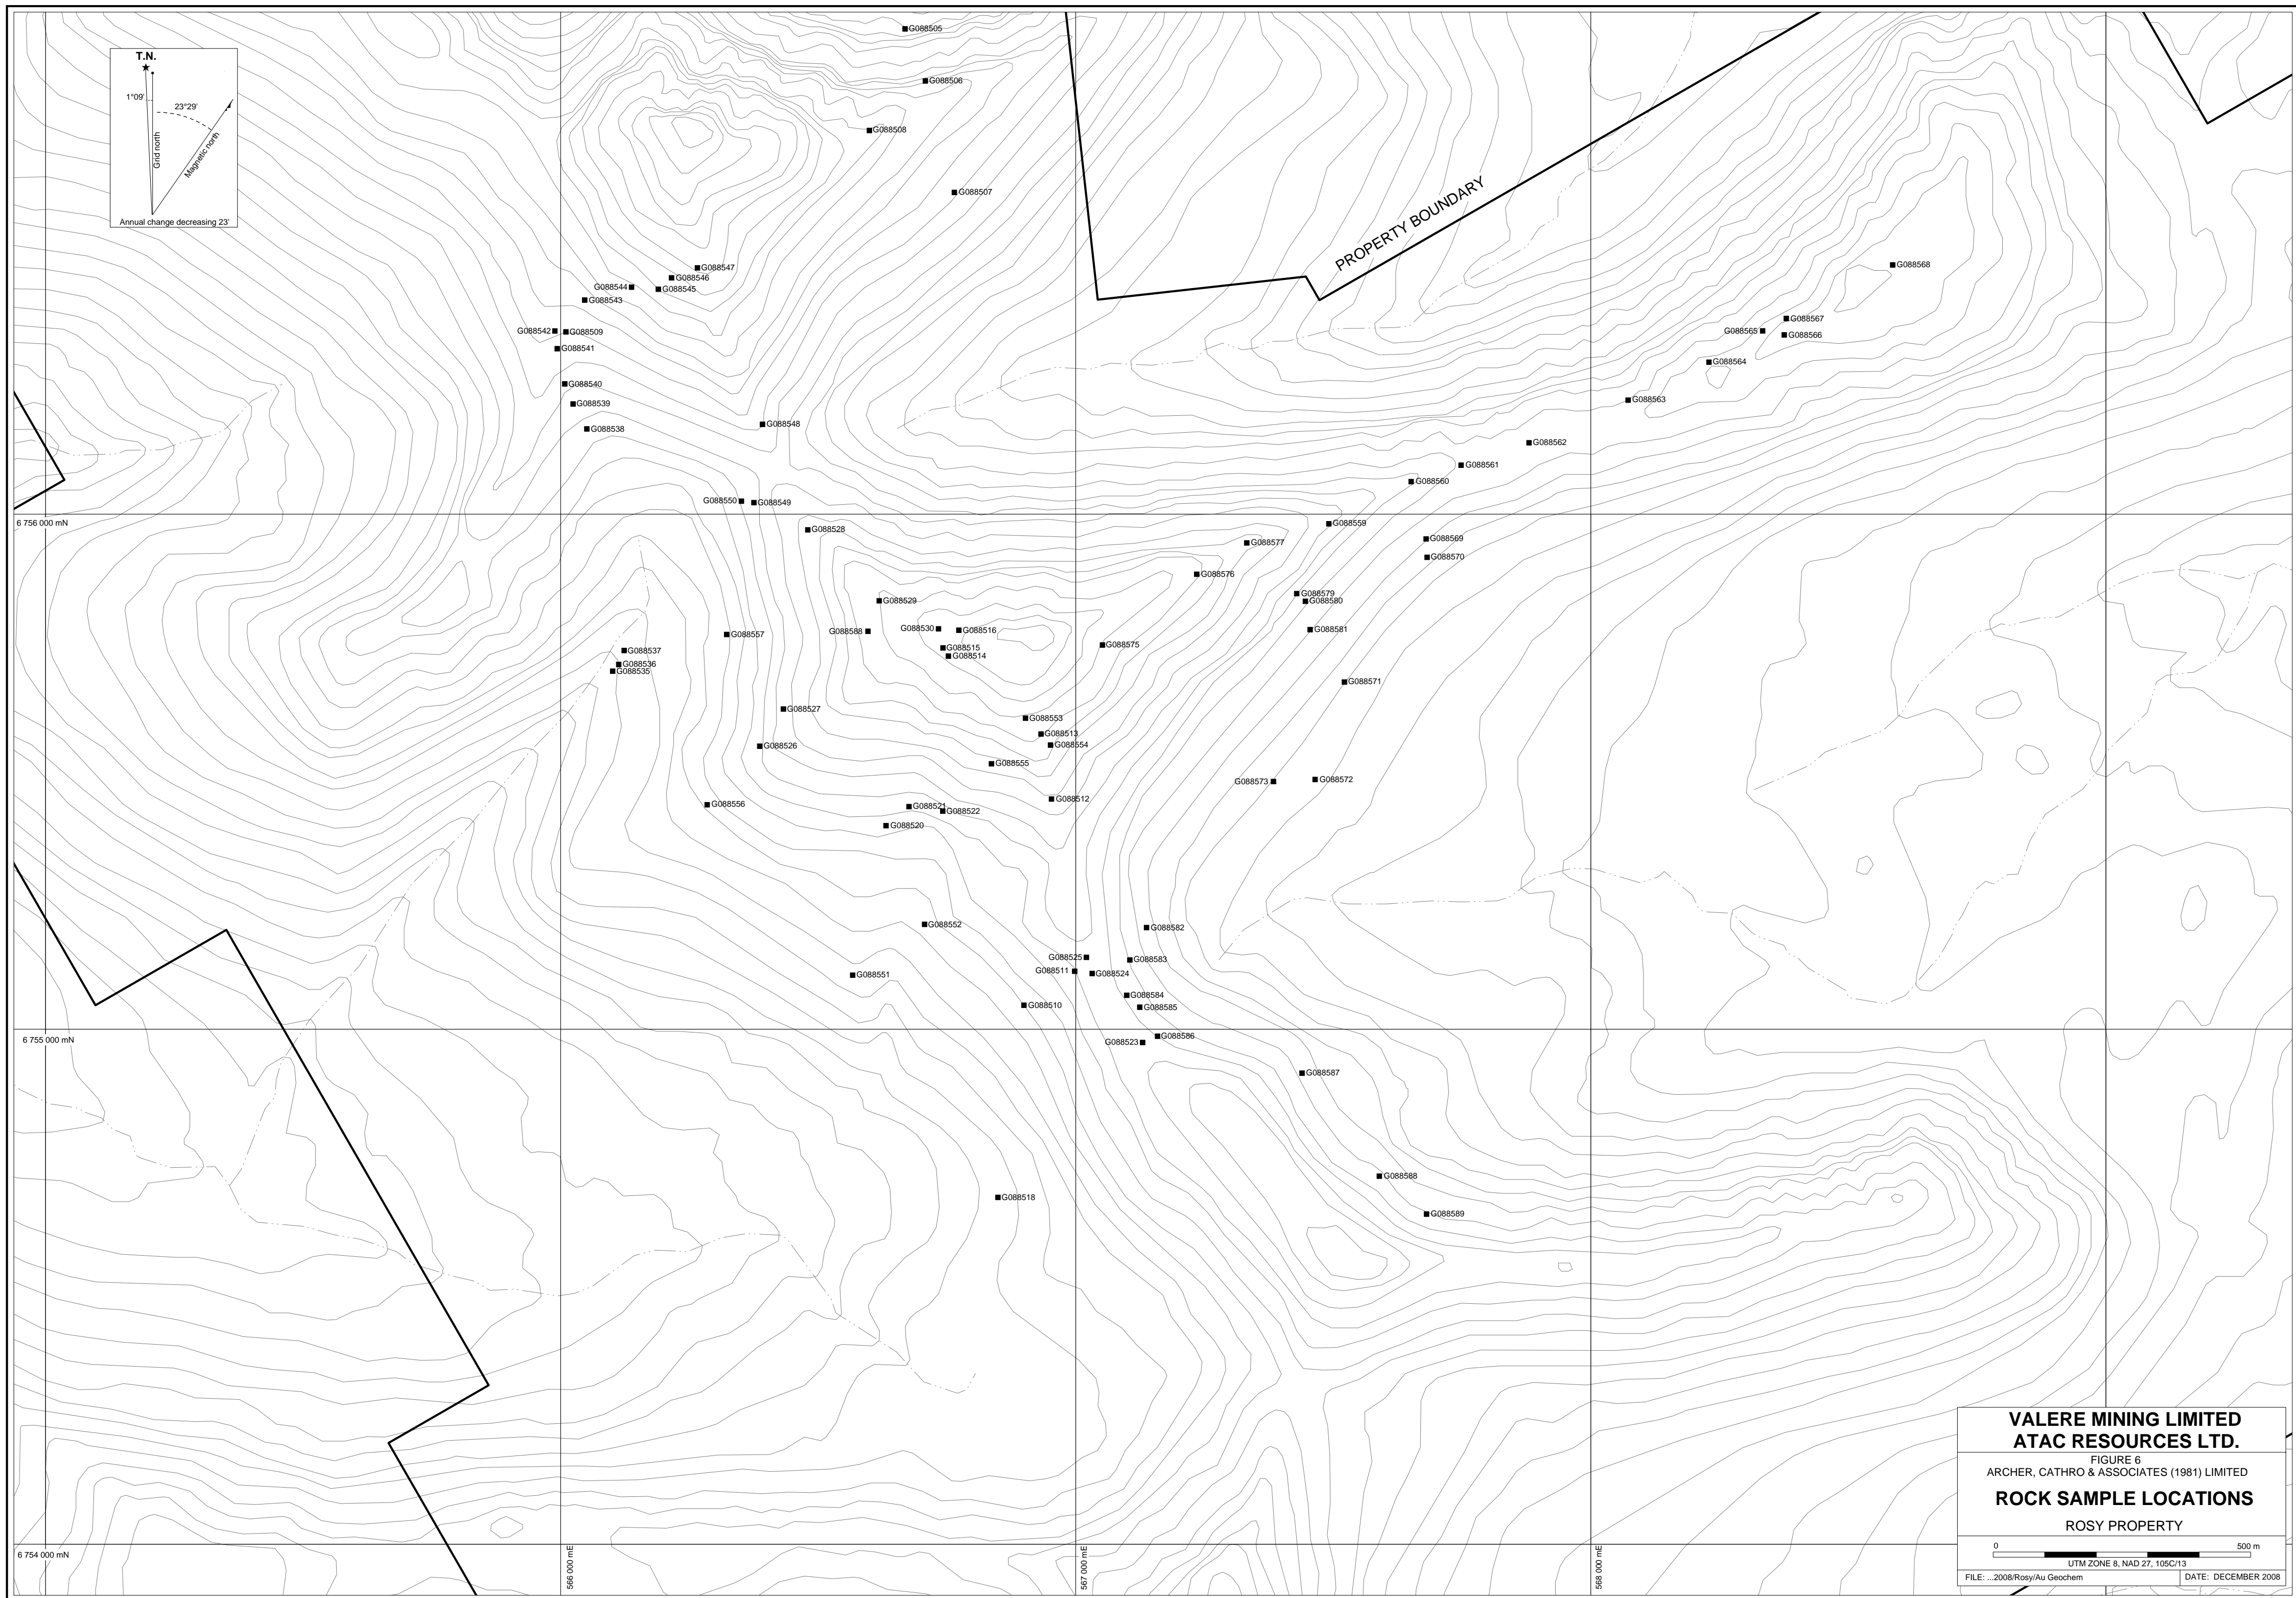

The other type of mineralization is found in intrusive rocks of EJgA. In most parts of the property, fresh EJgA contains trace pyrite and rare arsenopyrite, which weather to give the unit a weakly gossanous appearance.

