ACKNOWLEDGEMENTS

This report summarizes geological mapping, geochemical surveying, core logging and interpretation conducted by several geologists and geology students who worked as part of the 2007 Wernecke field crew. Scott Boyce, Thomas Branson, Kelsey Dodge, Heather Jaggard, Jim Lehtinen, Jeremy Major, Nick Mitchell, Neil Perk and Phil Seccombe all made contributions to the collection of geological information and interpretation of data that comprises this assessment report. Additionally, some of the written work contained herein is derived in large part from property summaries prepared by these individuals. Their contribution and hard work during the field campaign is acknowledged and appreciated.

1.0 SUMMARY

The Wernecke project area consists of 1,926 quartz claims (374 km^2) in 26 claim groups, scattered over an area of 60 by 70 km in the Wernecke Mountains, approximately 170 km northeast of Mayo in east-central Yukon. According to Yukon Government databases, the claims are held in the name of Fronteer Development Group Inc. The claims are being explored by a joint venture between Fronteer Development Group Inc. ("Fronteer" - 80%) and Rimfire Minerals Corporation ("Rimfire" - 20%), subject to underlying 2% NSR and 7.5-15% NPI royalties.

The Wernecke Mountains are underlain by approximately 13,000 m of fine-grained siliciclastic and carbonate rocks of late Paleoproterozoic age. Following deformation, mafic to intermediate dykes, sills and stocks intruded at ca. 1.71 Ga, apparently contemporaneously with extrusion of sub-aerial mafic lava flows of similar composition. Subsequently, large volumes of iron-rich, oxidized hydrothermal fluids invaded the sedimentary rocks, creating the extensive, crosscutting hematite breccia bodies known as the Wernecke breccias. Emplacement of these breccias was presumably controlled by regional structures.

Widespread iron oxide copper-gold (IOCG)-related mineralization was deposited in altered metasedimentary rocks associated with the Wernecke breccias and locally within the breccias themselves. Along with elevated Cu and Au, these large systems have elevated Ag-Mo-U-Co-Bi-Ni and rare earth elements (REE) Ce and La.

The earliest widespread exploration on the Wernecke properties occurred in the late 1960s and focused on Cu. During the 1970s widespread exploration focused on U-Cu-Au-Co. Significant exploration during 1992-1997 focused on the Cu-Au potential based on the newly formed IOCG mineral deposit model. Mapping, prospecting, airborne and ground geophysics and 14,721 m of diamond drilling in 103 holes were completed by 1997. The properties were dormant from 1998 until 2006 when a surface-based exploration program re-evaluated many airborne radiometric and surface geochemical anomalies for uranium potential. Several uranium only and IOCG targets were drill-tested during 2007 totalling 6,538 m in 28 holes focused on seven different targets.

The most significant of the Cu-Au targets lie on the northeastern edge of the Bonnet Plume valley, which is thought to follow a major fault splay within the Richardson Fault array. Drilling in the Hoover Central zone intersected 126.72 m @ 0.44% Cu; 12 km to the southeast, holes on the Slab Mountain and Slab Northwest zones hit up to 110.05 m @ 0.30% Cu. Fieldwork in 2006 and 2007 led to the recognition of significant new U and Cu-Au mineralization on the Fireweed, Jazz / Thunder Mountain, Mica-Hail, Pagisteel, Ursus, Slats and TVA properties.

Although significant surface uranium mineralization has been discovered during the last two years of exploration on the Werneckes properties, the IOCG-type targets have the best potential for bulk tonnage mineral deposits. High-grade uranium mineralization is common on several of the Wernecke properties but the areal distribution and width of these hot spots are typically very restricted. By contrast, zones of hydrothermally altered and Cu-Au-Ag-Mo-U-Co-Bi-REE mineralized sedimentary and brecciated rock occur over large areas. Unfortunately, grades demonstrated to date have been low. The real challenge moving the Wernecke Project forward is to utilize geological and geophysical techniques to better target drilling within these hydrothermal systems. The IOCG-related Cu-Au zones should be first priority targets while structurally-controlled U targets should be second priority.

A $3.0M exploration program is recommended for the Wernecke project in 2008. Detailed target selection should occur during a first phase of geological mapping and ground geophysics (IP, EM, gravity). A second exploration phase of diamond drilling should follow.

2.0 INTRODUCTION

The Wernecke project is focused on a 60 by 70 km area in the Wernecke Mountains, approximately 170 km northeast of Mayo in east-central Yukon (Figure 1). This area was the focus of uranium exploration in

the 1970s and 1980s and of copper and gold exploration in the 1990s. Several very large exploration programs have been completed in the area. In all, 14,721 m of diamond drilling in 103 holes has been completed within (or very proximal to) the current land position prior to the 2007 program.

Several well-known IOCG exploration targets exist on the property, while the uranium potential of the area is once again becoming a focus (Hunt et al., 2006; Lewis and Burke, 2007). Both types of deposits generally show a high degree of structural control and are hosted in altered metasedimentary rocks of the Proterozoic Wernecke Supergroup. The Wernecke breccias–a distinct family of discordant map-scale haematitic hydrothermal deposits–are closely associated with most mineralization identified to date. Remobilization of uranium likely was widespread and the genesis of uranium mineralization equivocal.

The current round of exploration activity by Fronteer Development Group began in 2006 (Heffernan et al., March, 2007). That program focused on uranium potential of the area. Numerous new targets–mostly airborne radiometric anomalies–were delineated and tested by geological and geochemical surface methods. These new discoveries pointed to the potential for structurally controlled uranium deposits. The 2007 program, as described here, tested both IOCG and uranium targets by drilling and surface geochemical and mapping surveys.

3.0 RELIANCE ON OTHER EXPERTS

The author did not rely on other experts regarding legal, environmental, and political or other such issues.

4.0 PROPERTY DESCRIPTION AND LOCATION

The Wernecke project comprises 26 separate properties in the Wernecke Mountains of east-central Yukon Canada, approximately 170 km northeast of Mayo (Figure 1). The Wernecke properties lie within the Mayo Mining District, centred at 65° north latitude and 134° west longitude. The claims are located on NTS map sheets 106C/13, 106C/14, 106D/9, 106D/16, 106E/1, 106E/2, 106E/8, 106F/3 and 106F/4 within an area measuring approximately 60 by 70 km.

The 26 properties are made up of 1926 quartz claims covering 37,351 hectares near the Bonnet Plume River (Figure 2). Property boundaries were delineated from the digital GIS claim maps available from the Yukon Mining Recorder and were located in the field by hand-held GPS units. These claims and their expiry dates are detailed in Appendix B. Records of the Yukon Department of Energy, Mines and Resources indicate that all claims are held by Fronteer. Separate documents indicate that they are held by a Joint Venture between Fronteer (80%) and Rimfire (20%). Newmont Canada Limited (“Newmont”) and Breakwater Resources Ltd. (“Breakwater”) share a 2% NSR and the underlying vendors retain a 7.5-15% NPI on the Wernecke project claims.

Surface rights over the Wernecke properties are owned by the Yukon Territory. Neither significant surface disturbance nor any major environmental liabilities were noted during field examinations. Exploration permits must be obtained from the Yukon Department of Energy, Mines and Resources prior to carrying out the exploration program outlined in this report. A five-year Class 3 Mining Land Use Approval was granted by the Yukon Mineral Resources Branch to Fronteer on April 19, 2007.

5.0 ACCESSIBILIY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, PHYSIOGRAPHY

The Wernecke properties are best accessed by helicopter from a base camp on the 885 m-long Copper Point gravel airstrip, located in the Bonnet Plume River valley. The Copper Point strip is suitable for most fixed wing aircraft, generally serviced out of Mayo or Whitehorse (500 km to the south). Other airstrips in the area, including Bear River, Wind River, Dolores Creek and Bonnet Plume River Mines are of limited or

unknown serviceability. Several lakes in the area, including Fairchild, Kiwi, Quartet, Gillespie, Pinguicula, Glacier and McClusky are suitable for float-equipped aircraft.

The Wind River winter tote road, originating near Elsa, was built through the area in the 1950's. It has been re-activated sporadically ever since, being used most recently in 2006 to mobilize heavy equipment as far as the Blende property of Eagle Plains Resources.

Elevations in the area range from 540 to 2500 m above sea level and relief varies from gentle in the valley bottoms to rugged on mountain slopes. Vegetation ranges from bare slopes above treeline to stunted spruce, dwarf alder and willow at lower elevations. Climate is characterized by six months of cold winter and three to four months of warm summer, with May through September most suited to exploration. The average daily January and July temperatures for Mayo are -29°C and 15.2°C, with annual precipitation of 306 mm, of which 40% is snow.

6.0 HISTORY

6.1 Previous Work

The first copper occurrences were noted by trappers working in the area at the turn of the century. The Slab mineral showing was first staked in 1910. In 1935, the McClusky copper occurrences were staked and the Bonnet Plume and Wind River area received sporadic exploration for copper over the next twenty years. Exploration activity was stimulated in the early 1960s when California Standard Company through their subsidiary, Crest Exploration Limited, worked on their world-class banded iron deposit in the Snake River area. In the early 1960s, the first copper showing was found at Dolores Creek by L. Brown. Bonnet Plume River Mines Ltd. conducted exploration from 1967 to 1969, at which time limited diamond drilling was completed (Laznicka and Edwards, 1979).

In 1971, the discovery of zinc-lead showings in the MacKenzie Mountains to the east brought exploration activity to the southeastern portion of the Wernecke Mountains. Continued lead-zinc exploration in the Proterozoic basin led to the discovery of uranium mineralization in 1974 by Archer, Cathro and Associates Ltd. In the period 1975 to 1980, a number of major companies (Urangesellschaft, Noranda) and joint ventures (Wernecke Joint Venture, Mountaineer Mines-Pan Ocean Oil Limited, Prism Joint Venture) were involved in exploration of breccia-related uranium mineralization. Also at this time, Pan Ocean drilled coal resources on their lower Bonnet Plume leases and outlined in excess of 500 million tonnes of low sulphur, high volatile bituminous coal in Cretaceous strata.

The 1980s saw minor work throughout the project area. Archer Cathro, Texaco, and Cyprus Gold embarked on limited exploration to test the gold potential of some of the known uranium or copper occurrences. Exploration in the 1990s was conducted by BHP Minerals, Kennecott Canada, International Prism, Cominco, Zelon Enterprises and the Fairchild Joint Venture ("FJV"), on both copper-gold and zinc-lead targets.

In the mid-1990s, the FJV – comprising Westmin (now Breakwater) and Newmont – recognized the IOCG potential of the Wernecke breccias and spent a total of US$5.5 million on more than 20 properties, focusing on their copper-gold potential. Newmont flew a regional airborne magnetic and radiometric survey and conducted extensive geochemical sampling and geological mapping prior to drilling twelve prospects for a total of 14,600 m (Gorton and Stammers, 2000).

In early 2006, Fronteer and Rimfire optioned the 410 key claims still held by Newmont and Breakwater, along with their geochemical/geophysical database. As funding partner, Fronteer staked an additional 1,600 claims and carried out extensive geological and geochemical fieldwork (Heffernan et al., March, 2007) and an airborne gravity survey in 2006 (Selman, 2006).

6.2 2007 Exploration Program

Exploration in 2007 comprised a surface program of diamond drilling, geological mapping, prospecting, soil and silt sampling and ground magnetics. All fieldwork was helicopter-supported and based out of a centrally located camp at the Copper Point airstrip in the Bonnet Plume River valley. Field crews collected a total of 906 rock samples, 112 silt samples and 3150 (including 220 MMI-type) soil samples (including QA/QC samples) between April 25th and October 12th, 2007 (Table 1). Equity Engineering Ltd. of Vancouver, BC was contracted to manage and execute the surface exploration program and has been retained to report on the results as described herein.

Table 1: Surface Samples Collected during the 2007 Program

Sample Type	Total*	ALS Chemex Analytical Codes
Rock	906	Au-AA23, ME-MS61
Soil	2930	Au-AA23, ME-MS41
MMI Soil	220	ME-MS18
Silt	112	Au-AA23, ME-MS41

*includes ~10% QA/QC samples

Standard, reconnaissance-style soil samples were collected at claim post locations, along contour soil lines and several soil grids. Soil samples were marked with orange flagging and all sample sites were marked with a Tyvek tag with the sample number marked on the tag with a china marker. Soil samples were taken from B-horizon soils wherever possible but due to steep terrain and poor soil development, the majority of samples were of colluvium or talus fine material. Characteristics of the sample site were recorded on a sample form for later reference. A field duplicate soil sample was collected about every 20th sample and sample blanks were inserted every 60th sample (Appendix E).

On two properties (Hoover and Arch), soil samples were collected and analyzed by Mobile Metal Ion (MMI) techniques. The depth of sampling is related to the physics and chemistry of the capillary rise and evapo-transpiration process, and is therefore related to distance below the soil interface irrespective of soil type. As such, in undisturbed environments samples were collected below the true soil interface at a consistent depth of 15 cm. Initially, the upper surface soil layer was scraped away thereby eliminating loose organic matter, debris, and any possible contamination. Between sample sites, material and equipment was brushed to eliminate residue from previous samples and flushed with the soil from the new sample site. During sample collection and handling, no jewelry (watches, rings, bracelets, and chains) were worn, as these can be a source of contamination. Once collected, samples were stored in zip lock plastic bags. MMI soil sample sites were marked similarly to standard soil sampling sites. Samples were submitted to ALS Chemex and analyzed with their complete MMI package (ME-MS18) at their Perth facility.

Rock samples were marked in the field by a combination of pink and blue flagging plus a small aluminum tag on which has been inscribed the sample number, the type of sample, the initials of the sampler, and the date the sample was taken. Characteristics of the rock sample were recorded on a sample form and the data from these forms has been included in Appendix D.

All rock and soil samples were located using a hand-held GPS. Generally, a measurement was taken with an Exploranium GR-110 scintillometer and recorded for each rock sample and soil sample location.

6537.96 m of NQ2-sized diamond drilling in 28 holes was completed during the 2007 program (see Section 10.0 for details). All drill core was processed at a tent-style core shack established near the Copper Point camp. Percent recovery and percent rock quality descriptor (RQD) were measured and recorded for each drill run. A KT-9 magnetic susceptibility meter was used to measure magnetic susceptibility for each drill run. An average value for each run was determined by collecting 3-6 individual measurements. Radioactivity was measured and recorded for each drill run using a GR-135G Spectrometer. Drill core samples were collected using mechanical core splitters. Sample intervals are delineated by laboratory sample tags stapled into core boxes. All drill core was cross-stacked on site near the core shacks.

Samples were flown directly from Copper Point airstrip to the Alkan Air base in Whitehorse in rice sacks sealed with individually numbered security tags. The rice sacks were transferred to Canadian Freightways in Whitehorse and then delivered to the ALS Chemex Laboratories preparation facility in Terrace, BC. All soil and rock samples were analyzed for gold by 30 g Fire Assay-Atomic Absorption Spectroscopy Combination. Soil samples were submitted for a multi-element suite that employed an aqua regia acid digestion and a combination of Inductively Coupled Plasma Mass Spectrometry (ICP-MS) and Inductively Coupled Plasma Atomic Emission Spectrometry (ICP-AES) techniques. Rock samples were submitted for a multi-element analysis package that utilized a four acid digestion and a combination of ICP-MS and ICP-AES techniques. Certificates of Analysis are presented in Appendices H.1 to H.4. Pulp assays were carried out for high geochemical values of Au, Ag, Pb, or Zn; the assays were used for plotting and calculations. Pressed Pellet-Wavelength Dispersive X-Ray Fluorescence Spectrometry (XRF) analysis was carried out on pulps from samples that returned initial uranium values greater than 1000 ppm. As part of the QA/QC program, the reject material from these high-uranium samples was sent to Activation Laboratories of Ancaster, Ontario for prep and analyses by the same technique. “Metallics” assays for Au were carried out on rejects when initial geochemical values exceeded 10,000 ppb Au. The procedures, results and conclusions of the sampling QA/QC program are summarized in Appendix E.

A magnetic declination of 26.5° E was used for all compass measurements. Structural measurements are all reported utilizing the right-hand rule. All maps and UTM coordinates are referenced to the 1983 North American Datum (NAD-83; Zone 8).

7.0 REGIONAL GEOLOGY AND MINERALIZATION

7.1 Regional Geology

The Wernecke Mountains are underlain by approximately 13,000 m of fine-grained siliciclastic and carbonate rocks of the late Paleoproterozoic age. These rocks were deposited during two cycles of subsidence and uplift in a rift-related, intra-cratonic basin and were subsequently affected by up to three compressive deformation events, resulting in development of isoclinal folding, schistosity, and local kink banding (Brideau et al., 2002). Following deformation, mafic to intermediate dykes, sills and stocks intruded at 1.71 Ga (Thorkelson et al., 2001a), apparently contemporaneously with extrusion of sub-aerial mafic lava flows of similar composition. Subsequently, large volumes of iron-rich, oxidized hydrothermal fluids invaded the sedimentary rocks, probably along the same structures used by the intrusions, creating the extensive, crosscutting breccia bodies known as the Wernecke breccias.

The entire succession has been named the Wernecke Supergroup and has been divided into three groups (oldest to youngest): Fairchild Lake Group, Quartet Group and Gillespie Lake Group. To the east and south, the Hadrynian Pinguicula Group unconformably overlies the Wernecke Supergroup. Paleozoic strata bound the western margin and Cretaceous and Tertiary sediments fill the area to the north in the Bonnet Plume Basin.

The first recorded geological mapping in the area was by C. Camsell of the Geological Survey of Canada in 1905, who completed a topographic and geological survey between the Stewart River and Fort McPherson. In 1961, "Operation Ogilvie" was launched and the Nash Creek (1060), Larsen Creek (116A) and Dawson (116B&C) map areas were mapped under the direction of J.A. Roddick and L.H. Green (1972). Mapping of the Nadaleen River map sheet (106C) was started in 1971 by S. Blusson and released in 1974 (Open File 205). The geology of the Wind River (106E) and Snake River (106F) map areas was mapped by O.K. Norris (Open File 279) in 1975. Since 1976, the Geological Survey of Canada, led by R.T. Bell, G.D. Delaney and W.O. Goodfellow have been mapping the Proterozoic basin and studying the uraniferous breccia complexes. Delaney (1985) provides the most updated discussion of the Proterozoic stratigraphy whereas Bell (1978, 1982, 1986a, b; 1977) focused on the mineralogy, morphology and genesis of the breccia complexes. In addition to this published work, many stratigraphic sections were measured by Pamicon Developments Ltd. during their work programs. The following lithological discussion combines the

detailed Pamicon work and that of Delaney. Where applicable, the Fairchild, Quartet and Gillespie subgroups of Delaney (1985) have been bracketed after the Pamicon description.

The Fairchild Lake Group outcrops along the western edge of the Bonnet Plume River at Bond Creek and near the headwaters of the Little Wind River (Figure 3). The thickness is greater than 4,000 m and the base of this sequence has not been observed. The lowest members of the Fairchild Lake Group consist of light to dark green, fractured, chloritic siltstone grading upwards into light grey, massively bedded, siliceous siltstone (F-l). The remainder of the section consists of alternating repetition of the grey siltstone described above and an interbedded unit of narrow limestone (20%) and siltstone (80%) beds (F-2). The interbedded unit is recognized by its "ribbed" weathering. Overlying these units is a sequence of massively bedded, green calcareous siltstone, brown weathering dolomite and a coarser, light green sandstone or quartzite with local magnetite (F-3, F-4). The top of this section is marked by a 12.0 metre massively bedded, calcareous white quartzite overlain by thin bedded, green calcareous siltstone and minor limestone. The transitional (F-Tr) upper part of the Fairchild Lake Group is measured from the appearance of a well developed phyllite. Overlying the phyllite is a bed of black, soft silty shale, followed by 170 m of thick, massively interbedded section of brown weathering dolomite with black shale and topped by 120 m of pyritic, rusty weathering, black shale. Near the top of the dolomite sequence is a distinctive 12 metre thick marker horizon of white, recrystallized limestone. This sequence is typical of a thick miogeoclinal succession.

The Quartet Group consists of greater than 5,000 m of monotonous dark-grey weathering, fine-grained siliciclastic sediments. Immediately above the red brown weathering shale of the Fairchild Lake Group is a 330 metre thick section of dark grey to black weathering, laminated shales and silty shales (Q-l). The balance of the section is comprised of dark grey weathering siltstone and sandstone with interbeds of shale and quartzite (Q-2). Primary structures include cross and graded bedding, ripple marks and load casts. Massively bedded quartzites increase in frequency towards the top of the group. The base of Q-2 is marked by a 180 metre thick, rusty weathering, pyritic quartzite unit.

The base of the Quartet Group is interpreted by Delaney (1985) to have accumulated in a sediment starved basin with the thicker bedded siliciclastic sediments of Q-2 being typical of shallow marine sediments.

The Gillespie Lake dolomitic rocks exhibit a gradational contact with the underlying Quartet Group. The thickness of the transition zone varies from 25 m to as much as 700 m Delaney (1981) and consists of massively interbedded, brown to orange weathering dolomite and dark grey to black, calcareous siltstone or shale giving a striped appearance to this unit (G-TR). Delaney (1981) has subdivided the remainder of the group into G-2 through G-7, although none of these subgroups can be followed along strike due to dramatic facies changes. Above the transition zone, the Gillespie Lake Group is dominated by bright orange-weathering, grey dolomite with minor black shale, maroon shale and lesser quartzite, stromatolites, oolites and molar tooth structures occur near the top of the section. The Gillespie Lake Group is a 4,000 m thick section of terrigenous siliciclastic sediments and shallow marine platformal dolomites.

The overlying Pinguicula Group of Hadrynian age consists of a basal andesitic flow overlain by coarse unsorted conglomerate, alternating red and green siltstones/sandstones, and, finally by stromatolitic dolomite. This poorly studied group has been correlated to the Coates Lake Group or "copper cycle" in the upper part of the MacKenzie Mountains Supergroup (Jefferson and Ruelle, 1986). Its lower contact and upper contact, which is marked by glacial deposits of the Rapitan Group (Ekwi Supergroup), are both erosional unconformities.

Strata of the Wernecke Supergroup are cut by numerous hematitic breccia complexes that are enriched in iron, uranium, barium, fluorine, copper, cobalt, rare earths and gold. At least 86 breccias have been identified, which represents about 2% of the surface exposure in the region (Archer and Schmidt, 1978). No breccias cut the younger Pinguicula Group rocks.

The Wernecke Supergroup is cut by diorite dykes/sills and one body of peridotite. Several lamprophyre dykes approximately 1 m wide, with phenocrysts of fresh biotite up to 4 cm in diameter are found northwest of Fairchild Lake (Archer and Schmidt, 1978). K-Ar dating of biotite points to a Late Proterozoic or Early Cambrian age for these dykes (Delaney, 1981). Diabase dykes, tentatively assigned a Cretaceous age, occur in the southern half of the map-area.

7.2 District Structure

The main structural components of the Wernecke district are the southeast trending fault splays (Deslauriers, Knorr and Snake River Faults) of the Richardson Fault Array. These faults are interpreted to be deep-seated, long-lived, vertical structures which have undergone considerable right lateral and vertical movement. These faults separate the Wernecke Supergroup from younger Proterozoic rocks to the east. In the western part of the area, Lower Paleozoic rocks unconformably overlie the Wernecke Supergroup forming spectacular angular unconformities. On a regional scale, sedimentary rocks dip away from the Bonnet Plume valley causing the Proterozoic rock units to be exposed in a northwest trending anticlinal structure.

The Bonnet Plume valley is considered to be an expression of a major fault splay from the Knorr Fault and the Wind River from the Deslauriers Fault. A secondary northerly set of faults likely controls the topographic linears such as the Slats Creek pass and Fairchild Lake valley.

At least two late major orogenic events affected the Proterozoic strata in the Werneckes. These include the "Racklan orogeny" at the base of the Pinguicula Group (1.2 Ga) and a major rifting event at the base of the Rapitan Group (0.8 Ga), the "Hayhook orogeny" (Young et al., 1979).

Deformation due to the Racklan orogeny consists mainly of intense cross block faulting with steep reverse and normal block faulting and subsequent rotation of large blocks. Folding is normally an open style and the Richardson Fault Array was probably active (Delaney, 1981). This deformational phase is consistent with an extensional rifting environment producing mafic volcanic flows at the base of the Pinguicula Group and development of the breccia complexes.

Within the Lower Fairchild Lake Group, the deformation is more intense as folds are normally tight, isoclinal and locally recumbent. A large portion of the group is overturned south of Fairchild Lake. Since the degree of alteration and structural complexity of the Quartet and Gillespie Lake Groups is much less, it is suspected that an early deformational event affected the Lower Fairchild Lake Group, perhaps marking the boundary between the Aphebian and Helikian. Bell (1982) feels that these structural features were produced by the interaction of transcurrent faults producing areas of tension and compression creating variations in style and intensity of deformation.

7.3 Regional Mineralization

The Wernecke properties contain numerous iron oxide copper-gold (IOCG) showings (e.g. Thunder Mountain) and mineralized zones (e.g. Hoover) and this deposit model (originally proposed by Hitzman et al., 1992) is the principal guide to exploration. Of secondary importance, high-grade, structurally controlled uranium-only showings (e.g. Fireweed) also deserve consideration. It is unclear whether this uranium is re-activated from IOCG systems or was sourced independently.

The Wernecke breccias share many of the characteristics of iron oxide copper-gold (IOCG) deposits on a world wide scale, such as the Olympic Dam deposit in the Stuart Shelf of South Australia, which contains about 2.0 billion tonnes of ore at a grade of 1.6% Cu, 0.6 g/t Au, 0.06% U_3O_8, and 3.5 g/t Ag (Reeve et al., 1990). The IOCG deposit class incorporates a large range of high iron, low sulphur, multi-element deposits associated with hematite and/or magnetite breccias (Williams, 1999). IOCG deposits can be huge and many have a very high unit value due to their multi-element character and common high grades. The larger deposits occur primarily in Proterozoic rocks, usually in intra-cratonic settings associated with rift faults (Hitzman et al., 1992). They are characterized by a distinctive element suite of copper, gold, cobalt, silver, uranium, rare earth elements, barium, molybdenum and fluorine. IOCG deposits usually form a mineral district characterized by many similar deposits of widely varying size and grade (e.g Cloncurry District, Australia). Mineralization may occur in the breccias, in veins, or in replacement zones in the country rock. The deposits are localized along major faults, mostly in second order structures which may be either high or low angle. In a regional sense, roughly coeval felsic to intermediate intrusive and/or extrusive rocks may be spatially associated. Extensive, belt-wide, alkali metasomatism is very common and mineralization exhibits zonation from higher temperature sodic alteration to lower temperature potassic alteration. Metasomatic

effects within the mineral belts generally indicate an elevated level of heat flow associated with the hydrothermal systems, commonly anomalous with respect to regional metamorphic facies.

The high-grade structurally-controlled uranium class within the Wernecke properties typically comprise brannerite-bearing, irregular feldspar-quartz veins with chlorite-hematite alteration. Mineralization is also locally abundant on fault surfaces and may be associated with elevated gold and copper. This style of mineralization typically formed in late structures that cross-cut Wernecke breccia, consistent with remobilization from earlier IOCG systems. Hunt et al. (2006) have suggested the possibility for unconformity-related uranium deposits in the Wernecke Mountains, similar to the high-grade deposits of the Athabasca Basin, such as Rabbit Lake, Cluff Lake and Cigar Lake. Unconformity-related uranium deposits are hosted by shelf facies metasedimentary rocks of Early Proterozoic age (graphitic or sulphide-rich metapelites, calcsilicate rocks and metapsammites), regolith and unconformably overlying continental sandstones of Middle Proterozoic age. Orebodies are tabular, pencil-shaped or irregular in form, extending up to a few kilometres in length; most extend <100 m below the unconformity. Orebodies are localized by the intersection of regional and local faults with unconformity surfaces where mixing occurs between reduced basement and oxidised basinal fluids. Pitchblende, coffinite, uranophane, thucolite, brannerite and iron sulphides fill pore spaces or voids in breccias and vein stockworks. Deposits are accompanied by chloritization, hematization, kaolinization, illitization and silicification. Unconformity-related uranium deposits are associated with elevated Ni, Co, As, Pb and Cu, which can be used as pathfinder elements. Although a viable model for the Wernecke properties, structurally-controlled uranium is the closet fit to this model yet discovered.

8.0 GEOCHEMISTRY

Soil, silt and rock geochemistry has been used widely in the past to focus prospecting efforts on the Wernecke properties. These methods have also been widely employed during the recent exploration phases. Mobile Metal Ion (MMI) soil geochemistry – an alternate analytical technique – was implemented to a limited extent in 2007 in an effort to delineate possible buried mineralization under the Bonnet Plume river valley. Basic statistics for the various sampled media are described below. In subsequent sections, values corresponding to 98th percentile are considered highly anomalous, 95th percentile definitely anomalous, 90th percentile moderately anomalous and 75th percentile as high values.

8.1 Silt Geochemistry

In 2007, 28 standard, grab-style silt samples were collected from various properties during mapping and prospecting traverses. Additionally, 84 silt samples were collected during a helicopter-supported, regional-style silt blitz across a little-explored region in the Looksee and Thunder Mountain areas. The area was selected to check anomalous YGS and Fairchild silt sample areas which are coincident with a weak magnetic anomaly. Statistics for this dataset are summarized in Tables 2 and 3.

Heffernan et al. (2007) summarize silt datasets for 375 field-sieved Fairchild JV-era silts and for the RGS silts collected in the Wernecke project area. By comparison with these data sets, the 2007 percentile thresholds are similar to the Fairchild data but are consistently higher than the RGS for the area. The 2007 correlation coefficients show positive correlations between Cu-As-Bi-Co-Mo-Ni-U, a pattern that is similar to the Fairchild and RGS data. Au shows no strong correlations. The REEs U-Th-Ce-La all show positive correlations. Pb and Zn are strongly positively correlated and are likely related to sedimentary exhalative mineralization documented in the Gillespie Lake Group (Thorkelson, 2000b).

8.2 Soil Geochemistry

Because of different analytical techniques over the span of recorded exploration, soil geochemical data from exploration prior to 2006 has been compiled into a historical data set (Tables 4 and 5) and has been treated independently from the 2006 and 2007 soil data (Tables 6 and 7). The historical data set comprises 7841 samples collected mostly by the 1990s-era FJV programs whereas data prior to about 1990 is fragmented. A total of 2930 soil samples, including 215 QA/QC samples were collected from the project area in 2007. Percentile thresholds for both the historic and the 2006/2007 datasets were calculated independently and since the absolute value for each threshold is different within each data set, results are presented as percentiles rather than absolute values on geochemical maps.

Generally, soil development within the project area is poor and the majority of these samples were taken from talus fine material. The development of B horizon soil occurs only at lower elevations and in areas of relatively dense vegetation. In general, the percentile value thresholds for the 2007 soil data were higher than for the 2006 soils (Heffernan et al., 2007), likely because the 2006 field program was more regional whereas the 2007 program focused more on key mineralized areas.

Sample results below analytical detection were defined as null and excluded from correlation calculations

The historic and more recent datasets show many similarities in the magnitude of the percentile thresholds and in the correlation coefficients. Au is most strongly positively correlated with Ag-Co-Cu-Mo-U. REEs U-Th-Ce-La show moderate to strong positive correlations. The base metals Pb and Zn show very high positive correlation, moderate correlation with Ag but very low to negative correlations with other metals. Thus, the IOCG-type Au-Ag-Cu-Co-Mo-U metal signature (Porter, 2002) is well represented in the Wernecke project soil dataset.

8.2.1 Mobile Metal Ion (MMI) Soil Geochemistry

Soil grids were established at the Hoover and Arch properties, mostly over alluvium-covered areas of the Bonnet Plume River valley. Minor colluvium underlies the grid at Hoover near drill hole HV07-23. At Hoover, samples were collected at 50 m intervals on 13 lines 100 m apart. Three reconnaissance lines were completed to the edge of the Bonnet Plume River. At Arch, samples were collected at 100 m intervals from six lines spaced 250 m apart. Standard MMI sampling techniques were employed for this program as described in section 6.2.

Response ratios were calculated for the sampling data to allow for easier multi-element interpretation as recommended by Birrell et al. (2004). Data were divided by the lowest quartile threshold to determine a peak to background ratio, or response ratio (RR). Results below analytical detection were assigned half of the detection limit and then retained for calculations. Accordingly, RRs of two or less are considered low and RRs greater than five (i.e. five times background) are generally considered significant.

Figures 4 and 5 display stacked bar charts for the Hoover and Arch soil grids. The elements Ag-Au-Ce-Co-Cu-La-Mo-U were used for the stacked bar charts because these IOCG-related metals and REEs showed the greatest range of RR values. Other metals (e.g. Ni) returned fairly consistent values so the range of response ratios is minor.

At Hoover, some of the highest composite RR stacks occur, not surprisingly, closest to the slope breaks. As such, these soils were collected immediately downslope of known Cu-Au mineralization. It is therefore likely that some lateral dispersal of mobilized ions occurred from the exposed mineralization. Locally a few REE spikes were detected south of HV07-23 on several grid lines. A 300 by 300 m region of elevated U occurs mid-way between HV97-17 and -18 (two failed holes from the last FJV drill attempt at Hoover). Although U and other REEs are not generally elevated in the known Hoover mineralization, metal zonation is a possibility in these systems. A hypothetical hydrothermal system beneath the Bonnet Plume valley may have very different characteristics to what is exposed to the east.

At Arch, little in the way of RR systematics is indicated (Figure 5). Some isolated samples show spikes of U or other REEs and a few samples to the east show elevated Co but Cu and Au are consistently quite low.

Since these are the first MMI data for the Wernecke properties, it is difficult to interpret them unambiguously. Drill-testing of the Hoover anomalies is not warranted based on these data alone.

8.3 Rock Geochemistry

Rock geochemistry from exploration prior to 2006 has been compiled into a historical data set and has been treated independently from the 2006 and 2007 data due to differing analytical procedures and detection limits. On accompanying maps, the percentile values – calculated independently on each sub-set of the rock data - are plotted rather than the absolute values. As with the soil data, different analytical techniques and detection limits preclude merging the data directly. The historical data set comprises about 3700 rock samples collected from within the project area. Nearly all of this data is from exploration programs carried out in the mid 1990s as part of the FJV project.

In 2006, a total of 585 rock samples were collected from within the project area while 975 rocks were collected in 2007. Percentiles and correlation coefficients determined for the historical and 2006-2007 data sets are presented below in Tables 8 through 11.

Table 8: Historical Rock Geochemistry Percentiles

Percentile	Ag (ppm)	Au (ppb)	Bi (ppm)	Co (ppm)	Cu (%)	Mo (ppm)	Ni (ppm)	Pb (ppm)	Sb (ppm)	Th (ppm)	U308 (%)	Zn (ppm)

9.0 PROPERTY GEOLOGY AND MINERALIZATION

9.1 Arch Property

The Arch property (Map 3) is located along the southern edge of the Bonnet Plume River valley. The northern and eastern portions of the property were mapped, prospected and drilled during the FJV programs of the 1990s. The claims were staked to cover an airborne magnetic high and several Wernecke breccia occurrences. Historical results indicate a copper-mineralized fault zone with up to several percent chalcopyrite and geochemical values of up to 2.82% Cu with anomalous Au (Klatt and Stammers, 1994). Drilling intersected similar zones of fracture-controlled chalcopyrite and chalcopyrite-scapolite veins cutting biotite hornfels.

In 2007, ten rock samples were collected during several mapping and prospecting traverses on the claims following up anomalous historical and 2006 geochemical results. Significant results of these samples are presented in Table 12. At the north-eastern corner of property, a 10 cm-wide U-bearing vein was discovered cutting calcareous homolithic breccia. The vein has a strike length of at least 2 m and trends to the west-northwest. A select sample collected from the vein returned 0.11% U (sample 846455). New areas of minor copper mineralization related to shear zones were also encountered in the central area of the property, with assays returning 0.10% and 0.23% Cu. The Zelon Cu Minfile occurrence in the southeast bowl of the property was sampled and returned Cu values between 0.17% to 0.58%. The latter sample (847121) also assayed 0.56 g/t Au.

294 soil samples were collected on the Arch property along three contour soil lines and on a small grid. 168 grid samples – collected along six, 2.5 km-long lines – were analysed by Mobile Metal Ion (MMI) geochemical techniques. The grid was established to test the bedrock below overburden as a less expensive tool than drilling. Grid lines were spaced 250 m apart and samples were collected every 100 m. The results (Figure 5) from the MMI grid highlight a few patchy areas with anomalous Ag, Au, Cu, Ni, and U, however there is no anomalous signal to noise ratio for any one element over a large area.

Of the three contour soil lines, the one contouring along the eastern drainage, north of the Vulture showing, has a seven sample multi-element anomaly with 80th percentile and above values for Ag±As±Bi±Co±Ni±Pb±Zn. This soil line crosses the creek and has a single sample on the eastern slope whereas the rest of the samples are on the western slope. Opposite the ridge to the west of this anomaly is the Zelon showing. At the end of the soil line along slope to the east of Breccia creek, a single sample returned 80th percentile and above Ag-As-Bi-Cu-Pb-U-Zn. Both of these soil anomalies could be prospected upstream and upslope.

Further work on this property should include additional mapping and prospecting along the western portion of the claim. Mapping and prospecting should be performed slightly north and upslope of the DR showing at the southwestern margin of the property, at the outcrops along Breccia creek, upstream and upslope of the two soil anomalies, and on either side of the ridge near the Zelon Cu showing. No additional soil sampling on the property is recommended as nearly all slopes have been sampled.

Table 12: Arch Property Significant Mineralization

Significantly, an error was discovered in the 1996 assessment report on the Arch property (Vance et al., 1996). The error found is in Table 9.2.1 which reports 11.8 m of 0.52 % Cu in hole XA95-5. When compared to the drill logs and the original certificates the actual results are 0.05% Cu. Given that this was the best interval for the 1995 drill program on Arch, the property's prospectivity is diminished.

9.2 Arctos Property

Written permission was provided to Dave Kuran by Bernie Kreft for Wernecke personnel to examine this property which is available for option to Fronteer. Both the Orb showing (which is on Fronteer ground) and the Arctos showing were examined and sampled and significant mineralization is presented in Table 13.

The Orb showing comprises a 20 by 20 m area of sub-cropping Gillespie Lake Group massive dolomite that is intensely to weakly silicified. Minor hydrothermal dolomite occurs within the silica-dominated zones. Minor chalcopyrite occurs along fractures within the most strongly altered zones. Previous reports indicate very high-grade copper described as large pods and blebs. These were quite clearly select samples and no mineralization of this sort was observed. There is a remote chance that the area observed was not the actual showing but owing to gentle topography most ground in the area was examined.

The Arctos showing is exposed within a moderately steep creek gully. It comprises a 1.25 m-wide fault zone exposed in outcrops on both sides of the creek. The fault zone is characterized by bleached to reddish, altered Wernecke Breccia that registers 600 to 4000 cps. A discontinuous white quartz-carbonate vein occurs within the fault and is up to 40 cm wide. This vein locally contains pods of massive chalcopyrite. Minor malachite and uranophane coat weathered surfaces. Specular hematite is widespread and indicates that the reddish colour is likely fine hematite dusting rather than potassium feldspar. The fault zone strikes about 170^{o} and dips moderately to the west.

Outcrop is continuous up and down stream from the showing for 50 to 100 m. These exposures cut nearly perpendicular to the mineralized fault providing a convenient cross-section. No other mineralization is present in the cliffs around the Arctos suggesting that it is an isolated, narrow zone without much hope for linking together several similar zones.

More work on the Arctos is warranted. The broad areas of anomalous soil samples, however, may indicate buried mineralization. The final recommendations from the Fairchild JV-era report (Dickie and Stammers, 1995) included a modest drill program for the Arctos which seems warranted.

Table 13: Arctos Property Significant Mineralization

Sample#	Showing	Au ppm	Ag ppm	Bi ppm	Co ppm	Cu ppm	Mo ppm	Ni ppm	Pb ppm	Sb ppm	Th ppm	U ppm	Zn ppm
839627	Arctos	0.803	0.58	1.17	32.4	6120	19.15	6	4.1	2.17	15.5	39.7	2

9.3 Auks Property

The Auks property is located approximately 4 km east-southeast of the Olympic property (Map 5) and comprises 56 claims, 20 of which were staked in 2007. In 1997, the FJV drilled seven holes in the Auks area (Stammers, 1997a). The first three holes targeted Cu-Au soil geochemistry and exposures of Wernecke Breccia. The remaining four holes tested a large, deep-seated, circular magnetic high, whose depth was modelled by Newmont geophysicists at 800 m below surface. The three holes spotted on soil geochemistry encountered long intervals of low but anomalous Cu and Au values within hematite breccia; the best intersection was in hole LY97-01, with 82.5 m averaging 1037 ppm Cu and 16 ppb Au. The first three holes testing the magnetic high encountered hematite breccia, dolomitic siltstone and interbedded argillite/siltstone without significant alteration or mineralization so they were terminated before reaching target depths. The last hole, LY97-10, intersected magnetite-bearing diorite below 380 m, but magnetic susceptibility measurements for the diorite were still considered too low to explain the large magnetic anomaly. Its best intersection was 16.5 m grading 1300 ppm Cu and 23 ppb Au in hematite breccia from 114.05 m.

Work on this property during the 2007 season included reconnaissance mapping, prospecting, and soil sampling. The mapping and prospecting was conducted within an airborne gravity anomaly comprising the eastern extent of the current Auks property. A rugged N-S trending ridge line of orange-weathering dolomite underlies this part of the property and given the arguments of Barnett (2007), this topographic high likely caused the gravity anomaly. Additionally, very little alteration or mineralization is present in this well-exposed part of the property. Along the east-facing slope, a previously unmapped heterolithic breccia body crops out which seems to trend for at least several hundred metres to the north with a potential width of 100 m.

A total of 138 soil samples were collected along four contour lines east of the Auks Property, down-slope from the airborne gravity anomaly target. The analytical results from these samples show slightly elevated levels within few soils taken at the southern extent of the contour lines, specifically Ni, Cu, Co, and Mo.

9.4 Caribou Property

The Caribou property (Map 4) was staked in 2006 to cover a 1.7 by 1.9 km radiometric anomaly (>10 cps) centred about 8 km due north of Fairchild Lake. The northern part of the property covers a faulted contact between the Quartet Group and Phanerozoic rocks. Weak U geochemical anomalies were detected in 2006 so a single contour soil line for 34 samples and a prospecting traverse were completed in 2007. No significant mineralization was found in float or outcrop. Ten continuous soil samples returned >75th percentile U with a peak of three samples returning >90th percentile. These samples also returned sporadically elevated Au, Pb and Zn. This soil anomaly has not been explained.

9.5 Fireweed Property

The Fireweed property comprises a block of 126 mineral claims north of the Slats Property centered 15 km WNW of the Copper Point Camp (Map 8). Several Minfile occurrences are located within the property including Otis (U), Radio (Cu-U) and Wombat (U). Significant sample results from within the entire property are evident in the Table 14.

The Fireweed property lies on the western limb of the Bonnet Plume River Anticline and features green phyllite and calcsilicate of the Fairchild Lake Group (PFL) and grey to black phyllite and slate of the Quartet Group (PQ). These units have faulted contacts. Three large Wernecke Breccia (Pwb) bodies and associated metasomatised sedimentary rock underlie the property and are seemingly controlled by regional N-S trending faults. The northernmost breccia is an E-W trending mushroom shaped body. Mapping in 2006 and 2007 revealed that much of these “breccia bodies” are actually faulted and sheared metasomatised sedimentary rock with much smaller volumes of actual breccia. Numerous N-S trending, subvertical faults cross-cut the area, some of which feature spotty, narrow (<30 cm wide) zones of U mineralization (Archer, 1976) (Map 1).

The Fireweed claims have been explored since the late 1970s by numerous companies including Archer Cathro, Pan Ocean Oil-Mountaineer Mines Joint Venture and the Fronteer / Rimfire joint venture in 2006. The Fireweed boulder field showing was discovered in 2006 (Heffernan et al., 2007) within a target delineated by an 8 cps airborne uranium radiometric anomaly occurring 350 m from the Otis U showing (Archer, 1976). The Otis was drilled with a single diamond drill hole which tested a NORTH-NORTHWEST-trending, brannerite-bearing fault which is approximately 100 m from a breccia body (Archer, 1980). The drillhole did not intersect significant mineralization and no further work was conducted on the Otis.

9.5.1 Fireweed Boulder Field

The Fireweed boulder field covers a 400 by 200 m area on a grassy west-facing plateau. The plateau is underlain by variably foliated, grey to green chloritic±sericitic phyllite and lesser schist to the north of the plateau. Zones of higher strain are common and are marked by chlorite-sericite shear zones. Three main foliations were mapped including north trending (340-010° strike), east trending and northeast trending (015-045° strike). The northern trend is the dominant across the plateau. At least three generations of veins occur roughly concordant to the main foliations. These include S to SW striking quartz-pink hemititic plagioclase-chlorite±brannerite, south-striking quartz-chlorite veins, and quartz-specularite ± pink hematitic plagioclase veins with N, NW and NE strikes. Abundant 080-100° striking subvertical quartz veins occur adjacent to NE

striking chloritic shear zones along the southern margin of the plateau. Rare veins with associated Cu mineralization occur at both ends of the plateau. Uranium mineralization consists of medium to coarse-grained brannerite within moderate to strong pink hematitic plagioclase-specularite altered and veined chloritic phyllite.

No uranium mineralization comparable to that of the boulders sampled in 2006 was observed in outcrop. At the northern edge of the plateau, anomalous scintillometer readings were returned from sooty coated (secondary uranium phases?), east-trending, steeply south-dipping fractures. At the southern end of the plateau, a few small patches of elevated radioactivity (to a maximum of 1400 cps in outcrop) correspond to areas of strong quartz-pink hematitic plagioclase breccia veining with jarosite staining. Scintillometer and ground magnetic surveys were completed over the Fireweed boulder field in 2007 and are discussed in Section 11.

Four blast trenches were completed across the inferred structural lineament at Fireweed in 2007 using a small heli-portable excavator. Thick overburden and subcrop prevented trenches 2 and 3 from reaching bedrock. Trench 1 exposed limited outcrop and trench 4 had the best exposure. Both trenches 1 and 4 provided good structural data and confirmed the dominant south-southwest trend of the hematitic plagioclase-quartz veins hosting U mineralization. All four trenches were chip sampled along their entire length. No significantly anomalous results were returned, although a single sample returned 234 ppm U.

9.5.2 Kelsey Zone

24 claims were added to the Fireweed property in 2007 to extend the northeast margin of the existing claim group. These claims were added to cover the contact between Fairchild Group sedimentary rocks and homolithic breccia. The contact is characterized by elevated radioactivity and locally minor copper mineralization (Table 15). The Kelsey Zone was discovered on a slope facing the Bonnet Plume River 2.1 km NNE from the Fireweed boulder field in 2007. This altered and mineralized zone resembles the Fireweed boulder field material. Uranium mineralization is associated with a zone of irregular pink plagioclase alteration zones with quartz and hematite. The northern portion of the plagioclase-quartz alteration zone has an adjacent 4 m-wide blow-out of strongly weathered calcite with scintillometer readings of 700-1200 cps. Mineralization of this portion of the alteration zone consists of strongly weathered chalcopyrite (?), hematite and secondary malachite/azurite. No uranium minerals were observed in the carbonate vein. All the visible copper mineralization is hosted within the carbonate vein and the adjacent pink plagioclase-quartz alteration zone hosts only uranium.

Table 15: Fireweed Property Significant Mineralization, Kelsey Zone

Sample#	Showing	Au ppm	Ag ppm	Bi ppm	Co ppm	Cu ppm	Mo ppm	Ni ppm	Pb ppm	Sb ppm	Th ppm	U ppm	Zn ppm
839506	Fireweed	0.05	1.09	24	21.2	5390	5.17	21.5	2.6	0.42	14.3	7.3	16
839507	Fireweed	0.563	0.44	2.35	5	136500	0.69	9	5.7	0.26	0.2	1.4	22
839509	Fireweed	0.007	0.16	0.16	16.7	445	1.04	84.6	50	6.63	37.4	810	26
839901	Fireweed	0.018	0.29	1.86	6.8	107	5.58	14.7	100	3.62	108	1200	20
839909	Fireweed	0.19	0.2	0.38	35.9	19.1	0.87	149.5	38.4	1.02	8.9	128	118

The margins of the mineralized pink plagioclase alteration zone are diffuse and moderately well defined with strong chlorite bordering the anomalous uranium zone. The alteration zone is concordant with local bedding and trends 340º, dipping about 65º. The zone is hosted in metamorphosed weakly chloritized dolomitic siltstone of the Fairchild Lake Group which are 100 m south, across strike from a heterolithic breccia body. The contact presumably was a conduit for uranium-rich fluids.

The alteration zone was exposed in four trenches over 430 m and varies in width from 4-5 m. Chip samples of both the mineralized alteration zone and the unmineralized host were collected where solid bedrock was exposed and grab sampled were only sub-crop was uncovered.

9.5.3 Fireweed West

The Fireweed West area is located 2 km west-southwest of the Fireweed Boulder field on the west side of Slats Creek. The majority of the outcrop is around the rim of a north facing grassy plateau. The area has a weak airborne radiometric (KTh) anomaly as well as a coincident magnetic high.

Homolithic Wernecke breccia crops out on the edges of the plateau and likely underlies the plateau, based on the airborne magnetic signature. The matrix of the breccia is fine-grained, orange to brown with specular hematite and carbonate cement. Clasts are 1-10 cm, sub-angular, grey to black siltstone. Alteration comprises plagioclase, magnetite, hematite and pyrite. The lower slopes off the plateau are underlain by phyllitic grey to green siltstone with minor interbeds of mudstone and dolomite and show gradational contacts. Up to 5% disseminated hematite and magnetite occur on fractures and in millimetre-scale porphyroblasts throughout the unit. Bedding-concordant milky quartz veins contain up to 10% calcite and host the pyrite and copper mineralization. Disseminated to semi-massive magnetite and trace amounts of pyrite were observed associated with quartz carbonate veins along the periphery of the breccia. Sample 846372 (Table 16) was collected from a silica-carbonate altered siltstone proximal to the breccia contact which recorded 1500 cps on the hand-held scintillometer. This sample returned significant values including 30.3 g/t Au and very high Bi-Ni-Pb and >1000 ppm Se and contains trace visible gold and a gun metal grey sulphide phase that is likely bismuthinite or some unusual Bi-Se phase. Other float samples in Table 16 were collected from silica-iron carbonate-potassic feldspar-hematite altered siltstone, locally with net-textured semi-massive chalcopyrite (e.g. 846366) and disseminated brannerite (e.g. 846369).

Table 16: Fireweed West Significant Results

Sample#	Type	Au ppm	Ag ppm	Bi ppm	Co ppm	Cu ppm	Mo ppm	Ni ppm	Pb ppm	Sb ppm	Th ppm	U ppm	Zn ppm

9.5.4 Discussion and Recommendations

Mineralization on the Fireweed property appears to be related to fault zones and Wernecke breccia contacts where fluids were concentrated. Elevated Au and Cu in soil occur proximal to major lineaments (interpreted as faults) and at breccia and Fairchild Lake Group contacts. Uranium values do not typically report well in soil geochemistry (Heffernan et al., 2007) but the elevated values that are present tend to be near major structures and along the margins of breccia bodies.

The Fireweed boulder field received the most attention with detailed mapping, trenching, ground magnetics and scintillometer survey and a five hole drill program. All the mapping and surveys indicate that the most prospective zone was targeted by the drill program but results were disappointing. This could be in part due to the course podiform nature of the brannerite mineralization which was observed in boulders on surface. At this time no further work is warranted on the Fireweed boulder field and nearby area.

The Kelsey zone has limited potential and is a relatively narrow zone – four to five meters – with low uranium assay values. Likewise the copper mineralization is spotty and discontinuous. The carbonate vein hosting the mineralization does not contain any uranium and may be related to a later event. No further work is recommended for this area.

Three days of prospecting and mapping were completed at the Fireweed West. Three soil contour lines were completed below the plateau with spotty results and poor continuity of anomalous values. In spite of this, several noteworthy rock samples - including 846372 which returned 30.3 g/t Au - were collected in the area. Follow up prospecting and more detailed mapping of the area should be undertaken. Unlike the

Fireweed Boulder Field, this area has a more widespread alteration and metal signature consistent with a Wernecke breccia-associated IOCG system.

9.6 Glacier Lake Property

The Glacier Lake property is located north of Dolores Creek approximately 30 km east-southeast of the Copper Point Camp and is discussed in detail by Heffernan et al. (2007). In 2007, a single mapping and prospecting traverse was completed in the northeast corner of the property within a 2006 U-Cu-Co soil anomaly. One float sample with trace chalcopyrite that registered 2000-3000 cps returned 1600 ppm U. The area is underlain by abundant heterolithic Wernecke breccia and diorite but overall mineralization is rare.

9.7 Hoover Property

Only reconnaissance mapping and sampling were completed at the Hoover property this year since extensive surface geochemical sampling and mapping were completed by the FJV in the 1990s (Baknes and Stammers, 1993; Jones, 1995b). Detailed descriptions of the geology of the area are provided in these earlier reports.

9.8 Jazz-Thunder Mountain (JTM) Property

The Jazz-Thunder Mountain property (Map 12) comprises an isolated group of claims 40 km southeast of the Copper Point airstrip. The Jazz Claims were first staked by Westmin in 1992 for their copper and gold potential. Westmin, and subsequently the FJV explored the property until 1997 when they drilled eight holes (Stammers, 1997b). Most holes targeted a strong, north-trending, west-dipping magnetic high identified by Newmont's airborne survey, but the first two were directed at copper-bearing surface mineralization. Many of the drill holes intersected short intervals of either coarse blebby chalcopyrite-pyrite or carbonate veinlet-hosted chalcopyrite. Mineralization is localized at hematite breccia/sediment or breccia/diorite contacts. The best drill intersection returned 8650 ppm Cu and 185 ppb Au across 1.1 m. Detailed geology of the Jazz Claims from the FJV work is presented by Owerko (1995) and Stammers (1997b).

In 2006, Fronteer discovered the Ewe-1 and Ewe-2 (later called the Thunder Mountain) showings, 5.5 km northwest of Jazz while conducting reconnaissance prospecting radiometric anomalies for uranium mineralization. Significantly, the Ewe-2 showing returned two high grade rock samples of 110.5 g/t Au with 0.48% U and 92 g/t Au with 0.58% U. The occurrences are associated with previously unmapped Wernecke Breccia. 42 claims were staked to cover the showing and to make the claims contiguous with the Jazz claims. Follow-up work that year consisted of further prospecting and contour soil sampling.

In 2007, the Ewe-1 and Ewe-2 were examined and the associated Wernecke Breccia bodies were mapped in detail. A major soil grid comprising 233 samples collected at 50 m intervals from lines 100 m apart was completed across the broad valley that hosts the two showings (Map 6). Several days of prospecting were also completed to follow-up 2006 soil anomalies. Blast and hand-trenching were completed at Ewe-2 and the Ewe-1 was chip sampled. The Equalizer Showing – a new high-grade Mo-Au-U showing – was discovered in a creek gully 150 m west of the Ewe-1 showing.

The Thunder Mountain area (i.e. the far western part of the Jazz-Thunder Mountain Property) is characterized by a 1.5 km-wide flat bottomed valley draining towards the northeast. Surrounding this valley are rugged, typically impassable cliffs with long talus slopes enveloping the slope breaks. The valley is dissected by several creeks that provide nearly continuous outcrop exposure. In general, exposure is good in the valley but large areas are covered by moraines and rock glaciers, including some in the upper parts of the valley where glacier ice was observed in sink holes.

Geologically, the area is underlain by east-striking, moderately south-dipping, siltstone with lesser mudstone of the Quartet Group (PQ). A unit of sandstone is exposed west of the Ewe-2 Showing and is probably part of the upper Quartet Group. These sedimentary units are cut by two main elongate homolithic and heterolithic composite bodies of Wernecke breccia with minor diorite. The breccia body in the Uwe-2

area trends northwest and is at least 1.1 km long by about 100 m wide. The breccia body near the Uwe-1 showing trends east-west and is at least 900 m long by about 200 m wide.

The breccia is generally discordant to siltstones and sandstones of the enclosing Quartet Group stratigraphy. Best metal values appear to correlate with heterolithic breccia within bodies of composite breccia that comprise both heterolithic and homolithic varieties. Heterolithic breccia has sharp, faulted contacts with homolithic breccia and adjacent metasedimentary rocks, hosts enclaves of diorite, and commonly carries higher background radioactivity of about 400 cps. By contrast, homolithic breccia generally lacks anomalous radioactivity (background of about 250 cps), clasts invariably represent the adjacent rock type (typically siltstone) and transitional contacts with host metasediments are common.

9.8.1 Mineralization

The Ewe-1 showing is characterized by moderate U scintillometer readings to 1100 cps hosted by steeply-dipping fine-grained sandstone. Conspicuous erythrite (cobalt bloom) and malachite coat the showing outcrop consistent with the presence of 0.5-2% disseminated chalcopyrite and trace cobaltite. Mapping in 2007 revealed an extension of the known area of uranium mineralization to the southeast. Scintillometer readings to 3500 cps have now been identified in outcrops and float that comprise heterolithic Wernecke breccia, over an area of approximately 200 by 150 m. Secondary uranium (uranophane) was noted as a yellow coating on float in one location. Additionally, the copper-cobalt style of mineralization extends for at least 50 m of strike length north of the Ewe-1 showing. Outcrops of Wernecke breccia are also identified in bluffs south of the Ewe-1 showing continuing to the east where they merge with a large body of Wernecke breccia intruding Quartet Group siltstone, exposed in cliffs approximately 500 m east of Ewe-1.

The Equalizer - a new U-Mo-Au showing - was discovered in a creek west of the Uwe-1 showing. It comprises several cm-scale pods of coarse-grained molybdenite within a 3 by 3 m area of heterolithic Wernecke breccia that has >1000 cps. Maximum scintillometer response is 8000 cps. Brannerite and molybdenite occurs as fine, disseminated grains. Visible gold is common within limonitic crusts associated with the most abundant molybdenite and samples of this material returned >1% Mo and 10.1 g/t Au (Table 17). The zone is localized along the contact between heterolithic and homolithic breccia which is defined by a 25 cm-wide brittle fault structure which truncates the mineralization.

Table 17: 2007 Jazz Thunder Mtn. Property Significant Mineralization

The Ewe-2 showing is characterized by centimetre-scale pods of limonitic crust with elevated radioactivity (350 to 650 cps but up to 9000 cps) and locally visible gold (bonanza-grade 2006 samples were collected from this material). Additionally, high copper-gold in rock chip samples (to 6.8% Cu, 1.6 ppm Au) were returned from outcrops northwest of the Ewe-2 showing. An eight metre-long trench was blasted to bedrock to examine the geological setting of bonanza-grade gold mineralization and associated U at the Ewe-2 showing (rock samples returning 110 and 92 ppm Au in breccia float). Heterolithic breccia (bht) is encountered throughout the trench. Typical alteration assemblages include abundant chlorite and moderate amounts of calcite, muscovite, plagioclase, quartz and hematite. Silicification is variable. Six chip samples were taken along the length of the trench. Scintillometer readings are consistent throughout the trench (near 500 cps); anomalous values are lacking. Anomalous readings taken at surface prior to opening the trench are attributed to limonite-rich crusts identified in surface samples that gave readings to 1500 cps. These do not appear to persist to depth.

Several areas that returned elevated Ni-Co-U-Au in soils in 2006 were prospected. Anomalous soil samples taken along much of the length of the most southwesterly line of sampling at Thunder Mountain remain unexplained, despite prospecting the source of this multi-element anomaly. Many samples along this soil line lie in the 98 percentile range for Co and Ni, the 95 percentile range for Cu and Mo, and the 85 percentile range for Au. Samples along this line generally represent siltstone talus – boulders of Wernecke breccia are uncommon.

The Ewe-1 showing outcrop was continuously chip sampled in 2007 (Table 18). The zone is elevated in Au-Co-Cu-Mo-Ni and returned 11.75 m (essentially true width) of 0.23 g/t Au, 481 ppm Co and 0.55% Cu. The chip samples extended from about 11 m outbound of a Wernecke breccia body with sampling conducted towards the breccia. The last significant sample (847165) was collected from breccia while the next sample collected within the breccia returned insignificant values.

Table 18: 2007 Ewe-1 Chip Samples

Sample#	True width (m)	Au ppm	Ag ppm	Bi ppm	Co ppm	Cu ppm	Mo ppm	Ni ppm	Pb ppm	Sb ppm	Th ppm	U ppm	Zn ppm

9.8.2 Conclusions & Recommendations

All bedrock mineralization discovered so far at Thunder Mountain is associated with Wernecke breccia body contact. The most significant showings locally exhibit high grades in Au, Mo, Co but the areal extent of mineralization is very limited. The Au-U-Mo-Ni-Ag-Co-Cu metal association and alteration is consistent with IOCG systems and these metal enrichments occur over a broad area. As such, it is not wise to completely write off the Thunder Mountain area. No targets are yet drillable, but a Wernecke breccia body contact with a coincident geophysical anomaly could easily elevate the area to a very high priority drill target. The subtle topography and broad areas without outcrop exposure would make the Thunder Mountain valley area amenable to induced polarization, ground magnetic and ground gravity surveys.

With limited tonnage potential for the observed coarse-grained, supergene-style gold in cm-wide limonitic crusts which returned bonanza-grade gold values in 2006, the real target for Thunder Mountain is a lower-grade, IOCG-type bulk tonnage deposit.

9.9 Mica-Hail Property

The Mica-Hail property (Map 11) is located 12 km southwest of the Copper Point airstrip and comprises the Hail, Rh, Ch, Pg and HE claims. The property was explored for uranium by Zelon Enterprises and the Prism Syndicate from 1976 to 1978 and by Texaco from 1980 to 1983. From 1992 to 1997 the area was explored by the FJV for Cu-Au IOCG deposits (Caulfield, 1992a, b; Owerko et al., 1994; Stammers, 1993). Several Cu±Au showings were identified but none were drilled.

The property is underlain by Fairchild Lake Group (PFL) rocks in the north which have been faulted over folded Quartet (PQ) and Gillespie Lake Group (PGL) rocks which underlie the southern half of the property. Large regions of northwest-trending Wernecke breccia crop out across the southern half of the property along a faulted contact. The regional-scale northeast-striking, steeply west-dipping Pagisteel Fault runs the entire length of Mica Creek, bisecting the area. Numerous smaller northwest-striking faults cross the area.

Three large, ≥8 cps U radiometric high anomalies occur within this area (Map 2). The first is a 2 by 1.4 km, oval-shaped anomaly (539000mE; 7198500mN) straddling the northern end of a large Wernecke Breccia (Pwb) body and coincides with the uraniferous boulder field on the Hail claims. An irregular uranium radiometric high (>8 cps) contains several smaller ≥10 cps anomalies including a 1.8 km-long north-south, oval anomaly centred on Mica Creek (538320mE; 7194900mN) and a northeast-elongate dumbbell shaped zone (535850mE; 7194600mN).

In 2007, fieldwork on the Mica claims consisted of mapping, prospecting and soil sampling along the Pagisteel Fault corridor. Contour soil and silt sampling, mapping, prospecting and trenching were completed on the Hail claims. Mapping and prospecting on the Hail focused on exploring the Lost Chris and Bullet Showings (Owerko et al., 1994) as well as between them and the Hail boulder field, which lead to the discovery of the Central Hail area.

9.9.1 Hail U boulder field

The Hail boulder field is located 1.5 km west of Mica Creek. The boulders occur across a 160 by 60 m area. At the top of the field the radioactive boulders stop at a thick veneer of Wernecke breccia talus. The area was sampled in the early 1980s and returned encouraging U results.

The densest part of the anomaly is confined to a 50 by 60 m area. The boulders compromise sheared and brecciated, metasomatised albite-actinolite altered pelitic rock, with rare malachite and brannerite. According to Hajek (1980), the boulder source is a shear zone located up slope. Low-magnitude (~300 cps) radioactive material was located in this area (Heffernan et al., 2007).

A second possible source is the sheared contact between the breccia and Quartet Group sedimentary rocks which crop out immediately east of the boulder train. This contact is covered by a thin layer of talus but the location can be inferred by the change in float lithology and a change in regolith from colluvium to grass covered soil.

In 2006, a total of 29 samples were taken from boulders across a 140 by 55 m area. Seventeen boulders sampled from the densest part of the train averaged 0.13% U, of which 13 samples returned greater than 0.08% U with a maximum of 0.25% U. Sampling of the same boulder train by previous workers returned values up to 5.9% U.

During the 2007 program, trenching upslope of the bolder field and mapping of the trench and surrounding area were undertaken. The mapping was unsuccessful at locating the source of the Hail boulders, although two uraniferous boulders were found 150 m upslope of the boulder field that returned 300 and 400 ppm U in rock samples 847018 and 847019, respectively (Table 19).

An 18 m-long blast trench was completed with the aid of a Kubota excavator 2 m above the furthest upslope boulder. The south end of the trench was exposed to bedrock for 5 m with slightly elevated scintillometer readings due mainly to minor faulting. The northern part of the trench was primarily large, blocky subcrop with intense clay alteration between fractures of the host breccia. An 8 m interval exhibited elevated scintillometer response above 300 cps to a maximum of 500 cps over the subcropping area. Two

samples were taken from the trench at the southern end to test the mineralization across the faulted zones but results were insignificant.

Further blast trenching and excavation at the existing trench could be undertaken to reach bedrock on the northern end where the strongest scintillometer readings were located. However, the area's uraniferous mineralization seems to be highly localized and likely represents only a small anomalous zone.

9.9.2 Lost Chris and Bullet Showings

The Lost Chris Showing, located on the western side of the Hail property, consists of disseminated and stringer chalcopyrite and pyrite associated with siderite-ankerite±quartz stockwork veins. The Bullet showing is located 250 m to the northwest of the Lost Chris Showing. Abundant mineralized float in talus between the two showings indicates that both zones represent a single continuous structure (Owerko et al., 1994).

In 2007, mapping, soil sampling, hand trenching and prospecting were carried out in the area of the Lost Chris and Bullet showings. Mapping in the area delineated the orientation of the Lost Chris and Bullet showings and provides more evidence that these two showings are part of a single structure. Mapping to the east, on the opposite side of the ridge, revealed a shear zone along strike of the Lost Chris and Bullet Showings, which is likely related to the late stage hydrothermal event thought to be the source of the mineralization in this area (Owerko et al., 1994).

Twenty two rock samples were taken in the area, mainly grab and chip samples (Table 19). Mineralization is typically hosted in, or related to, carbonate (siderite-ankerite)-quartz stockwork hosted by mudstone and altered sedimentary rocks. Several in situ samples returned >1% copper including two continuous 2.5 m long chip samples (847016 and 847017) taken from a hand trench which returned an average of 2.5% Cu, 1685 ppm As, 454 ppm Co and 283 ppm Ni.

Another 2 m long chip sample (847015) returned 269 ppb Au, 20.8 ppm Ag and 2.8% Cu while float sample 846394 returned 671 ppb Au, 143 ppm Co, 3.3% Cu and 169 ppm Ni. A single float boulder found 170 m upstream of the Bullet showing and adjacent to an outcrop of metasomatized sedimentary rocks wedged between Quartet shales and Gillespie Lake dolomite returned highly anomalous Au-Ag-Bi-Cu-Sb-Zn (Sample 847022). A 2 m chip sample taken from the adjacent outcrop returned 0.6% Cu.

An error was discovered in the report by Owerko et al. (1994) during the 2007 program. Samples from the Lost Chris Showing were reported as: (a) a 13 m grab sample (433423) across a siderite-ankerite vein that returned 160 ppb Au, 2.77% Cu and 157 ppm Co, and (b) a 2 m chip sample (937627) of quartz-iron carbonate altered mudstone which returned 90 ppb Au, 8900 ppm Cu and 148 ppm Co. The assayed values of the chip samples were switched as noted in a later table which reports sample 937627 as 2 m of 2.77% Cu, 160 ppb Au and 157 ppm Co and sample 433423 as 13 m of 8900 ppm Cu, 90 ppb Au, and 148 ppm Co. This area has not been tested at depth and although a drill plan was in the early stages of development when this error was found, this discovery lowered the prospectivity of the area.

9.9.3 Hail West Cu-Au-Ag Showing

Downstream from the Lost Chris and Bullet Cu showings, two zones of quartz-iron carbonate-chalcopyrite veining with true widths of up to 25 cm were discovered in 2006 (Heffernan et al., 2007). Samples returned anomalous Cu-As-Au-Ag-Co-Ni with maximum values of 24% Cu, 9550 ppm As, 4.12 ppm Au, 123 ppm Ag, 0.70% Co and 0.33% Ni. These Hail West veins have similar orientation and mineralogy to the Lost Chris and Bullet veins and have been compared to mineralization at the Gremlin, Reid and the Eagle properties (Owerko et al., 1994).

A single contour soil line for 94 samples was completed at about 1050 m elevation. It stretches from the Hail boulder field and continues towards the northwest, past Lost Chris and Hail West across Ursus creek. A single soil sample, 842487, was highly anomalous in Au-Ag-As-Bi-Co-Cu-Ni-U. Additionally, the samples collected over the area of rock sample 847302 were 90th percentile and above in As-Bi-Cu-Co-Ni.

These veins are only exposed in deeply incised gullies dissecting an area mostly covered by talus. The mineralized veins are interpreted to lie within a northwest-trending structural zone with a minimum strike extent of 200 m. No drilling has been conducted in this area and further mapping and possible hand trenching across the slope should be performed prior to drilling.

9.9.4 Central Hail

The Central Hail showing is located within a north-northwest facing bowl opposite the ridge and upslope and to the west of the Hail Boulder field. It comprises an 800 m by 350 m area underlain by Wernecke breccia with structurally-controlled copper mineralization. A total of thirty-five rock samples were taken in the area and those with significant mineralization can be found in Table 19. In general, gold and copper are poorly correlated, with higher gold values not being associated with higher copper values.

The area was sampled in the 1990s, although samples were mainly collected from float in the lower bowl (Owerko et al., 1994). Similar outcrop mineralization is present upslope of the 1990s samples. Mineralization consists of chalcopyrite blebs in calcareous (mainly ankeritic and rarely dolomitic) clasts and fracture infill within breccia or disseminated in the matrix of the breccia with patchy malachite when found proximal to fractures and fault planes. Samples of outcrops and subcrop exhibiting elevated radioactivity returned anomalous REEs including up to 1970 ppm Th and 1% La (847008 and 847010) but generally low U values.

Soil sampling in the area was limited to the contour line mentioned in the previous section. A single sample (842496) with >90th percentile As-Bi-Cu-Mo-U is worthy of follow up. The remainder of the line to the east did not return much of interest, however, this could be attributed to the poor soil development in the bowl where the Central Hail is located. Further mapping in the area to determine structural controls on copper mineralization should be undertaken during any future exploration campaigns due to the large areal extent of copper mineralization in this area.

9.9.5 Pagisteel Fault corridor

During the 2007 program, the field work on the Pagisteel Fault corridor consisted of mapping, prospecting and soil sampling. A total of 264 soil samples were collected along the Pagisteel Fault Corridor. These samples were collected from two contour lines along the southeast facing slope on the valley and infill soil sampling to complete the sampling grid from the 2006 program over the Pagisteel Fault along Mica Creek. The grid, which initially had 200 m line spacing, now has 100 m line spacing with 50 m sampling stations and was also extended to the northeast following the recommendations from Heffernan et al. (2007).

Results define a multi-element Au-As-Bi-Co-Mo-U anomaly about 4 km long coincident with the Pagisteel Fault corridor valley. Poor soil is developed in the valley with much of the area underlain by very coarse colluvium. In the cliff outcrops above the valley, however, several narrow fault zones contain minor mineralization and these structures are generally recessive. It is likely that the source of the soil anomalies in the valley floor are sourced from fanning out of a small mineralized outcrop further upslope. In spite of this, however, a 6.1 m wide zone of strong copper mineralization was intersected in a drill hole that tested the Pagisteel Fault within the valley floor (see section 10.2).

A total of 19 rock samples (Table 19) were taken along the Mica Creek corridor from float and outcrop on either side of the valley, including nine samples taken up to 500 m southwest of the claim's southern boundary. Samples mainly tested the copper mineralization related to alteration, lithological contacts and veining found in the valley. The mineralized float likely came from the contact zones of the breccia bodies with the sedimentary rocks, and along the numerous faults. Numerous minor showings with up to 5% chalcopyrite were discovered during mapping and many of these outcrops and float boulders are commonly bleached owing to sericite and/or silica alteration. This material resembles the mineralization found at the contact zones.

Significant mineralization was found at several locations and numerous rock samples returned greater than 1% Cu. Of note are rock samples 846034, which returned 9.9% Cu, 4.1 g/t Au, 233 ppm As and 544 ppm Ni; and 846033, which assayed at 277 ppb Au, 421 ppm As, 4.0% Cu, and 544 ppm Ni. Both samples

were collected on open ground to the south of the property boundary. In general, gold values did not correlate with copper values and no new uraniferous mineralization was found.

Current mapping indicates left lateral displacement to the northwest of the stratigraphy and earlier structures. These late, open faults are consistently oriented at approximately 310^{o} and dip steeply to the north. Additional field work that should be completed in this area includes mapping of the ridgeline along the northwest side of the corridor. Also, it is recommended that the area south of the claim boundary be further mapped and perhaps staked due to the results from rock samples collected off the property boundary and the zone of anomalous soil samples along the southeastern side of Mica Creek.

9.9.6 Conclusions & Recommendations

The dominant trend of structures, mineralization, orientation of the large Hail breccia unit and the proximity to the Reid showing indicate a possibly deeper NW trending structural control that is the source of the abundant mineralization found in this area.

Trenching across the slope between the Lost Chris and Bullet showings, as well as the Hail West area, to determine if the zones are continuous should be carried out to further define the mineralized vein densities. If abundant veining and continuous zones can be located then either of these areas should be considered a potential Cu-Ag-Au drill target. Also, further mapping in the Hail West downstream of the Lost Chris and Bullet showings in the area of the anomalous rock and soil samples should be undertaken.

Additional trenching to north of the existing trench on the Hail boulder train is recommended as an effort to discover the source of the boulder train. Further mapping should be carried out in the Pagisteel corridor and the Central Hail. Also, it is recommended that mapping priority be given to the southwest boundary of the Mica claims, which is not currently staked but assays returned significant Cu-Au mineralization, less than 500 m from the southern edge of the property.

Table 19: Mica-Hail Property Significant 2007 Mineralization

9.10 Olympic Property

The Olympic property (Map 5) is located on the west side of the Bonnet Plume River across from Delores Creek. The area is underlain by Gillespie Lake sedimentary rocks which have been cut by several discondant Wernecke breccia bodies.

Following a program of preliminary ground geochemistry, mapping and IP geophysics, the FJV drilled four holes in the Olympic area in 1994, including one on the current Olympic property targeted at two breccia bodies (Caulfield, 1994a, b). The holes intersected both homolithic and heterolithic breccia phases, hosted by carbonaceous siltstone/mudstone, calcareous siltstone and dolomite. A trend from distal pyrite to chalcopyrite to bornite within the breccia core was apparent in drill core, but overall sulphide concentrations were relatively low. Hole OY94-02 - drilled peripheral to the Athens Breccia - returned only three samples with >1,000 ppm Cu and a maximum value of 240 ppb Au.

In 2006, reconnaissance mapping, prospecting and soil contour lines were conducted on the Olympic Property. This work was focused within airborne radiometric anomalies. Soil and rock sampling generally supported the earlier FJV results. A 400 by 300 m, >8 cps anomaly located 800 m west of the Tow Minfile occurrence yielded five contiguous soil samples with highly anomalous Au-Ag-Mo-Cu-Co-U plus high Au, Cu and U was returned from rock samples (Heffernan et al., 2007).

During 2007, a 10 person-day program of geological mapping, prospecting and follow-up soil geochemistry was carried out on the Olympic property over the southeast block which hosts the Tow showing and anomalous soil geochemistry. Follow-up mapping indicates a structurally complex setting with dominantly southwest-trending, thin slivers of Wernecke breccia within a sequence of dolostone and mudstone. The mudstone appears to be, in part, faulted segments along the margins of the breccia body. The northern contact of the breccia unit appears to lie along a friable maroon mudstone which commonly has carbonate stringers and/or brecciated carbonate veins also found in the breccia. In addition, specular hematite occurs erratically along fracture surfaces and within the dolomite stringers. The boundaries of the breccia bodies are variably black mudstone matrix breccia with siltstone fragments with minor intensely limonitic pyrite boxwork. Within the bounding bodies of the mudstones and faults and dolostones are commonly intensely foliated (phyllitic), extremely contorted and brecciated with dolomite stockwork-stringers. The phyllites are intensely sericitized and are light green and likely represent a large metasomatized block within the confines of the Wernecke Breccia.

Three different styles of mineralization were identified during the 2007 program. The most common style is chalcopyrite in narrow dolomite veins which appear to be tectonically late since they commonly crosscut Wernecke breccia. These veins are erratically oriented and are generally less than 15 cm wide. The second style of mineralization is sulphide blebs and veinlets containing minor chalcopyrite and registering scintillometer readings up to 4000 cps. All of these zones are generally limited to less than 1 to 2 m strike length. The third style is stratabound, sedimentary exhalative Pb-Zn mineralization which is known to be hosted by Gillespie Lake Group shale such as the nearby Cord and Goodfellow Minfile occurrences. This style of mineralization was found in float in the north-flowing creek at the eastern edge of the Olympic property. Significant rock samples from 2007 are presented in Table 20.

103 contour samples were collected in the southeast of the claim block around the Tow showing and highlighted an area with anomalous Cu-Co-Ni-U (Map 4). The anomaly is closed to the northwest but is open to the southeast. This anomaly is spatially associated with Wernecke breccia and covers an area 1400 m by 500 m. One contour soil line (18 samples) was completed on the northern end of the claims. A moderate U-Mo-Co and coincident weak Cu-Au anomaly was outlined. This poorly constrained soil anomaly is located in the same area as radiometric highs.

Four man days were spent prospecting, sampling and mapping in the vicinity of airborne radiometric anomalies at the northern extreme of the Olympic property and immediately to the north. The northeastern radiometric anomaly appears to be due to a high local background. Within the Olympic property boundary, a large body of Wernecke breccia was found to be locally Cu-bearing, and a narrow “pink-plagioclase” vein in the breccia returned 1000 cps.

Additional mapping and prospecting should be completed in the southeast part of the claims to define the distribution of breccia bodies and to further define the extent of mineralization. Soil sampling should be

completed on the north end of the claims and the contour soil line in the southeast of the property needs to extended to the south.

9.11 Pika Property

The Pika property (Map 5) is located south of the Dolores Creek Valley, approximately 18 km southeast of Fairchild Lake. The Pika 1-36 claims were first staked in 1993 based on mineralization reported by Derek Thorkelson at the 1993 Yukon Geoscience Forum. The Pika 37-60 were staked based on favourable stream sediment geochemistry and on a discrete bull's eye airborne magnetic high. These claims had lapsed but were re-staked in 2007.

The property comprises Wernecke breccia and diorite-associated Au-U-Cu mineralization that is associated with breccia contacts. Wernecke breccia crops out over 4 km and the property is situated near a contact between the Quartet and Gillespie Lake groups (Montgomery, 1995). Minor supergene mineralization is associated with the well-exposed Pinguicula Group unconformity on the Pika property (Thorkelson, 2000a) but likely represents a small exploration target.

The FJV conducted first-pass soil and rock geochemistry and discovered the Pika, Pika West and Coope showings that generally comprise elevated Cu-Au-Co associated with Wernecke breccia (Montgomery, 1995; Stammers, 1994, 1995a). The Coope is exposed for 100 m along a northwest flowing creek and comprises a semi-continuous zone of chalcopyrite, pyrite, hematite and carbonate stockwork and veining. Assays up to 40 ppb Au were obtained and two chip samples across 2.0 m returned 2.04% Cu and 1.78% Cu.

In 2007, six soil contour lines were completed to extend the geochemical coverage of the property and the soil grid over the Coope showing was expanded to the south and west. The new data generally is consistent with the 1990s soil results. High Au-Ag-As-Bi-Cu-Pb-Sb results were obtained throughout the soil grid over the Cooper showing. Soil contour lines around the Pika East show a coherent Au-U soil anomaly. In both areas further mapping and follow up prospecting is warranted.

Two samples from strongly silicified siltstone outcrops near the Pika East returned high Cu values in 2007 (Table 21).

Table 21: Pika Property Significant Mineralization

9.12 Radio Property

The Radio property (Map 1) covers an area due south across the Bonnet Plume River from the Hoover Zone. It includes the 1990s FJV Wolverine property (Stammers, 1995c; Stammers, 1998b; Vance and Rainsford, 1996) located along the northeastern contact of the current Radio property. The Wolverine property was staked to cover an arcuate magnetic high adjacent to the Bonnet Plume River valley. Hydrothermal magnetite is present in outcrop within this anomaly (Vance and Rainsford, 1996) which coincides with a minor IP chargeability anomaly. A single reconnaissance gravity survey was conducted across a single line perpendicular to the magnetic high trend. Results showed a strong regional gradient with values decreasing from the southwest but superimposed on this gradient is a 1 milligal residual anomaly. A reconnaissance drill hole (XA95-1) was drilled in 1995 in the core of the gravity anomaly and intersected magnetite, calcite and minor veinlet chalcopyrite that returned several intervals <2 m containing 1000 to 3000 ppm Cu with gold values up to 250 ppb (Stammers, 1995c). In 1997, the FJV drilled two more holes at Wolverine (Stammers, 1998b). One hole was lost in overburden while another hole intersected anomalous Cu mineralization (0.22% over 7.5 m) associated with vein magnetite-pyrite-chalcopyrite-calcite. The Radio

property is underlain by black weathering shale and finely laminated siltstone of the Quartet Group or, to the north, by overburden.

In 2006, three >10 cps airborne radiometric anomalies to the south were investigated by reconnaissance soil sampling and minor, scattered but elevated Ag-Mo-U-Ni-Co results were detected and a white quartz vein boulder collected from a main creek returned 2.9 g/t Au.

In 2007, two days of reconnaissance mapping and prospecting focused on a northeast-draining creek and westen ridges of the Radio Property. The traverses began at the 2006 sample that returned 2.9 g/t Au which is apparently derived from Quartet Group siltstone since exposures of this unit dominate this drainage. Several similar boulders occur in the creek and a small outcrop of silicified and quartz-chalcopyrite-veined siltstone was located within the creek bed. Samples of the mineralized material returned 0.90% Cu but otherwise low metal values. The extent and significance of this style of mineralization is likely minor given the abundant outcrop exposure but very rare mineralization observed in the area.

No further work is recommended on the southern part of the Radio Property, however, the magnetic, gravity and IP anomalies on the margin of the Bonnet Plume valley are still unexplained.

The Radio Break area was prospected in 2007 in an attempt to locate and investigate historical Cu-U showings (Yeager and Ikona, 1976). A large circular 10 cps U radiometrics anomaly centred over 531400E, 7211350N was also ground checked during the process. A large area of sporadic hematite-jarosite-malachite stained cliffs centred at 530760E, 7210100N, very close to the faulted PQ-PFL contact was located 500 m south of the Radio Minfile occurrence. Malachite coatings on biotite-chlorite schist and milky white quartz-chalcopyrite-bornite-malachite vein stockworks in silicified metasedimentary float were found downstream from the showing. Two Cu float samples (286859 and 286860) of this material was collected which returned 404 and 5260 ppm Cu respectively. No radioactive material was encountered. The large airborne U radiometric anomaly coincided with black shales assigned to PQ with high background gamma readings.

9.13 Reid Property

The Reid property (Map 11) was initially staked in 1993 to cover the area surrounding the Reid showing, located 12 km south of the Copper Point airstrip. Previous work on the property carried out in 1994 included reconnaissance style mapping, prospecting, stream sediment sampling and contour soil sampling. In 2006, two rock samples and 75 soil samples were collected.