ROCK GEOCHEMISTRY

Two distinct vein zones, R1 and R2, have been located on the property. R1 was discovered by prospecting in 2008 while R2 was previously reported. Ninety-three rock samples were taken in 2008 (Figure 6). Rock sample descriptions are located in Appendix II; sample handling and analytical procedures are explained in Appendix III; and, Certificates of Analysis are provided in Appendix IV. Results for gold, silver and arsenic are illustrated thematically on Figures 7, 8 and 9, respectively.

Both historical and 2008 data sets show strong correlations between gold, arsenic and antimony, and weak correlations between gold and silver.

The R1 vein was found in a recent soil slump on a steep, talus covered hillside. Outcrops peripheral to the slump consist of fresh EJgA. The slump exposed a 15 to 20 m wide, 20 m long area of rusty orange soil containing quartz-carbonate vein float and minor amounts of altered EJgA. A one metre diameter mineralized outcrop is the only bedrock exposure. It is composed

of grey quartz with rare chalcedonic clots. Mineralization consists of finely disseminated pyrite and arsenopyrite, millimetre-scale stringers of arsenopyrite, minor tarnished pyrite cubes up to five millimetres across and rare limonitic pits. Interior fracture surfaces exhibit yellow, scorodite coatings while exterior surfaces have a distinct black colouration. Four samples of quartz vein material were collected from the slump area. These samples returned values ranging from 2140 to 4420 ppb gold. Four float samples of altered EJgA were also collected, with two of the four yielding greater than 1000 ppb gold (1090 and 1790 ppb, respectively). Both of these specimens are described as hosting fine, clear to white, quartz veinlets with minor disseminated pyrite and trace disseminated arsenopyrite.

The R2 vein lies in a large saddle 800 m southwest of the R1 vein. It is situated near a ridge crest within a 20 m wide area of orange-brown rusty soil containing scattered quartz-carbonate vein float. The highest historical gold value from quartz-carbonate samples taken from this zone is 35,920 ppb gold. The 2008 sampling yielded five anomalous samples, which graded between 2410 to 5840 ppb gold.

A number of moderately to strongly anomalous vein samples have been collected from various other locales in the northern half of the property. Work to date has not demonstrated that any of these locales is large enough or high enough grade to warrant designation as a significant vein zone.

There are no reported anomalous gold or silver results from type-two, intrusion hosted mineralization.

SOIL GEOCHEMISTRY

A total of 933 soil samples were collected during the 2008 program. Soil sample locations are illustrated on Figure 10. Sample handling and analytical procedures used in 2008 are explained in Appendix III, and Certificates of Analysis are provided in Appendix IV. Gold, silver and arsenic results are illustrated thematically on Figures 11, 12 and 13, respectively. These figures also illustrate soil geochemical values obtained from previous programs, which were the subjects of earlier assessment reports (Garagan, 1987 and Eaton 1999 and 2004).

The compiled soil geochemical data have identified anomalous gold values in several areas of the property. Many of the anomalous values coincide with known veins or linears suspected to mark vein traces, but others are unexplained. Some of the anomalies are open to extension into untested areas. There is a positive correlation between gold, silver and arsenic values. Thresholds for strongly anomalous values have been set at 200 ppb for gold, 10 ppm for silver and 1000 ppm for arsenic. Peak values are 1820 ppb, 30.9 ppm and >10,000 ppm, respectively. Four main clusters of anomalous values have been identified and they are briefly described in the following paragraphs.

Anomaly A is 500 m long and forms a linear northwesterly trending band, that corresponds to the R1 vein. Eight soil samples taken on a south-facing side hill returned greater than 500 ppb gold and six of those exceeded 1000 ppb, to a maximum of 1820 ppb gold. To the north, this anomaly extends across a ridge crest onto a cliff-face, which could not be sampled, and from

there under a talus- and till- covered valley. To the south, the anomaly projects into a broad silt covered valley.