During the 2007 program, three person days were spent mapping at 1:500 scale, and two person days spent prospecting on the property. Eight rock samples (Table 22) were collected, including rock sample 846098, collected from subcrop with 3 m of exposure, which assayed at 2.25% U. This sample is characterized by moderate silicification and weak jarosite, hosting 1 cm biotite plates as well as 0.5-1 cm crystals of brannerite. It appears the brannerite is related to the selvage of a 5 cm carbonate vein crosscutting the sample (Map 3).

A total of 26 soil samples were collected on the Reid property, generally along soil lines running perpendicular to Mica Creek. These were collected to gain further geochemical data for the Pagisteel Fault corridor. Few anomalous results were returned consisting of isolated Au and Th.

9.13.1 Reid Showing

The Reid showing proper is an extremely gossanous fault “lozenge” which is hosted near the southern bounding fault within a larger fault zone. Within the fault zone, numerous smaller-scale faults and folds appear ductily deformed. The deformation of the shale/siltstone has left a relatively resistant black siltstone-mudstone block which is extremely limonitic and jarosite covered. Mineralization consists of quartz and dolomite stringer veins and thin veins with pyrite and chalcopyrite. Locally a silver-coloured sulphide phase was noted and is likely arsenopyrite or a cobalt mineral such as cobaltite or smaltite. Secondary phases include limonite, jarosite, malachite, azurite and very rare erythrite. This limonitic block is not uniformly mineralized but has podiform mineralization associated with veins. Along strike and downslope the sulphide mineralization is very sparse although the appearance of heavy malachite and azurite on the numerous

fracture surfaces give an impression of a much larger mineralized zone. Other mineralization was generally hosted in narrow discontinuous faulted vein segments and along fault structures.

9.13.2 DR Zone

The DR Zone is best known for 9.0 m of continuous chip samples that returned 2.2% Cu (Jones, 1995a). The showing is poorly exposed since it occurs at low elevation adjacent to Mica and Ursus Creeks. The showing comprises moderately north-dipping sericite and chlorite-altered siltstone. These sedimentary rocks host widespread vein and fracture-controlled chalcopyrite and minor albite alteration is also locally associated with the mineralization. Jones (1995a) suspected that Mica and Ursus creeks might coincide with major structures that truncate the mineralized zone. Several small outcrops occur on the east side of Mica Creek that show similar mineralization and alteration to the main DR Zone. It is thus interpreted that the zone is not cut off by a Mica Creek-coincident fault. Additionally, unmineralized outcrops are present along both sides of the creek to the north. These outcrops provide a northern boundary to the mineralization and, although two conjugate sets of chalcopyrite-bearing fractures are present (Jones, 1995a), are consistent with an approximate 085^{o} trend to the zone as a whole.

As noted by Jones (1995a), the outcrop mineralization of the DR zone was not detected in soil geochemistry. 32 soil samples from northwest oriented lines were collected over the DR showing. No significant multi-sample, multi-element anomalies were delineated so extensive, thick till cover over much of mid to lower areas of the Mica-Hail and Reid properties likely masked the geochemical signature of the DR zone.

Drill-testing of the DR zone (section 10.4) failed to intersect mineralization comparable to the chip samples from 1995 so it is tempting to down-grade the DR zone. The poor exposure of the area, the uselessness of soil geochemistry to detect mineralization and the apparent structural complication make the DR zone worthy of a reevaluation. Trenching, IP geophysics, MMI soil geochemistry are tools that should be considered for future exploration at the DR.

Table 22: Reid Property Significant Mineralization

9.14 Slats Property

The Slats Property (Map 9) trends north-northwest and comprises 114 claims including the Pitch, BL, Blende, and SL groups. The claims are located approximately 28 km west of Fairchild Lake and 15 km south of Quartet Lakes. The Slats Property is contiguous with the TVA Property to the southeast and narrowly contacts the Fireweed Property to the northwest. Earliest known mineral exploration occurred on the Slats Property in the early 1900s. Extensive mineral exploration took place in the mid- to late-1970s followed by a second phase of activity in the mid 1990s. The earlier work focused on U mineralization on the Arctos group of claims by the Mountaineer Mines Ltd. / Pan Ocean Oil joint venture. Work done at that time includes rock, soil and water sampling from grids and several trenches.

The area is underlain by north-northwest-trending, generally west-dipping siliciclastic to dolomitic rocks of the Gillespie Lake group (Thorkelson and Wallace, 1998). These sedimentary units have been intruded by diorite and heterolithic breccia bodies which form locally complex map patterns but in general lie along two layer-concordant trends. Airborne magnetic and radiometric highs trend concordantly to these

breccia bodies. Some of the highest airborne uranium radiometric anomalies detected from the 1994 Newmont airborne survey occur on the Slats Property (Map 2). Shale in contact with the diorite or breccia typically displays strong hematite, moderate to strong silica, weak carbonate and moderate chlorite metasomatism. Locally, within or near diorite and/or breccia, greenish grey sericite, chlorite, and chlorite-serpentine (?) schist is present. The schist is interpreted to be the result of focused deformation caused by rheological differences (Montgomery and Stammers, 1995).

Work in the mid 1990s was undertaken by the FJV and focused on 140 claim units roughly coincident with the present day claims. The claims were originally staked to cover northwest trending linear magnetic highs coincident with airborne radiometric anomalies. The initial surveys were followed up with more detailed airborne geophysics, grid sampling, contour soil surveying and geological mapping at a 1:5000 scale over the Wallbanger and Frosty zones – the two main geochemical anomalies delineated. A program of diamond drilling was undertaken by the FJV in both areas including 611 m drilled in the Frosty area and 562 m at the Wallbanger zone. Drill targets comprised soil and geophysical anomalies as well as outcrop mineralization. During 2006, exploration focused on soil sampling and prospecting within five uranium radiometric anomalies with a focus on uranium prospecting. In general, the 2006 scintillometer surveying showed an incremental increase toward the center of the uranium anomalies that were broadly coincident with lithological changes from dolostone to phyllite to breccia. This suggests that the airborne radiometric data is a reliable indicator of ambient radiation levels in the area. Outcrops and boulders of breccia returned typical scintillometer values of up to 600 cps.

The 2007 work initiated with mapping and prospecting near the Pitch Showing to follow-up sample 286487 and follow-up of 2006 float sample 286497 that returned 0.07% U from an area between the Frosty and Wallbanger grids. Widespread and potentially significant areas of radioactivity were found in both areas and subsequent delineation of these mineralized areas indicates that at least three significant and several smaller showings occur in a 6 km-long, north-south corridor along the length of the Slats Property (Table 23).

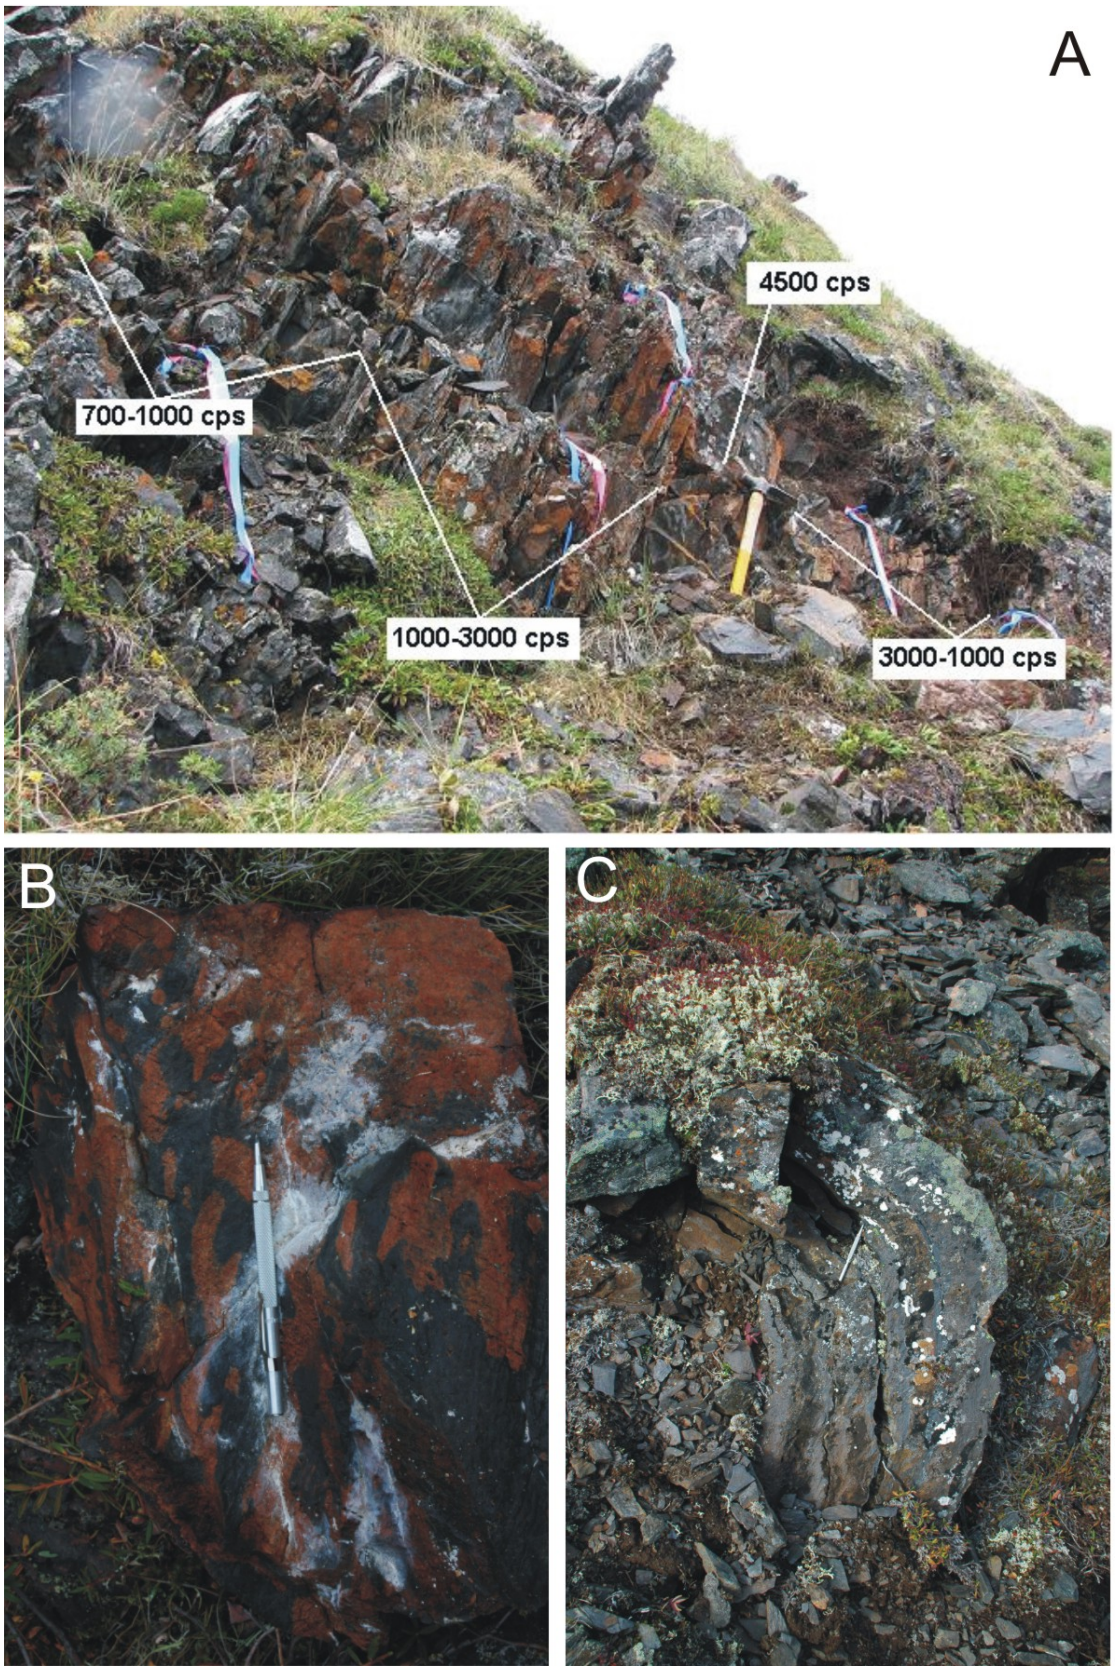

Figure 6: MDV Zone. (A) outcrop with average scintillometer readings. Bedding is steeply dipping to the west (left in image). Continuous chip sampling was done across this outcrop and returned 2.2 g/t Au along the right-hand margin of the photo where lower scintillometer response was recorded. (B) Typical alteration texture of MDV radioactive material. (C) Outcrop scale fold at MDV.

9.14.1 Pitch Showing

Several anomalous 2006 rock sample sites from the southern part of the Slats Property - including sample 286487 that returned 0.12% U over 1 m - were revisted in 2007. Most of these samples were collected along an east-west trending narrow ridge line near the southern part of the Slats Property. The Pitch Minfile occurrence (106D 078) plots 700 m to the northeast so it is possible that this area is the original Pitch.

Zones of elevated radioactivity originate in strongly chlorite-altered, steeply west-dipping, north-south trending shear zones within Wernecke Breccia and chlorite-rich mudstone that are both characterized by reddish hematite and/or potassic alteration. Along with anomalous uranium, the area also has elevated Cu-Co-Ni-Mo in several rock samples. Elevated radioactivity is present within a broad (~70 m wide) zone of higher strain cut by numerous sub-metre-scale discrete shear zones characterized by schistose breccia. Prospecting and mapping along strike to the north and south delineated the zone over a total strike length of about 1.5 km, including a mineralized zone ~700 m northwest of the central zone which recorded >10,000 cps but only 272 ppm U. The continuity of mineralization between these localities is partially covered by talus slopes and therefore unknown.

9.14.2 MDV Zone

The MDV Zone was discovered by re-visiting the location of a 2006 float sample which returned 0.07% U. There, a boulder train was followed to an outcropping zone of metasomatized siltstone/mudstone characterized by 5,000 to >10,000 cps. The 40 by 70 m zone is characterized by pervasive fine-grained specular and earthy hematite (Mauler, 2007). Significant surface uranium mineralization at the MDV showing is found within a unit of inter-bedded, variably altered sedimentary rocks (fine to medium grained clastics) and bedding parallel breccia units (~10-50 cm thick) of unknown origin.

The MDV showing is found within a north-northwest trending, bedding parallel shear zone. Several outcrop-scale fold hinges are exposed in the area. Structural control is thought to play an important role at the

showing with folding possibly providing thickening of the mineralized unit. In general, stratigraphy strikes south-southeast and dips moderately to the west. Folding appears to be asymmetric with fold hinges and bedding / cleavage intersection lineations plunging gently to the northwest.

The strongest mineralization occurs within moderate to strongly hematite altered units that display a characteristic red/black striped pattern (Figure 6B), possibly due to preferential replacement of calcareous regions within the protolith. Uranium mineralization is fine-grained (not visible) and disseminated throughout layers of the altered sedimentary rocks up to several meters thick. Chip samples cross outcrops within the mineralized zone returned elevated Au-Ag-Bi-Mo-Ni-Pb-Sb-Th-U (Table 24). A 2.0 m-wide chip sample across one MDV outcrop returned 2.2 g/t Au along the margin of the most highly radioactive material (samples 847316-17). The outcrop recorded 400 to 3000 cps.

Table 24: MDV Zone 2007 Chip Samples

Sample#	Width (m)	Au ppm	Ag ppm	Bi ppm	Co ppm	Cu ppm	Mo ppm	Ni ppm	Pb ppm	Sb ppm	Th ppm	U ppm	Zn ppm

The MDV Zone is a complex area that has been affected by strong hydrothermal alteration and by widespread deformation. It is clearly not a mineralized zone with a simple planar geometry. Au-U mineralization, with associated elevated Ag-Bi-Mo-Ni-Pb-Sb-Th-REE, is most closely associated with strong hematite alteration and metasomatism. Mapping and logging the distribution of these pervasively metasomatized sedimentary rocks (mts) shows that the alteration is irregular and difficult to extrapolate. Likewise, bodies of heterolithic breccia also show irregularity and it is likely that these breccias were emplaced as irregular bodies. The breccia issue is further clouded by two probable types of breccia that locally appear very similar. Bedding parallel breccia layers as thin as about 5 cm are strongly hematite-altered and look very much like Wernecke breccia. It seems improbable that violent emplacement of Wernecke breccia could result in such fine bedding parallel layers. It is most likely, therefore, that these are pebble conglomerate beds laid down during deposition of the stratigraphic pile.

Some breccias with the MDV Zone, however, are clearly Wernecke breccia and form irregular bodies. They are also locally sheared and foliated suggesting that the folding and shearing within the area is late tectonic. Elsewhere, such as at Slab Mountain, Wernecke breccia contains cleaved, folded and crenulated sedimentary fragments indicating that breccia emplacement post-dates regional, likely Racklan-aged, folding (Thorkelson et al., 2001b; Thorkelson and Wallace, 1993). By contrast, it appears that at the MDV zone, folding and cleavage development post-dated or was synchronous with Wernecke breccia emplacement.

Folding of the sedimentary rocks within the MDV zone is cryptic but becoming better understood. Three outcrop-scale anticlinal hinges occur within the MDV Zone. Not surprisingly, these have similar orientations to bedding / cleavage intersection lineations which indicated the observed hinges are property-scale features (c.f. drag folds or slump features). Both plunge about 20-30^{o} towards 300^{o}. All bedding within the MDV zone, however, dips to the west indicating that the folds are overturned. This is supported by younging reversals observed in STM07-06 and by younging indicators in STM07-05 suggesting that most of the hole is overturned. Since the folds plunge towards 300^{o}, the holes drilled this year at MDV are highly oblique to the fold hinges which probably explains some of the apparent complexity evident on Cross Sections 17 to 19 (see Diamond Drilling section).

Regionally, the MDV Zone lies immediately west of a large north-trending, steeply west-dipping normal fault (Thorkelson and Wallace, 1998). This structure defines the contact between a panel of overturned Gillespie Lake Group dolomites and Wernecke breccia according to the regional mapping. At the

MDV, the ridge to the west is marked by orange weather dolomites in stark contrast to the purple-red siltstone lower down the slopes in the MDV. Further north, this contact is better exposed as a distinct fault. The folding at MDV may be linked to the late-stage movement along this major structure. On a regional scale, this structure and another one to the east are concordant with corridors underlain by Wernecke breccia. It is not a stretch, therefore, to link the emplacement of the breccias with these structures. The MDV folding might also be related to movement along these structures. Perhaps a transpressional stress regime was active between the parallel structures during breccia emplacement. This caused asymmetric, property-scale folding, cleavage development and focusing of hydrothermal fluids emulating from the breccias. Although no direct link between the MDV breccias and mineralization can be demonstrated, the metal signature, alteration and proximity of mineralization and breccias point to a large IOCG mineralizing system.

Although not yet well understood, the MDV Zone and the Slats property, in general, are worthy of further exploration. Structural preparation of the area by folding, the generally more coarse-grained (more porous?) nature of the sedimentary rocks, pervasive metasomatism and its location between two linear corridors of Wernecke breccia make the MDV Zone more perspective.

9.14.3 Atomtan Showing

Several outcrops with high scintillometer counts (5,000 to >10,000 cps) have been found approximately one kilometre along strike to the north from the MDV Zone. Significantly, this altered radioactive rock returned high-grade Au and U. A selected sample (846422) returned 18.2 g/t Au and 1.01% U. Significant rock geochemistry for the Atomtan are given in Table 25. Mineralization at Atomtan appears to follow steeply SE-dipping foliation planes in strongly hematite altered siltstones. Widths range up to 6 m and the outcrop has been traced for nearly 30 m along strike. Additional sporadic uranium mineralization is encountered in a 3 m-thick hematite layer approximately 200 m further to the NW from Atomtan. The hematite layer has been affected by asymmetric, NW-plunging folding, similar to that noted at the MDV zone.

Table 25: Atomtan Showing 2007 Samples

9.15 TVA and Nuck Properties

The TVA and Nuck properties are located about midway between the Bonnet Plume and Bear Rivers (Map 10). Parts of the Nuck claims are coincident with portions of the historic TVA 4-22 claims and cover the Gnuckle Cu-U occurrence (Minfile 106D/16-062). The property was expanded with additional staking in 2007.

The Gnuckle was first identified for Cu mineralization in 1968 by Cyprus Exploration Ltd. but was not staked until 1976 when the tenure was secured for its uranium potential. Mineralization consists of coarse-grained brannerite in quartz veins cutting strongly silicified Quartet group sedimentary rocks proximal to a Wernecke breccia body (Map 3). During the course of the Wernecke Joint Venture program in the 1970s, the area around the occurrence was mapped, soil-sampled and a radiometric survey was undertaken.

From 1992 to 1995 the FJV completed rock and grid soil sampling, mapping at 1:2,500 scale and airborne geophysical surveys. This program outlined a northeast-trending thrust fault hosting the majority of the mineralization including the Hem and Roid zones. The Hem zone is coincident with a northeast-trending magnetic high. Additional mineralized or anomalous zones reported by Klatt and Jones (1995a) that are currently on these claims include the North Gnuckle, South Gnuckle and White Gnuckle zones all of which are defined by multi-sample Cu-Mo-Co-Au-Ag-Ni soil anomalies.

The FJV drilled seven holes in the vicinity of the TVA and Ursus properties in 1995 (Klatt and Jones, 1995b). Four of the five holes drilled on the Roid zone were not completed due to ground conditions and technical difficulties. The successful hole encountered localized copper and cobalt mineralization in variably altered shaley dolomite including native copper and chalcopyrite-chalcocite veinlets. Two holes were drilled on the Hem Zone testing additional soil geochemical anomalies. These holes encountered widespread copper mineralization within variably altered and mineralized dolomitic shale, with disseminated chalcopyrite and pyrite and zones of specularite-carbonate-magnetite-chalcopyrite veining. Significant mineralization encountered in these holes is summarized in Table 26.

Table 26: Significant TVA 1995 Drill Intersections

Drill hole	From (m)	To (m)	Interval (m)	Au (ppm)	Co (ppm)	Cu (%)
UT95-05	50.2	79.9	29.7	N/A	325	0.20
UT95-06	2.00	186.06	184.06	0.07	N/A	0.15
UT95-07	79.75	86.62	6.87	0.03	46	0.26

Work performed on the property in 2006 included the collection of rock samples from two prospecting traverses. Samples taken in Gnuckle Creek displayed slightly elevated Mo-Ni-Bi-Co-Pb-Sb. All samples collected were float, however, and may not have been a good indication of mineralization style at the Gnuckle and White Gnuckle zones. Samples taken from the Hem Zone include two from the intercalated shale carbonate unit of the Gillespie Lake group, both of which displayed elevated Au-Bi-Cu-Mo-U. A grab sample taken from fracture-controlled chalcopyrite-magnetite-pyrite mineralization displayed high grades of 5.2% Cu, 0.81 g/t Au, 278 ppm Mo and 0.014% U. The remaining three samples were collected near a previously mapped southeast verging thrust fault juxtaposing chlorite-K-feldspar altered Wernecke Breccia from chlorite-K-feldspar-quartz altered metasomatite. This relationship was confirmed and supported the proposition of thrust fault-controlled mineralization by Klatt and Jones (1995a). Notable results from these samples include 0.98 g/t Au, 0.69% Cu and 0.15% U and 1.58 g/t Au, 303 ppm Co, 3.02% Cu and 0.013% U.

60 soil samples were collected along two contour lines parallel to Gnuckle Creek and during the course of claim-post tagging of the Nuck claim group. The contour lines in the Gnuckle creek valley were located approximately 100 m upslope from lines sampled in the mid 1990s. The 2006 contour line on the northwest side of the creek, combined with the historical soils, define two multi-sample, multi-element anomalies. The anomaly farthest west occurs 550 m downslope of the North Gnuckle zone and comprises a Au-Co-Cu anomaly with weak U. A second anomaly occurs approximately 500 m to the east and consists of Au-Co-Cu-Ni-U. Both of these anomalies occur down slope of a previously mapped thrust-fault. The South Gnuckle zone is coincident with a Ni-Co anomaly. Recommendations for the TVA and Nuck properties following the 2006 work included further drill-testing of the Hem Zone, mapping and prospecting in the Gnuckle Creek area, and prospecting in the vicinity of the Au-Cu-Ag soil anomaly along trend with a magnetic high.

A considerable amount of work was performed on the TVA-Nuck properties during the 2007 field season, with the bulk of the work carried out on TVA. Work performed included claim-staking, prospecting, detailed geological mapping, soil sampling (336 samples), rock sampling (348 grab and chip samples), scintillometer surveying (12 line-km), magnetometer surveying (28 line-km), trenching (approximately 50 m), and diamond-drilling (1147 m). Much of the work completed was prospect-specific. The four main prospects investigated during 2007 were: Rio, Hem, Jem and Gnuckle. Significant rock samples collected in 2007 from the TVA property are presented in Table 27.

9.15.1 Rio Zone

The Rio boulder field was discovered in 2007 by prospecting an airborne radiometric anomaly in the south-central portion of the TVA claim block where little prior work was known. Thirty-nine samples from uranium-bearing boulders were collected and sent for laboratory analysis. The best sample returned 0.51% U (839878) and 28 select boulders returned an average grade of 0.28% U.

The area is underlain by Gillespie Lake Group interbedded siltstone and (locally cherty) dolomite with local metasomatization. Much of the dolomite contains coarse porphyroblasts of andalusite, possibly related to the pods of heterolithic Wernecke breccia which have intruded the sedimentary sequence in several locations. Approximately 70 m north of the Rio Zone is an extensive unit of back Quartet Group shale, at surface in fault contact with siltstone and dolomite. The Quartet shale has a higher background scintillometer count than the other sedimentary rocks, and hence appears anomalous on the scintillometer survey contour map. A number of faults and shear zones cut the sedimentary rocks in the vicinity of the Rio Zone, with the dominant fault set – to which the mineralization appears related – trending between 240° and 270°.

Trenching to expose mineralized bedrock on the Rio zone was carried out during the 2007 field season (Figure 7). Initially a few shallow pits were dug by hand in an attempt to reach bedrock and discover the source of the mineralization. In late-July/early-August, three trenches (roughly 50 m in total length) were blasted and then mucked out using a small Kubota excavator, which was slung onto the property via helicopter. The trenches were then cleaned, mapped in detail, surveyed with scintillometer and magnetic-susceptibility meter, and chip-sampled. All three trenches were oriented at approximately 150^{o}, roughly perpendicular to the trend of the uraniferous boulder train.

Trench 2 (the middle trench and the first excavated) exposed a 5.5 m wide (close to true width) zone of yellowish-green, intensely sericitized dolomite(?) which gave a scintillometer count of up to 1500 cps. This rock is similar to the float constituting the uraniferous boulder train. The zone strikes at roughly 250^{o} and has a sub-vertical dip. It is strongly sheared over 1.5 m at its northern contact with cherty dolomite. An intensely magnetite-carbonate-pyrite-altered unit which was initially mapped as a diorite but may in fact be metasomatized sedimentary rock occurs immediately adjacent to the U-mineralized zone to the south. This in turn is in contact with a malachite-stained Wernecke breccia unit. The trench cuts across what appears to be the hinge of a very gently-folded anticline.

Trench 3 (the uppermost trench) intersected the uranium-mineralized zone exposed in Trench 2, although it is substantially narrower here. The continuation, however, of a second mineralized structure present in a nearby outcrop was also better exposed within a separate blast trench 8 m south of the main trench. This second zone is markedly different in mineralization style from that of the “main” zone being characterized by silicified, carbonatized, hematized and cut with quartz/carbonate stringers containing visible grains of probable brannerite (Mauler, 2007). It is 2-3 m in width and trends sub-parallel to the main zone. Malachite and trace chalcopyrite were also noted locally in Trench 3.

Trench 1 (the lowermost trench) failed to intersect the main zone, with maximum scintillometer counts of only 500 cps. Based on geological interpretation and limited hand-trenching, it is probable that even though the trench cut across the strongest part of the boulder train, the mineralized zone trends a few metres to the north (Figure 7). Chip-sampling returned low uranium values, with a maximum of 105 ppm (sample 846162) across the sericitized shear exposed in Trench 2, and all other values less than 30 ppm. Despite this, it was decided to drill-test the zone, in the hopes that the strong uranium mineralization encountered in several of the boulders would also be intersected at depth. Drill results are discussed in section 10.3.

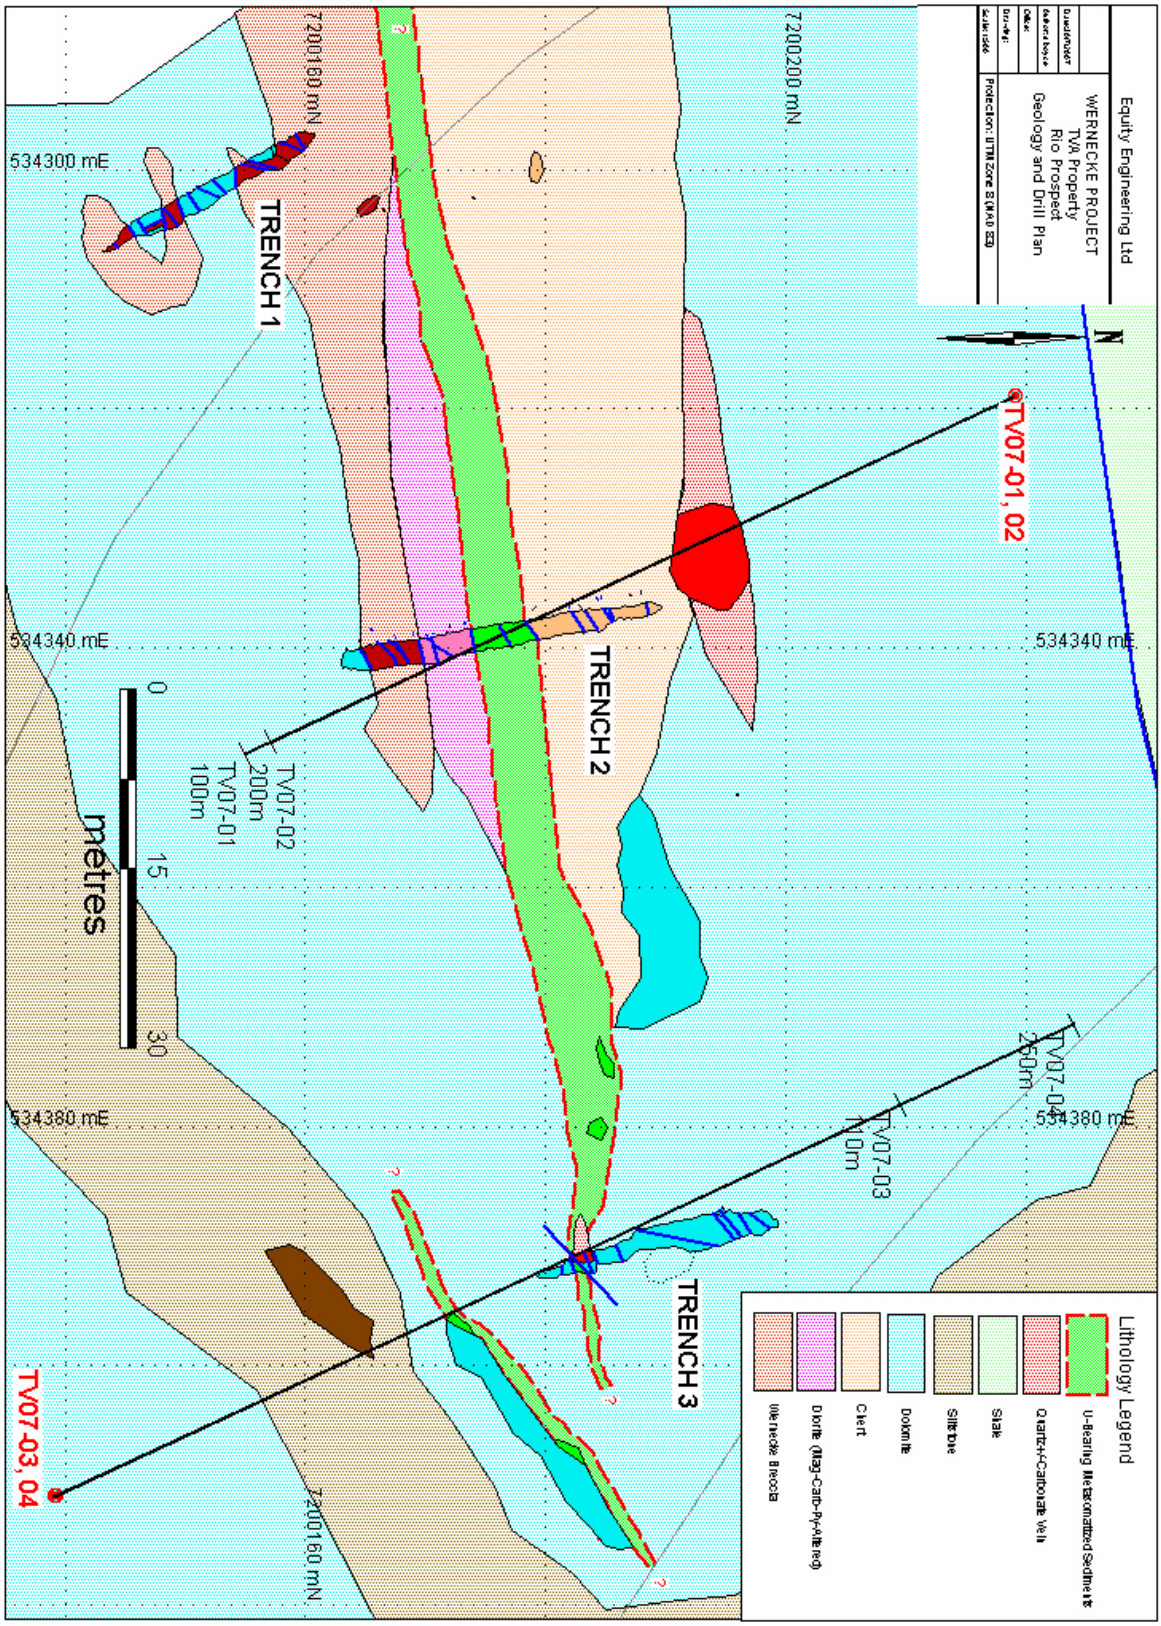

Figure 7: Rio Zone geological interpretation, trenches and surface drill traces.

9.15.2 Hem Zone

The Hem Zone is an historical Cu prospect with a limited amount of previous drilling, but encouraging Cu-U-Au results from grab samples taken during the 2006 program. The area is underlain by dolomite, cherty dolomite and siltstone with local pods of Wernecke breccia and rare diorite. Bedding of the sedimentary rocks generally strikes west-southwest and dips moderately to steeply to the north; the hinge of a tight isoclinal fold was noted at one outcrop location. Late major faults trend northwest, oblique to the ridgeline of Ursus Peak (which broadly parallels the Hem Zone proper). Most rocks have been metasomatized, with the predominant alteration minerals being chlorite and magnetite and locally specular hematite. Petrographic work on drill-core suggests that the hematite is a replacement of magnetite (Mauler, 2007).

Detailed mapping during the 2007 field season delineated two zones–the Hem proper and the Lower Hem zones (Maps 2 and 9). The Hem proper (Figure 8) has a known strike-length of about 450 m and a width of 3-5 m, with an azimuth of 250^{o} and a dip of approximately 55° to the north. The southern half of the Hem zone is represented by a footwall contact between a massive specular hematite unit (1-5 m wide) that overlies magnetite-chlorite-rich sedimentary rock and, locally, Wernecke breccia. The contact is interpreted to be a thrust fault which happens to be roughly conformable with local bedding. A more steeply-dipping shear zone locally trends along the contact. The contact zone exhibits a significant amount of secondary-copper staining and locally uranophane. The northeast end of the Hem zone is represented by a large (approximately 40 m by 20 m) intensely-chloritized outcrop (siltstone protolith?) which returned strongly anomalous scintillometer counts, locally in the high 1000's. A total of 41 chip samples were collected from this outcrop; unfortunately, uranium assays were only weakly anomalous (a maximum of 289 ppm over 2 m from sample 839724). The high scintillometer readings are therefore most likely attributed to a mass effect. Copper mineralization at Hem proper occurs along the specular hematite-magnetite-chlorite contact and has also apparently been remobilized into rare <30 cm-wide quartz-chalcopyrite veins that are concordant to the northwest-trending fault set.

The Lower Hem is less extensive and less well-defined than the Hem proper, and lies roughly 70 m downslope and to the south. It appears to have a similar orientation to that of Hem proper. At its known northeast limit it is distinguished by a gossan containing a number of thin beds of semi-massive pyrite. Continuous chip sampling across 16.5 m of this pyritic zone returned elevated Au-As-Co-Mo-Sb but the highest best result was 162 ppb Au over 1.5 m. Its southwest end is represented by another (narrower than the Hem proper) massive specular hematite unit in contact with semi-massive magnetite. Like the Hem proper, the Lower Hem is also cut by northwest-trending faults and similarly-trending quartz-chalcopyrite veins. One of these veins returned 19.8% Cu (sample 839706).

Figure 8:. View of the Hem Zone, looking northeast toward Ursus Peak. The three large outcrops located close to the ridge-top express the zone; the grey rock is massive specular hematite, and the oxidized rock below it is mineralized magnetite-rich sediments/breccia. The Lower Hem lies immediately below the outcrops at the far right of the photograph.

9.15.3 Jem Zone

During August two person-days were spent mapping and sampling in the vicinity of an 18.3 g/t Au grab sample (sample 839764) collected earlier in the field season, 350 m downslope and to the south of the Hem zone. The sample came from intensely silicified and carbonatized dolomitic(?) sedimentary rock with abundant pyrite and minor chalcopyrite in fault-contact with Quartet Group shale and proximal to two Wernecke breccia bodies. Mineralization is associated with siderite-quartz veining trending roughly due west and dipping steeply to the north. The showing is approximately 40 m long by 15 m wide and open on all sides except to the east. Thirty chip and grab samples were collected over the showing but results from these were consistently low. Drill-testing of the Jem zone, therefore, is not warranted.

9.15.4 Gnuckle Zone

In all, two days were spent by geologists investigating the Gnuckle Creek Cu-Au showing, which constitutes a contact between silicified sedimentary rock and Wernecke breccia. Two pieces of coarse brannerite (2 cm diameter) giving counts of up to 7000 cps were found in the soil a few metres away. A detailed scintillometer survey was conducted over the area on a 20 m by 10 m spacing (see section 11.1.2). Because no strong trends or particularly strong anomalies were identified with this survey, and because there is a parsity of outcrop in the area, it was decided to make Gnuckle a lower priority for trenching and to focus instead on trenching on the Rio Zone and on other properties in the Wernecke project area.

A uraniferous hand trench, apparently several years old, was found approximately 300 m southwest of the Gnuckle showing; no record of this has been found in reports for the area.

9.15.5 Conclusions and Recommendations

- At Rio, the source of the uraniferous boulder field was identified and sufficiently evaluated through trenching and drilling. The zone appears to be very restricted in width and probably also strike-length. The

uranium mineralization seems to be very patchy and low-grade despite the locally high-grade results from surface boulders. No further work is proposed here.

- Drilling completed on the Hem zone (described in section 10.3) demonstrated that it is prospective for Cu-Au mineralization. The drill program should be completed, with UT07-12 continued to its planned depth, plus a third hole should be drilled at the northeast end of the zone where uranium mineralization is strongest.
- Further work is possibly warranted around the Gnuckle Zone, including detailed geological mapping, sampling the old hand-trench, and trying to pinpoint the source of the two brannerite pebbles, possibly by trenching.
- The magnetometer survey uncovered a number of magnetic anomalies that were not followed-up due to time and weather constraints. Two anomalies in particular, located north-northeast of the Hem zone, warrant investigation.

9.16 Ursus Property

The Ursus property (Map 3) comprises 14 contiguous claims located directly south of the TVA claims. The claim group was first staked in 1976 by Harman Management Ltd. to cover the Ford U and Cu showing (Minfile 106D16-52). The property was subsequently worked by Pan Ocean Oil from 1977-1980 at which time the claims were allowed to lapse. The ground was restaked and additional work (collection of 61 rock samples and limited prospecting and mapping) was performed by the FJV from 1992-1995. At that time, the Ursus and the previously described TVA claims formed a contiguous block. The majority of the work, however, was focused on the TVA claims to the north.

Mineralization occurs as disseminated and podiform chalcopyrite in calcite stringers and veins. Several select samples from the 2006 program returned elevated Cu-Au-Ag. Exceptional values from these samples include 16.6% Cu, 0.2 g/t Au and 19.15 g/t Ag (sample 286734) and 18.2% Cu, 0.2 g/t Au, and 29.9 g/t Ag (sample 286733).

Work completed in 2007 on the property included mapping, soil and silt sampling, scintillometer prospecting, and trenching. Ninety soil samples were collected along two contour lines. Follow up on 2007 anomalous Cu-U-Co-Mo-Ni soil results led to the discovery of the Dodge brannerite showing. Subsequently a scintillometer grid and trench were completed at the Dodge showing.

The bulk of the rock samples collected was in the vicinity of the Dodge Showing and will be discussed in the following section. Six of the rock samples, however, were taken elsewhere on the property. Of those samples, two returned 1.85% Cu and 2.49% Cu (samples 839937 and 839665 respectively). All rock samples with significant mineralization can be found in Table 28.

Table 28: Ursus Property Significant Mineralization

Sample#	Showing	Au ppm	Ag ppm	Bi ppm	Co ppm	Cu ppm	Mo ppm	Ni ppm	Pb ppm	Sb ppm	Th ppm	U ppm	Zn ppm

9.16.1 Dodge Showing

The Dodge Showing (Map 3) is located in the center of the Ursus property and was discovered by following up a brannerite-bearing boulder field. Brannerite occurs in outcrop along the ridgeline and as subcrop downslope to the east grading into a corresponding uraniferous boulder train continuing down the slope. Thirty rock samples, several registering >10,000 cps were collected throughout the boulder train and over 80 boulders exceeding >500 cps were flagged. The uraniferous zone is approximately 30 m wide and

extends over 200 m downslope. The mineralization is similar to that of Fireweed, characterized by coarse-grained brannerite disseminated in plagioclase-hematite-altered siltstone proximal to Wernecke breccia bodies.

After the initial discovery was made, a scintillometer grid survey (discussed more in section 11.1.2) was established and additional mapping was undertaken in the surrounding area. A 40 m-long trench was blasted along the eastern side of the Dodge showing on Ursus ridge and was excavated with the Kubota excavator. The trench exposed siltstone with weak to moderate chlorite alteration. Two veins were exposed within the northern end of the trench and are composed mainly of plagioclase, chlorite and quartz and occur in association with narrow faults.

A 30 cm wide zone of brannerite-bearing veinlets was intersected 5 m from the southern end of the trench and reads 3500 cps. This brannerite zone seems to be associated with an area of faults located directly to the south. A second zone of brannerite is found to the north at approximately 14 m. This zone is approximately 20 cm wide and is characterized by disseminated brannerite along a poorly defined veinlet registering 900 cps. This material resembles the uraniferous, brannerite-bearing boulders found on surface.

A total of 38 rock samples, six from subcrop and three from the trench, were taken in the area of the Dodge showing, mainly from the float of the associated boulder train. For the 35 samples taken, the average uranium content is 760 ppm, and 11 returned greater than 0.10% U, to a maximum of 0.21% (846303). Of 18 samples analysed that recorded greater than 1000 cps on the scintillometer, these averaged 0.11% U. Additionally, after further analysis, the soil samples taken downslope of the Dodge returned greater than 80th percentile for at least one sample in all the major metallic elements that percentiles were calculated for, except for Au (Table 29).

Table 29: Dodge Showing (Ursus Property) Significant Mineralization

Further work on this property is not of a high priority, due to the limited scale of the Dodge showing and lack of significant mineralization found in outcrop. Additional mapping and prospecting could be carried out to the west of the Dodge showing, although the geochemistry is not highly significant in this area. The strong geochemical anomalies in the major elements found downslope of the Dodge showing warrants that more work be carried out to further define this target.

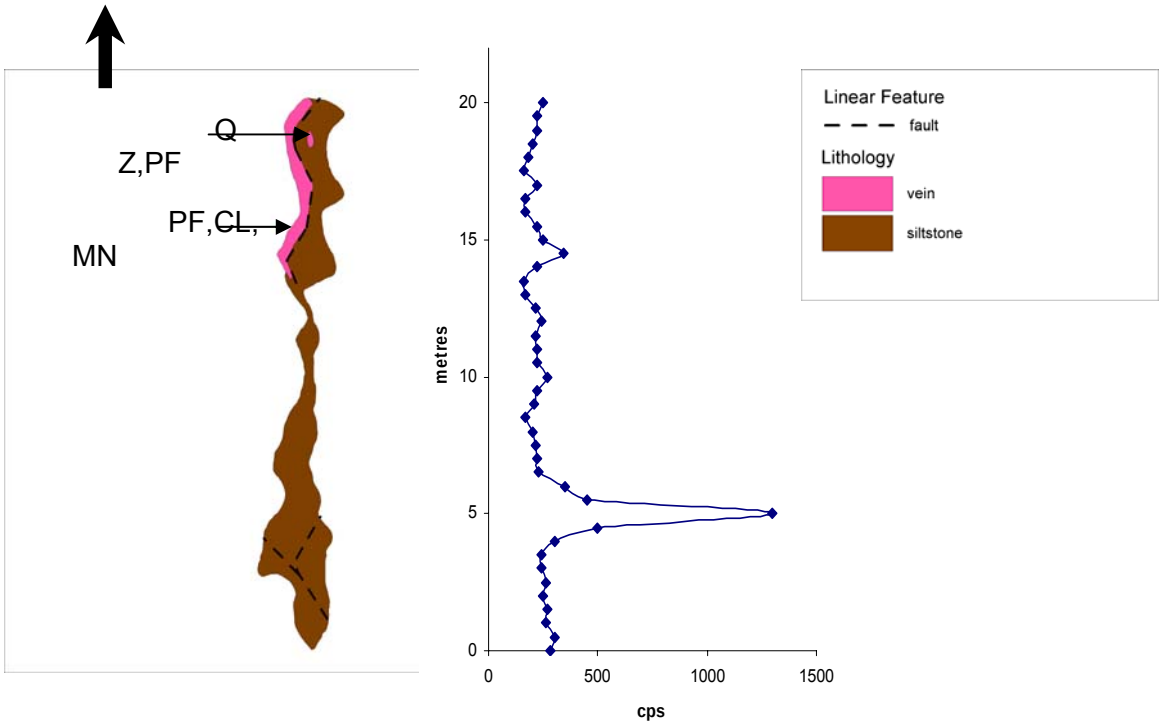

Figure 9: The Dodge trench mapping, with corresponding scintillometer readings.

9.17 VB Property

The VB property (Map 4) comprises 204 contiguous units located directly north of Fairchild Lake which were staked in July, 2006 to cover the historic Otter, Vole and Beaver properties (Caulfield, 1995, 1996; Dick and Harmeson, 1981). The ground was originally staked based on favourable geology similar to that at the Main Otter copper-cobalt showing (Stammers et al., 1978) located several kilometres to the south on the west side of the Fairchild Lake (not on Fronteer-held ground). Claims northwest of the lake were first staked in 1979 as the Otter 89-124 claims. The following year the Vole 1-43 claims were staked northeast of Fairchild Lake. Work in 2006 focused on reconnaissance mapping and geochemical surveys of two radiometric anomalies located on the eastern part of the property. Values were generally low, however, a few rock samples in one radiometric target returned 0.2 to 0.3 ppm Au and the final sample on the soil line about 1 km west of the radiometric anomaly returned 20 ppm U.

In 2007, 93 soil samples were collected from four contour lines in two areas. The 2006 soil line near the central north part of the property was extended to the property boundary and a second line added. This area was also prospected. The 2007 results confirmed the anomaly and scattered >90th percentile U in soil values extend for 800 m to the northwest along with scattered elevated Ni-Mo-Zn. Prospecting in this area failed to located significant mineralization in float or outcrop and, as such, this soil anomaly remains unexplained.

Two contour lines and prospecting were completed in the southwest corner of the property in an area highlighted as an airborne gravity anomaly. Nine scattered samples returned >90th percentile U and isolated samples returned highly anomalous Zn-Ni-Co but no coherent anomaly was delineated. A few quartz veins without significant sulphide phases and pyritic gossan were sampled but returned low values. Given that this gravity anomaly coincides with high topography, the anomaly could likely be a processing artefact (Barnett, 2007). No obvious follow up work is recommended for the VB property but it remains a tier two target.

9.18 Regional Targets

9.18.1 Chico Showing

Two days of reconnaissance mapping and prospecting in an area southeast of the Reid property on the historic Vulture claims was completed to follow up U soil anomalies from 2006 soil lines. The Vulture claims are no longer active and the area is currently on open ground. This area is underlain by moderately to strongly chlorite and weakly sericite-altered siltstone and is characterized by a broad airborne radiometric high. A strong foliation is present in the siltstones and the area appears to be dissected by a large regional-scale shear zone. Several small heterolithic breccia bodies occur in the area.

A boulder field comprising 20-30 boulders of siltstone and a single boulder of heterolithic breccia registering 1000-2500 cps was discovered within a strong U in soil anomaly. The boulders are strongly silicified and characterized by pink-red alteration that is either earthy hematite or potassic alteration. An outcrop source upslope from the boulders consisted of a 10-15 cm wide shear zone that trends ~290°. This structure is hosted in pinkish-red siltstone that is strongly silicified and produced up to 8000 cps. Two more similar structures occur ~200 m to the southeast. A select sample from the uraniferous structure returned 0.2% U and 0.33 g/t Au.

9.18.2 Reconnaissance in the Look See area

During the course of a regional silt sampling program, a 5 to 7 m-wide quartz vein was discovered as well as numerous malachite showings. Follow-up prospecting in this area discovered a large vein and fault structure named the Triple J Showing. The structure is a multi-episode quartz and iron carbonate vein which has erratic sulphide mineralization of chalcopyrite, pyrite and a cobalt mineral which is likely smaltite or cobaltite. The vein complex is located in very steep terrain and was sampled in place and from float material directly below the cliffs hosting the veins. The vein was strongly faulted and was up to 7 m width where accessible for measurement.

Results of the Triple J showing and other lesser gossanous and quartz vein showings in the area are shown in Table 30. The hydrothermal system in this area shows elevated Au-Ag-Bi-Co-Cu-Ni-Sb. The highest grade material from the actual showing returned 0.36 g/t Au and 1.8% Cu and was collected from a locally sourced float quartz vein hosted in siltstone with 2% chalcopyrite, 2% pyrite and 1% cobaltite. Only six person days of prospecting were completed in this area.

10.0 DIAMOND DRILLING

6537.96 m of NQ2-sized diamond drilling in 28 holes was completed during the 2007 program (Table 31). Drilling was completed by three different drill contractors including Foraco Drilling of Kamloops, BC, Cabo Drilling of Surrey, BC and Dorado Drilling of Vernon, BC. Seven different targets were tested including Central Hoover, Pagisteel, MDV, HEM, Rio, DR and Fireweed Boulder Train. This drilling was focused on a combination of follow-up targeting of 1990s Fairchild JV drilling and testing of new targets delineated by the 2006 and 2007 field programs. In all, 4084 drill core samples were collected including 395 quality control samples.

10.1 Hoover Central, Hoover Property

The FJV drilled eight holes on the current Hoover property in 1994 (Jones, 1995b; Stammers, 1995b), testing surface mineralization in two areas. Significant mineralization from this drilling is summarized in Table 32. Five holes were drilled southeast of Radio Creek, in the Central Zone, hitting altered sedimentary rocks and Wernecke breccia. Four of these holes yielded long Cu±Au intervals, with the best sections correlating to

the strongest brecciation and stockwork calcite-quartz veining. The other three holes were drilled northwest of Radio Creek, intersecting only weak Cu-Au mineralization.

The 1995 Hoover drilling (eight holes) was designed to extend the Central Zone mineralization along strike and down-dip and to test a covered target marked by a magnetic low along strike to the northwest of the Central Zone (Jones, 1995b). Thick overburden frustrated the first objective, with both holes abandoned in thick overburden. Six holes tested the geophysical anomaly along three sections covering 1,200 m of its strike length, intersecting scattered Cu-Au mineralization within variably altered phyllite. Two further drill holes on the Central Zone in 1997 were unable to penetrate thick fluvial overburden, whose minimum depth is 116 m, the depth at which the second hole was abandoned (Stammers, 1998a).

In 2007, nine holes were drilled as follow-up holes from the 1990s drilling. The more recent holes tested the Central Zone along strike and as infill drilling and attempted to determine the orientation of the zone and find higher-grade zones. The drilling showed the zone to be steeply dipping and to be generally controlled by a heterolithic breccia / sedimentary rock contact. Locally higher grade copper and gold mineralization was encountered, however, over narrow intervals. The zone is at least 500 m long and is very generally planar, however, mineralized intervals vary from 25 to about 125 m thickness.

Table 32: Significant Hoover Drill Intersections

Drill hole	From (m)	To (m)	Interval (m)	Au (ppm)	Cu (%)
HV94-03	121.76	193.72	72.99	0.32	0.42
HV94-05	3.05	284.70	281.65	0.06	0.23
HV94-07	309.50	381.50	72.0	0.07	0.22
HV94-08	31.17	157.89	126.72	0.08	0.44
HV95-12	92.00	104.00	12.00	0.20	0.35
HV07-19	214.80	238.00	23.2	0.21	0.39
and	264.60	313.00	48.4	0.12	0.28
HV07-21	273.40	350.00	76.6	0.11	0.23
HV07-22	79.70	168.20	88.5	0.11	0.55
HV07-25	170.00	254.00	84.0	nil	0.12
HV07-26	319.30	327.00	7.9	0.29	1.20
HV07-27	19.50	58.00	38.5	0.17	0.64
and	204.70	219.00	14.3	0.62	2.15

10.1.1 HV07-19 (az. 060°, dip -45°, 436.00 m)

This hole (Cross Section 1) was a ~200 m step up from HV94-07 which intercepted 72 m of 0.22% Cu. HV07-19 intersected siltstones from 11.3-316.1 m that correlate with a unit logged in HV94-07 as hornfels. From 316.1 m to the end of the hole, heterolithic Wernecke Breccia was intersected. Mineralized intersections included 23.2 m (0.21ppm Au; 0.39% Cu) at 214.8 m depth, and 48.4 m (0.12ppm Au; 0.28% Cu) at 264.6 m. Increased calcite alteration was observed within the mineralized zone. Chalcopyrite mineralization typically occurred as stringers and blebs associated with calcite veins within the siltstone, and as blebs within the matrix of the breccia.

10.1.2 HV07-20 (az. 240°,dip -60°, 68.00 m)

This hole collared in phyllite and upon intersection of siltstone at about 51 m, the hole intersected several metres of rubble, sand, and gravel at 59 m (Cross Section 2). This was thought to be a large fault zone and the hole was abandoned in favour of a steeper inclination.

10.1.3 HV07-21 (az. 240, dip -70°, 374.00 m)

This hole (Cross Section 2) was a re-drill of HV07-20. This hole (as well as HV07-20) were designed to target mineralization encountered in HV94-03 and was drilled down-slope in an effort to avoid drilling through problematic valley fill overburden.

The hole encountered unmineralized phyllite to 58 m and then cored siltstone (locally crackle brecciated) to 374 m (EOH). Homolithic Wernecke Breccia was encountered from 89 to 117 m. Abundant chalcopyrite mineralization was encountered in three separate zones corresponding to Cu and Au mineralization. Core is strongly oxidised to about 135 m as evidenced by common copper carbonates and iron oxide-coated fractures.

10.1.4 HV07-22 (az. 260°, dip -70°, 340.00 m)

This hole was targeted as an up-dip test of holes HV94-05 and HV94-08. After 8.9 m of overburden a heterolithic breccia unit was intersected that included localized chalcopyrite mineralization up to 2% (Cross Section 3). From 83.4-83.8 m a narrow fault breccia unit was encountered. From 83.8 m to the end of the hole a siltstone was intersected. A 88.5 m mineralized section (0.11ppm Au; 0.55% Cu) was intersected in this hole beginning at 79.7 m.

10.1.5 HV07-23 (az. 270°, dip -65°, 236.5 m)

This hole was designed to test the southern extension of the Central Hoover Zone under the thick over-burden of the valley bottom (Cross Section 4). It intercepted siltstones from top to bottom and had to be shut down early due to the drill pad becoming unstable. No significant copper mineralization was seen in HV07-23; however 2-3% magnetite was intersected at 208 m and continued until the end of the hole. Strong chlorite, moderate-strong silica, and weak-moderate calcic alteration occurred throughout the hole.

10.1.6 HV07-24 (az. 090°, dip -45°, 136.00 m)

This hole was designed to test the south-east extension of the Central Hoover Zone along the hill slope (Cross Section 4). It intercepted siltstones from top to bottom and had to be shut down early due to the drill pad becoming unstable (same drill set-up as HV07-23). No significant copper mineralization was seen in HV07-24; however 1% magnetite was intersected at 104 m and continued until the end of the hole. Strong chlorite, moderate silica, and weak-moderate calcic alteration occurred throughout the hole.

10.1.7 HV07-25 (az. 080°, dip -45°, 413.0 m)

This hole tested the continuation of the mineralized zone ~225 m north of HV07-19 at a similar elevation (Cross Section 5). After 5.7 m of overburden, a heterolithic breccia unit was intersected and continued to a depth of 47.2 m where it changed to a homolithic breccia which continued to a depth of 101.1 m. A magnetic diorite unit was then intersected from 101.1-129.9 m that contained trace-1% pyrite. A similar heterolithic breccia to the one seen earlier in the hole was intercepted again from 129.9 m to the end of the hole. From 169.7 m to the end of the hole, chalcopyrite mineralization occurs in a similar style to that seen within the breccia unit of HV07-19.

10.1.8 HV07-26 (az. 240°, dip -75°, 327.2 m)

This hole was designed to test the up-dip continuity of the mineralized zone on section with holes HV94-07 and HV07-19 (Cross Section 6). After 6.4 m of overburden, a grey-black phyllite was intersected down to a depth of 233.2 m where it came in contact with a heterolithic breccia unit. The heterolithic breccia continued to a depth of 260.9 m where it came in contact with a siltstone similar to the one seen in the upper part of HV07-19. The siltstone unit continued for the remainder of the hole and contained the only significant mineralization seen in the hole. At a depth of 319.3 m, 7.9 m of mineralization (0.29ppm Au; 1.20% Cu) occurred within a calcite-quartz crackle breccia of siltstone. This style of mineralization is similar to that seen in the siltstone unit of HV07-19.

Unfortunately the drill encountered significant problems at a depth of 327.2 m and after several days had to be shut down. The core barrel became stuck in some blocky ground (possible fault) and was eventually lost down the hole.

10.1.9 HV07-27 (az. 310°, dip -45°, 310.5 m)

This hole was designed to test the continuity of mineralization between holes HV07-19 and HV07-25 as well as the strong mineralization seen near the end of HV07-26 (Cross Section 6). After 3.0 m of overburden, a grey-green siltstone unit was encountered to a depth of 267.4 m. A fault gauge/shear zone was intersected from 267.4 m to 268.2 m which marked the contact between the above siltstone unit and a lower heterolithic Wernecke Breccia. The breccia continued from 268.2 m to the end of the hole at 310.5 m. A 38.5 m mineralized interval (0.17 ppm Au; 0.64%Cu) occurred at 19.5 m depth. A second interval of 14.3 m (0.62 ppm Au; 2.15% Cu) occurred at a depth of 204.7 m.

10.1.10 Discussion

Drilling at the Central Hoover Zone in 2007 identified Cu-Au mineralization over a broad area of similar grade to that intersected by the FJV. Mineralization appears to be related to the western contact between sedimentary rocks of the Fairchild Lake Group and a Wernecke breccia body. Sedimentary rocks (dominantly phyllite) near the eastern contact with the breccia body are not mineralized, but do have moderate-strong magnetite alteration or possibly regional metamorphic magnetite porphyroblasts. This contact may be a post-mineralization fault. In general, the breccia is steeply dipping and trends north-northwest. The breccia is not strictly planar but is likely somewhat irregular. Locally on surface two orthogonal breccia orientations or present.

Mineralization at the Central Hoover zone appears to be related to carbonate-rich fluids which likely originated from the breccia body. Within the sedimentary rocks, chalcopyrite occurs as veinlets, stringers, and blebs associated with carbonate veining. Within the breccia, chalcopyrite dominantly occurs as blebs and disseminations within the matrix. These styles suggest that the timing of mineralization is synchronous with the formation of the breccia. Mineralization is not continuous within the breccia body which suggests other factors also control mineralization. The Central Hoover zone has abundant folding, faulting, and fracturing, suggesting structure may play an important role in mineralization.

Regional airborne magnetic data at the Central Hoover zone show strong magnetic highs to the northwest (centred near HV94-01) and southeast (east of HV97-17). These magnetic highs trend north-south and are joined by a moderate magnetic high trending northwest across the Central Hoover zone. This moderate magnetic high may represent a regional scale dilation zone providing space for the breccia body and/or mineralizing fluids.

At the north end of the Central Hoover zone near Radio Creek, mineralization appears to trend north-south rather than following the breccia contact along the hill slope towards the Irene Showing. Drill hole HV94-04 failed to intersect significant mineralization, despite drilling across the western contact of the breccia. Drill hole HV07-25, however, intersected 84 m of mineralization (0.12 g/t Au; 0.08% Cu) below 170.0 m. This may indicate a finger of the breccia body, or a second breccia body, following a northward trend near Radio Creek which is not exposed on surface. Alternatively, Radio Creek may represent a post-mineralization fault which displaces the mineralized zone.

At the south end of the Central Hoover zone, mineralization trends underneath thick fluvial cover of the valley bottom. Several attempts have been made to trace mineralization to the south without success. Holes HV07-23 and HV07-24 cored un-mineralized siltstone, however, both holes contained encouraging alteration assemblages and magnetite.

Future drilling at the Central Hoover zone should focus on extending the zone north and south as well as targeting further higher grade zones. Extending the zone to the south would require drilling through the thick over burden of the valley bottom. Similarly, step-down holes from HV94-03 and HV94-07 could be accomplished by drilling from the edge of the valley bottom, but would require drilling through significant

overburden. In order to extend the zone northward, drilling would need to be attempted to the north of Radio Creek, east of HV94-04.

10.2 Pagisteel Fault Zone, Mica Hail Property

PG07-01 was drilled to test for mineralization at depth across the poorly-exposed Pagisteel Fault. The hole was drilled with an azimuth of 120^{o} and a dip of -50^{o}. Owing to poor exposure, little data were available for targeting. The selected location targeted rusty limonitic and malachite-coated felsenmeer with vein quartz and chalcopyrite that returned encouraging results from the 2006 program and follow-up work during the 2007 program. The hole ended prematurely at a depth of 152.4 m instead of the targeted depth of 250 m, due to an increasing probability of losing a drill rod string in squeezing ground and due to cold temperatures and increasingly inclement autumn weather.

10.2.1 PG07-01 (az. 120^{o}, dip -50^{o}, 152.4 m)

This hole (Cross Section 7) intersected several zones of fault breccia and fault gouge characterized by strongly slickensided graphitic argillite–evidently structures associated with movement across the Pagisteel Fault. Recovery was locally poor, although some near continuous runs of fault gouge were cored intact. The upper 18.3 m of the hole was overburden overlying several intervals of heterolithic and monolithic Wernecke breccia hosting quartz ± calcite ± pyrite veins and veinlets with minor hematite to about 54 m. The remainder of the hole is mainly metasomatized sedimentary rock with intervals of the graphitic argillite and minor zones of heterolithic breccia and shale. Petrographic examination of metasomatite from 74 m depth indicates that the sedimentary rock is pervasively quartz ± illite / sericite ± chlorite ± hematite altered and cut by numerous veinlets comprising quartz-chlorite-dolomite and associated pyrite and chalcopyrite (Mauler, 2007).

The most significantly mineralized zone occurs from 117.3 to 123.4 m. This 6.1 m wide zone (likely near true width) contains 5% disseminated chalcopyrite with 5% pyrite and returned 2.57% Cu, 0.97 g/t Au and 980 ppm Co and elevated REEs. This was the only interval with abundant chalcopyrite mineralization which gradually decreased over the 3 m below this interval to approximately 0.2% chalcopyrite by 126 m depth.

Another well-mineralized zone of semi-massive hematite, pyrite and magnetite with trace chalcopyrite occurs from 71.5 to 80.8 m; however, this zone returned low geochemical values. The best result from this interval is 0.31 g/t Au and 193 ppm Cu over 1.40 m. Deeper in the hole, a 0.40 m wide sample centered on a 5 cm-wide zone of 10% chalcopyrite returned 2.1% Cu and 23 ppb Au from 149.10 m.

The 6.1 m-wide intercept in PG07-01 is encouraging given that this is the first ever drill hole in this part of the Pagisteel Fault corridor which is characterized by strong soil geochemical anomalies for 2.5 km strike length. The most conspicuous evidence of the Pagisteel Fault in PG07-01 – the graphic argillite fault gouge zones – postdate the alteration and copper mineralization in the intervening sedimentary and breccia wallrocks. Clearly a mineralizing hydrothermal system was active prior to the final movement along the Pagisteel structures, however, it remains to be demonstrated how extensive this earlier system is along strike. Further drilling of the Pagisteel corridor is recommended, possibly after conducting an electromagnetic ground geophysical survey. Induced polarization surveys would likely be of limited use given the abundance of graphite in the system.

10.3 TVA Property (Rio and HEM Zones)

The FJV drilled seven holes on the TVA a property in 1995 targeting soil geochemical anomalies (Klatt and Jones, 1995a). These holes encountered widespread copper mineralization within variably altered and mineralized dolomitic shale with disseminated chalcopyrite and pyrite and zones of specularite-carbonate-magnetite-chalcopyrite veining. The Hem Zone was targeted by two drill holes (UT07-11 and -12, total 666.3 m) in 2007 as follow-up tests to the broad intercept of UT95-06 and to target uranium, copper and gold mineralization. The Hem Zone drill program was not completed due to drilling difficulties related to bad

weather conditions: one deep hole (UT07-11) was completed; a second hole (UT07-12) was abandoned while still in mineralization; a third planned hole was not drilled.

These holes cored altered siltstone with numerous zones of Wernecke breccia and associated metasomatized sedimentary rock. Both holes encountered moderately copper-gold mineralized zones associated with pyrite and chalcopyrite and REE (Ce and La) enriched zones associated with iron oxide replacement zones. U values were consistently low. Both holes intersected strong pyrite and magnetite mineralization. The massive specular hematite unit which represented a "hanging-wall" to the Hem Zone was not intersected in either hole. Significant mineralization encountered in these holes is summarized in Table 33.

Table 33: Significant Hem Zone Drill Intersections

Drill hole	From (m)	To (m)	Interval (m)	Au (ppm)	Ag (ppm)	Co (ppm)	Cu (%)	Ce (ppm)	La (ppm)
UT95-06	2.00	186.06	184.06	0.07	N/A	N/A	0.15	N/A	N/A
UT95-07	79.75	86.62	6.87	0.03	N/A	46	0.26	N/A	N/A
UT07-11	332.5	354.61	22.11	0.13	4.26	98	0.38	280	260
UT07-12	178.4	189.97	11.53	0.04	0.63	105	0.31	116	75
UT07-12	149.84	158.21	8.37	0.18	0.50	205	0.36	359	318

Also on the TVA property, three holes (UT07-08, -09, -10) were drilled targeting the Rio Zone in August for 480.5 m. High-grade uranium mineralization is indicated at Rio by an uraniferous boulder field and a radioactive sericite-altered fault zone exposed in outcrop and by trenching (Map 9). Strongly albite-sericite-carbonate-altered sedimentary rocks interleaved with Wernecke breccia were encountered with scattered elevated Au-Cu-Co-Mo-REE. Highest results were 0.80 g/t Au and 0.43% Cu over 0.29 m. Uranium values were consistently low.

10.3.1 UT07-08 (az. 170°, dip -42°, 142.34 m)

UT07-08 (Cross Section 8) was the first hole drilled on the Rio Zone targeting the uranium mineralization exposed in Trench 2. However, as in the trenches, assay results were disappointing. The hole intersected a package of sedimentary rocks (chert/dolomite/siltstone) which were locally intruded by narrow intervals of Wernecke breccia. Between 52.8–77.1 m, a strongly metasomatized zone was intersected, rendering identification of the protolith of sediments between 52.8–60.0 m and 74.2–77.1 m impossible (the two sedimentary units were separated by a breccia unit). The latter of these metasomatized sedimentary units likely corresponds to the sericitic, weakly uraniferous, sub-vertically-dipping zone encountered in Trench 2. The former metasomatized unit was strongly magnetite-carbonate-pyrite-altered and returned weak gold and copper assay values (Table 34). The best interval returned 1.22 m of 0.43% Cu and 0.47 g/t Au from 57.0 m. The hole was shut down in relatively unaltered siltstone.

Table 34: UT07-08 Significant Assay Results

Hole ID	Sample#	From m	To m	Interval	Au ppm	Ag ppm	Bi ppm	Co ppm	Cu ppm	Mo ppm	Ni ppm	Pb ppm	Sb ppm	Th ppm	U ppm	Zn ppm

UT07-08	846757	57.93	58.22	0.29	0.835	2.02	1.84	469	4320	349	71	4.8	1.19	4.3	14.3	9

10.3.2 UT07-09 (az. 335°,dip -45°, 166.73 m)

This hole (Cross Section 9) was drilled downslope from Trench 1, in the opposite direction to UT07-08 to test for a downward extension of the main sericite-rich uraniferous zone, as well as a second, subparallel, potassic/hematitic zone exposed in outcrop just east of the trench. UT07-09 failed to intersect any significant mineralization. Wernecke breccia was intersected to 30.3 m; followed by dolomite and metasomatized (silica, potassium-feldspar(?)) siltstone to 49.5 m, whereupon more Wernecke breccia was intersected. Between 70.3–85.0 m strong magnetite-carbonate-pyrite-silica-albite alteration was encountered (of both Wernecke breccia and a sedimentary unit). Dolomite/cherty dolomite were then intersected to 104.6 m, followed by a black shale unit (probably Quartet Group). A bull-quartz vein was intersected between 111.4-118.0 m. Below this to the end of the hole was a mix of siltstone, shale and Wernecke breccia; a fault zone was intersected from 155.7–164.5 m.

10.3.3 UT07-10 (az. 155, dip -42°, 171.4 m)

This was the third hole testing the Rio Zone (Cross Section 8) and tested directly across the uraniferous boulder-field to target the zone at about 100 m depth. The hole did not intersect the zone; however, a narrow zone of uraniferous mineralization was encountered at 132.5 m, hosted within a 2 cm-wide quartz ± pyrite ± brannerite vein oriented 20° to the core axis. A 0.35 cm wide sample centered on this vein returned 167.5 ppm U. Other mineralization within the hole is mainly disseminated and vein-hosted pyrite varying from trace to 10%. Locally large (2-3 cm) blebs of pyrite are hosted within veins. Locally magnetite is found up to 10% whereas chalcopyrite and hematite are found in trace amounts throughout. A 1.75 m wide sample of heterolithic Wernecke breccia with 10% magnetite from 64.25 m returned 0.26 g/t Au and 149 ppm Mo.

The lithologies encountered in this hole were: metasomatized sediments, shale, and breccia, both monolithic and heterolithic, which had undergone varying degrees of silicification, albitization, and chloritization, as well as potassic and sericitic alteration. The single monolithic breccia phase represented brecciation of shale caused by fluids resulting in angular shale clasts hosted in a fine-grained matrix. Sulphide mineralization within the hole was mainly disseminated and vein-hosted pyrite varying from trace to 10%; locally large (2-3 cm) blebs of pyrite were hosted within veins. Towards the bottom of the hole, abundant chloritic andalusite porphyroblasts were intersected.

10.3.4 UT07-11 (az. 160°, dip -45°, 459.58 m)

UT07-11 was drilled to test both the central portions of the Hem and Lower Hem Zones at depth (Cross Section 10). To 131.7 m, alternating units of siltstone and Wernecke breccia were intersected. Below this a 0.9 m unit of metasomatized sedimentary rock (intense silica / weak potassium feldspar) was intersected which contained trace brannerite. This unit corresponds to the down-dip projection of the Hem proper, although it is somewhat different in mineralization style. The interval between 132.6 and 221.9 m was dominated by strongly chloritized Wernecke breccia, with the exception of a narrow interval of siltstone/dolomite. This breccia unit correlates with a breccia complex mapped on surface. Below this to 245.9 m siltstone was encountered, similarly chloritized. From 245.9 to 333.2 m locally albitized/silicified sediments (probably all siltstone) with minor pyrite and trace chalcopyrite were intersected. Between 333.2 and 354.6 m monolithic breccia was intersected; this was crackle-brecciated with a chlorite-magnetite matrix, hematized, and contained 0.5-4% chalcopyrite and was weakly anomalous on the scintillometer. A 28.68 m interval starting at 332.5 m returned 0.13 g/t Au and 0.38% Cu (Table 35). Chalcopyrite occurred in a number of hosts: in the breccia matrix, with magnetite, and in particular in quartz+/-carbonate veining which was generally at low angles to the core axis. Siltstone was then intersected to 401.2 m; this was generally altered by magnetite-chlorite-dolomite-pyrite-specular hematite. A 2 m-wide shear zone marked the contact between these altered siltstones and a chloritized, sericitized Wernecke Breccia containing 0.5% disseminated pyrite. Between 411.4 and 424.9 m an intensely altered zone (silica-carbonate-albite-sericite) with 10% pyrite and 12% magnetite and abundant white quartz-vein material was intersected; protolith is most likely siltstone. More Wernecke breccia was then encountered, to 440.9 m, which was sericitized and chloritized and contained minor pyrite. The hole ended in patchily silicified siltstone, locally crackle-brecciated, with approximately 4% pyrite. The hole was shut down due to drilling limitations. No significant uranium

mineralization was intersected in UT07-11. Likewise, the massive specular hematite beds mapped on surface and associated with both the Upper and Lower Hem were not intersected.

Table 35: UT07-11 Intersections

Drill hole	From (m)	To (m)	Interval (m)	Au (ppm)	Cu (%)	Ag (ppm)	Ce (ppm)	Co (ppm)	La (ppm)

10.3.5 UT07-12 (az. 125°, dip -45°, 206.7 m)

UT07-12 (Cross Section 11) was drilled to test the south-western end of the Hem Zone (both Hem proper and the Lower Hem). The 125° azimuth also allowed it to obliquely test chalcopyrite-bearing quartz veining mapped on surface (running at az. 160°). The hole collared in Wernecke breccia with red (potassic) clasts. A major siltstone unit was intersected at 79.0 m and continued to 116.4 m; the lower portion of this unit was altered (silica / probable potassium feldspar), and the section between 87.5 and 88.4 m was moderately anomalous on the scintillometer (up to 400 cps with core in box). This correlates reasonably well with the projection of the Hem proper zone from surface. Strong magnetite mineralization also begins at this approximate depth (83.5 m), and continues to the bottom of the hole. In addition, a zone of approximately 5% quartz-carbonate-chalcopyrite veining was logged starting at 87.5 m and continuing to the base of the unit. Most of these veins were at low angles to the core axis. Between 116.4 and 117.6 m semi-massive magnetite was intersected, followed by a hematized siltstone which was weakly anomalous on the scintillometer locally. Between 128.7 and 130.9 m another unit of massive magnetite was drilled, which was followed by more hematized siltstone to 149.8 m. The bottom 15 m of this siltstone contained 15% pyrite. This was followed by a breccia unit containing magnetite, pyrite and 0.5% chalcopyrite; the upper 8.4 m of this unit returned low Cu, Au and very low U values (Table 36). From 165.9 to 191.4 m, altered (earthy hematite/ sericite/ dolomite/ weak silica/ possible weak potassium feldspar) siltstone was intersected; the top 3m of this unit was anomalous on the scintillometer, although not by laboratory analysis. Another section of weak Cu mineralization occurred within this unit (11.6m of 0.31% Cu); this mineralization may be related to low angle quartz-carbonate-magnetite-specular hematite veining. Below this to 194.9m a section of semi-massive pyrite was drilled, which was followed by semi-massive magnetite to 200.1m. Metasomatized (silica/ albite/ carbonate/ potassium feldspar) sediments with strong pyrite and minor chalcopyrite were then drilled to the end of the hole. The hole was abandoned before its planned depth of 250m due to the waterline and drill-string freezing.

Table 36: UT07-12 Intersections

Drill hole	From (m)	To (m)	Interval (m)	Au (ppm)	Ag (ppm)	Co (ppm)	Cu (%)	Ce (ppm)	La (ppm)

UT07-12	178.4	189.97	11.53	0.04	0.63	105	0.31	116	75
UT07-12	199.35	200.60	125	0.03	5.15	13	0.48	459	493

10.4 Reid Property (DR Zone)

During the 2007 field program, two holes were completed targeting the previously un-drilled DR Zone. Both holes targeted 070º striking fracture controlled carbonate-quartz-chalcopyrite veins which returned 2.2% Cu over 9.0 m of continuous chip sampling (Jones, 1995a). Holes DR07-01 and -02 are shown on Cross Section 13.

10.4.1 DR07-01 (az. 340°, dip -45°, 177.00 m)

This hole (Cross Section 12) was drilled beneath the anomalous surface outcrops towards 340° at an inclination of -45°. The hole cut fine-grained, greenish to light and dark grey siltstone throughout the hole to a final depth of 177.0 m. This consistent protolith showed variations, however, in alteration style and intensity.

From 12 to 125 m and from 138 to 177 m, the hole comprises moderately chlorite-sericite and weakly dolomite altered siltstone with trace chalcopyrite-pyrite-hematite. Locally the unit shows alternating biotite-rich and biotite-poor layers that are likely primary laminations and show partial retrogression to chlorite. The rest of the rock comprises extremely fine-grained quartz and sericite (Mauler, 2007). Trace, very fine-grained magnetite and sub-millimeter green chloritoid (?) porphyroblasts are present through the unit. Fine laminations (S_0) are oblique to the moderately developed foliation (S_1). Thin (1-5 mm) calcite veinlets cut both fabrics and are common throughout the hole. Trace wisps of sphalerite are also found throughout but are closely associated with the chlorite.

A core unit from 125.05 to 137.75 is strongly to intensely silicified and weakly chlorite and sericite altered. The margins of this unit and minor portions of the inner unit are brecciated. Breccia clasts have diffuse irregular margins and are quartz matrix supported. Minor chlorite veins and segregations are associated with dolomite-hematite-pyrite and trace chalcopyrite.

Trace chalcopyrite is associated with chlorite segregations and quartz-carbonate veins throughout the hole but never in concentrations more than about 1% and analytical results are generally low. The highest grade sample from DR07-01 returned 8940 ppm Cu and 0.11 g/t Au over 0.70 m from 125.05 m (the top contact of the silicified unit).

10.4.2 DR07-02 (az. 340°, dip -45°, 172.90 m)

This hole (Cross Section 12) was drilled to test for an extension of the extension of the DR Zone 60 m southwest of DR07-01. Despite being collared very close to DR07-01, this hole cored a different lithology, encountering fine-grained sandstone with minor siltstone throughout. Primary sedimentary structures are rare in this hole and alteration is dominated by strong to moderate silica-chlorite-albite-rutile-calcite (Mauler, 2007). Trace chalcopyrite occurs within this hole but geochemical values were insignificant.

10.4.3 Discussion

Both DR Zone-targeted holes intersected variably altered sedimentary rock with trace chalcopyrite and sphalerite. Core axis angles from bedding and foliation planes are consistently less than about 25°, consistent with the north-dipping bedding orientations exhibited by surface outcrops throughout the DR Zone. Vein core axis angles were higher and more variable suggesting that the interpreted southeast dip to the mineralized zone, as determined from chalcopyrite-bearing fracture and vein measurements (Jones, 1995a), might be the appropriate interpretation for this zone. Given that neither hole encountered significant copper mineralization, however, a re-evaluation of the preferred drilling direction should be undertaken prior to further testing this zone. Possibly the zone dips north-easterly and these holes cut under or over the zone.

DR07-01 and -02 encountered distinctly different lithologies even though they were collared only 60 m apart. Based on surface structural data, both holes were drilled in the same direction that local bedding is dipping. DR07-02 likely cored a sandstone-dominated part of the Fairchild Lake Group stratigraphic pile that lies below the siltstone exposed at the DR cliffs and encountered in DR07-01. The consistent west-striking, moderately north-dipping orientation of bedding in the DR Zone is consistent with a sandstone/siltstone contact trending obliquely to the drill traces of DR07-01 and -02. Alternatively, a fault structure could lie between holes DR07-01 and -02, but no evidence (e.g. surface lineament) exists to support this. Furthermore, the alteration and mineralization encountered in the two holes are quite similar suggesting that each area tested was influenced by the same hydrothermal system.

The geochemical results of the DR Zone are discouraging and it is easy to down-grade the entire target. Further, more detailed chip sampling and structural mapping could be useful to further define the mineralized zone and to confirm the 2.2% Cu over 9.0 m (this result is based on 2 samples only). More detailed structural mapping should focus on the controls of the mineralization. Complications, such as the

presence of two main sets of chalcopyrite-bearing fractures, suggest that the mineralization may not merely be controlled by an 070°-trending structure.

10.5 Fireweed Property (Fireweed Boulder Field)

Five holes totalling 1028 m of drilling was completed on the Fireweed property targeting the source of the Fireweed boulder field. It was postulated that the uraniferous float was sourced from a linear, approximately south-southwest trending fault or shear zone. Significant U mineralization was not intersected by this drilling. Pink plagioclase-hematite veining – similar to that which hosts uranium mineralization – was intersected in all drill holes.

10.5.1 FW07-01 (az. 100°,dip -45°, 163.68 m)

FW07-01 and FW07-02 were drilled from a single drill platform located 5 m south of trench 1 and 10 m SW of a small isolated magnetic high. This hole (Cross Section 13) intersected variably chlorite and sericite altered phyllite with minor shale intervals. Irregular quartz-plagioclase-hematite ± magnetite veins and breccias are common throughout the hole and generally comprise 10-35% of the rock. Scintillometer counts of the rock are consistently at background levels.

10.5.2 FW07-02 (az. 100°,dip -70°, 197.51 m)

This hole (Cross Section 13) is dominantly composed of thinly laminated siltstone with fine-grained magnetite layers and fine-grained disseminated magnetite/hematite over printing bedding and foliation. Alteration is predominantly weakly chloritic and sericitic. Minor pink quartz-hematite-plagioclase veins with granular to euhedral hematite magnetite comprise 1% of the unit. There is a slight increase in scintillometer counts above background at the bottom of the hole. Uranium enrichment is not visible, but increased counts up to 190 cps were recorded on the surfaces of faults and fractures.

10.5.3 FW07-03 (az. 100°,dip -45°, 155.45 m)

FW07-03 (Cross Section 13) and FW07-04 were both drilled from the same drill platform situated between trench 2 and 3 on the northern edge of a strong magnetic high. Veins of quartz-hematite-plagioclase with minor magnetite and minor Fe-carbonate are common in the lower portion of the drill hole. These veins are hosted in weakly to moderately chloritized siltstone (FLG). The siltstones are generally thinly laminated with moderately well-developed cleavage and fine-grained specular hematite and magnetite overprinting the foliation. Trace amounts of sphalerite and chalcopyrite are present in late stage quartz veinlets. Scintillometer counts are consistently at background. Minor faulting is noted at 134.54 m and may correlate with the inferred surface lineaments.

10.5.4 FW07-04 (az. 100°, dip -70°, 206.65 m)

This drill hole (Cross Section 13) intersected thinly laminated siltstone with layers of fine-grained magnetite and fine-grained disseminated magnetite/hematite overprinting bedding and foliation. The unit is weakly chloritised with minor sericite alteration. Quartz-hematite-dusted-plagioclase veins with granular to euhedral hematite and magnetite comprise about 15% of the interval and are found throughout. Consistent bedding is easily discernible throughout the unit, but has been disrupted by the veins which are sub-parallel to foliation. This drill hole returned no significant values in the geochemistry and scintillometer counts were not above background.