Anomaly B is 350 m long and coincides with the R2 vein. Part of this anomaly is defined by results from a pre-2008 detail grid. The three best soil samples from that grid averaged 670 ppb, with a peak value of 835 ppb gold (Eaton, 2004). The highest value from samples taken in 2008 yielded 581 ppb gold.

Anomaly C lies between Anomalies A and B. It is 250 m long and exhibits a northwest trend, subparallel to Anomaly A. The maximum value is 648 ppb gold. This anomaly is located near two anomalous rock samples collected during a previous program but a bedrock source has not been identified.

Anomaly D comprises a cluster of five soil samples spread over a 300 m by 150 m area. The highest sample yielded 571 ppb gold. This anomaly is located in the southern part of the property where little prospecting and mapping have been done.

Isolated anomalous results have also been obtained from samples taken in other parts of the property. The most noteworthy are found on the northern half of the claim block. They are typically associated with narrow, recessive vein zones and rusty linears.

DISCUSSION AND CONCLUSIONS

The Rosy property hosts widespread gold-and-silver bearing veins that appear to be spatially and temporally associated with Late Cretaceous intrusive activity. The lithochemical signature and textural features observed in veins and vein float, suggests that they are developed in a distal part of a large hydrothermal system, probably in a low sulphidation, epithermal setting. The nearby Red Mountain porphyry deposit is likely part of the same system. It exhibits a pronounced lithophile signature, which is characteristic of many Cretaceous age intrusions that are related to precious metal deposits elsewhere in Yukon.

The two best mineralized zones discovered to date on the property are the R1 and R2 veins. Neither is well exposed and both are open to extension along strike into talus-, till- and silt-covered areas. These veins and their associated soil geochemical anomalies (A and B) should be tested with a few shallow drill holes.

While drilling is underway, the other main soil geochemical anomalies (C and D) should receive further exploration including detailed mapping, prospecting and hand trenching. Reconnaissance-scale geochemical sampling, mapping and prospecting should be conducted across newly staked parts of the property.

APPENDIX III
SAMPLE AND ANALYLICAL PROCEDURES

SAMPLE HANDLING AND ANALYTICAL PROCEDURES

All rock and soil samples collected during the 2008 program were sorted into rice bags and sealed with a plastic zap strap on the Rosy property. Samples were sent to the Whitehorse airport via Bell 206 B helicopter owned by Capital Helicopters (1995) Inc. on July 18 and 23 and September 11 and 27.

Sample bags were received at the airport by Archer Cathro personnel and taken to the Archer Cathro office where they were temporarily stored prior to shipment. All samples were shipped via Greyhound Courier Express to ALS Chemex in North Vancouver, British Columbia.

Rock Geochemical Samples

All rock sample sites in 2008 were marked with orange flagging tape labelled with the sample number. The location of each sample was determined using a handheld GPS unit. All samples sent for shipment were double bagged with pre-numbered sample tags placed in the bags.

The rock samples were submitted to ALS Chemex in North Vancouver, British Columbia where they were dried and fine crushed to -2 mm. A 250 g split was then pulverized to 75 micron and a portion of this material was digested in aqua regia before being analyzed for 34 elements by the inductively coupled plasma-atomic emission spectroscopy technique (ME-ICP41). All rock samples were then analyzed for gold using fire assay technique (AU-ICP21).

Soil Geochemical Samples

All soil geochemical samples collected on the property were located by means of compass and hipchain surveys with frequent checks using handheld GPS units. Sample locations were marked with orange flagging tape and labelled with sample number and grid coordinate, where applicable. Soil samples were collected using mattocks and were placed into individual pre-numbered kraft paper bags.

The soil samples were sent to ALS Chemex, where they were dried and screened to minus 180 microns. One split of the screened fraction were dissolved in aqua regia and analyzed for 34 elements by ME-ICP41. A second split was fire assayed for gold using AU-ICP21.