10.5.5 FW07-05 (az. 100°,dip -55°, 307.55 m)

This drill hole (Cross Section 13) is situated on the western margin of a strong magnetic high 40 m south of trench 3. This drill collar was moved slightly south and to the west of the original planned site in order to intersect where projected NE and SW trending lineaments intersect. The hole cored moderately chloritised phyllite throughout. Millimetre-scale lamina of hematite and magnetite are typical throughout the unit, with secondary re-crystallized magnetite overprinting foliation and bedding. Similar veins to those

encountered in previous holes are present, but are narrower and more evenly spaced throughout. The unit has slightly elevated scintillometer counts of 180 cps along fracture planes and in faulted sections. The elevated scintillometer readings are confined to the bottom of the hole, however, no visible uranium mineralization was identified.

10.5.6 Discussion

At this time no further work is warranted on the Fireweed boulder field and surrounds. Available data indicate that the area drilled was the most prospective for hosting a structurally controlled uranium-enriched vein system, yet no brannerite was observed in the five holes drilled.

FW07-05 was relocated to test the intersection of a NE and SW trending lineaments interpreted as faults on the property. This hole was positioned to test the possibility that the mineralization might have been focused at the intersection of these two structures. Based on the drill results, this model is invalid since the pink quartz-hematite-plagioclase veins were smaller and no assayed values retuned high uranium.

None of the five diamond drill holes returned anomalous values in any metals of interest. Given the course-grained nature of the brannerite in the Fireweed boulder field, and that similar alteration/veining were encountered in all five drill holes to some extent, perhaps no brannerite was intersected due to a nugget effect. Even if this is the case, it is unlikely that significant brannerite concentrations are present at Fireweed.

10.6 Slats Property (MDV Zone)

Fronteer / Rimfire drilled six holes for 1217 m at the MDV Zone testing scattered surface outcrops exhibiting elevated radioactivity. The drill holes intersected heterolithic Wernecke breccia and metasomatized sandstone, siltstone and minor pebble conglomerate beds with widespread hematite and localized potassic (K-feldspar) alteration (Mauler, 2007). Radioactivity was generally low but in one hole reached 735 cps from core. Minor chalcopyrite was intersected. The highest value returned was 0.40% Cu and 0.24 g/t Au over 0.7 m in STM07-04 while a shallow interval starting at 27.50 m in STM07-06 returned 0.18% Cu over 24.00 m (Table 37).

Table 37: MDV Drill Intersections

Drill hole	From (m)	To (m)	Interval (m)	Au (ppm)	Cu (%)	U (ppm)	Ag (ppm)	Ce (ppm)	Co (popm)	La (ppm)
STM07-01	132.90	139.50	6.60	0.03	0.24	6	0.21	125	84	67
STM07-02	84.00	85.10	1.10	0.01	24 ppm	151	0.32	501	23	598
STM07-02	105.00	108.00	3.00	0.01	0.21	3	0.13	49	119	26

STM07-06	111.00	119.00	8.00	0.02	0.15	8	0.16	135	56	87

10.6.1 STM07-01 (az. 070°, dip -90°, 202.50 m)

This hole (Cross Section 14) was designed to test the down-dip continuity of the northern region of surface mineralization at the MDV Zone. The hole intersected siltstones from 3.0-36.1 m above a unit of mixed breccia and siltstones between 36.1-98.0 m. Another unit of siltstones was encountered from 98.0-143.6 m that is strongly chlorite altered and sheared between 121.5-143.6 m. A unit of metasomatized sedimentary rock – similar in appearance to mineralized outcrops on surface – was intersected between 143.6-151.8 m but did not have elevated scintillometer counts. A 6.60 m-wide interval from 132.9 m returned

0.24% Cu but low Au and U values. Mixed siltstones and breccias were encountered for the remainder of the hole. The hole ended in siltstones at 202.5 m

10.6.2 STM07-02 (az 070°, dip -70°, 147.00 m)

Drilled from the same set-up as STM07-01, this hole tested ~30-50 m down-dip of the main MDV surface mineralization (Cross Section 14). The hole cased into siltstones at 4.5 m that continued until 21.0 m. Mixed breccias and siltstones were encountered from 21.0-55.4 m with a semi-massive to massive hematite unit between 44.0-45.6 m. From 55.4-87.9 m, a section of metasomatized sedimentary rocks with elevated scintillometer counts up to 555 cps was intersected. A 1.10 m wide zone at 84.0 m returned 151 ppm U and strongly elevated REEs but low values for other metals. This unit looks very similar to mineralized outcrops seen at surface and is interpreted to be the down-dip extension of surface mineralization. Further interbedded siltstones and breccias occurred from 87.9 m to the end of the hole at 147 m. More semi-massive to massive hematite units were found at 90.2-91 m and 120.7-122.0 m.

10.6.3 STM07-03 (az. 070°, dip -70°, 176.00 m)

This hole (Cross Section 15) was drilled ~50 m south-southeast from holes STM07-01 and STM07-02 and was designed to test the down-dip continuity of the southern portion of surface mineralization. After casing through 4.5 m of overburden, a breccia unit with interbedded siltstones was intersected to 49.8 m followed by a siltstone unit to 106.6 m. A semi-massive to massive hematite unit was observed at 106.0-109.85 m. From 109.85-132 m, a section of metasomatized sedimentary rocks with elevated scintillometer counts up too 550 cps were intersected. This unit has a very similar alteration texture to mineralization found on surface and in hole STM07-02. A semi-massive to massive hematite section was found within the metasomatized sediments from 130.2-131.4 m. The remainder of the hole intersected mixed breccias and siltstones ending in breccia at 176 m.

10.6.4 STM07-04 (az. 070°, dip -50°, 165.00 m)

Drilled from the same set-up as STM07-03, this hole was planned to further test the down-dip continuity of surface mineralization seen at MDV (Cross Section 15). After casing to 4.5 m, mixed breccias and siltstones were encountered from 4.5-112.95 m. Between 79.5-81.85 m a semi-massive to massive hematite unit (bed?) was observed. From 112.95-120.5 m the target zone of metasomatized sediments with elevated scintillometer counts up to 1000 cps was intersected. Further mixed breccias and siltstones were seen in the remainder of the hole which ended within a breccia unit at 165 m.

Figure 10: Metasomatized sedimentary rock in drill core from STM07-04. Red crayon writing (113.8 and 114.4 respectively) shows the depth in meters while yellow (735) is scintillometer cps. Dark purple is fine-grained specular hematite.

10.6.5 STM07-05 (az. 250°, dip -45°, 241.50 m)

Drilled down slope from all other holes at MDV and into the hill (Az. 250°), this hole was planned to test the continuity of the mineralized zone at depth beneath the surface mineralization (Cross Section 15). After 2.13 m of casing, a unit of metasomatized sediments similar to the targeted zone was intersected but did not have elevated scintillometer counts. The remainder of the hole encountered interbedded siltstones and breccias to a depth of 241.5 m. A semi-massive to massive hematite unit was intersected between 60.7-65.7 m. The hole finished in a unit of sheared siltstones from 180.5-241.5 m with a strong foliation fabric seen throughout. This hole failed to intersect any significant mineralization.

Several way-up indicators (flame structures, graded beds) in this hole indicate younger up hole. Given that this hole is being drilled down-dip, and that bedding on surface is generally steeper than -45°, this indicates that this hole cored down an overturned fold limb at moderate angles to bedding. This is consistent with fold structures mapped on the surface.

10.6.6 STM07-06 (az. 070°, dip -70°, 284.70 m)

This hole was drilled to test the continuation of the zone ~50 m south along strike from holes STM07-04 and STM07-05 (Cross Section 16). After 5.1 m of casing a semi-massive to massive hematite unit was intersected to 6.5 m. The remainder of the hole encountered mixed siltstones and breccias to a depth of 284.7 m. A narrow section of sheared siltstones with a strong foliation was intersected from 56.5-59.6 m. Narrow regions (<30 cm) of siltstones with elevated scintillometer readings were encountered at depths of 237.4 m and 270.1 m with up to 300 cps and 235 cps, respectively.

11.0 GEOPHYSICS

11.1 Scintillometer Surveys

Scintillometer surveys were completed on grids established over the Fireweed, Rio, Hem and Gnuckle zones. Readings were taken with a handheld GR-110 Exploranium scintillometer at ground level along 20-50 m spaced lines at 10-15 m intervals. In areas of mixed talus and outcrop, such as Hem, a note was made at each station identifying the surface material as either talus or outcrop. This quick but semi-quantitative method aided in providing a non-biased radioactivity image for these boulder fields. Readings were plotted without taking into account the mass effect between soil and rock.

11.1.1 Fireweed

At Fireweed, the scintillometer data showed fairly good correlation with the distribution of uraniferous float boulders in and around the area of 2007 drilling (Figure 11). An arcuate area defined by readings greater than about 250 cps extends across the Fireweed plateau. Locally values as high as 1270 cps core the anomalous zones. The anomaly is open to the south but is underlain by a broad south facing talus slope with abundant phyllite and siltstone outcrop that only shows rare radioactive areas so this is likely a mass effect or a result of downhill dispersion of minor radioactive material. Scattered, elevated values persist downslope from the upper part of the boulder field for about 500 m.

11.1.2 TVA / Ursus (Rio, Hem, Gnuckle grids)

A scintillometer survey was conducted over the Hem zone at 50 m line-spacing and generally 15 m stations (Figure 12). Some station adjustments had to be made due to the steepness of the terrain. The Hem Zone proper trends intermittently to the northeast and the strongest readings occur in the northeast part of the grid. Lower Hem also returned a strong localized response in the southwest of the survey area.

At the Rio zone, a scintillometer survey was conducted over the area of a radioactive boulder field covering an area roughly 450 by 300 m (Figure 13). Point readings were taken with the instrument every 10 m along lines 20 m apart. The survey was useful in confirming the anomaly expressed by the boulders and extending the uranium anomaly further uphill. In general the Rio zone scint grid returned lower values than the other grids. An elevated area to the north is truncated by a narrow drainage and probably is a result of elevated background talus material sourced from the north.

The Gnuckle scintillometer grid (Figure 14) outlined a 75 m wide, east-southeast trending zone of elevated readings up to 3,500 cps. Coarse-grained brannerite was discovered in the core of this area.

11.2 Magnetometer Surveys

The purpose of the surveys at both TVA and Fireweed was to detect magnetic highs and provide information that could be used to aid in locating mineralization. The information from both surveys was processed and contoured using minimum curvature.

Two GEM Systems GSM 19 Overhauser Magnetometers were used for the survey (Table 38). The instruments were rented from Terraplus Inc., Richmond Hill, Ontario. The base station was set up 100 m south of the Copper Point camp at a location away from electromagnetic interference generated by the camp. The time, date and readings were stored at 5 second intervals on both the base and field Magnetometer.

Survey data were downloaded each day and corrected for diurnal drift. Five to seven stations on the grid were re-read each day in order to level the data to readings taken on the first day of the survey.

Results of the survey were compiled in a Geosoft database, contoured and plotted. The contouring method was minimum curvature and the grid cell size was 25% of the sample spacing. Data was processed and plotted by Bob Stirling of Whitehorse, Yukon.

Table 38: Magnetometer Specifications

Model:	
	GSM-19 v6.0 Overhauser Magnetometer (GEM Systems)
Performance	
	Sensitivity: < 0.015 nT / √Hz
	Resolution: 0.01 nT
	Absolute Accuracy: +/- 0.1 nT
	Dynamic Range: 10,000 to 120,000 nT
	Gradient Tolerance: > 10,000 nT/m
	Sampling Rate: 60, 3, 2, 1, 0.5, 0.2 sec
	Operating Temperature: -40C to +55C
	Operating Ranges: Temperature: - 40oC to +60oC
	Power Source: Internal 12V, 2.6Ah sealed lead-acid battery standard
Operating Modes	
	Manual: Time, date and reading stored automatically at minimum 3 second interval.
	Base Station: Time, date and reading stored at 3 to 60 second intervals.
	Input /Output: RS-232 or analog (optional) output using 6-pin weatherproof connector
	Storage - 4Mbytes (# of Readings)
	Mobile: 209,715
	Base Station: 699,050
	Gradiometer: 174,762
	Walking Magnetometer: 299,593
Dimensions	
	Console: 223 x 69 x 240 mm
	Sensor: 175 x 75mm diameter cylinder
Weights	
	Console: 2.1 kg
	Sensor and Staff Assembly: 1.0 kg
Standard Components	
	GSM-19 console, GEMLinkW software, batteries, harness, charger, sensor with cable, RS-232
	cable, staff, instruction manual and shipping case.

11.2.1 Fireweed

A magnetometer survey was completed over the Fireweed boulder field, at 20 m line spacing and 10 m stations. The survey showed a strong magnetic high centred up slope 100 m from the eastern limit of the boulder field (Figure 15) in an area underlain by phyllite (Map 8). Likely this elevated magnetism is caused by disseminated magnetite that forms common porphyroblasts in the phyllite units of the area. The boundaries of the grid encompass the magnetic high. There are several isolated spot highs and three 100 m linear highs in the SW part of the grid. The survey points were recorded with a hand-held GPS and coordinates recorded in NAD 83 UTM zone 8N. A total of 10.2 km of grid line were surveyed at the Fireweed.

11.2.2 TVA/Nuck

The grid at TVA was located by chain and compass and points marked on the ground with a metal tagged picket at 25 meter stations and with flagging and tyvek tags each 12.5 m. The line spacing was 100 m and the sample spacing was 12.5 m. The survey points were located with a hand-held GPS.

The TVA/Nuck contoured magnetometer survey results delineate the magnetite mineralization (locally semi-massive to massive) associated with the Hem zone (Figure 16). This mineralization generally has weak Cu-Au-U mineralization associated with it. The magnetometer survey also highlighted additional magnetic anomalies located northeast of the Hem zone that warrant further investigation.

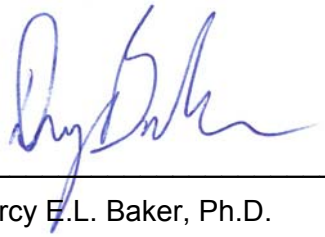
12.0 DISCUSSION AND CONCLUSIONS

The 2007 Werneckes project followed up on significant results from the 1990s FJV exploration and also on the 2006 exploration that assessed the uranium potential of the area. As such, numerous different properties were explored by soil, silt and rock geochemistry, mapping, prospecting, trenching and diamond drilling. Significant advances include:

- Hoover Zone: 40-90 m-wide drill intercepts of Cu and Au mineralization were returned from phase one drilling including 0.56% Cu and 0.11 g/t Au over 89 m in HV07-22 and 0.86% Cu and 0.22 g/t Au over 16 m in HV07-21. The final June drill hole (HV07-26) was lost in a 7.9 m-wide mineralized section grading 0.29 g/t Au and 1.20% Cu at the bottom of the hole. Hole HV07-27 was drilled in October to follow up this hole and intercepted 14.3 m of 0.62 g/t Au and 2.15% Cu from 204.7 m. The 1990s and 2007 drilling indicates that the Hoover zone is a steeply dipping zone at least 500 m long that is very generally planar, however, mineralized intervals vary from 25 to about 125 m thickness. Mineralization is outbound but proximal to a heterolithic breccia / sedimentary rock contact. Locally higher grade copper and gold mineralization was encountered, however, over narrow intervals. Future drilling at Hoover should track the zone to the south under the Bonnet Plume River valley which has proved difficult to drill.
- Slats Property: numerous zones of anomalous radioactivity with associated gold mineralization were discovered within a N-S corridor. The MDV Zone returned a 2.0 m-wide chip sample across one of many radioactive outcrops of 2.2 g/t Au. The highly radioactive Atomtan showing returned 18.2 g/t Au and 1.01% U from select samples and massive hematite-replaced sedimentary rocks in the area returned elevated gold. Significantly, the MDV to Atomtan area has had little work because it was found late in 2007 so no geochemical results were followed up. This area should be systematically mapped and sampled.
- Thunder Mountain: following on the 2006 discovery of bonanza-grade gold samples at the Ewe-2 showing, mapping and prospecting further delineated the mineralization to be associated with breccia-sedimentary rock contacts. Other showings in the area (e.g. Equalizer) show elevated Co-Mo-Au-U but low potential for large tonnage deposits. The Ewe-1 showing, however, returned of 0.23 g/t Au, 481 ppm Co and 0.55% Cu over 11.75 m (essentially true width) of continuous chip sampling. The poorly-exposed areas of the Thunder Mountain property could be economically surveyed for larger concentrations of sulphide phases by induced polarization geophysics since the topography is subtle.
- Pagisteel Fault Corridor: a single drill hole tested the poorly exposed Pagisteel Fault and intersected 10% combined pyrite-chalcopyrite over 6.1 m (likely near true width) that returned 2.57% Cu, 0.97 g/t Au and 980 ppm Co and elevated REEs. Little is known of the corridor owing to nil exposure. Strong soil geochemical anomalies occur over 2.5 km along the structure but these could be caused by talus dispersion from narrow mineralized zones in the cliffs above. Nonetheless, the significant drill result on the first subsurface test of this regional fault structure warrants
- TVA Property: narrow zones of Cu±Au mineralization were intersected when drilling on the Hem Zone. The drill program was not fully completed. A large outcrop at the NE end of the Hem Zone characterized by extremely high scintillometer counts returned disappointing U assay values, suggesting strong mass effect.
- Radioactive boulder fields: similar to the Fireweed boulder field discovered in 2006, follow-up prospecting of radiometric highs and U-in soils resulted in discovery of the Rio (TVA Property) and the Dodge (Ursus Property) boulder fields in 2007. At the Rio, 28 boulders averaged 0.28% U. At the Dodge, 18 float and outcrop samples recording 1000 cps or greater averaged 0.11% U. Intercepting material of similar grade in drill holes, however, has been shown to be difficult. Drilling at the Fireweed Boulder Train and at the Rio Boulder train failed to intercept significant radioactive material (one of three holes finalized at Rio; all Fireweed results finalized). Radioactive boulder fields, as such, are not prospective targets.

- Hole UT07-08 (drilled under the Rio Zone) returned 0.16 g/t Au over 5.72 m including 0.47 g/t Au over 1.22 m in an area of metasomatized sedimentary rocks with albite-sericite-carbonate-silica alteration and 2% pyrite
- Reid Property (DR Zone): two holes were drilled under the outcrops that returned a 2.2% Cu over 9.0 m in chip samples. Minor chalcopyrite was intersected in the drill holes but no drill results have been returned.

Respectfully submitted,



Darcy E.L. Baker, Ph.D.

Appendix C: Statement of Expenditures

STATEMENT OF EXPENDITURES
WERNECKE PROJECT
April 24 - October 18, 2007

PROFESSIONAL FEES AND WAGES:

Henry Awmack, P.Eng.		
4.38 days @ $650/day	$	2,847.00
Darcy Baker, Project Geologist		
162.38 days @ $650/day		105,547.00
Sandra Bayliss, Senior Sampler		
62.50 days @ $325/day		20,312.50
Tom Bell, Prospector		
44.00 days @ $475/day		20,900.00
Robin Black, Geologist		
7.00 days @ $525/day		3,675.00
Alice Bolton, Bullcook		
28.00 days @ $275/day		7,700.00
Thomas Branson, Geologist		
133.50 days @ $525/day		70,087.50
Gary Brown, Sampler		
32.00 days @ $275/day		8,800.00
Sharon Brown, Cook/First Aid		
90.50 days @ $500/day		45,250.00
Roy Buyck, Sampler		
98.50 days @ $275/day		27,087.50
Roy Buyck, Senior Sampler		
41.00 days @ $325/day		13,325.00
Kelly Anne Caulfield, Sampler		
33.00 days @ $275/day		9,075.00
Johnny Clayton, Sampler		
13.00 days @ $275/day		3,575.00
Andrea Clement, Cook		
12.50 days @ $450/day		5,625.00
Hedy Conwright, Bullcook		
108.50 days @ $275/day		29,837.50
Kevin Daffe, Sampler		
18.00 days @ $275/day		4,950.00
Jen de Medeiros, Sampler		
26.00 days @ $275/day		7,150.00
Kelsey Dodge, Assistant Geologist		
90.00 days @ $400/day		36,000.00
William Germaine, Sampler		
2.50 days @ $275/day		687.50
Robyn Henderson, Cook		
54.00 days @ $450/day		24,300.00
Heather Jaggard, Sampler		
153.36 days @ $275/day		42,175.00

STATEMENT OF EXPENDITURES
WERNECKE PROJECT
April 24 - October 18, 2007

Murray Jones, P.Geo.		
	0.63 days @ $650/day	409.50
Veronique Jones, Sampler		
	89.75 days @ $275/day	24,681.25
Anni Lawrence, Cook		
	20.00 days @ $450/day	9,000.00
Jim Lehtinen, P.Geo.		
	54.50 days @ $650/day	35,425.00
Jeremy Major, Geologist		
	37.00 days @ $525/day	19,425.00
Joe McCreery, Prospector		
	64.00 days @ $475/day	30,400.00
Greg McKenzie, Senior Sampler		
	70.25 days @ $325/day	22,831.25
Eva McLean, Senior Sampler		
	33.00 days @ $325/day	10,725.00
Nick Mitchell, Geologist		
	160.50 days @ $525/day	84,262.50
Nadine Palliser, Bullcook		
	9.00 days @ $275/day	2,475.00
Sam Penner, Senior Sampler		
	36.00 days @ $325/day	11,500.00
Neil Perk, Geologist		
	164.26 days @ $525/day	86,236.50
Edward Patterson, Sampler		
	17.00 days @ $275/day	4,675.00
Blaine Peter, Sampler		
	32.00 days @ $275/day	8,800.00
Morgan Quinn, Sampler		
	82.50 days @ $275/day	22,687.50
Neil Rushton, First Aid		
	121.00 days @ $400/day	48,400.00
Phil Seccombe, Ph.D. Geologist		
	61.00 days @ $650/day	39,650.00
Ed Sinnott, Camp Manager		
	115.50 days @ $400/day	46,200.00
Tim Sullivan, Prospector		
	21.00 days @ $475/day	9,975.00
Jan Tindle, Senior Sampler		
	83.00 days @ $325/day	26,975.00
Bill van Zanten, Sampler		
	18.00 days @ $275/day	4,950.00
Kristy Emery, CSR		
	5.00 hours @ $115/hour	575.00

STATEMENT OF EXPENDITURES
WERNECKE PROJECT
April 24 - October 18, 2007

Scott Parker, GIS/Logistics			
217.50 hours @ $75/hour	16,312.50		
Julie Robinson, GIS			
1394.00 hours @ $75/hour	104,550.00		
Neil Visser, Logistics			
213.00 hours @ $75/hour	15,975.00		
Clerical

Appendix D: Rock Sample Descriptions

MINERALS AND ALTERATION TYPES

AC	Actinolite	FP	feldspar	PF	plagioclase
AL	alunite	GA	garnet	PH	phlogopite
AM	amphibole	GE	goethite	PL	pyrolusite
AS	arsenopyrite	GL	galena	PO	pyrrhotite
AU	augite	GR	graphite	PY	pyrite
AZ	azurite	HB	hornblende	QZ	quartz veining
BA	barite	HE	haematite	RE	realgar
BI	biotite	HS	specularite	RN	rhodonite
BO	bornite	HZ	hydrozincite	SB	stibnite
BT	pyrobitumen	IL	illite	SD	siderite
CA	calcite	JA	jarosite	SI	silicification
CB	Fe-carbonate	KF	potassium feldspar	SK	skarn
CC	chalcocite	MC	malachite	SM	smithsonite
CD	chalcedony	MG	magnetite	SP	sphalerite
CL	chlorite	MI	mica	SR	scorodite
CP	chalcopyrite	MN	Mn-oxides	SS	sulphosalts
CU	native copper	MO	molybdenite	ST	smectite
CV	covellite	MR	mariposite/fuchsite	TP	topaz
CY	clay	MS	sericite	TT	tetrahedrite
DC	dickite	MT	marcasite	VG	gold
DS	diaspore	MU	muscovite	ZE	Zeolite
DU	dumortierite	NA	natroalunite	ZN	zunyite
EN	enargite	NE	neotocite		
EP	epidote	PA	pyrargyrite		

ALTERATION INTENSITY

w	weak	s	strong
m	moderate	i	intense

Rock Sample Descriptions Werneckes

Operator: Fronteer Development Group Inc. **Project:** FRG07-01 2007 **NTS:** 106

839501 Wernecke

Grid North: UTM 7211666 N | Grid East: UTM 527575 E | Elevation | Sample Width: 2 m | Type: Grab | Strike Length Exp: | True Width: 0 m | Host : phyllite | Alteration: msCL, mMS | Metallics: | Secondaries:

Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
<5	0.09	33.3	1.01
Ni (ppm)	**Co (ppm)**	**Bi (ppm)**	**U (ppm)**
12.4	3.3	0.02	0.7

Sampled By: NM 16-Jul-07

Plagioclase with disseminated specular hematite, secondary quartz host.

839502 Wernecke

Grid North: UTM 7211666 N | Grid East: UTM 527575 E | Elevation | Sample Width: 2 m | Type: Grab | Strike Length Exp: | True Width: 0 m | Host : phyllite | Alteration: msCL, mMS | Metallics: | Secondaries:

8	0.11	43.5	4.57
Ni (ppm)	**Co (ppm)**	**Bi (ppm)**	**U (ppm)**
14.4	8.6	0.27	5.7

Sampled By: NM 06-Jan-07

cps - 350. Mass of thin veinlets, 2-4 mm wide following a shear/fault zone. E/W zone is approximately 10 ft wide. Only small knob exposed.

839506 Wernecke

Grid North: UTM 7213378 N | Grid East: UTM 528978 E | Elevation | Sample Width: 0.3 m | Type: Float | Strike Length Exp: | True Width: 0 m | Host : dolomite thinly bedded | Alteration: wCA | Metallics: <1%CP, <1%CC | Secondaries: MC

Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
50	1.09	5390	5.17
Ni (ppm)	**Co (ppm)**	**Bi (ppm)**	**U (ppm)**
21.5	21.2	24	7.3

Sampled By: NM 06-Mar-07

Remobilized chalcopyrite with secondary sericite along fracture planes and bedding planes. Thinly bedded monzonite, 1 mm blobs of chalcopyrite.

Rock Sample Descriptions Werneckes

Operator: Fronteer Development Group Inc. **Project:** FRG07-01 2007 **NTS:** 106

839507 Wernecke

Grid North: UTM 7213428 N | Grid East: UTM 528924 E | Elevation | Sample Width: 1.5 m | Type: Select/Grab | Strike Length Exp: 3 m | True Width: 0.5 m | Host : dolomite with moderate chlorite | Alteration: wmCL | Metallics: 1%CP | Secondaries: mCC

Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
563	0.44	136500	0.69
Ni (ppm)	**Co (ppm)**	**Bi (ppm)**	**U (ppm)**
9	5	2.35	1.4

Sampled By: NM 06-Mar-07

This site seems to be on strike with U308, possibly continuation with change in chemistry, more carbonate

839508 Wernecke

Grid North: UTM 7213436 N | Grid East: UTM 528931 E | Elevation | Sample Width: 0 m | Type: Grab | Strike Length Exp: | True Width: 0 m | Host : dolomite | Alteration: mCL | Metallics: | Secondaries:

Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
9	0.13	407	0.39
Ni (ppm)	**Co (ppm)**	**Bi (ppm)**	**U (ppm)**
35.6	13.3	0.26	18.7

Sampled By: NM 06-Mar-07

350-500 cps. 2 m down slope from 839507 with cu monzonite, same system.

839509 Wernecke

Grid North: UTM 7213558 N | Grid East: UTM 528957 E | Elevation | Sample Width: 0 m | Type: Float | Strike Length Exp: | True Width: 0 m | Host : dolomite/siltstone | Alteration: wCA, wQZ | Metallics: | Secondaries:

Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
7	0.16	445	1.04
Ni (ppm)	**Co (ppm)**	**Bi (ppm)**	**U (ppm)**
84.6	16.7	0.16	810

Sampled By: NM 06-Apr-07

Plagioclase dusted with hematite (red) with secondary quartz. Moderate to strong chlorite alteration adjacent to veins. Width of veining approximately greater than 20 cm. Found in subcrop/float only.

839510 Wernecke

Grid North: UTM 7211556 N | Grid East: UTM 525538 E | Elevation | Sample Width: 0 m | Type: Grab | Strike Length Exp: | True Width: 0 m | Host : weak breccia | Alteration: sCA | Metallics: 3%HS | Secondaries:

Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
<5	<0.01	20.2	0.57
Ni (ppm)	**Co (ppm)**	**Bi (ppm)**	**U (ppm)**
23.2	16.6	0.12	2.6

Sampled By: NM 21-Jun-07

Adjacent to high Au sample taken 2006, carb veining/matrix with 2-5 mm clasts of hard pink/red. clasts jasper (?) or hematitic plagioclase. Talus field.

839511 Wernecke

Grid North: UTM 7211559 N | Grid East: UTM 535601 E | Elevation | Sample Width: 0 m | Type: Grab | Strike Length Exp: | True Width: 0 m | Host : weak breccia | Alteration: sCA | Metallics: 70%HS | Secondaries:

846424 Wernecke

Grid North:		Grid East:		Type: Chip	Alteration:	Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
UTM 7206788	N	UTM 527902	E	Strike Length Exp: 10 m	Metallics: 1%CP, 5%HS	10100	2.32	523	27.3
Elevation		Sample Width: 2.5	m	True Width: 2.5 m	Secondaries: sGE, sHE, mMC, Uranop	Ni (ppm)	Co (ppm)	Bi (ppm)	U (ppm)
		165°/50°		Host : brecciated silt sandstone(jasperite)		60.3	54.7	10.35	2200

Sampled By: TS cps 9999. Dip = 50Rt; Metallics5 = Branerite. Possible trace erythrite. This Zone is now the Atom Tan, the high grade is narrow but the whole zone probably runs 10 to 15 m.

846425 Wernecke

Grid North:		Grid East:		Type: Chip	Alteration:	Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
UTM 7206801	N	UTM 527894	E	Strike Length Exp: 20 m	Metallics: 0.5%CP, 5%HS	79	0.27	148.5	15.45
Elevation		Sample Width: 1	m	True Width: 1 m	Secondaries: mGE, mHE, tr MC	Ni (ppm)	Co (ppm)	Bi (ppm)	U (ppm)
		165°/50°		Host : layered and veined siltstone		46.8	12.4	1.18	19.4

Sampled By: TS cps 700 Dip = 50Rt; Possible trace erythrite. This Zone is now the Atom Tan, the high grade is narrow but the whole zone probably runs 10 to 15 m.

846426 Wernecke

Grid North:		Grid East:		Type: Grab	Alteration: QZ	Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
UTM 7207065	N	UTM 527577	E	Strike Length Exp: 300 m	Metallics: 40%HS, 0.5%CP	10100	258	258	3210
Elevation		Sample Width: 0.3	m	True Width: 0.3 m	Secondaries: mGE, sHE, tr MC, Urano	Ni (ppm)	Co (ppm)	Bi (ppm)	U (ppm)
		165°/50°		Host : massive hematite siltstone/sandstone		13.6	4.6	585	249

Sampled By: TS cps 1500. Large bed of massive hematite up to 8 m wide, usually doesn't run the scintillometer but locally strong radioactivity. Found some altered float below with no specular hematite that led me here that runs up to 3000 cps.

846427 Wernecke

Grid North:		Grid East:		Type: Float	Alteration:	Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
UTM 7207068	N	UTM 527590	E	Strike Length Exp:	Metallics:	1255	17.65	36.6	79.7
Elevation		Sample Width:		True Width:	Secondaries:	Ni (ppm)	Co (ppm)	Bi (ppm)	U (ppm)
				Host : altered siltstone poss breccia?		37.2	10.2	7.98	820

Sampled By: TS cps 1400. Trace to here. Some of the float to here ran as high as 3000 cps. Massive hematite bed just up hill.

846428 Wernecke

Grid North:		Grid East:		Type: Chip	Alteration: QZ	Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
UTM 7207103	N	UTM 527574	E	Strike Length Exp: 300 m	Metallics: 50%HS, 0.5%CP	47	1.14	7.9	62.3
Elevation		Sample Width: 5	m	True Width: 5 m	Secondaries: mGE, sHE	Ni (ppm)	Co (ppm)	Bi (ppm)	U (ppm)
				Host : sandstone/massive hematite		6.1	2.7	3.26	7.8

Sampled By: TS Huge massive hematite bed can be traced for 400m, possibley more. Some poddy radioactivity to the southeast (cps 150-200).

846429 Wernecke

Grid North:		Grid East:		Type: Chip	Alteration: QZ	Au (ppb)	Ag (ppm)	Cu (ppm)	Mo (ppm)
UTM 7207199	N	UTM 527501	E	Strike Length Exp: 300 m	Metallics: 50%HS	11	0.86	15.2	36.6
Elevation		Sample Width: 8	m	True Width: 8 m	Secondaries:	Ni (ppm)	Co (ppm)	Bi (ppm)	U (ppm)
				Host : massive hematite siltstone/sandstone		9.5	3.5	0.88	6.5

Sampled By: TS Massive hematite bed, may be related to radioactive section far to the northwest, no cps. Unit above seems to run a little higher 400-500. Trying to show extent of bed and check for gold numbers.

Fifth sample of 1 sequence. From 4-5m.

Appendix E: Quality Control / Quality Assurance

QUALITY CONTROL / QUALITY ASSURANCE

I Chain of Custody

All samples were packed in rice sacks and sealed with uniquely-numbered non-resealable security straps. Rice sacks were flown via chartered fixed-wing aircraft to Whitehorse where they were transferred to Canadian Freightways for trucking to ALS Chemex Labs Ltd. in Terrace, BC, an ISO 9001 registered laboratory. ALS Chemex reported that all bags were received in good condition, with all security straps intact, and with no evidence of tampering.

II Blank Sample Analysis

Blanks are samples which are known to be barren of mineralization and are inserted into the sample stream in the field to determine whether contamination has occurred after sample collection.

a. Soil Field Blanks

A total of 38 blank samples were inserted into the soil sample sequence (approximately 1 blank per 75 samples) and submitted for analysis. The blank material comprised fine-grained commercially available silica from the same company that supplies ALS Chemex Labs with their blank material.

Results of the soil blanks shown in the table above indicate that the blank samples consistently returned very low values for all elements of interest except Au. Three samples returned 13, 41 and 55 ppb Au and given that 9 ppb is the 75th percentile threshold for Au, these results are noteworthy. These data do not point towards widespread field or lab contamination but do point to rare contamination. Sample 842630, which returned 55 ppb gold was reported on a certificate that also reported on some very high Au in soil values up to 697 ppb. It is probable, therefore that some lab contamination occurred among this batch of samples during fire assay procedures.

b. Core Field Blanks

A total of 98 blank samples were inserted into the soil sample sequence (approximately 1 blank per 40 samples) and submitted for analysis. The blank material comprised fine-grained commercially available silica from the same company that supplies ALS Chemex Labs with their blank material.

Results of the core blanks shown in the tables above indicate that the blank samples consistently returned very low values for all elements of interest except Au. A few samples returned elevated ranges up to 32 ppb. Although this value is higher than expected for true blank material, this is still a very low value for core given that this approximately the 60th percentile threshold value for Au in rock samples.

III Duplicate Sample Analysis

Field duplicates are collection and analysis of two separate samples from the same field location or core interval. They are used to measure the reproducibility of sampling, which includes both laboratory variation and sample variation.

a. Soil Field Duplicates

A total of 43 field duplicate soil samples were collected (approximately every 60th sample) during the 2007 program and submitted for analysis. Most metals of interest and associated pathfinder elements were reproducible at 50-90% precision. Au and Cu were reproduced at 70% precision while U and Mo were reproduced at 60%. Bi-Co-Ni-Pb-Sb-REEs were reproduced at about 40% precision. Many of the soil samples collected during the 2007 field program were collected from poorly developed talus fine soils which may be inherently less reproducible than samples from well-developed soil profiles. The 2007 duplicates, however, showed better precision than the 2006 samples in spite of similar techniques and analytical procedures being used in both years. As both lab and field duplicates exhibited similar degrees of variability it is likely that this is due to the sample variability as opposed to laboratory variability.

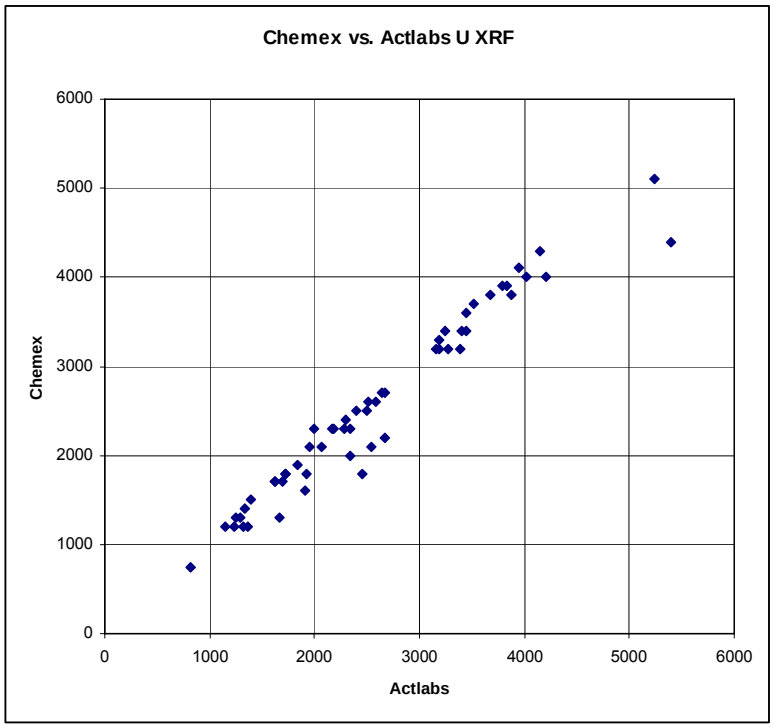
b. Core Field Duplicates

One in forty core samples were quartered and a duplicate sample was collected from the same interval for a total of 93 duplicate pairs during the 2007 drill program. The paired data were plotted to determine precision folloing the procedures of Thompson and Howarth (1978). Metals showed precision levels varying from 20 to 60%. Au-Co-Mo-U were reproducible at 60% precision, Ni and Ag at 50% precision and Cr-Pb-Sb at 20% precision. Thus, for the main elements targeted by the 2007 drilling-namely gold, copper and uranium-precision levels were fairly low. There are two main sources of this variation-laboratory analytical variation and sample variation. Given that ALS Chemex's internal duplicates typically suggest a laboratory analytical precision of about 10%, these field duplicates are most likely attributed to natural inhomogeneities within the sampled core. The bleb-like nature of brannerite, chalcopyrite and molybdenite where observed in hand sample and core from the Wernecke property is consistent with this interpretation.

IV Overlimits

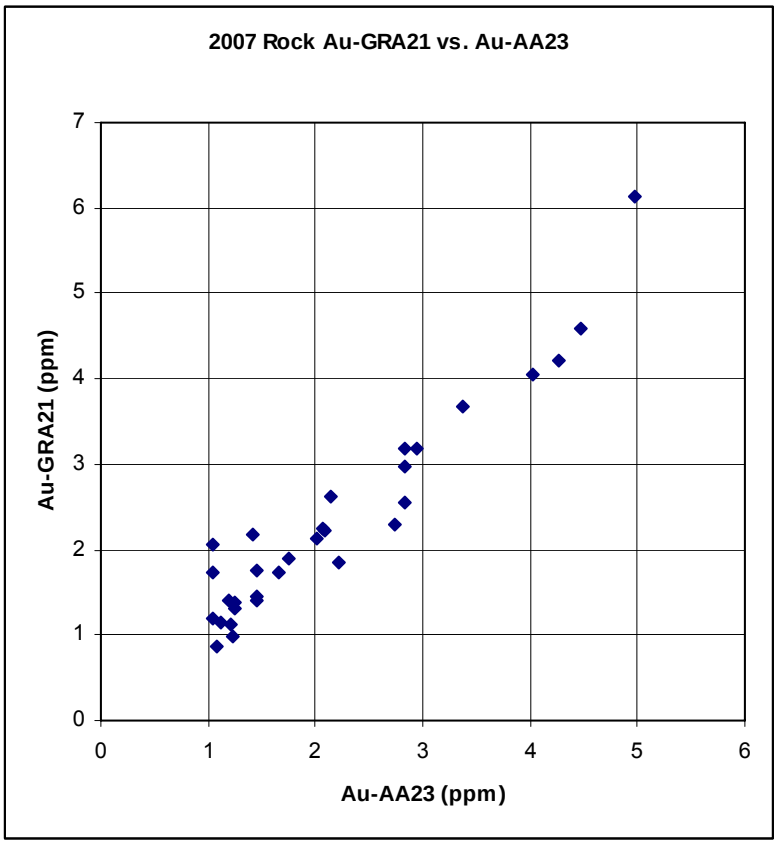
a. Rock Overlimits

All rock samples with U exceeding 1000 ppm by ICP analysis had their pulps subsequently reanalyzed by pressed pellet x-ray fluorescence (XRF). Excellent correlation was found between these two methods – similar to the results from 2006 (Heffernan et al., 2007). Additionally, the pulp material from 56 samples was sent to Activation Laboratories Ltd. (Actlabs) in Ancaster, Ontario, an ISO 17025-certified laboratory, for analysis by pressed pellet XRF. Values reported by Actlabs were on average 1.9% higher than those reported by ALS Chemex (see chart below). Although standards were used in the core sample stream in 2007, the sample size of the standards was too small for the pulps to be sent from Chemex to Actlabs so no standards have been analysed by Actlabs. In general, however, these interlab results fall within acceptable limits despite a few outliers.



Similarly, all rock samples exceeding 1000 ppb Au by initial 30 g fire assay and AA finish (method Au-AA23), totalling 39 samples, had their pulps subsequently re-assayed by ALS Chemex via 30 g fire assay with gravimetric finish (method Au-GRA21). Graphically comparing these results (see chart below) indicates a very good correlation between these two analytical methods with a slight under-reporting of Au values by the initial FA/AA. Several of these samples exceeded 10 g/t Au and two had sufficient reject material to complete screen assay. This limited dataset (as well as the three samples from 2006 that had screen assays

completed) indicates that there can be significant variability between gravimetric and screen analyses which is likely due to the sample size.



Sample	Au (gravimetric) (g/t)	Au (screen) (g/t)
846372	35.7	30.3
347302	9.36	8.39

All rock samples exceeding 10,000 ppm Cu, Pb, Zn by initial ICP analysis had their pulps subsequently assayed with a four-acid digestion and AA finish.

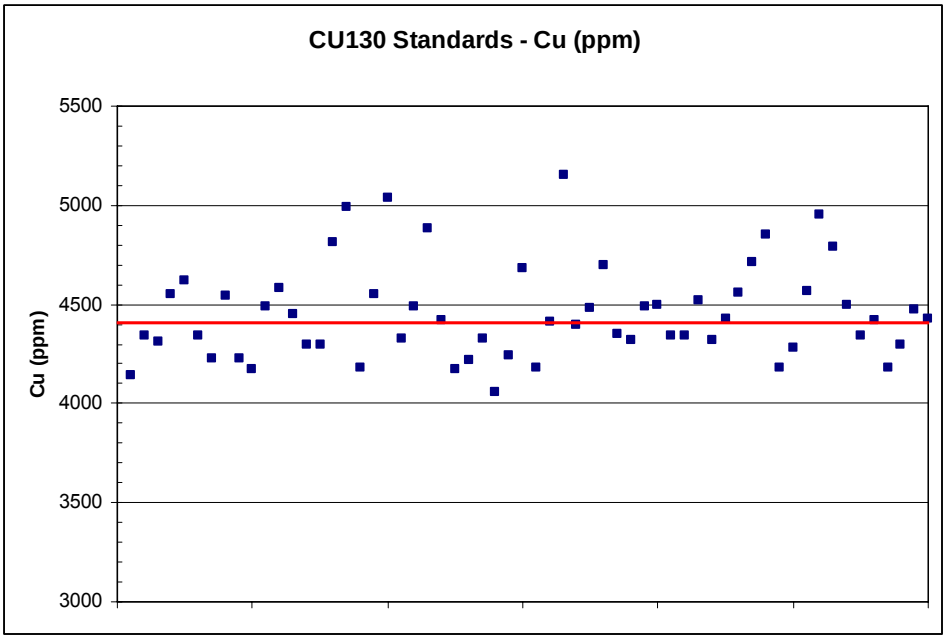
V Standards

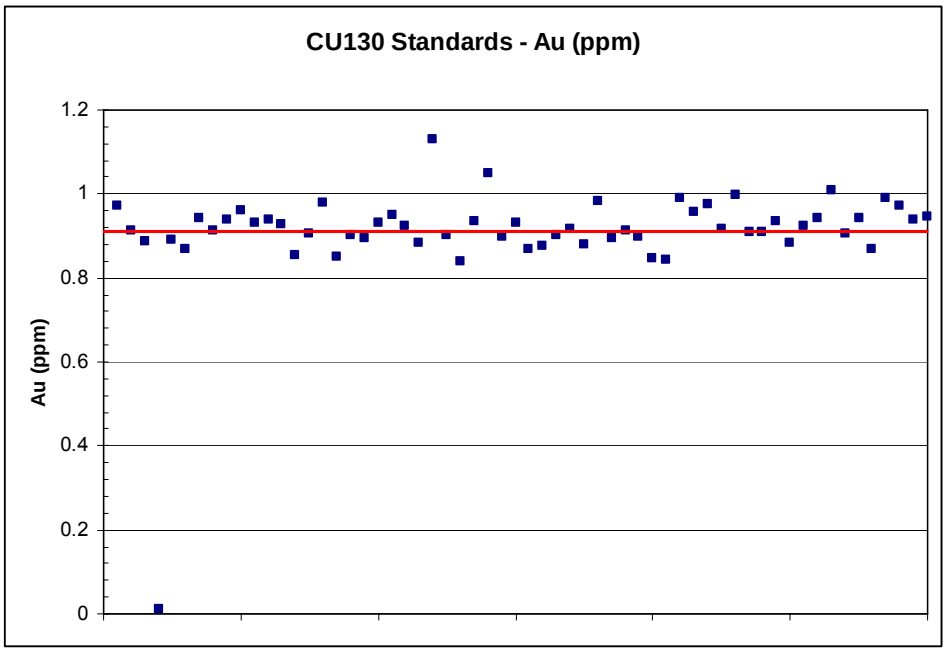
To gauge the accuracy and consistency of analytical results, five different standards were inserted into the core sample stream. A total of 94 standards, or approximately 1 per 43 core samples, were analysed in 2007. A Cu-Au-Mo-Ag standard (CU130) obtained from WCM Minerals and four uranium standards (BL-1, BL-4, RL-1 and UTS-4) obtained from CANMET Mining and Mineral Sciences Laboratories (a division of Natural Resources Canada) were used. In general, uranium standards were inserted into the sample stream where the targeted element was uranium, however the copper standard was used where copper was targeted. The certified values are provided in the table below.

Standard	Number Analysed	Au (ppm)	Ag (ppm)	Cu (ppm)	Mo (ppm)	U (%)	Th (ppm)
CU130	60	0.933	35.8	4400	740	-	-
BL-1	9	-	-	-	-	0.022	15
BL-4	6	-	-	-	-	0.173	n/a
UTS-4	6	-	-	-	-	0.101	15.4
RL-1	13	-	-	-	-	0.201	-

a. Cu-Au Standard

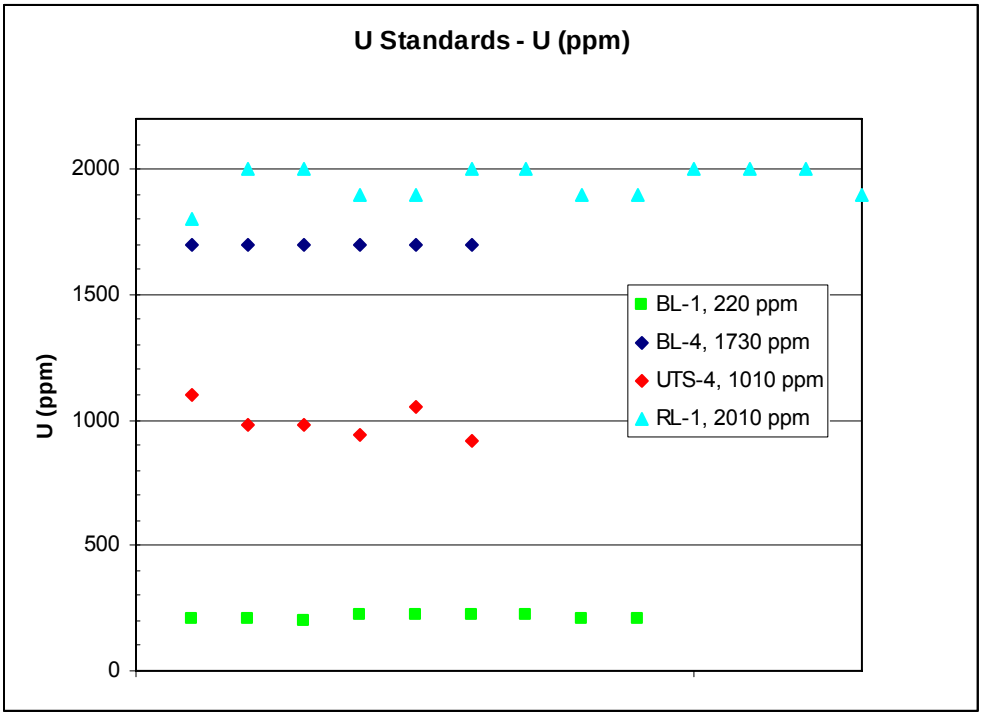
A total of 60 CU130 standards were inserted into the core sample stream. Analyses of standards returned values that compared fairly well with WCM Minerals' certified values. Results for Cu and Au are presented in the charts below and the red horizontal line indicates the certified values. A few samples fell outside a 10% accepted precision and one Au analysis returned 10 ppb for reasons that are unknown.





b. U Standards

A total of 34 U standards were inserted into the rock sample stream and these results were subsequently compared to the above certified values. All of these standards returned values that fell within 10% of the certified values as shown in the chart below.



VI Analytical Interferences

A number of certificates of rock, core and locally soil samples encountered interference effects when high Ca or Mo values were encountered. In these cases, ALS Chemex reported less-sensitive ICP-AES values as opposed to the ICP-MS values. A number of rock and core sample certificates noted that REEs may not be totally soluble with ICP-MS and that REE values for these certificates may be low.

VII Conclusions

- There is no evidence of tampering with the samples between collection and the laboratory.
- Consistently low values for all metals of interest in the blank analyses indicate that contamination of soil or core samples did not take place in the field, or in the lab.
- Field duplicate samples indicate that sampling is poorly reproducible at all but the lowest levels of precision. Most soils from this field program were collected from poorly developed talus fine soils which may be inherently less reproducible than samples from well-developed soil profiles. It is likely that this is due to sample variability as opposed to laboratory variability.
- Assaying of overlimit Au and U analyses shows that ICP geochemical analysis was reasonably accurate for Au and U in rock samples. Limited screen assaying of high-grade Au analyses indicates a fair degree of variability (±20%) between standard fire assaying and screen assaying and the presence of small quantities (<5 mg) of +80 mesh Au. Overlimit assaying for Ag, Cu, Pb and Zn was also carried out.
- Uranium and Cu-Mo-Au-Ag standards inserted into the rock sample stream compared well with known values of these standards with almost all samples and elements falling within 10% of, and scattering about, their known values. A single standard returned 10 ppb Au where the certified value is much higher. It is unknown how this could have occurred but the otherwise good performance of the standard reference materials suggests that widespread inaccuracies did not occur.
- Although not presented here, ALS Chemex carries out a full QA/QC protocol, including blanks, duplicates and standards, on laboratory handling and analysis of samples and satisfy themselves that results are satisfactory, prior to issuing certificates.

Appendix G: Geologist's Certificates

GEOLOGIST'S CERTIFICATE

Darcy E.L. Baker
1003 / 1127 Barclay Street,
Vancouver, BC, Canada

I, Darcy Baker, am President of Equity Engineering Ltd., with offices at Suite 700–700 West Pender Street in the City of Vancouver, B.C., in the Province of British Columbia.

I am a Geoscientist and President of Equity Engineering Ltd., with offices at #700–700 West Pender Street in the City of Vancouver, B.C., in the Province of British Columbia.

I am a graduate of Dalhousie University (1997) with an Honours Bachelor of Science degree in Geology, and am a graduate of the University of Newcastle, Australia (2003) with a Doctor of Philosophy degree in Geology, and I have practiced my profession continuously since 1997.

Since 1997 I have been involved in mineral exploration for gold, silver, copper, lead and zinc in Canada, Alaska and Australia.

I am presently a Consulting Geologist and have been so since May 2003.

Dated at Vancouver, British Columbia, this 31st day of January, 2008.

_____

Darcy Baker, Ph.D.

DRILL LOG

Project: Werneckes	**Collar Elevation (m):** 803.0
Hole DR07-01	**Azimuth (º):** 340
Location: 7199312 m North, 540839 m East	**Dip (º):** -45.0
Logged by: N. Mitchell	**Length (m):** 177.00
Drilled by: Dorado	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/09/15 **Date Completed:** 2007/09/18	
Dip Tests By: Flexit	
Objective Test fracture-hosted copper mineralization exposed along creek at DR Zone.	

Summary Log:

0-12.1 m CASING

12.1-125.05 m SILTSTONE (slts): grey-green MS and CL altered. Minor phyllite and local weak dolomite, trace CP associated with trace PY and HE.

125.05-137.75 m SILTSTONE (slts): grey to buff and locally green owing to CL alteration. Intensely SI-altered with local intense qz veining, wCL, wAB and possible wKF. Trace PY (associated with CL) SP and CP

137.75-177.0 m SILTSTONE (slts): weakly to mod. altered. Unit is blocky due to faulting. sMS, m-sCL, wDOL. Trace CP, PY found in dolomitized patches of unit.

177.0 m E.O.H.

From	To	Rocktype & Description

STRUCTURE:
The unit is broken and blocky, partially due to faulting as well as bedding and foliation at very shallow angles to core axis. Micro faults as well as tensional gashes also disrupt bedding and foliation.

Micro faults and gashes are often healed with quartz dolomite +/- calcite and generally intersect the bedding at a high angle.

Minor crenulations are observed late and are cross-cut by veining and faulting.

From	To	Rocktype & Description
125.05	137.75	slts

SILTSTONE: intensely silicified with intense quartz veining. Protolith difficult to identify but relict texture is consistent with alteraiton of siltstone. The upper contact is gradational with a marked increase in silicification and destruction of primary features. This unit is grey to buff and green where chlorite is common.

The margins of the unit and minor portions of the inner unit are brecciated; clasts are sub-angular and 2-20 mm. Clasts have diffuse irregular margins and are quartz matrix supported. Possibly later veins 10-30 cm (listed bellow) cross-cut core at low angles digesting host rock, margins are embayed and irregular.

ALTERATION:
Unit is strongly silicified with zones of albite and possible potassic alteration. Minor fractures and joints (1-2mm) are healed with chlorite. Minor hematite alteration also noted in the core.
« Silicification 4.00*»
« Chlorite 1.00*»
« Albite 1.00%» patchy 137.02-137.80 m
« K-feldspar 1.00*» patchy and suspect...possible hematite dusting.

STRUCTURE:
Veins comprise chlorite aggregates with minor dolomite +/- hematite and pyrite blebs. Unit is competent and much less broken than rock above, jointing is at high angles to core with minor faulting.

		MINERALIZATION:
		Very fine-grained chalcopyrite occurs mainly in chlorite aggregates and also in chlorite healed micro fractures as well as occasional blebs in the pervasive silicified unit. Unlike the rest of the unit, pyrite blobs and sub-euhedral crystals are found throughout the unit but are slightly more concentrated in chlorite veins. Trace wisps of sphalerite are also found in chlorite veins.
		« Chalcopyrite 0.20%»
		« Pyrite 3.00%» mostly associated with chlorite.
		« Sphalerite 0.01%»
137.75	177.00	slts
		SILTSTONE: Weakly to moderately altered with trace chalcopyrite. Colour is variable from light to dark green, and varies with chlorite content. Bedding is generally discernible throughout but has been disrupted by fractures, minor quartz-carbonate veining and small patches and lamina selective carbonate alteration.
		Lithology is consistent throughout and unit is equivalent to the upper siltstone unit
		ALTERATION:
		« Sericite 3.00*»
		« Chlorite 2.50*»
		« 137.75- 177.00 Dolomite 1 »
		MINERALIZATION:
		trace chalcopyrite occurs in dolomitized patches and in qz-ca-Kf-cb-dol-cp altered patches
		« Chalcopyrite 0.1»

Hole Number: DR07-01

From	To	Rocktype & Description

« Pyrite 0.5%»

STRUCTURE:

The unit is broken and blocky, partially due to faulting as well as bedding and foliation at very shallow angles to core axis. Mico faults as well as tensional gashes also disrupt bedding and foliation. Minor crenulations are observed late and are cross-cut by veining and faulting.

< @ 149.50 S2 Foliation 45.00° >

Summary Log:

FW07-01

LITHOLOGY:

0 - 4.57m Overburden

4.57 - 163.68m
PHYLLITE: Light grey to dark green, metasomatized siltstones of the Fairchild Lake Group. Siltstones are finely to thinly laminated, weakly to moderately well developed cleavage with fine grained specular hematite and less magnetite lamina concordant to bedding and over printing foliation.
Alteration
4.57 - 163.68m
Ms, Cl, +/- Si and Cb

Mineralization

33.61- 40.58m
127.22- 139.17m
Haematitic plagioclase and quarts veining cross cutting foliation and bedding with minor accessory iron carbonate. Strong chlorite alteration along the selvages of veins. Minor specularite and magnetite 3%.

Downhole surveys:

From	To	Rocktype & Description
0.00	4.57	OVBN No recovery, core recovered beginning at 4.57m.
4.57	16.22	slts Siltstone: Light green, thinly to finely laminated. The lower contact is sharp and defined by a sharp increase in chlorite alteration and Qz, plagioclase hematite veining. Bedding is generally discernible throughout but has been disrupted by fractures, jointing and veinlets of MG, HE and QZ. Bedding 72.00° S1 Foliation 72.00° S2 Foliation 26.00° V1 67.00-74.00° V2 26.00-35.00° Joints (S2) plains are smooth to rough and cross cut bedding, foliation and veins. Foliation is moderately well developed and is concordant to bedding. The entire unit is weakly to moderately CL altered with secondary weak sericite alteration. CL 2 MS 1 Pervasive fine-grained magnetite (primary?) lamina (3mm) with secondary fine grained disseminated magnitite/hemitite over printing bedding. Veins, V1 and V2 are compositionally identical quarts veins with varying amounts of magnetite and hematite, veins are typically 2-20cm wide with well developed margins and 3mm envelopes of moderately strong chlorite alteration. V2 are later and cross cut V1. Vein density is 3 veins per meter. MG 3% HE 5%
16.22	33.61	slts Siltstone: Darker green with strong chlorite alteration and moderate silicification. Thinly to finely laminated with minor limonite coating fractures and joints. The lower contact is gradational and based on the increase of hemititic plag veining. Unit is strongly veined (V1) with dominantly quarts, minor plagioclase iron

		The unit is strongly sheared at 114.64-115.61m and 118.47-119.30m, bedding and foliation are obliterated in these areas and the zones are brecciated, fragments 1-5mm, have rounded edges and have been rotated. The zones have strong silicification, moderate chlorite, weak sericite as well as patchy carb alteration. Within the shear zones are minor fragments of milky and glassy quartz, haematitic plagioclase (5% of total sheared unit) with silica, clotted chlorite and calcite matrix. Minor granular MG and HE 3-5mm blebs also occurs in matrix.

DRILL LOG

Project: Werneckes	**Collar Elevation (m):** 1234.0
Hole FW07-02	**Azimuth (º):** 100
Location: 7211916 m North, 527580 m East	**Dip (º):** -70.0
Logged by: N.Mitchell	**Length (m):** 197.51
Drilled by: Cabo	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/07/27 **Date Completed:** 2007/07/31	
Dip Tests By: Reflex	
Objective To test for structurally hosted uranium at the fireweed boulder field.	

Summary Log:

0.0 - 3.66 m CASING

3.66 - 50.77 m, 75.42 - 197.51m PHYLLITE (ph): Light grey to dark green, metasomatized siltstones of the Fairchild Lake Group. Siltstones are finely to thinly laminated, weakly to moderately well developed cleavage with fine grained specular hematite and less magnetite lamina concordant to bedding and over printing foliation.

50.77 - 75.42 m SHALE (shl): Shale with minor concordant interbeds of <30cm interbeds of siltstone contacts are sharp and well defined. Foliation and bedding are parallel.

ALTERATION:
CL, MS +/- CB, SI

VEINING:
29.87 - 31.41 m: Haematitic plagioclase and quarts veining cross cutting foliation and bedding with minor accessory iron carbonate. Proposed mineralized veins are dominantly hosted in phyllite. Strong chlorite alteration along the selvages of veins. Minor specularite and magnetite 3%.
184.31 - 194.57 m: Spotty uranium enrichment along fractures and joint plains hosted in zone of intense Qz veining with strong clotted chlorite altered phyllite. Readings of 150-190 Cps.

**Downhole survey log was completed but due to high magnetite values within bedrock, azimuth readings are not accurate and are not included within this log.

Downhole surveys:

From	To	Rocktype & Description
0.00	3.66	OVBN
		CASING: No recovery.
3.66	20.92	slts

Siltstone:

Light green, thinly to finely laminated. The lower contact is sharp and defined by a sharp increase in chlorite alteration and quartz, hematitic plagioclase and hematite veining.

< @ 20.92 Lower contact 68° >

Bedding is generally discernible throughout but has been disrupted by fractures, jointing and veinlets of mg Hematite and qz. The upper portion of the section is broken and fractured possibly from freeze/thaw.

Joint plains are smooth to rough and cross cut bedding, foliation and veins.

Foliation is moderately well developed and is concordant to bedding.

< @ 17.05 S1 Foliation 56° >

« 18.26- 18.42 fault » Fault material composed of gouge and clays. Contacts conformable to bedding.

The entire unit is weakly to moderately chlorite altered with secondary weak sericite alteration.

« 3.66- 20.92 Chlorite 2»

« Sericite 1»

Pervasive fine-grained magnetite lamina (3mm) parallel to bedding with secondary fine grained disseminated magnitite /hemitite overprinting bedding.

Quartz veins with varying amounts of magnetite,hematite and carbonate are typically 2-20mm wide with well developed margins and 3mm envelopes of moderately strong chlorite alteration. Approximately 3 veins per meter.

« 3.66- 20.92 Specularite 2%»

From	To	Rocktype & Description
145.91	164.36	slts

Siltstone:

Light green, broken unit with moderate shearing, strong quartz veins and carbonate veinlets. The lower contact is defined by the increase of quartz veining.

< @ 164.36 lower contact 64° >

Unit has pervasive strong sericite with moderate to weak chlorite alteration. Chlorite alteration is strongest along the margins of QZ veins and in small (1-2mm) altered clasts contained in veins. Carbonate veinlets have a bleached appearance along there margins (1-2mm)

« Sericite 3»

« Chlorite 2» along margines of veins Chlorite is stronger, very localized.

Unit is broken and sheared with minor faults listed below. Shearing is present in areas of strong Quartz veining. Veins have distorted margins and internal structures. Later carbonate veinlets cross cut all structures, bedding and Quartz veins.

< @ 140.62 FLT 45 78cm > clays and angular fragments of SLTS and qz

SILTSTONE: Unit is very strongly Quartz veined (70% of total unit), very strongly folded and sheared. Primary bedding and foliation is obliterated in areas of most intense veining. Minor micro faulting mimicking larger faults with cm scale displacement.
< @ 174.45 Bedding 77° >
< @ 174.50 S1 Foliation 77° >
< @ 181.67 Bedding 64° >
< @ 181.70 S1 Foliation 64° >
« 176.89- 176.99 FLT 77°» Fault
« 191.31- 191.58 fault FLT 85°»
< @ 169.17 micro faulting 1cm displacment FLT 70° 6cm >

Host rock in areas of intense Quartz veining is very strongly Chlorite altered with clotted chlorite along margins of Quartz veins and almost obliterates bedding and primary features. Portions of the host which are adjacent to the veins are also strongly silicifide Outboard of the veins bedding and primary features are moderately preserved but have been strongly sheared in places as well as folded with strong sericite alteration. In wider veins there is trace stubby dark green euhedral amphibole.
« 164.36- 197.51 Chlorite 4»
« 164.36- 197.51 Sericite 3»
« trace carbonate (ankerite?) »

There are minor amounts of fe-carbonate throughout generally along the margins of the Quartz veinlets or cross cutting bedding and foliation of host rock at random angles, later (?). Quartz veins pinch and swell and are generally discontinues, 1-35cm, 1 per 50cm at random angles TCA. Trace manganese patches and ovals on fracture and foliation plains. Trace amounts of malachite and chalcopyrite along fractures and foliation plains. No magnetite or hematite.
« Chalcopyrite , Malachite 0.01%»

There are nine zones, which have elevated scintillometer readings. The readings are associated with secondary uranium enrichment along fractures and breaks. A reading of 190Cps is associated with brick red haematitic plagioclase, 3cm wide, roughly concordant to foliation and remnant bedding.

DRILL LOG

Project: Werneckes	**Collar Elevation (m):** 1232.0
Hole FW07-03	**Azimuth (º):** 100
Location: 7211834 m North, 527567 m East	**Dip (º):** -45.0
Logged by: N.Mitchell	**Length (m):** 155.45
Drilled by: Cabo	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/07/31 **Date Completed:** 2007/08/03	
Dip Tests By: Reflex	
Objective To test for structurally hosted uranium on the Fireweed boulder train.	

Summary Log:

0.0 - 4.57m CASING

4.57 - 26.41m, 41.15 - 56.80 m Siltstone(slts): Siltstone with minor concordant interbeds of <30cm interbeds of shale contacts are sharp and well defined. Foliation and bedding are parallel. Fine grained specular hematite and lesser magnetite lamina concordant to bedding and fine grained crystals of specular hematite and magnetite over printing foliation.

26.41 - 41.15 m, 56.80 - 155.45 m PHYLLITE (ph): Light grey to dark green, metasomatized siltstones of the Fairchild Lake Group. Siltstones are finely to thinly laminated, weakly to moderately well developed cleavage with fine grained crystals of specular hematite and magnetite over printing foliation.

134.54 - 148.59 m Steep angle (TCA) minor faulting.

ALTERATION: Cl, MS +/- CB
VEINING AND MINERALIZATION: Haematitic plagioclase and quarts veining cross cutting foliation and bedding with minor accessory iron carbonate. Strong chlorite alteration along the selvages of veins. Minor specularite (4%) and magnetite (2%) trace spalerite and chalcopyrite.

**Downhole survey log was completed but due to high magnetite values within bedrock, azimuth readings are not accurate and are not included within this log.

Project: Werneckes **Hole Number:** FW07-03

From	To	Rocktype & Description
		Quarts veins with varying amounts of magnetite and granular crystals of hematite typically 2-10mm wide with sharp margins and no increase in chlorite alteration along margins. Veins cross cut foliation and bedding, vein density is 3 veins per meter. There are trace secondary sphalerite diffuse wisps and 3mm cubes mobilized along with 1-5mm Quartz veins. < @ 101.90 HE, QZ 60< @ 83.20 >° < @ 83.20 qz, trace Sphalerite vein 70.00° 1.00cm >
103.52	117.50	slts
		Siltstone: Very strongly sheared and brecciated with quartz, pink plagioclase clasts. The lower contact is gradational and defined by the decrease in quartz, pink plagioclase blebs and chlorite alteration. < @ 117.50 lower contact lower contact 67° > Foliation is moderately well developed outboard of shear zone. < @ 115.38 Bedding 70° > < @ 115.38 S1 Foliation 70° > Foliation and bedding are obliterated as well as any other primary features and early veining. < @ 116.12 he, mg, Chlorite vein 48° > Alteration is very strong in sheared zones 103.52-113.66m. « 103.52- 113.66 Sericite 4, Chlorite 2 shear » « pf, he, Quartz sheared vein 20%» < @ 108.45 S2 Foliation 50.00° > < @ 111.00 S2 Foliation 28.00° > Breccia clasts are 1-30mm milky quartz, pink plagioclase quartz clasts. Breccia clasts are irregular with moderately frayed edges. The breccia is matrix supported, matrix is composed of sericite and chlorite. Outboard of the shear zone bedding and primary features are preserved. Fine-grained magnetite lamina (3mm) parallel to bedding are found in un-sheared zones, secondary fine grained to granular disseminated magnetite / hematite over prints foliation and bedding. Quartz veins with minor magnetite / hematite and clotted chlorite are sub-parallel to foliation and bedding and are disrupted by joints and micro faults.

Summary Log:

0 -5.05 m CASING

5.05 - 206.65 m PHYLLITE (ph): Light green, thinly laminated, foliation is moderately well developed and is parallel to bedding, foliation and bedding are disrupted by later QZ and hematitic plagioclase veining with minor iron carbonate veinlets and blebs generally along the margins of the veins. Fine grained crystals of specular hematite and magnetite over-print foliation.

Alteration:
MS, CL +/- CB

VEINING:
"Pink" hematite dusted plagioclase (75%), quartz (25%) with irregular blebs of magnetite and acicular crystals of secular hematite.

		Unit has alternating 1-4mm lamina of strong chlorite and sericite alteration, likely due to original composition.
		« Chlorite 3.00*»
		« Sericite 2.00*»
		Fine grained disseminated magnitite/hemitite over printing bedding. Veins of quarts have varying amounts of minor magnetite and hematite; veins are typically 2-20mm wide with well-developed margins and 3mm envelopes of moderately strong chlorite alteration. There are minor amounts of fe-carbonate throughout generally along the margins of the Quartz veinlets or cross cutting bedding and foliation at random angles, later (?). Veins pinch and swell and are generally discontinues.
		Sub-unit outlined below is very strongly Quartz veined (70% of total unit), very strongly folded and sheared. Primary bedding and Foliation is obliterated in areas of most intense veining.
		« 155.24- 161.43 Quartz 90%, Chlorite 8%, fe-cb 2%, Hematite 2%, mg 1% QZVN »
		« 167.68-16827.0 Quartz 90%, Chlorite 8%, fe-cb 2%, Hematite 2%, mg 1% QZVN »
		« 196.00- 197.00 Quartz 90%, Chlorite 8%, fe-cb 2%, Hematite 2%, mg 1% QZVN 30.00°»
		Mineralization,
		« Hematite 2.00%»
		« mg 1.00%»
		Trace manganese patches and ovals on fracture and foliation plains.
		Very minor trace malachite along gjoint planes.
		« 175.11- 206.65 Malachite 0.01%»

Project: Werneckes	**Collar Elevation (m):** 1202.0
Hole FW07-05	**Azimuth (º):** 100
Location: 7211774 m North, 527455 m East	**Dip (º):** -55.0
Logged by: D. Baker	**Length (m):** 307.55
Drilled by: Cabo	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/08/08 **Date Completed:** 2007/08/13	
Dip Tests By: Reflex	
Objective To test the southern part of the Fireweed U-bearing boulder field.	

Summary Log:

0.0 - 5.79 m CASING

5.79-307.55 m PHYLITE (ph): fine-grained metamorphosed sedimentary rock, grey to light green depending on alteration, not the protolith. Foliation and bedding fabric are prominent with cm-scale banding (bedding) concordant to foliation. Chlorite alteration increases slightly with quartz veining. Unit periodically veined with QZ-HS-CL-MG.

ALTERATION: MS, CL

MINERALIZATION: Trace py associated with QZ +/- FP, HS, MG, CL. 2-3% combined hematite magnetite lamina.

PHYLLITE: pale, olive green platey rock. Well-developed foliation appears to be a composite of bedding and cleavage. Distinct colour separates it from intervals above and below but all units are seemingly the same protolith - this unit is characterized by sericitic alteration and veining only.

Veining comprises numerous irregular quartz-plagioclase-chlorite-muscovite veins from 1 cm to 20 cm. These veins truncate layering but have largely been transposed into the foliation. Boudin structures and wrapping of the foliation around the veins is widespread suggesting the veins are pre-folding / foliation development. The veins locally contain abundant wall rock fragments forming stockwork zones. In general, this interval appears to have been the focus of an early kinematic hydrothermal event causing veining and sericite alteration of the sedmentary wallrock.

« Sericite 3.00*» pervasive; « Chlorite 2.00*» chlorite is generally confined to veins, « Silicification 1.00*»

« 156.00- 157.60 Specularite 2.00%» as very fine, flakey grains in foliation, gives rock a darker colour

« 157.60- 168.70 Sericite 4.00*» , intense sericite with 15% veins comprising 70% quartz, 20% plagioclase and 10% chlorite

« 173.43- 179.70 qz-pl-cl vein », about 50% sericitised wallrock fragments that are largely flattened in the foliation. Vein is locally pink presumabley due to fine-grained hematite

From	To	Rocktype & Description
183.70	307.55	ph

PHYLLITE: similar to unit at top of hole. Typically grey-green with sub-cm banding defined by alterating lighter and darker beds. Foliation is generally concordant with bedding; rock breaks readily along distinct foliation planes.

« Sericite 2.00*» « Chlorite 1.00*» « mg 1.00%», magnetite forms as fine (< 1mm) subhedral disseminated grains

Foliation is locally crenulated and rare cm-scale gouge zones indicate a minor late faulting event.

Veining is common but not intense anywhere within this interval. Main types of veins include early (deformed) quartz-plagioclase-chlorite veins (like those common in previous interval) and later, planar quartz-calcite-hematite-dolomite-chlorite veins that are generally about 1 cm wide.

Sulphide phases are very rare. A massive plagioclase with minor quartz vein at 235.5m contains about 1% fine-grained chalcopyrite and minor, fine-grained pyrite occurs near the bottom of the hole in bedding parallel layers.

Objective Up-dip test of suspected sub-vertical mineralization encountered in HV94-07	

Summary Log:

0-11.3 m CASING

11.3-316.1 m SILTSTONE (slts): Light-dark green, metasomatized siltstone of the Fairchild Lake Group. Locally altered to dark green/black (amphibole?). Texture varies from well laminated to crackle breccia with rotated clasts of laminated siltstone over a scale of centimeters.

316.1-436.0 m HETEROLITHIC BRECCIA (bht): Grey-green-brown heterolithic breccia with clast sizes of 0.01 cm to 10 cm. Locally varies to homolithic breccia and diorite over a scale of meters.

MINERALIZATION:
11.3-30.4 m 0.3-0.5% CP
11.3-214.8 m 0.1% SP
214.8-436 m 0.3-3.0% CP, 0.5-2.0% PY

ALTERATION:
11.3-214.8 m SI-CL-MS-CA
214.8-436 m CA-CL-SI-BI

Notes:

-alteration changes from moderate Silicification - Chlorite to strong Calcite - Chlorite @ ~214m. Mineralization also significantly picks up @ 214m.

-trace Sphalerite from 0-180m appears to disappear in the Chalcopyrite mineralized zone. Possible Zunyite zonation similiar to porphyry systems. Lower temp Zunyite halo grading to higher temperature cp-py mineralization near breccia.

178-214.8m Chalcopyrite mineralization is structurally controlled and occurs along fractures and as blebs within crackle breccia.

214.8m Chalcopyrite - Pyrite mineralization is much more pervasive and occurs as disseminations and blebs throughout.

26.00	-59.20	287.50

Project: Werneckes **Hole Number:** HV07-20

From	To	Rocktype & Description
0.00	18.80	OVBN OVERBURDEN: casing to 18.3 m, core recovered beginning at 18.8 m
18.80	51.70	ph PHYLLITE: pale grey to light brown with an ubiquitose mm-scale foliation. Foliation surfaces have a characteristic sheen owing to fine-grained phylosilicates. Magnetite is common and occurs in two main styles: 1) as disseminated euhedral isolated grains up to 2 mm across and 2) as foliation-concordant bands comprising >50% euhedral to subhedral magnetite with minor chlorite, pyrite, Fe-carbonate and silica. Three grains of chalcopyrite occur within this interval and are generally in close association with magnetite. These magnetite-rich bands are typically foliation-concordant but also occur oblique to the main fabric where they are variably folded or boudinaged - depending upon their original angle to the principal compressive stress direction. The main foliation is axial-planar to these folds. This indicates that the foliation is a composite fabric where bedding and cleavage (S1) are nearly parallel. A subtle lineation occurs on foliation surfaces and is parallel to magnetite band fold axes. This lineation is likely an S0/S1 intersection lineation. Later (D2) kink bands are common at low angles to core axis. These bands deform

		SILTSTONE: grey to brown, moderately oxidised. Common manganese-coated fractures and orange-brown fracture coatings. Protolith is somewhat equivocal here but bedding is locally present. Across other small sections the texture is more massive and appears granitic / plutonic at 56.1m (diorite?)
		Magnetite is common and occurs both disseminated and in bands like previous interval although the banding is more common here. Specular hemaetite, silica and pyrite are more common as well.
		Approaching the bottom of the hole only gravel and broken rock fragments were recovered. The hole was abondoned in favour of a -70 degree hole from the same site at this point due to concerns that the hole had been deflected closer to the surface. Downhole surveys are suspect due to high magnetite content.

Objective Up-dip test of mineralization encountered in HV94-03. Hole steepened after encountering bad ground in HV07-20.	

Summary Log:

0-15.5 m CASING

15.5-58.8 m PHYLLITE (ph): pale grey to light brown with an ubiquitose mm-scale foliation. Magnetite is common as disseminated euhedral isolated grains and as foliation-concordant bands, 3% magnetite, 0.5% specularite, minor pyrite

51.7-89.4 m SILTSTONE (slts): moderately oxidised, 6% magnetite, 1.5% specularite

89.4-117.1 m HOMOLITHIC BRECCIA (bhm): purple-green, minor crackle breccia, tr chalcopyrite, 3% specularite, moderate chlorite, calcite

117.1-201.6 m SILTSTONE (slts): mineralized with 1.5% chalcopyrite and 0.5% specularite from 117.1 to 135.4

201.6-216.4 m HOMOLITHIC BRECCIA (bhm): well-developed breccia texture, common chalcopyrite belbs, 1% chalcopyrite, 2% magnetite, localized specularite

216.4-374 m SILTSTONE / SLATE (slts/slt): strong calcite, moderate silica, 0.3% chalcopyrite, 3% magnetite, trace pyrite and hemaetite to 250 m. Stronger (0.8%) chalcopyrite from 273 to 354. Weaker alteration below 354 m and mineralogy is more likely metamorphic derived (garnet, biotite).

374.0 m = EOH

SILTSTONE: grey to brown, moderately oxidised. Upper contact is gradational. Common secondary Fe-oxide coated fractures and metre-scale zones of strongly broken core comprising manganese-stained, strongly oxidised siltstone. Bedding is locally discernable but alteration is quite strong obliterating most primary features. Locally (e.g. at 76.3m) texture is crackle breccia comprising sericite-altered sedimentary rock broken with a cement comprised predominantly of chlorite

Magnetite is common and occurs both disseminated and in bands like previous interval although the banding is more common here and generally concentrated in broader (5-10 cm) bands. Specular hemaetite, silica, calcite and pyrite are common in these bands. This Fe-oxide bands are locally folded suggesting they pre-date some fabric development.

		Magnetite-sulfide veins appear to increase down interval but oxidation is strong to intense so sulfide species are difficult to identify
		< @ 75.00 Bedding 27° >
89.40	117.10	bhm
		HOMOLITHIC BRECCIA: purple-green competent rock. Very good coring section with minimal oxidation. Texture is variable from in situ crackle breccia with 50 cm zones of consistent primary layering visible (indicating only minor brecciation) to zones with well-developed fragmental texture. Locally, fragments vary in colour and alteration suggestive of bht. This variability, however, is similar to the variability in sedimentary layering observed where the siltstone protolith is coherent. Therefore, it seems that this breccia body is derived from disintegration of a sedimentary sequence with minor primary variation.
		Breccia cement and fracture infill comprise predominantly bright green chlorite, specular hemaetite and calcite with minor pyrite. Fracturing has no apparent preferred orientation.
		Trace chalcopyrite locally occurs in associataion with chlorite-calcite fractures. The breccia is devoid of magnetite.

From	To	Rocktype & Description

SILTSTONE: moderately to strongly altered and mineralized with chalcopyrite. Colour is variable from grey, green, sandy brown and varies from cm-scale lamination to lamination. Colour is also reflected in alteration intensity. Bedding is generally descernible throughout but has been disrupted by fractures, small hydrothermal breccias and alteration such that the rock overall has a more massive appearance than the phyllite.

Surficial oxidation is locally strong to intense, particularly to about 150m and is conspicuous owing to secondary copper oxides (tenorite) and carbonates (malachite, azurite) coating fracture surfaces.

MINERALIZED ZONE FROM 117.1 TO 135.4:
« 117.10- 135.40 Calcite 3», pervasive and fracture coating
« Silicification 1.00*», localized and associated with small hydrothermal breccias

HOMOLITHIC BRECCIA: grey, conspicuous breccia texture throughout most of interval comprising fragment-supported, pebble-sized fragments. Bottom of interval looks to be more of a hydrothermal breccia / vein rather than Wernecke Breccia. Fragments are typcially grey, fine-grained and silceous - consistent with siltstone fragments. Cement is variable including grainy rock flour, calcite-chlorite and magnetite between 203.8 and 209.8.

Upper contact is oxidized and characterized by broken, rounded core. Contact is likely a fault.

Chalcopyrite mineralization is common as blebs and irregular masses associated with calcite and minor pyrite. Malacite commonly coats fractured, oxidised surfaces.

« Calcite 3.00*», pervasive and common along hariline fractures
« Chalcopyrite 1.00%»
« Pyrite 0.10%»
« 201.60- 216.40 Specularite 1.00%»
« mg 2.00%»
« Chlorite 2.00*»

« 203.80- 209.80 mg 15.00%» as breccia cement, locally a crackle breccia with fine magnetite cementing fragments

Lower contact is gradational into siltstone

From	To	Rocktype & Description
216.40	249.10	slts

SILTSTONE: green-grey-brown sedimentary rock. Colour varies from lamination to lamination and apparently with grain size which varies from mudstone to fine sandstone. Beds are typically 5 to 10 mm thick. Colour variation is probably due to alteration - including preferential alteration of more porous (i.e. more coarse) beds. Bedding orientation is convoluted and core axis angles are variable. Locally bedding is folded within core but an axial planar cleavage is not present or is very poorly developed.

From	To	Rocktype & Description
		Calcite is pervasive and occurs commonly within veins and along hairline fractures. Chlorite and magnetite are also common metasomatic minerals but tend to be more confined to certain laminations. Rare biotite occurs in several mm-scale books associated with calcite veins and small brecciated zones.
		« Calcite 3.00*»
		« Silicification 2.00*»
		« Chlorite 2.00*»

		SLATE / SILTSTONE: dark grey-black, finer sedimentary rock than previous interval. Well-bedded with cm-scale laminations. More coase (fine ss) beds are characterised by calcite-chlorite-garnet (metamorphic assemblage). Finer beds are siltstone with layers of distinctly brown-coloured fine grained mineral - interp as biotite.
		Locally bedding is strongly folded.
		Calcite veins and stockwork zones are present but less common than in previous interval and never contain chalcopyrite here.

		SILTSTONE: chalcopyrite-mineralised zone. Similar to 216 to 249 but with common chalcopyrite associated with calcite veins and veinlets (< mm wide). Colour is brownish-green-grey. Locally calcite veinlets are present only in the finer-grained (more competent) beds whereas the more coarse beds have not fractured to form these veins. A couple different morphologies exist incluing larger lensoid veins that have oblique, discontinuous veinlets emmanating from them - likely extension veins. No vein relation or style is common enough to draw much in the way of generalizations of the orientation of stress axes. Overall though, style is brittle and overprints bedding and metamorphic assemblages.
		Bedding is mostly at low core axis angles but locally is folded and irregular.
		« Calcite 2.00*»
		« Chlorite 1.00*» , generally associated with calcite-rich beds (preferential alteration of sandy layers) and locally with chalcopyrite
		« mg 2.00%»
		« Chalcopyrite 0.80%» , commonly in low angle calcite +/- dolomite veins
		« Pyrite 0.10%»
		« Biotite 1.00*» locally in calcite veins but common as fine-grained aggregates in bedding-concordant layers

Project: Werneckes **Hole Number:** HV07-21

From	To	Rocktype & Description
		Chalcopyrite increases in this zone and is most abundant in a fractured alteration / vein zone between 370.4 and 371.8. Biotite is also a common phase within calcite-calcopyrite veins
		« 369.00- 374.00 Biotite 2» « Chalcopyrite 1.00%» « Chlorite 2.00*»
		« 370.40- 371.80 Chalcopyrite 3.00%»
		374 = EOH, shut down 74m past target based on decreased chalcopyrite mineration between 354 to 369 and on low abundance of chalcopyrite from about 300 m.

Dip Tests By: Reflex	
Objective Updip test of mineralization in HV94-05 and HV94-08.	

Summary Log:

0.0-8.9 m CASING

8.9-83.4 m HETEROLITHIC BRECCIA (bht): moderate calcite, weak chlorite alteration, 0.3% pyrite, 1.5% specularite, localized chalcopyrite up to 2% (e.g. from 57.2 to 68.0 m)

47.0-50.0 m DIORITE (di): weak calcite, 0.5% specularite, broken contacts

83.4-83.8 m FAULT BRECCIA (fltbx)

83.8-340.0 m SILTSTONE (slts): moderately altered to 168 m with calcite-chlorite-dolomite and 0.8% chalcopyrite, 0.5% magnetite, weakly altered from 168 to 222 m. Strongly mineralized from 272 to 277 with 2.5% chalcopyrite but then alteration and mineralization decreases.

340.0 m = EOH

Project: Werneckes **Hole Number:** HV07-22

From	To	Rocktype & Description
47.00	50.00	di

DIORITE: medium-grained, green, contacts are broken and orientation unknown. More massive with few fractures and rare calcite veins.

« Specularite 0.50%» « Calcite 1.00*» minor reddish-brown alteration product, trace quantity, might be sphalerite or luecoxene.

From	To	Rocktype & Description
50.00	83.40	bht

HETEROLITHIC BRECCIA: Wernecke Breccia. Similar to unit above diorite.

« Calcite 2.00*» « Chlorite 2.00*»
« Specularite 5.00%» generally as disseminated subhedral to bladed grains

« 50.00- 51.40 0.3% Chalcopyrite »

« 51.40- 52.40 Silicification 3.00*» « Calcite 1.00*» distinct massive, pinkish unit with irregular contacts with breccia. Might be a large fragment os an alteration zone. Likely the former since a few similar, pebble-sized fragments occur in adjacent breccia

« 52.40- 65.00 Pyrite 3.00%» as euhedral, rounded grains up to about 3 mm that locally givethe rock a spotted appearence.

« 57.20- 68.00 Chalcopyrite 2.00%» mostly as blebs and fracture-controlled grains associated with chlorite and calcite. Locally coarse-grained chalcopyrite is intergrown with specular hemaetite within a fragment but this mineralisation is also (like all other chalcopyrite) associated with calcite along fracture and with chlorite. Specular hemaetite appears to be earlier and is likely a replacement of fragments. This feature is farily common within this breccia unit where some fragments are comprised of about 80% specular hemaetite.

« 62.00- 83.40 Dolomite 2.00%» , euhedral in caclite-chlorite veins

			FAULT BRECCIA: poor recovery, clay-rich fault zone. No sample because little material recovered.
83.80	168.20	slts	
			SILTSTONE: metasomatised sedimentary rock. Bedding is generally visible characterised by cm-scale laminations varying from fine sandstone to siltstone. Metre-scale hydrothermal breccias with calcite cement locally obliterate bedding. Generally this unit is light brown to darker green - most of this bleaching appears to be caused by alteration, although oxidation (surficial) is locally strong evidenced by brown, grungy carbonate and locally limonitic fractures.
			The unit is mineralised with chalcopyrite and minor pyrite. Specular hemaetite and coarse-grained magnetite are locally present typically forming dark bands.
			Calcite is common as hairline fracture throughout, as pervasive alteration and as veins and breccia cement.

222.80 272.80 slts

SILTSTONE: more strongly altered rock. Colour variation depending on alteration intensity from dark brown to sandy brown. Locally hard, fine-grained alteration phase is localized along fractuers - albite?

Local chalcopyrite associated with calcite veins.

Calcite is weak to strong depending on the grain size of the protolith - more coarse beds have strong calcite.

0.00	11.20	OVBN CASING: no core recovered
11.20	136.00	slts SILTSTONE: light-dark green/brown, well laminated siltstones of the Fairchild Lake Group. Local crackle breccias of the siltstone with carbonate-chlorite goundmass. Abundant late Calcite - Quartz veining throughout carrying trace chalcopyrite and pyrite. Ductile and brittle deformation are both evident as the laminations are locally folded, occuring a varying angles to the core axis, as well as off-set by micro faults. The style of alteration is variable with pervassive moderate Chlorite - Silicification - Calcite alteration occuring within preferential layers (permeable?) perserving the original texture (bedding?) and also occuring pervassively throughout destroying the original texture locally. Alteration: « Chlorite 3.00*» « Silicification 2.00*» « Calcite 2.00*» « Biotite 1.00*» ??? core has a slight brown colour to it, possibly due to fine grained hydrothermal biotite. from 28.5-30.0m is a zone of strong Chlorite - Sericite alteration. The zone occurs nearly parallel with the core axis however and may only represent a thin vein of alteration. « 96.51- 124.00 Calcite 1.00*» « 124.00- 136.00 Calcite 2.00*»

Project: Werneckes **Hole Number:** HV07-24

From	To	Rocktype & Description

Mineralization:

Mineralization is genneraly controlled by Calcite veins and micro fractures. A few zones of broken up rock also contain Malachite along fractures likely due to fluid being able to flow along the fracture zones.

« 11.20- 36.10 Specularite 0.10%»
« 36.10- 44.80 Chalcopyrite 0.10%» « Malachite 0.10%» occuring within mm Calcite veins
« 44.80- 45.50 Chalcopyrite 0.50%» « Malachite 0.50%» zone of broken fractured rock
« 45.50- 55.00 Chalcopyrite 0.10%» « Malachite 0.10%»
« 55.00- 61.00 Chalcopyrite 0.50%» « Malachite 0.50%» mineralization occurs in several Calcite veins 2-10 mm wide that run parallel to core axis.
« 61.00- 73.00 Chalcopyrite 0.10%» « Pyrite 0.10%» « Malachite 0.30%»

« 36.10- 52.00 mg 0.50%» « Specularite 0.30%» occuring in veins with Calcite up too 3cm wide.
« 52.00- 76.00 Specularite 0.10%»
« 64.00- 136.00 Sphalerite 0.10%»
« 94.00- 97.50 Pyrite 0.10%» in Calcite veins
« 97.50- 102.30 Chalcopyrite 0.10%» « Malachite 0.10%» in Calcite veins

« 104.00- 136.00 mg 1.00%» as thin (mm) thick veins that are sometimes bedding parallel and sometimes not. They do not appear to be controlled by bedding, but may preferentially occur along bedding.

Structure:
< @ 38.40 highly frx with strong Chlorite and weak ja? alt flt/frx zone 45° 30cm >
« 42.60- 43.30 Calcite vein with frags of slts up too 5cm vein 30-25°»

« 44.80- 45.50 0.5% Chalcopyrite and Malachite with trace Chalcocite flt/frx zone 55°»
« 55.00- 61.00 several Calcite veins with Chalcopyrite - Malachite - Specularite at low (near paralell) angle to core. vein »
« 62.20- 63.20 Fault zone with Chalcopyrite - Malachite along

Objective To test for northern strike extension of the Hoover Central Zone at Radio Creek	

Summary Log:

0-5.7 m CASING
5.7-47.2 m HETEROLITHIC BRECCIA (bht): dark green - light grey with rounded-angular clasts mm to >10cm. Clasts comprise fine-grained sediments both massive and layered. Matrix dominately CA-CL and varies from grey to green depending on the intensity of CL alteration.
47.2-101.1 m HOMOLITHIC BRECCIA (bhm): light-dark grey with subangular-rounded clasts 1-10 mm in size. Texture varies from a matrix supported massive breccia to a micro-breccia in which the original textural layering of the silstone is present.
101.1-129.9 m DIORITE (di): dark green-black, fine-medium grained massive diorite with moderate CL and weak CA-SI-EP alteration. Unit is magnetic throughout and contains trace-1% pyrite and specular hematite.
129.9-413.0 m HETEROLITHIC BRECCIA (bht): similar to the heterolithic breccia unit described above. 0.3-2% CP mineralization from 169.7-413m.

MINERALIZATION:
5.7-413.0 m 0.1-5.0% HS, 0.1-1.0% PY, 0-2.0% MG
169.7-413.0 m 0.3-2.0% CP

ALTERATION:
5.7-413.0 m wk SI, wk-mod CA, wk-mod HE, wk-int CL

Project: Werneckes **Hole Number:** HV07-25

From	To	Rocktype & Description
0.00	5.70	OVBN CASING: No core recovered
5.70	47.20	bht HETEROLITHIC BRECCIA: dark green - light grey, heterolithic Wernecke Breccia. Clasts vary from well rounded to angular, mm to >10cm, and are locally red owing to hematite alteration. Clasts comprise fine-grained sediments that are both massive and layered. The matrix varies from deep green color to grey depending on the intensity of chlorite alteration. The core is extremely competent. Although the core is so competent, it is not particularily hard. The clasts have undergone moderate silicic alteration in general, but the matrix is relatively soft being made up of Calcite - cl. Vary few brittle fractures or veins are seen in the core, most Calcite veins are irregular in shape and appear to be syn-formational to the breccia. Mineralization is limited to trace amounts of Chalcopyrite - Pyrite and <1% hs. Alteration: « 5.70- 23.50 Chlorite 3.00*» « 23.50- 47.20 Chlorite 2.00*» « 5.70- 47.20 Calcite 2.00*» « Silicification 1.00*» « 5.70- 18.30 Hematite 2.00*» « 18.30- 47.20 Hematite 1.00*» Mineralization: « 5.74- 47.20 Specularite 0.10%» « 44.10- 46.80 Pyrite 0.50%» « 44.70- 45.40 mg 2.00%» Structure: Diorite dyke « 44.70- 45.40 dyke with disseminated mg and py. Diopside 35°»

HOMOLITHIC BRECCIA: light-dark grey homolithic Wernecke Breccia. Clasts are subangular to rounded, 1-10 mm, grey/black in color, and composed of fine grained sediments (siltstone). The texture vaires from a matrix supported massive breccia to one in which the original textural layering of the siltstone is present, but the silstone has been micro-brecciated into clasts < 5mm. A few sections of heterolithic breccia < 3m thick occur within the unit. The core is very competent, however more brittle features (planar veins and fractures) are seen then in the bht unit above. Alteration is dominatly Calcite - Chlorite with weak silicic. Mineralization is limited to trace Chalcopyrite - Pyrite and < 1% hs.

Alteration:

« Calcite 2.00*» « Silicification 1.00*» « Chlorite 2.00*» « Hematite 1.00*»

« 81.00- 82.50 Calcite 3.00*»
« 82.50- 101.10 Calcite 2.00*»

Mineralization:
« Specularite 0.10%»

Structure:
< @ 58.10 Calcite vein 40° 3cm >
< @ 60.10 Calcite with PY blebs vein 55° 1cm >
< @ 75.70 Calcite - Specularite vein 90° 7cm >< @ 78.60 Calcite - Specularite vein 5cm >
« 82.50- 83.00 bht » gradational contact
« 88.40- 90.70 bht » gradational contact

From	To	Rocktype & Description
101.10	129.90	di

DIORITE: dark green-black, fine-medium grained massive diorite. Moderate chlorite and weak calcic-silica-epidote alteration. Unit is more fractured and contains more planar veins than units above. Due to more fracturing and veining, this unit does not contain the long complete sections of core seeing in the breccia's above. The contact between the homolithic breccia above and the diorite occurs over a 2cm wide, gradational zone that is marked by an increase in calcic alteration. The unit is magnetic throughout containing up too a few percent magnetite. Trace-1% pyrite and specular hematite also occur as disseminations within the diorite.

Alteration:

« 101.10- 114.70 Calcite 1.00*»
« 114.70- 116.40 Calcite 2.00*»
« 116.40- 129.90 Calcite 1.00*»

« 101.10- 129.90 Chlorite 3.00*» « Epidote 1.00*» Chlorite is pervasive while Epidote is more fracture controlled.

Project: Werneckes **Hole Number:** HV07-25

From	To	Rocktype & Description
		« Silicification 1.00*» locally moderate
		Mineralization:
		« mg 7.00%» pervasively disseminated throughout the diorite. Occuring as fine grained clusters likely secondary? but not sure.
		« 101.10- 120.00 Pyrite 0.30%» typically disseminated
		« 120.00- 122.00 Pyrite 1.00%»
		« 122.00- 129.90 Pyrite 0.30%»
		Structure:
		Unit is mostly massive. Calcite and Epidote veins are found at several orientations but do not contain any mineralization. The unit is locally fractured with evidence of oxidation, but no significant faults or fracture zones are seen.
129.90	413.00	bht
		HETEROLITHIC BRECCIA: color and texture is similar to heterolithic breccia described above. This unit is much more fractured than the earlier one and locally contains significant chalcopyrite mineralization. Alteration is primarily Calcite - Silicification - Chlorite - Hematite but varies in intensity throughout the unit. A narrow (1m) section of Chalcopyrite - mg mineralization occurs at 158m. Significant Chalcopyrite mineralization (1-2 %) begins at 169.7m coinciding with the first appearance of talc in the hole. Talc appears to be occuring with or replacing calcite. It is unclear if zone of significant mineralization is part of the same breccia unit, or if is a seperate breccia event that occured later.
		Alteration:
		« 129.90- 161.00 Chlorite 2.00*»
		« 161.00- 166.00 Chlorite 1.00*»
		« 166.00- 266.40 Chlorite 2.00*»
		« 266.40- 290.10 Chlorite 1.00*»

DRILL LOG

Project: Werneckes	**Collar Elevation (m):** 912.9
Hole HV07-26	**Azimuth (º):** 240
Location: 7217475 m North, 535642 m East	**Dip (º):** -75.0
Logged by: N. Perk	**Length (m):** 327.20
Drilled by: Foraco	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/06/17 **Date Completed:** 2007/06/25	
Dip Tests By: Reflex	
Objective To test for mineralization up-dip from HV07-19 and HV94-07	

Summary Log:

6.4-233.2 m PHYLLITE (ph): Grey-black, fine-grained with alternating very-fine grained dark layers and slightly coarser light grey layers. Foliation defined by alignment of fine grained mica and appears to be bedding parallel. Asymmetric folds and micro faults occur throughout section.

233.2-260.9 m HETEROLITHIC BRECCIA (bht): Dark grey with sections of dark green (cl) and dark red (he) due to alteration. Unit contains sections of crackle breccia, homolithic breccia, phyllite and siltstones that may be large clasts.

260.9-327.2 m SILTSTONE (slts): Pale-dark green, fine grained, finely bedded silstones. Layered texture is locally destroyed by intense alteration. Unit is cut by numerous sets of calcite and quartz veins. Contact with above breccia occurs over several meters of mixed siltstone, breccia, and crackle breccia. The contact between these individual rock types is sharp.

MINERALIZATION:

180.9-233.2 m	1.0-5.0% MG
233.2-260.9 m	3.0-5.0% HS
281.0-308.0 m	5.0-10.0% MG
319.3-327.2 m	1.0-2.0% CP

ALTERATION:

6.4-233.2 m	str MS, wk-str CA, wk CL
233.2-327.2 m	mod-str SI, wk-mod CL, wk-mod CA

Downhole surveys:

0.00	-75.00	240.00

Project: Werneckes **Hole Number:** HV07-26

From	To	Rocktype & Description
0.00	6.40	OVBN CASING: No core recovered
6.40	233.20	ph PHYLLITE: grey-black, fine-grained phyllite of the Fairchild Lake Group. Bedding alternates between very fine-grained dark layers to fine-grained light grey layers typically < 2mm thick. A foliation is defined by the allignment of fine-grained mica (sericite, muscovite?) and appears to be bedding parallel. Asymetric folds and micro faults occur throghout the section. Multiple stages of veining (mostly Calcite and qz) must have occured as some veins are folded and faulted while others are not. Alteration: « Sericite 3.00*» « Calcite 1.00-3.00*» pervassive and as veins. Calcite alteration shows variation likely due to the grain size of the primary layers within the package. Coarser layers being more permeable were more condusive to fluid flow and became more strongly altered. « Chlorite 1.00*» Mineralization: Mineralization is mostly in trace amounts so it will not be entered as actual values. 0-98m Pyrite occurs in trace amounts as euhedral crystals within Calcite veins mostly and locally as blebs. 98-180 Trace Chalcopyrite and mg. Chalcopyrite occurs as small blebs and stringers associated with Calcite veins. mg occurs as blebs in Calcite veins and also as desseminations or a replacement within thin (< 2cm) layers parallel to bedding. Pyrite mineralization appears to decrease in this section. This may represent a slight zonation of distal Pyrite mineralization changing to Chalcopyrite - mg as we approach the main zone (or breccia?).

		dark red (hematite) due to alteration. The unit is highly variable with sections of crackle breccia, homolithic breccia, phyllite and siltstones that may be large clasts. The contact between the breccia and the overlying phyllite is sharp and appears to be intrusive with the breccia truncating bedding in the phyllite. At the contact, 3-5% magnetite in the phyllites is exchanged for 3-5% specular hematite in the breccia. Alteration: « Silicification 3.00*» pervassive silicification of the breccia « Calcite 1.00*» « Chlorite 1.00*» « Hematite 1.00%» Mineralization: « Specularite 3.00-5.00%» « Pyrite 0.10%»
260.90	327.20	slts
		SILTSTONE: Pale-dark green, fine-grained and finely bedded siltstones of the Fairchild Lake Group. Layered texture is localy destroyed by intense alteration. Unit is cut by numerous sets of Calcite and Quartz veins. Contact with above bht occurs over several meters of mixted silstone, breccia, and crackle breccia although the contact between these individual rock types can be sharp. In this respect, the contact should be thought of as a zone, rather than a sharp intrusive contact. Alteration: « Chlorite 2.00*» « Calcite 2.00*» « Silicification 2.00*» the alteration of this unit is stronger than seen in units above and occurs pervassively.

Dip Tests By:	
Objective To test for the high grade mineralized zone encountered at the bottom of hole HV07-26.	

Summary Log:

0-3m CASING

3- 13.5m SILTSTONE (slts): olive green, mMS, wCL-SI, 0.5% TOR alteration. 3% MG. Trace SP.

13.5- 90.9m SILTSTONE (slts): olive green, moderate MS, weak CA-CL-SI-AB?, 0.5% TOR alteration, trace native copper and possible cuprite on oxidized fractures at 57.2m. 0.3% CP up to 25% CP locally.

90.9- 204.7m SILTSTONE (slts): sCL, wCA-MS. Trace CP

204.7- 267.4m SILTSTONE (slts): well mineralized at top of interval (2% CP) decreasing to bottom (0.5% CP). sCA. mCL-CA.

267.4- 268.2m SHEAR ZONE (fltbx): strongly foliated bht. 2% PY

268.2- 310.5m HETEROLITHIC BRECCIA (bht): mCA, wCL. 0.1% CP, 3% HS, 1% MG

310.5m EOH

Project: Werneckes **Hole Number:** HV07-27

From	To	Rocktype & Description
0.00	3.00	OVBN CASING: no recovery
3.00	13.50	slts SILTSTONE: light grey to green, coherent, laminated rock. Unmineralized. Bedding is typically at low angle to core axis. Magnetite is common « 3.00- 13.50 mg 3.00%» as irregular blebs and as 5 mm wide beds with about 50% medium-grained magnetite (i.e. preferential replacement). Note that the next interval is mineralized but magnetite is absent. Trace, disseminated reddish sphalerite, « Sphalerite 0.01%» Alteration is dominated by silica-sericite-chlorite with minor black tourmaline. « Sericite 2.00*» « Chlorite 1.00*» « Silicification 1.00*» « Tourmaline 0.50%» , identification based on colour and hardness and strongly euhedral (short stubby) crystal form, area of massive tourmaline at 6.9 m Petrographic Sample: HV07-27 6.8m tourmaline? black stubby, euhedral mineral in quartz < @ 7.20 bedding 14° > < @ 10.60 bedding 38° >
13.50	90.90	slts SILTSTONE: coherent, well-laminated, pale olive green to dark grey sedimentary rock. Top of this unit defined by the prescence of chalcopyrite which varies across this interval from trace to 2%. Also the lack of magnetite was noted in this interval - chalcopyrite zone begins where magnetite disappears. Trace red sphalerite is disseminated throughout and locally seems to be coeval with chalcopyrite. Typical texture comprises olive green rock with 30% dark grey to black mm-scale layers that are interpreted to be preferentially altered beds (although this colour could be a primary effect too). Locally, at least, this dark colouration

Project: Werneckes **Hole Number:** HV07-27

From	To	Rocktype & Description
		is due to fine-grained tourmaline alteration.
		« Sericite 2.00*» « Silicification 1.00*» « Chlorite 1.00*» « Calcite 1.00*» « Dolomite 1.00%» « 13.50- 90.9 Tourmaline 0.50%» « Albite 1.00», not possitive on albite identification - see petrographic report
		Overall sulphide content of « Chalcopyrite 0.03%» « Sphalerite 0.01%»
		COPPER MINERALIZED ZONE (19.5 to 26.4 m): Characterized by several irregular, ragged-shaped, veins of massive chalcopyrite with minor pyrite, typcially as fine rims around the more massive chalcopyrite. Although irregular, the chalcopyrite-bearing veins are typically at high angle to core axis. These veins are generally sulphide-only, but earlier quartz carbonate veins are also common in this interval. Common neoticite along fractures.
		« 19.50- 26.40 Chalcopyrite 1.50%» « Pyrite 0.20%» , moderately hard, bone coloured alteration phase near the strongest mineralized zone
		Petrographic Sample: HV07-27 23.8m albite? nature of alteration and mineralization
		COPPER MINERALIZED ZONE (51.0 to 59.0 m): Elevated chalocpyrite « 51.00- 59.00 Chalcopyrite 1.00%» « Molybdenite 0.01%» trace molybdenite at 54.0 m associated with quartz vein, also minor native copper dendrites along fracture surface and possibly cuprite as pink-red, resinous secondary crystal growth, euhedral. Native Copper also along stronly oxidised fracture at 57.2 m. Overall, zone is moderately oxidised « Malachite 1.00%» « Jarosite 1.00*» « Geothite 1.00%». Chalcopyrite generally occurs as irregular blebs and along fractures. Abundant, irregular stock-work of Chalcopyrite at « 54.80- 55.20 m Chalcopyrite 10.00%» . Common neotocite along fractures.
		« 87.60- 90.90 Chlorite 2», chlorite increases towards bottom on interval. Contact is gradational and defined here by a change from sericite-albite-chalcopyrite to chlorite-calcite-pyrite dominated assemblages.
		< @ 13.60 calcite-chalcopyrite vein 40° 5mm >

From	To	Rocktype & Description
		Protolith is equivalent to the above unit but alteration and mineralization differs. This unit generally lacks chalcopyrite. To about 125 m, 2-15 cm wide intervals with abundant coarse-grained pyrite as large almalgamations and blebs associated with calcite and / or quartz veins are common. At 96.4 m, pyrite is associated with elevated scintillometer counts up to 415 cps.
		Calcite veins locally have tourmaline selvedges and although they cut sharply across bedding, vein margins are typically cauliflower-shaped. Some calcite veins contain cm-scale irregular masses of a green-brown, prismatic phase - amphibole? Petrographic sample HV07-104.6 collected to identify this mineral but herein called hornblende. Rare gypsum-calcite veins below 153.3 m.
		« Chlorite 3.00*» « Calcite 1.00*» « Sericite 1.00*» « Chalcopyrite 0.01%»
		« 90.90- 144.00 Sphalerite 0.01%» fine, red sphalerite, absent below about 144 m
		« 110.00- 193.5 Sericite 2.00», lighter, soft, sandy brown with less chlorite
		« Chlorite 2.50*» , magnetite increases as fine bedding-concordant layers « 120.00- 136.00 mg 1.00%»
		« 126.00- 130 Specularite 0.50%» associated with discrete, planar quartz veins
		« 138.00- 193.50 Tourmaline 0.50%»
		« 162.90- 163.80 Chalcopyrite 0.50%» « Pyrite 2.00%» « Tourmaline 3.00%» « Silicification 2.50*» fractures healed by quartz, bedding discordant slip planes

193.50	204.70	slts

SILTSTONE: similar to previous interval but with minor chalcopyrite mineralization. Represents a transitional zone between upper unmineralized interval and lower, strongly mineralized interval.

Coherent, well-laminated sedimentary rock. Pale brown to olive green to grey. Colour typically varies between layers.

« Chlorite 2.00*» « Sericite 2.00*» « Silicification 1.00*» « Calcite 2.00*» pervasive calcite particularly in movre coarse-grained beds;« Tourmaline 2.00%» generally associated with fractures, also forming mm-scale veins, appears coeval with chalcopyrite; « Chalcopyrite 0.30%» generally as fracture-connected blebs and with thin planar to irregular calcite veins.

204.70	219.00	slts
		SILTSTONE: Chalcopyrite mineralized zone. Well-bedded, coherent, competent rock; pale brown to grey. Bedding at a consistently low angle to core axis.
		Well mineralized with common fine, fracture-controlled and lesser disseminated chalcopyrite and conspicuous irregular chalcopyrite veins with ragged margins. Locally forming mesh-texture and chalcopyrite-cementing stockwork zones. These zones consistently cut core axis at a high angle, although locally sulphides have also precipitated along bedding planes. Locally pyrite forms intimate intergrowths with chalcopyrite. Euhedral tourmaline forms selvedges to mineralized areas. Magnetite is locally present within chalcopyrite patches.

DRILL LOG

Project: Wernecke	**Collar Elevation (m):** 1325.0
Hole PG07-01	**Azimuth (º):** 120
Location: 7194720 m North, 537818 m East	**Dip (º):** -50.0
Logged by: T. Branson	**Length (m):** 152.40
Drilled by: Cabo	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/09/27 **Date Completed:** 2007/10/02	
Dip Tests By: Flexit	
Objective To test the Pagisteel Fault valley near the mineralized felsenmeer.	

Summary Log:

0-18.29m CASING

18.29-55.3m BRECCIA (bht,m): dark purple grey with red HE altered beds. wCL, wHE, wKF. Trace PY, CP. Faulting in lower part of unit.

55.3-82.6m METASOMATISED SEDS with GRAPHITIC ARGILLITE (mts/fltg): black, heavily sheared argillite found throughout interval. Sediments grey. sSI, sAB, sCB, wCL. Trace CP, PY. @71.5-73m massive sulphide unit with 35% HS, 15-50% PY.

82.6-117.3m BRECCIA/SILTSTONE (bht,m): dark purple grey to green. wCL, mKF, sMS, wSI. Trace PY, CP. Fault gauge throughout interval.

117.3-126.5m COPPER MINERALIZED ZONE: green and white. sCL, mSI. 5% PY, CP and higher locally.

126.5-152.4m SHALE/BRECCIA (shl, bht,m): black and locally grey. Topped by fault gauge. wCL, m-sSI. Trace PY, CP, MO, HS.

152.4m EOH

Project: Werneckes **Hole Number:** PG07-01

From	To	Rocktype & Description
		< @ 23.25 quartz vein 40° 10cm >
		Lower contact has poor recovery up to a quartz vein that terminates the monolithic breccia < @ 23.37 Contact 40° >
23.37	24.90	bht
		HETEROLITHIC BRECCIA. Dark purplish grey. Weakly chloritized along fracture surfaces and within quartz stringers. Clasts composed of coarse-grained to pebble sized quartz, hematized and potassic clasts, as well as host rock clasts, mainly angular. Hematite forms along edge of quartz clasts and blowouts.
		Mineralization: « Specularite 0.10%» formas as small bladed crystals along edges of quartz clasts and blowouts
		Alteration: « Chlorite 1.00*» « K-feldspar 1.00*»
		Structure: No significant structures
		Veining: « quartz stringers 1% 1mm» irregular orientations < @ 23.50 quartz vein 40° 1cm >
		Lower contact has poor recovery and reverts back to the monolithic breccia seen above this section.
24.90	29.40	bhm
		MONOLITHIC BRECCIA. Dark purplish grey. Host rock, with varying colour from dark grey to purplish has been weakly brecciated by quartz-carbonate +/- chlorite +/- hematite veins and veinlets, also hosting trace pyrite near the bottom contact.
		Mineralization: « Specularite 2.00%» mainly associated with quartz carbonate veins and rarely disseminated. « Pyrite 0.01%», trace most of the section, but near the bottom contact is hosted in quartz veining and stringers.

From	To	Rocktype & Description

related to quartz-carbonate veins and veinlets. Hematite also related to veining, forming as selvage. The host rock has been weakly brecciated by the veining and is only composed of fine-grained sediment (siltstone?) Reddish bands are likely hematite altered beds.
Tiny, 1mm, possible metamorphic porphyroblasts hosted in relict bedding, more abundant than in previous section where they were present.

Mineralization:
« Specularite 0.10%» mainly related to veining, but also weakly disseminated
« Chalcopyrite 0.01%», trace amount

Alteration:
« Specularite 2*», forms bands replacing relict bedding
« Chlorite 1.00*»

Structure:
< @ 33.00 bedding 32° >
< @ 35.40 bedding 25° >

Veining: 35
« quartz+/-carbonate veinlets 1% 2-5mm» randomly oriented, hosting hematite and chlorite.

Other:
< @ 33.60 Heterolithic brecciation 90° 10cm >

Lower contact is semi sharp but irregular, proabaly caused by brecciation.

36.40 38.22 bht

HETEROLITHIC BRECCIA.
Dark grey. Weakly chloritized. Clasts composed of mainly angular coarse-grained, some >pebble sized, quartz, calcite, hematized and potassic clasts, as well as host rock clasts. Matrix composed of fine to medium grained components of the clasts.

Mineralization:
« Specularite 0.10%» forms as selvage on veining and disseminated in groundmass

32°

25°

From	To	Width	Sample	Au ppm	Ag ppm	Cu ppm	U ppm	Mo ppm
36.40	38.22	1.82	244238	-0.005	0.03	34	5.5	0.55

Project: Werneckes **Hole Number:** PG07-01

From	To	Rocktype & Description
		Alteration: « Chlorite 1.00*» , picks up in intensity at contact to moderate, but only over a small interval < @ 38.20 Chlorite 2* >
		Structure: No significant structures
		Veining:« quartz carbonate stringers 1% 1mm»
		Lower contact is difficult to distinguish but an increase in chlorite alteration and a loss of clasts were the deciding factors.
38.22	55.30	bhm
		MONOLITHIC BRECCIA. Grey to pinkish grey. Weak chloritic, hematitic and potassic alteration throughout. Varying degrees of calcite veining from 1-5% forming veinlets and stringers. Trace specular hematite. Unit is cut by several faults and terminates in a large fault gouge zone, possibly the Pagisteel fault. Unit's appearance is similar to monolithic breccias above in the hole.
		Mineralization: « Specularite 0.10%» , weakly disseminated, and commonly associated with calcite.
		Alteration: « Chlorite 1.00*» « K-feldspar 1.00*» « Specularite 1.00*», « 53.35- 55.30 Clay 3.00*»
		Structure: < @ 43.90 Fault > < @ 45.60 Fault > < @ 54.65 Fault 70° >, graphitic and black, probably a small offshoot of the vein at bottom contact
		Veining: « calcite stringers 1.00-5.00% 1.00-2.00mm», irregularly oriented
		Other: < @ 49.25 brecciation texture 20cm > changes to a network of grey carbonate fragmenting the host rock.

Project: Werneckes **Hole Number:** PG07-01

From	To	Rocktype & Description
		Lower contact appears to be related to a quartz+/-calcite vein that is in contact with the breccia, although the recovered core is highly broken.
83.75	105.30	bht
		HETEROLITHIC BRECCIA. Pale greyish green. Strongly sericitized, weakly chloritic, siliceous and potassic. Matrix composed of fine grained calcite, sericite, quartz and chlorite, hosting rounded to angular, coarse grained to cobble sized earthy hematite, kspar, sericite and silica altered clasts. Trace pyrite, hematite and chalcopyrite.
		From 96.2 to 102.5, the sericite alteration hosts an unusual texture of short (1-2mm) elongated crystals that resemble the shape of biotite
		Mineralization: « Specularite 0.10%», « Pyrite 0.20%», weakly disseminated throughout. Trace « Chalcopyrite 0.01%»
		Alteration: « Sericite 3.00*» « K-feldspar 1.00*» « Chlorite 1.00*» « Silicification 1.00*» throughout.
		Structure: < @ 96.30 possible bedding 43.00° >, although within the breccia, it may not signify anything.
		Veining: « 83.75- 105.30 calcite+/-quartz veining 0.5% 1-5mm», forms as veinlets in irregular orientations < @ 95.90 calcite+/-quartz vein 62° 1cm >
		Other: « 83.80- 86.90 wash out 5ft» « 86.90- 89.90 wash out 5ft», Both these sections have poor recovery and are heavily broken.
		Lower contact is defined by decreasing sericite alteration and the brecciation of a dark purplish grey siltstone lacking the altersation seen in this heterolithic breccia.

Project: Werneckes **Hole Number:** PG07-01

From	To	Rocktype & Description
		MONOLITHIC BRECCIA/SILTSTONE.
		Dark purplish grey. Weakly chloritic, potassic and hematitic. Beginning of unit is brecciated by sericite altered matrix hosting 1% pyrite from 105.3 to 106.0, gradually grading into a calcareous matrix with grey silicified host rock, either siltstone or shale, with no pyrite over 10 cm then becomes weakly crackle brecciated by calcite stringers for the rest of the unit. Trace hematite and chalcopyrite throughout.
		From 106.0 then recovered core is highly broken with few pieces over 5cm
		Mineralization:
		« 105.30- 106.00 Pyrite 1.00%»
		« Specularite 0.01%», « Chalcopyrite 0.01%»
		Alteration:
		« Sericite 2.00*» from 105.3-106.0m
		« Chlorite 1.00*» « K-feldspar 1.00*» « earthy Specularite 1.00*»
		« Clay 4.00*» from 114.3 to 117.3, with very poor recovery. 3m corresponds to 55cm of actual core recovered.
		Structure:
		< @ 106.60 fltg 5cm >
		< @ 108.45 fltg 20cm >, no competence, and mainly clay
		« 114.30- 117.30 fltg 3m»
		Veining:
		« 106.00- 114.30 calcite veinlets 1% 1-3mm»
		Lower contact is broken and rubbly with no clear indication of the nature of the contact.
117.30	126.50	mts
		COPPER MINERALIZED ZONE.
		Poor recovery
		Green and white. Strong chlorite alteration, moderate silicification. 5% chalcopyrite, 5% pyrite, and locally up to 30% for both minerals. They forms as a network entwined with quartz stockwork for the first 3m, with trace hematite.
		The next 3m there is an increase in hematite which is disseminated, as well as

		Veining:
		Boudinage « quartz+/-carbonate veins 5% 1-3cm»
		Lower contact is somewhat arbitrary, but is defined by appearance of distinguishable clasts, although the following unit could be just a more intensely altered section of metasomatized shale because the bottom of the unit grades back into shale.
133.36	137.20	bht
		HETEROLITHIC BRECCIA.
		Grey. Strongly silicified, moderately albitized, weakly chloritic throughout. Potassic, albitic, sericitic and siliceous clasts hosted in the breccia. Clasts are difficult to identify as the matrix and clasts blend into one another. Pyrite is disseminated and hosted in chloritic veinlets. Hematite is weakly disseminated and locally forms in small (1-3mm) blebs. Magnetite is also locally disseminated within the breccia over the same interval as the hematite. Trace chalco disseminated throughout, and is also hosted in quartz +/- carbonate veins near lower contact.
		This unit may represent an intense metasomatic event altering the host shale and is not a typical Wernecke Breccia, although the unit is highly fragmented.
		Mineralization:
		« Pyrite 1.50%» disseminated and hosted in chloritic veinlets
		« 134.30- 135.45 mg 2.00%» , disseminated
		« Specularite 0.20%»

		Structure:
		< @ 137.00 Laminations 25° >, begin to see laminations following in the same orientation as the bedding in the lower unit
		Veining:
		« carbonate veinlets 0.5% 1-2mm», irregular orientations
		< @ 135.80 carbonate+/-quartz+/-chalcopyrite vein 28° 5mm >
		Lower contact is defined by change to visible bedding and is formed by breccaition of the lower metasomatized shale by a quartz carbonate blowout, hosting chalcopyrite.
137.20	152.40	shl
		SHALE.
		Black and locally grey. Upper contact is strongly albitized, but grades out after 50 cm. Moderately silicified up to 145.45, where a 1.7 meter fault cuts through the unit and from there on, is no longer silicified. Also, after the fault, bedding becomes more horizontal compared to the upper part of the unit. Weakly chloritic throughout. From 139.0 to 144.8, 1% quartz+/-pyrite+/-chalco veinlets form mainly along bedding, as well as having some irregularly oriented veinlets Also hosted in the veinlets is a bright green mineral/alteration, which appears to be neither chlorite because it is too bright nor is it as dull as malachite. The color is aquamarine.
		After the fault gouge zone, bedding is near horizontal and graphite coats bedded surfaces as well as pyrite.
		Mineralization:
		« 137.20- 144.80 Chalcopyrite 0.50%» hosted mainly in quartz veinlets and rarely as fracture coating.
		« 137.20- 152.40 Pyrite 1.00%» hosted mainly in quartz veinlets and commonly as fracture coating.
		< @ 149.40 Chalcopyrite 10% 5cm >, rounded quartz+/-carbonate+/-chalco cobble clasts
		Alteration:
		« 137.20- 137.70 Albite 3.00*», « 139.00- 140.20 Albite 2.00*»
		« 137.20- 145.45 Silicification 2.00*»

Objective Test below the MDV Zone below the main outcrop.	

Summary Log:

0-3.0 m CASING
3-36.10 m SILTSTONE (slts): dark purple-red with varying grain size throughout unit. Irregular quartz-carbonate veins cut the interval. Layers of medium grained specular hematite also cut interval in cm-scale. Strong earthy hematite alteration.
36.10-98.05m BRECCIA (bht,m): grey to pinkish-purple with interbeds of siltstone throughout interval. Breccia varies from clast to matrix supported. CP 0.1%, HS 1-5%
98.05-121.5 m SILTSTONE (slts): description same as above although no occurrence of specular hematite beds. HS 1-5%, CP 0.1-0.2%, PY 0.1%
121.5-143.6 m SHEARED CHLORITE-SILTSTONE (slts): dark green to black owing to strong/intense chlorite alteration. Interval is highly fractured and is interpreted to be a regional shear zone. PY 0.1-0.25%, CP 0.1%, HS 0.1-1.0%, MC 0.1-1.0%
143.6-151.8 m METASOMATISED SEDIMENTS (mts): red to purple extensively altered sediments with patchy striped texture similar to “zebra texture” of mineralized zones. HS 1-5%, CP 0.1-0.25%, PY 0.1-0.25%
151.8-174.0 m SILTSTONE (slts): same as above. HS 0.1-3.0%
174-193.9 m BRECCIA (bht,m): same description as above. HS 0.1-1.0%, CP 0.1%, PY 0.1-0.25%
193.9- 202.5 m SILTSTONE (slts): same description as above. HS 0.1-0.5%, CP 0.1%

Project: Werneckes **Hole Number:** STM07-01

From	To	Rocktype & Description
0.00	3.00	OVBN CASING: nil recovered material comprising pebbles and gravel.
3.00	36.10	slts SILTSTONE: dark purple-red, some laminations present defined by variable grain size (some fine sandstone layers). Beds are typically cm-scale. Unit is cut by a pervasive bedding concordant foliation. From outcrop mapping this is evidently the persistent slately cleavage but the bedding/cleavage relation is not as obvious in core. Abundant (~8%) white to brick red irregular veinlets and stockwork cement cut the interval. Based on a weak reaction to HCl, these are likely dolomite. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting). The pervasive purple colour is also due to very fine-grained specular hematite grains. Interval is cut by several cm-scale layers of medium-grained specular hematite that are typically concordant to cleavage and bedding « Hematite 3.00*» as very fine grains and as coarse grains within veins also associated with chlorite and quartz. « Chlorite 1.00*» as vein selvedges « Dolomite 2.00*» moderate dolomite alteration throughout interval is moderately oxidized to about 7.7m and then is fairly fresh < @ 9.00 cleavage 31° > < @ 11.60 bedding 43° > < @ 19.30 cleavage 40° > < @ 26.00 cleavage 25° > « 26.10- 26.60 Quartz - Dolomite - Chlorite - Specularite - siderite vein 13°», discondant to bedding, deformed, reddish dolomite looks like it could be red (potassium) feldspar but it is difficult to be certain

36.10	98.05	bht

HETEROLITHIC BRECCIA: grey to pinkish-purple heterolithic breccia of unknown origin (hydrothermal or sedimentary?). The breccia unit is interlayered/interbedded with siltstone units. Clasts size ranges from mm-scale to 10cm in diameter with sub-rounded to angular clasts. Breccia varies on meter scale from clast supported to matrix supported. The fine-grained matrix comprises, in order of abundance, specular hematite, calcite, chlorite, and quartz(?).

Varying occurrences (5-15%) of white to brick red irregular veinlets and stockwork cement cut the interval. Based on a weak reaction to HCl, these are likely dolomite. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting). The pervasive purple colour is also due to very fine-grained specular hematite grains.

Alteration:

« Hematite 2.00*» locally weak. typically stronger on clasts than matrix.
« Chlorite 1.00*»
« Silicification 1.00*»
« Dolomite 3*» as stockwork veining

Mineralization:

« Chalcopyrite 0.10%» typically as disseminations within dolomite veins
« Specularite 1.00-5.00%» pervasive throughout

Summary Log:

Significant mineralization: URANIUM at 59.3-86.45m (180-382cps)

0-4.5 m CASING

4.5-55.4 m SILTSTONE AND HETEROLITHIC BRECCIA (slts, bht) interbedded. Beds range from 4-17m throughout interval. Grey to red/purple depending on HS alteration. Breccia varies from clast to matrix supported. PY 0.1%, CP 0.1%, HS 0.1-2.0%. Two massive sulphide beds are found; 30cm and 1.5m in width. These beds contain HS 5-50% and CP 0.1%. Irregular white quartz-carbonate veins cut interval.

55.4-87.9 m METASOMATISED SEDIMENTS (mts): red to purple fine grained altered seds. Patchy and discontinuous striped texture similar to "zebra texture" of mineralized zones. URANIUM MINERALIZATION found within this interval; from ~59.3-86.45m range of uranium mineralization 180-382cps. FL 0.1%, HS 0.1-1%

87.9-90.2 m SILTSTONE/SANDSTONE (slts, sst): same as above. Specular hematite beds form intervals mm to cm-scale throughout.
90.2-91.0 m MASSIVE HEMATITE (mxHS): same as above: HS 10-70%, PY 0.1-2.0%

HETEROLITHIC BRECCIA: grey to pinkish-purple heterolithic breccia of unknown origin (hydrothermal or sedimentary?). The breccia unit is interlayered/interbedded with siltstone units. Clasts size ranges from mm-scale up to 10cm in diameter with sub-rounded to angular clasts. Breccia is primarily matrix supported but is clast supported on smaller cm-scale layers. The fine-grained matrix comprises, in order of abundance, specular hematite, calcite, chlorite, and quartz(?).

Varying occurrences (1-5%) of white to brick red irregular veinlets and stockwork cement cut the interval. Based on a weak reaction to HCl, these are likely dolomite. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting). The pervasive purple colour is also due to very fine-grained specular hematite grains.

At 27.25m a petrographic sample was taken. This specific hand sample was chosen as it is a representative sample of this heterolithic brecciated interval. A better identification of the red (earthy hematite?) alteration as well as the mineralogy within the interval is desired from thin section anaysis.

SILTSTONE: black to red/purple, laminations present defined by variable grain size. Beds are typically cm-scale. Unit is cut by a pervasive bedding concordant foliation. Coarser grained sandstone beds cut through interval and tend to be cm to ~1m in thickness. These coarser grained beds are characterized by red/purple stained clasts which are oriented in direction of foliation. These clasts range in size from mm to ~5cm in diameter and are sub-rounded to sub-angular.

Quartz/carbonate veining occurs in metre-scale sections throughout this interval. The white to reddish veins are ragged and discontinuous and tend to follow foliation direction. Based on a weak reaction to HCl, these veins are likely dolomite. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting).

The pervasive purple colour throughout the coarser-grained matrix and siltstone material is due to very fine-grained specular hematite grains.

There are 3 separate sections throughout this siltstone interval of massive sulphides. These massive sulphide units are characterized by the higher concentrations of specular hematite and pyrite.

At 97.4m a petrographic sample was taken. An interesting texture characterizes this area defined by quartz carbonate veining which seems to be associated with chalcopyrite mineralization. Petrographic analysis would be good for this specific sample to see how the veining and mineralization are associated, if at

MASSIVE HEMATITE: black to purple coarse-grained unit. Interlayered with coarser grained clastic units. Clasts range from mm-size to ~1cm in diameter. Earthy hematite alteration within the clasts result in the purple colour. This interval is dominantly specular hematite (>50%) with approximately 10% pyrite.

Minor amounts of quartz/carbonate veining is present within this interval.

At 121.5 a petrographic sample was taken. Further inspection on the mineralogy and alteration within this massive hematite interval is desired.

Alteration:

« 120.70- 121.10 Geothite 2*»
« 120.70- 122.00 Hematite 1*»

Mineralization:

« 120.7- 122.0 Pyrite 0.5- 10.0% »
« 120.7- 122.0 Specularite 10.0- 70.0% »

Structure:

SILTSTONE: black to red/purple, laminations present defined by variable grain size. Beds are typically cm-scale. Unit is cut by a pervasive bedding concordant foliation. Coarser grained sandstone beds cut through interval and tend to be cm to ~1m in thickness. These coarser grained beds are characterized by red/purple stained clasts which are oriented in direction of foliation. These clasts range in size from mm to ~1cm in diameter and are sub-rounded to sub-angular.

Minor amounts (<0.5%) of white to red quartz/carbonate veining is seen within this interval. This veining tends to follow foliation but cross-cuts sporadically throughout. Based on a weak reaction to HCl, these veins are likely dolomite. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting).

The pervasive purple colour throughout the coarser-grained matrix and siltstone material is due to very fine-grained specular hematite grains.

Alteration:

« 122.00- 138.00 Sericite 1.00* » sericite alteration is blebby and discontinuous and tends to follow foliation direction but also forms halos of alteration surrounding specular hematite beds.
« 122.00- 141.30 Silicification 1.00* »
« 122.0- 141.3 Hematite 1-2* »
« 122.0- 141.3 Chlorite 1* »

Mineralization:

« 122.0- 141.3 Specularite 0.5- 50.0% » beds of specular hematite are found scattered throughout this unit. These beds range in size from 1- 10cm in width and have up to 50-70% specular hematite concentrations. Some of these beds of specular hematite follow bedding direction but there are occurrences where they are blebby and discontinuous. This mineralization could be interpreted as being produced from fluid flow through the area and mineralizing coarser grained beds.

Project: Werneckes **Hole Number:** STM07-03

From	To	Rocktype & Description
0.00	4.50	OVBN CASING: no core recovered
4.50	49.80	bht HETEROLITHIC BRECCIA: dark green to purple-red depending on degree of chlorite and earthy hematite alteration. The breccia unit is interlayered/interbedded with siltstone units. Foliation/bedding direction is evident from preferred orientation of clasts. Clasts size ranges from mm-scale up to 10cm in diameter with sub-rounded to angular clasts. Breccia is primarily clast supported but is matrix supported on smaller cm-scale layers. The fine grained matrix comprises chlorite, specular hematite, calcite and quartz(?). According to Thorkelson's mapping of the Wernecke Breccia in this area, feldspar's occupy a percentage of the matrix. The alteration of these rocks make it difficult to discern specific abundances. Varying occurrences (1- 10%) of white to brick red ragged, discontinuous, irregular veinlets and stockwork cement cut the interval. Based on a weak reaction to HCl, these are likely dolomite. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting). Likely Wernecke Breccia based on previous mapping of the area. Alteration: « 4.50- 7.30 Hematite 1.00*»« 7.30- 13.00 Hematite 2*»« 13.00- 41.50 Hematite 1.00*» « 41.50- 44.60 Hematite 1*»« 44.60- 49.80 Hematite 1.00*» The degree of earthy hematite staining varies throughout this interval. Colour changes from black/green to a purple/red during stronger earthy hematite alteration. « 4.50- 49.80 Chlorite 1.00-2.00*» There is a varying degree of chlorite alteration throughout this interval. Shear zones have a higher concentration of chlorite. « 4.5- 49.80 Silicification 1.00*» Mineralization:

From	To	Rocktype & Description
		HETEROLITHIC BRECCIA: dark green to purple-red depending on degree of chlor
		and earthy hematite alteration. The breccia unit is interlayered/interbedded
		with siltstone units. Foliation/bedding direction is evident from preferred
		orientation of clasts as well as colour change between beds. Clasts size ranges
		from mm-scale up to 10cm in diameter with sub-rounded to angular clasts.
		Breccia is primarily clast supported but is matrix supported on smaller
		cm-scale layers. The fine grained matrix comprises chlorite, specular hematite,
		calcite and quartz(?). According to Thorkelson's mapping of the Wernecke
		Breccia in this area, feldspar's occupy a percentage of the matrix. The
		alteration of these rocks make it difficult to discern specific abundances.
		Varying occurrences (1- 10%) of white to brick red ragged, discontinuous,
		irregular veinlets and stockwork cement cut the interval. Based on a weak
		reaction to HCl, these are likely dolomite. The brick red veins also show the
		same reaction with acid so these are likley carbonate veins with earthy
		hematite within mineral cleavage planes (hematite dusting).
		Metasomatised sections of breccia are present within this interval . These
		meta-breccia sections show intense sericite alteration and clasts show strain
		shadows in direction of shear.
		Alteration:
		« 144.60- 150.20 Silicification 2.00*»

Location: 7206058 m North, 527910 m East	**Dip (º):** -50.0
Logged by: H. Jaggard	**Length (m):** 165.00
Drilled by: Dorado	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/09/03 **Date Completed:** 2007/09/06	
Dip Tests By: Flexit	
Objective To test the MDV Zone 50m to the south of STM07-01 and STM07-02, but at a shallower angle than STM07-03.	

Summary Log:

0-4.5 m CASING
4.5-79.5 m HETEROLITHIC BRECCIA and SILTSTONE (bht, slts) interbedded: dark green to purple-red. Irregular quartz-carbonate veins found throughout interval. Fault zone from 42.5-54.2m characterized by low rock recovery, altered rocks and fault gangue. From 75-79.5m, cm-scale beds of 50-70% specular hematite occur. CP 0.1%, MC 0.1%, HS 0.1-0.25%, PY 0.1%. Alteration MS, HE, CL
79.5-81.85 m MASSIVE HEMATITE (mxHS): black to purple coarse grained unit. HS 20-70%
81.5-112.95 m SILTSTONE: black to dark purple depending on hematite alteration. Irregular quartz carbonate veinlets throughout as well as cm-scale beds of 50-70% specular hematite. HS 0.5-5%
112.95-120.5 m METASOMATISED SEDIMENTS (mts): red to purple with patchy, discontinuous striped texture similar to "zebra texture" of other mineralized zones. A massive sulphide unit 25cm in thickness is found within interval. URANIUM MINERALIZATION from 112.95-115.4m producing 180-735cps. HS 0.5-30%, CP 0.1%
120.5-130.6 m HETEROLITHIC BRECCIA (bht): dark green to purple red. Minor amounts of quartz carbonate veining throughout. CP 0.1%, HS 0.5-10%. HE and CL alteration.
130.6-152.5 m SILTSTONE (slts): black to red purple. Minor amount of irregular quartz carbonate veinlets throughout. CP 0.1-0.25%, HS 0.1-5%, PY 0.1%. HE alteration.
152.5-165.0 m METASOMATISED BRECCIA (bhtc): dark grey to red purple, moderately to intensely altered. HS 0.5-5%. MS alteration.
165.0 m E.O.H.

From	To	Rocktype & Description
0.00	4.50	OVBN CASING: no core recovered
4.50	16.00	bht HETEROLITHIC BRECCIA: dark green to purple-red depending on degree of chlorite and earthy hematite alteration. The breccia unit is interlayered/interbedded with siltstone units. Foliation/bedding direction is evident from preferred orientation of clasts as well as colour variation between beds. Clasts size ranges from mm-scale up to 10cm in diameter with sub-rounded to angular clasts. Breccia is primarily clast supported but is matrix supported on smaller cm-scale layers. The fine-grained matrix comprises chlorite, specular hematite, calcite and quartz(?). According to Thorkelson's mapping of the Wernecke Breccia in this area, feldspar's occupy a percentage of the matrix. The alteration of these rocks as well as small grain size makes it difficult to discern specific abundances. Varying occurrences (1- 10%) of white to brick red ragged, discontinuous, irregular veinlets and stockwork cement cut the interval. Based on a weak reaction to HCl, these are likely dolomite. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting). These veinlets show no preferred orientation. Highly chloritized, sheared rocks begin the interval suggesting a shear zone close to surface. However, the low recovery of core typically seen within the first 8-10m of a hole makes this assumption less likely. Likely Wernecke Breccia based on previous mapping of the area. Alteration: « 4.5- 16.0 Silicification 1*»« Sericite 1*»« Hematite 1.00*» « Geothite 1.00*» « 4.50- 11.00 Chlorite 2.00*» « 11.00- 16.00 Chlorite 1.00*» Mineralization:

HETEROLITHIC BRECCIA: black to purple-red depending on degree of hematite alteration. The breccia unit is interlayered/interbedded with siltstone units which tend to have moderate/intense sericite alteration. Foliation/bedding direction is evident from preferred orientation of clasts. Clasts size ranges from mm-scale up to 10cm in diameter with sub-rounded to angular clasts. Clasts are red to purple due to hematite alteration and tend to be surrounded by sericite alteration. Breccia is primarily clast supported but is matrix supported on smaller cm-scale layers. The fine-grained matrix comprises chlorite, specular hematite, calcite and quartz(?). According to Thorkelson's mapping of the Wernecke Breccia in this area, feldspar occupies a percentage of the matrix. The alteration of these rocks make it difficult to discern specific abundances.

Minor amounts (<1- 3%) of white to brick red ragged, discontinuous, irregular veinlets and stockwork cement cut the interval. Based on a weak reaction to HCl, these veinlets are likely comprised of dolomite and quartz. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting).

Likely an interval altered by massive fluid flow. Evidence is preferred orientation of clasts as well as sericite alteration throughout unit.

Alteration:
« 72.6- 75.0 Sericite 1.00*»

		SILTSTONE: black to dark purple depending on degree of hematite alteration. Bedding lamination present defined by changes in grain size. Beds of 50- 70% specular hematite are scattered throughout interval with beds mm to cm's in thickness. Very fine-grained material makes it hard to distinguish composition of siltstone, but is likely specular hematite, calcite, chlorite and quartz(?). Minor amounts (<1%- 2%) of white to red, patchy, discontinuous veins and stockwork is present throughout this interval. Veins are typically mm-scale in width and show little preferred orientation in direction of foliation. Based on a weak reaction to HCl, these veins are likely composed of dolomite and quartz. The red staining to some of the veins is due to earthy hematite alteration. The end of this interval is dominated by highly altered siltstones with interbedded breccia beds. An increase in faulting occurs as well as sericite and chlorite alteration. Foliation is more prominent due to orientation of clasts and colour variations between beds of different grain sizes. HETEROLITHIC BRECCIA: black to purple-red depending on degree of hematite alteration. Clasts size ranges from mm-scale up to 10cm in diameter with sub-rounded to angular clasts. Clasts are red to purple due to earthy hematite alteration. Breccia is primarily clast supported but is matrix supported on smaller cm-scale layers. The fine-grained matrix comprises, in order of abundance, specular hematite, chlorite, calcite and quartz(?). According to Thorkelson's mapping of the Wernecke Breccia in this area, feldspar occupies a

From	To	Rocktype & Description

percentage of the matrix. The alteration of these rocks make it difficult to discern specific abundances of the matrix. Clast lithology is difficult to identify due to hematite and silica alteration. Foliation and bedding directions are identified by clast orientation and change in earthy hematite alteration between beds.

Minor amounts (<1- 3%) of white to brick red veining throughout this interval. Based on a weak reaction to HCl, as well as hardness, these veins are likely comprised of dolomite and quartz. The brick red veins also show the same reaction with acid so these are likley carbonate veins with earthy hematite within mineral cleavage planes (hematite dusting).

Likely Wernecke Breccia.

Project: Werneckes	**Collar Elevation (m):** 1507.0
Hole STM07-05	**Azimuth (º):** 250
Location: 7206100 m North, 527980 m East	**Dip (º):** -45.0
Logged by: N. Perk	**Length (m):** 241.50
Drilled by: Dorado	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/09/06 **Date Completed:** 2007/09/10	
Dip Tests By: Flexit	
Objective To test the MDV Zone for a possible eastern dip to the MDV mineralization.	

Summary Log:

0-2.13 m CASING
2.13-32.70 m METASOMATIZED SEDIMENTS (mts): Black with red patches, fine grained,similar texture to the mineralized zone but is not as strongly altered. Protolith was likely siltstone. Sedimentary structures show the unit to be right way-up. Alteration is mHE, wCL.
32.7-41.8 m SILTSTONE/BRECCIA (slts, bht) Grey-black unit of interbedded siltstones and breccias. Origin of breccias is unknown, but seem likely sedimentary. Alteration is w-mHE, wCL, with mGE as secondary locally.
41.8-52.0 m BRECCIA/SILTSTONE (bht, slts): Orange-green, strongly altered and oxidized breccias and siltstones. Alteration is w-mHE, w-mMS, and w-sCL with m-s secondaries GE-JA.
52.0-60.7 m SILTSTONE (slts): Grey-black, fine grained, thinkly bedded silstones. wHE, wCL alteration.
60.7-65.7 m SEMI-MASSIVE TO MASSIVE HEMATITE (mxHS): Black, nearly complete replacement of what appears to have been a breccia unit.
65.7-180.5 m SILTSTONE (slts): Dark purple-black, thinly bedded siltstones. Alteration is w-sHE, wCL, and local mSI.
180.5-241.5 m SHEARED SILTSTONE (slts): green/red-grey stilstones with strong fabric (shear). Fabric varies from weak to strong with local fine grained schists in high strain zones. Alteration is m-sHE, m-CL, and local mMS.

MINERALIZATION: No significant mineralization observed. HS mineralization vaires greatly throughout. Trace PY and CP occur locally.

Downhole surveys:

From	To	Rocktype & Description
0.00	2.13	OVBN
		CASING: Some rock recovered, unknown if it is in place or not.
2.13	32.70	mts
		METASOMATIZED SEDIMENTS: Black with red patches, fine-grained, weak to strong alteration. Unit is not as strongly altered as metasomatized sediments within the mineralized zones, but displays the characteristic 'zebra striped' texture. Unit is cut by thin (<2 cm) Dolomite veins making up less than 2% of the unit. Protolith appears to be siltstone, primary bedding is observed in several locations. Several sedimentary way-up indicators (flame structures) are observed and show the unit is 'right way up'.
		« 29.60- 30.20 Breccia with flame structure at lower contact, likely sedimentary in origin. bht 30°»
		« 31.50- 32.10 Breccia with sharp contacts, upper contact is planar while lower contact is irregular. bht 30°»
		« Pyrite 2.00%» within Calcite veins and minor disseminations in matrix.
		Alteration:
		« Hematite 2*» as isolated patches
		« Chlorite 1.00*» locally

From	To	Rocktype & Description
		Origin of breccias is unknown, but are likely sedimentary. Breccias vary from matrix to clast supported. Clasts are primarily composed of fine grained sediments with weak-strong Hematite alteration and are sub-angular to angular.
		Alteration:
		« Hematite alteration 1.00-2.00*»
		« Chlorite 1.00*»
		« 37.00- 39.00 Geothite secondary 2.00*»
		Mineralization:
		« Pyrite 0.50%» as narrow (<1 cm) veins that cross -cut bedding.
		« Specularite 5.00-20.00%» as disseminations within beds, complete replacement of clasts, and nearly complete replacement of beds.
		Structure:
		< @ 34.50 zone of broken core. fault 30cm >
		< @ 35.50 zone of broken core. fault 10 cm>
		< @ 39.50 foliation within breccia. S1 Foliation 45° >
		< @ 41.50 Bedding 30° >
41.80	52.00	bht,m
		BRECCIA/SILTSTONE: Orange-green, strongly altered and oxidized breccias and siltstones. Unit is interpreted to represent a large scale fault/shear zone with moderate to strong Chlorite alteration, abundant oxides. Unit is highly fractured with numerous fault and shear zones.
		Alteration:
		« 41.80- 43.60 Hematite 2*» « Sericite 2.00*» « Geothite secondary 3.00*» « Jarosite secondary 2.00*»
		« 43.60- 52.00 Chlorite 3.00*» « Hematite 1.00*»
		Mineralization:
		« 41.80- 44.50 Specularite 10.00%» « Pyrite 0.30%»
		« 44.50- 52.00 Specularite 2.00%»
		Structure:
		« 45.00- 52.00 shear/fault zone with strong chlorite alteration. 30°»

From	To	Rocktype & Description
52.00	60.70	slts

SILTSTONE: grey-black, fine grained, thinly bedded silstones. Unit is cut by thin do veins ~5%. Alteration is relatively weak compared to the above units. Several beds <3 cm thick are nearly completely replaced by hs.

Alteration:
« Hematite 1*»
« Chlorite 1.00*»

Mineralization:
« Specularite 7.00%»

Structure:
< @ 57.20 Bedding 20° >

From	To	Rocktype & Description
60.70	65.70	mxHS

MASSIVE HEMATITE: Nearly complete Specularite replacement of what appears to have been a breccia unit. Section is massive with no remenant primary structures and black in color. 63.8-64.2 m has slighly higher than average scintillometer counts, up too 170 cps.

Alteration
« Hematite 4*»

Mineralization:
« Specularite 30.00-70.00%»

From	To	Rocktype & Description
65.70	180.50	slts

SILTSTONE: dark purple-black, some laminations defined by variable grain size (some fine sandstone layers). Beds are typically cm-scale.

Abundant (~3-5%) white irregular veinlets and stockwork cement cut the interval. Based on a weak reaction to HCl, these are likely dolomite. Dolomite rhombs up to 1 cm are also common throughout. The pervasive purple colour is also due to very fine-grained specular hematite grains.

95.5 -106 zone of stronger alteration with Pyrite - Chalcopyrite mineralization and a Barite vein. Dolomitic veining is more abundant through this section (~8%).

Alteration:

From	To	Rocktype & Description
180.50	241.50	slts

SHEARED SILTSTONES: green/red grey siltsontes with strong fabric (foliation) throughout the unit. Color varies on cm scale with alternating alteration phases (do - Hematite - Chlorite - ms). Unit also has a dark purple color due to fine-grained Specularite throughout.

Foliation varies from weak to strong throughout. More compentent layers are boudinaged locally. A fine grained schist is developed in some higher strain sections.

180.5-205m core is very blocky and broken with fault gouge in numerous locations indicating this section represents and major brittle structure (possibly a late fault).

Alteration:
« Hematite 2-3*» « Dolomite 3» « Chlorite 2.00*»
« 201.00- 241.50 Sericite 2.00*»

DRILL LOG

Project: Werneckes	**Collar Elevation (m):** 1528.0
Hole STM07-06	**Azimuth (º):** 70.0
Location: 7205999 m North, 527934 m East	**Dip (º):** -70.0
Logged by: N. Perk	**Length (m):** 284.70
Drilled by: Dorado	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/09/10 **Date Completed:** 2007/09/14	
Dip Tests By: Flexit	
Objective To test the MDV Zone at its southern extent.	

Summary Log:

5.1-6.5 m SEMI-MASSIVE TO MASSIVE HEMATITE (mxHS): Black, nearly complete replacement of what appears to have been a breccia unit.
6.5-21.5 m BRECCIA/SILTSTONE (bht, slts): Dark green/grey with red. Breccia is interbedded with siltstone. mHE, mCL, mMS, mDO.
21.5-56.5 m SILTSTONE/BRECCIA (slts, bht): Dark green-red unit of interbedded siltstones and breccias. Origin of breccias is likely sedimentary. w-sHE, w-mCL,w-mDO, with local mSI.
56.5-59.6 m SHEARED SILTSTONE (slts): green/red-grey stilstones with strong fabric (shear). Fabric is moderate throughout. wHE, mCL, mMS,and sDO.
59.6-88.7 m BRECCIA/SILTSTONE (bht, slts): Same as above. mHE, wCL, w-mMS, mDO.
88.7-107.2 m SILTSTONE/BRECCIA (slts, bht): Grey-black unit of interbedded siltstones and breccias. Origin of breccias is likely sedimentary. w-mHE, mDO, wCL, wSI.
107.2-148.9 m BRECCIA/SILTSTONE (bht, slts): Dark green/grey breccia with red. Breccia is interbedded with siltstone. m-iHE, wCL, wMS, m-sDO, w-mSI.
148.9-192.0 m SILTSTONE (slts): Dark grey-black, fine grained, thinkly bedded siltstones with dark purple hue likely to fine grained HS. wHE, wCL, w-mSI, w-mDO.
192.0-203.5 m BRECCIA/SILTSTONE (bht, slts): Grey-red, weak-moderately sheared. Interbedded units. mHE, mDO, wCL, wMS.
203.5-284.7 m SILTSTONE (slts): Black-brick red, fine grained, thinly bedded siltstones. Possibly a less altered equivalent to mineralized metasomatized sediments observed in other holes. mHE, wCL, w-mDO, wMS, wSI.

MINERALIZATION: Little significant mineralization observed. HS mineralization vaires greatly throughout. Trace PY and CP occur locally. 200-300 CPS within silstones at 237.4 m and 270.1 m.

Project: Werneckes **Hole Number:** STM07-06

From	To	Rocktype & Description
		pebble/breccia units of unknown origin, likely sedimentarty. Bedding is difficult to recognize due to fine-grained texture and pervasive alteration but appears to be on a mm-cm scale.
		Unit is cut by (~5 %) Dolomite - Quartz discontinous veins, blebs, and stockwork. Veinlets show no prefered orientation. Locally these veinlets are brick red in color, this is likely due to a 'dusting' of Hematite on the Dolomite - qz.
		Alteration:
		« 21.50- 44.00 Hematite 1*» « Chlorite 2.00*» « Dolomite 1.00*»
		« 44.00- 56.50 Hematite 3.00*» « Chlorite 1.00*» « Dolomite 2.00*» « Silicification 2.00*»
		Mineralization:
		« 21.50- 56.50 Chalcopyrite 0.10-0.30%» as blebs and stringers
		« Pyrite 0.10-0.30%» as disseminations
		« 21.50- 56.50 Specularite 1.00-3.00%»
		Structure:
		< @ 29.50 S1 Foliation 40° >
		< @ 44.00 broken core with strong Chlorite frags, possibly a minor fault 40cm >
		< @ 55.30 Bedding 70° >
56.50	59.60	slts
		SHEARED SILSTONES: green/red grey siltsontes with strong fabric (foliation) throughout the unit. Color varies on cm scale with alternating alteration phases (dol - Hematite - Chlorite - ms). Foliation is moderate throughout. More compentent layers are boudinaged locally.
		Alteration:

		SILTSTONE: Dark grey-black, fine grained, thinly bedded (mm scale), with a dark purple hue likely due to fine-grained hs. Grain size is dominately silt with occasional fine sand and pebble breccia beds.
		Unit is cut by (3-5 %) irregular Dolomite - Quartz veins that lack a prefered orientation. Locally these veins contain trace amounts of Chalcopyrite and/or py.
		Foliation appears to be bedding parallel throughout the section. No sedimentary structures indicating younging or 'way-up' were found.
		« Several Quartz - Calcite veins with trace Pyrite and euhedral chlorite. Veins are 1-7 cm in width and cut the unit at various angles. »
		Alteration:
		« Hematite 1*» « Chlorite 1.00*» « Silicification 1.00-2.00*» « Dolomite 1.00-2.00*»
		Mineralization:
		« Specularite 1.00-3.00%»
		« 171.00- 176.00 Pyrite 0.10%» as stringers within Quartz - Calcite

changes from red to black as grain size decreases within a bed.

Although this unit is not as strongly altered as the mineralized zone seen at surface and in other drill holes, it does have a similar appearance and is possibly a less altered (more distal??) equivalent.

Assuming that bedding is graded 'normal' (from coarse to fine upwards), these graded beds provide a good indication of 'way-up'. Cross-beds are seen in several locations and support that the beds are indeed graded 'normally'. A detailed look at the 'way-up' throughout this unit shows at least two reversals. Surficial mapping in the area has identified several fold hinges, suggesting that folding is responsible for 'way-up' reversals within this section.

Alteration:

« 206.50- 293.80 Hematite 2*» stronger within the coarser beds.

« Chlorite 1.00*» « Dolomite 1.00-2.00*» « Sericite 1.00*» « Silicification 1.00*»

Mineralization:

« Specularite 1.00-3.00%» very fine grained, giving the unit a purplish hue, difficult to estimate an accurate percentage.

DRILL LOG

Project: Weneckes	**Collar Elevation (m):** 1533.0
Hole UT07-08	**Azimuth (º):** 170
Location: 7200214 m North, 534320 m East	**Dip (º):** -42.0
Logged by: S.Boyce	**Length (m):** 142.34
Drilled by: Cabo	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/08/15 **Date Completed:** 2007/08/18	
Dip Tests By: Flexit	
Objective To test for U mineralization at the Rio Zone.	

Summary Log:

0 - 6.7 m CASING
6.71 - 15.7 m CHERT (cht): light tan colour; 7% qz-ca-py veinlets; py 0.7%.; trace mc.
15.7 - 17.7 m WERNECKE BRECCIA (bht): silicified, grading from strong to weak downhole; py 0.5%.
17.7 - 46.7 m SILTSTONE (slts): 10% ca-qz-py veining; minor to trace py, trace cp.
46.7 - 52.8 m CHERT (cht): Trace cp.
52.8 - 60.0 m METASOMATIZED SEDIMENTS (mts): mottled colour; possible siltstone protolith; w-mAB, MS, CB alteration; sSI; py 2%.
60.0 - 74.2 m WERNECKE BRECCIA (bht): sSI, mCL, m-sHE; minor mg-cb-py zones; py 1-2%, trace cp.
74.2 - 77.1 m METASOMATIZED SEDIMENTS (mts): sMS, wSI and resembles U-mineralized zone in Trench 2 above; rest of unit sSI and wMS with 3% qz veining; unit weakly foliated; below 75.84m 8% py along foliation planes.
77.1 - 78.8 m WERNECKE BRECCIA (bht): i-SI, m-MS; py 0.5%.
78.8 - 92.0 m CHERT(cht): wMS; 3% qz veining; 0.5% HS, trace cp.
92.0 - 102.7 m DOLOMITE (dol): apple green; iSI, mMS, probable weak potassic alteration; trace sulphides.
102.7 - 114.3 m WERNECKE BRECCIA (bht): sSI; local sMG; w-mMS/AB/CB alteration; w-mHE; HS 0.5%.
114.3 - 118.8 m SHALE/SILTSTONE (shl): healed graphitic fault zone?
118.8 - 142.3 m SILTSTONE (slts): upper part of unit iSI, sMS, with 5% irregular qz veining, trace sulphides and trace probable fine brannerite; Wernecke breccia from 127.8 to 142.3m, similarly altered; lower part of unit weakly altered only (silicified).
142.3m = EOH

Project: Werneckes **Hole Number:** UT07-08

From	To	Rocktype & Description
0.00	6.71	OVBN CASING. No core recovered.
6.71	15.72	cht CHERT. Light tan. Highly siliceous. Generally massive but faint bedding planes noted locally. Strong pervasive silica alteration (or original composition). « Silicification 3.00*» Weak pervasive sericite alteration. « Sericite 1.00*» Abundant qtz>calcite>pyrite-chlorite veinlets. Veinlets are randomly oriented, dirty looking due to limonitic oxidation.« qtz>calcite>py-chlorite veining 7.00%» Pyrite in unit is associated with veining « Pyrite 0.70%» « Limonite 1.00*» Trace malachite - stain on fracture surface at 7.84m. malachite < @ 7.84 coating fracture surface > < @ 12.40 bedding 35° >
15.72	17.72	bht HETEROLITHIC BRECCIA. Colour mottled off-white to grey to dark grey, with overall colour darkening downhole. Pebble-sized clasts vary from black to reddish to yellowish; many of them are quite siliceous. Breccia represents contact between chert above and siltstone below, and in fact may be two narrow breccia dykes at upper and lower contacts with a siltsone raft/section in between. Matrix is probably carbonate>silica although difficult to tell due to later alteration. Contacts are abrupt but irregular. The entire unit has been subjected to subsequent quartz-calcite alteration, probably related to the veining in the above chert unit, with the intensity of silicification decreasing from strong to weak downhole. Although veinlets are present in this unit as well they are less discrete, more discontinuous. Pyrite is also associated with the vein material, particularly in the upper half of the unit. calcite alteration « veining and matrix 3*»

From	To	Rocktype	& Description
			silicification « intensity increases downhole 2*»
			pyrite « wispy, associated with veining 0.5%»
17.72	18.67	slts	
			SILTSTONE.
			Colour dark grey. Faint bedding visible.
			Cut by 10% calcite-qtz>pyrite veinlets; in the upper part of the unit these are
			parallel to bedding planes, but in the lower part of the unit they form a
			stockwork.
			bedding < 68 deg.>
			calcite alteration « 3*»
			py « associated with veinlets 0.5% »
			« calcite-quartz>pyrite 10%»
18.67	23.47	slts	
			SILTSTONE (DEFORMED).
			Colour very dark grey. Same unit as above but deformed due to contrast between
			relatively soft siltstone and adjacent hard quartz vein. Calcite-qtz veinlets
			have also been totally deformed, resulting in blebs of this material. Minor
			graphitic component.Trace pyrite.
			calcite alteration « 2.00*»
			« Graphite 3.00%»
			silica alteration « deformed veining and patchy alt'n 2* »
			Moderate, localized « shear fabric 40-50°»
23.47	31.02	vn	
			QUARTZ VEIN.
			Mottled dark grey, yellow-brown, off-white, tan with wispy rust overprint.
			Upper contact sharp at 35 deg tca.. Core at lower contact broken so not
			possible to measure.
			Vein has been subjected to later brittle facturing (crackle-breccia), with
			calcite-qtz>pyrite infilling. Locally this vein material has been weathered-out
			leaving pits/vugs, particularly towards the upper contact, and there is
			significant limonite staining due to oxidation of sulphides.There are also
			trace pink blebs/streaks which could be carbonate or kspar or hematite
			staining.
			It is conceivable, based on the colouration, that this is a fine-grained

METASOMATIZED SEDIMENTS.
Colour mottled yellow-green, grey, red, black; very chaotic appearance. Difficult to be sure of protolith but possibly siltstone. Locally laminated/bedded; appears to grade into heterolithic breccia below. Upper contact sharp. Constitutes contact between siltstone and breccia below. Unit has been strongly silicified, patchily hematized (hence the red tinge) (or kspar altered?), and locally subjected to strong magnetite-pyrite+/-carbonate alteration. Magnetite is medium- to coarse-grained and anhedral. Overall pyrite content is 2%, but reaches 7% in magnetite-rich zones, where it often occurs as inclusions with magnetite grains. Unit contains 1% quartz veining, up to 4cm wide, many with chlorite selvages, appear barren of sulphides.

Alteration/mineralization minerals and percentages are as follows:
« strong pervasive silicification 3.00*»
carbonate (not calcite), may be overprinted by silica « moderate, identification not positive carbonate alteration 2.00*»
« weak Sericite 1*»
weak fracture/vein-related « Chlorite 1.00*»
« possible moderate Albite 1.00*»
« disseminated, stringers, and associated with magnetite Pyrite 2%»
« moderate patchy hematization 2.00*»

Magnetite-pyrite-silica+/-carbonate rich zones are as follows:
« 53.2- 53.4 magnetite 40%»
« 57.00- 57.47 magnetite 20%»
« 57.93- 58.22 magnetite 30%»

Structures:

From	To	Rocktype & Description
		« 52.80- 59.95 quartz veining 1%»; dominant orientation « 52.80- 59.95 60°»
		From 55.6 and 56.5 a section that may be a heterolithic breccia, but subjected to the same alteration as the rest of the unit. Discrete clasts are difficult to recognize, but section has been cut by numerous chlorite stringers.
		« 55.60- 56.50 bht »
59.95	68.63	bht
		HETEROLITHIC BRECCIA.
		Very chaotic in appearance and colouration - mottled green, dark grey, off-white, orangy, yellow-brown, red. Clasts are often difficult to recognize; many of the most discrete clasts are a reddish hue, pebble-size and sub-rounded - although the latter property may simply be a factor of alteration rather than transport.
		The entire unit is strongly pervasively silicified; this silica overprint makes determination of other minerals by their hardness and reactivity to HCl difficult.
		Chlorite appears to be the dominant matrix constituent, along with possible sericite. These often occur as irregular stringers, to resemble a crackle breccia, but in some short sections they are so abundant as to make the breccia locally clast-supported.
		Overall, clasts are typically lighter-coloured and may have undergone albitization and/or carbonate alteration prior to the silica overprinting.
		Minor magnetite is present, with a magnetite-pyrite+/-carbonate zone similar to those noted in the previous unit of metasomatized sediments present between « 60.36- 60.55 magnetite 35%». Contacts of this zone are fairly sharp at 55 deg tca.< @ 60.36 magnetite zone contact 55° > < @ 60.55 magnetite zone lower contact 55° >
		Alteration:
		« strong silicification 3*»« moderate chlorite 2*» « poss carb (not cal) 2*» « weak sericite 1*» « possible albitization 2*» « weak, patchy mag 1*» « moderate patchy staining hematite 2*» « 61.37- 62.55 moderate staining limonite 2»
		Mineralization:
		« disseminated pyrite 2%»
		« 59.95- 68.63 trace chalcopyrite 0.01%»
		Veining:
		Trace late (post-silicification) qtz-calcite veinlets are present, with no

From	To	Rocktype & Description
77.08	78.80	bht
		HETEROLITHIC BRECCIA.
		Mottled creamy, light green, pale yellow, pale reddish-brown. Much of unit has fluidized texture; clasts are most obvious towards lower contact. There is a cobble-sized clast of the unit below (chert) adjacent to the lower contact. The upper 20cm of the unit is a creamy colour and may be intensely albitized as well as silicified; this section is also foliated whereas the rest of the unit is more massive.
		Intense pervasive « Silicification 4.00*» .
		Moderate overall « Albite 2.00*»
		Moderate « Sericite 2.00*»
		Weak « Chlorite 1.00*»
		Weak probable « carbonate 1*» in matrix.
		Disseminated « Pyrite 0.50%».
		From « 77.08- 77.28 weak foliation 60°».
78.80	91.96	cht
		CHERT.
		Striped grey, tan and red-brown on a 0.5 to 5mm scale (representing bedding), very distinctive appearance. Highly siliceous. Uncertain whether red-brown striping is due to kspar or hematite.
		Cut by «qtz+/-kspar veining 3%»; these veins contain significant amounts of specular hematite and (lesser) chalcopyrite. Many of the wider veins contain pink probable kspar; the widest resemble breccia dykes with numerous inclusions of wallrock. These veins seem to have no preferred orientation, and many are irregular/discontinuous.
		Overall « Chalcopyrite 0.20%» ; « Specularite 0.50%»
		« 83.06- 83.24 pink qtz-kspar vein »
		« 83.93- 84.30 pink qtz-kspar vein »
		« 87.23- 87.48 pink qtz-kspar(?) w 20% wallrock inclusions vein »
		« 88.03- 88.11 kspar-spec hem with large rotated wallrock clast vein »
		« 89.60- 90.35 qtz-kspar veining 20%»

		DOLOMITE.
		Apple green with light orange-red blebs/vein material. Aphanitic. Intensely silicified (pervasive overprint), strongly sericitized. Orange-red vein material constitutes 4% of the unit; it is irregular in form cryptocrystalline and is probably kspar with silica; it contains 0.5% pyrite. This vein material is also cut by more regular and discrete later pale grey qtz vein material (5% of unit), ranging from 1mm to 7cm in width; minor probable pink carbonate was also noted in a few of these veins. Qtz veins are barren of sulphides. The veins tend to be at a relatively high angle to the core axis. Unit silicification may be later or synchronous with the (qtz) veining as the overprint affects them as well (e.g. suspected carbonate cannot be scratched) Trace specular hematite and possible trace chalcopyrite were noted elsewhere in the unit.
		Upper contact gradational over 30 cm.

DOLOMITE.
Mottled green-grey (predominant), pale orange-brown to red-brown, off-white. Aphanitic. Intensely silicified « Silicification 4.00*» , strongly sericitized « Sericite 3.00*» , strong kspar alteration « K-feldspar 3.00*» . 5% off-white qtz veining « qtz veining 5.00%». Highly irregular, orange/red colouration is likely potassium feldspar overprinted by silicification. Unit somewhat similar to that between 91.96 and 102.72.
At approximately 126.05m three 2-5mm red haloes resembling radiation haloes/burns within an orangy band. They possibly surround tiny grains of brannerite (dark mineral with some light-coloured flecks?) but identification not conclusive. No reaction on the scintillometer. Two or three other tiny red specks occur within the unit.
« Pyrite 0.01%»
< @ 123.55 upper contact 55.00° >< @ 127.85 lower structure 38.00° >

MONOLITHIC BRECCIA (WERNECKE BRECCIA).
Dirty yellow-brown, brecciated by a stockwork of dark green (chloritic) stringers/veinlets. Locally red-brown patches. Clast-supported (80%). This narrow unit lies between a sediment and an obvious heterolithic Wernecke breccia and is a transitional lithology. Clasts are probably altered siltstone.

Moderate pervasive silicification « Silicification 2.00*» , moderate chloritization as matrix material (20%) « Chlorite 2.00*» , weak carbonate alteration also as matrix « Calcite 1.00*» , weak « Sericite 1.00*», probable moderate potassium feldspar alteration « K-feldspar 2.00*» , weak albitization « Albite 1.00*» .
Minor « 127.85- 131.40 qtz-calcite-hem/pyrite veining 0.2%»; selvages are hematite/limonite and probably represent oxidized pyrite.

Summary Log:

0 - 3.1 m CASING
3.1 - 30.3 m WERNECKE BRECCIA (bht,): sHE, m-sSI; minor CA-QZ-LI veining; 0.5% HS in top 5m, below this 1% magnetite; trace pyrite.
30.3 - 45.4 m DOLOMITE (dol): bleached; mSI, CA; AB alteration; PY 0.5%
45.4 - 49.5 m METASOMATIZED SILTSTONE(?) (slts): salmon-pink; sSI, 10% chlorite stringers; occasional zones of MG-CB-PY alteration; PY 0.5%.
49.5 - 70.3 m WERNECKE BRECCIA (bht,m): sSI grading to w-SI downhole; localized potassic alteration, m-MS; 2-5% QZ-CA+/-CL veining; interval contains 2.3m section of shale.
70.3 - 76.5 m METASOMATIZED WERNECKE BRECCIA (bht): sAB, mSI, wMS; PY 2%
76.5 - 81.0 m METASOMATIZED SEDIMENTS (mts): sMG, CB, SI; minor PY.
81.0 - 85.0 m METASOMATIZED WERNECKE BRECCIA (bht): similar to above, slightly higher MG, SX; PY 3%.
85.0 - 104.6 m DOLOMITE/CHERTY DOLOMITE (dol): sMS, wSI; PY 0.5%.
104.6 - 111.4 m SHALE (shl): probable Quartet Group; upper contact appears to be conformable; mostly unaltered; 0.3% QZ-LI >PY>CP veining; PY 0.5%, trace CP
111.4 - 118.0 m QUARTZ VEIN (vn): PY 2%.
118.0 - 138.3 m SILTSTONE (slts): mSI; 2% veining; trace CP
138.3 - 147.4 m WERNECKE BRECCIA (bht,m): sSI, mCB, weak potassic alteration; 0.5% CP, trace PY, associated with minor QZ-CA-HS veining.
147.4 - 155.7 m SILTSTONE/SHALE (slts): probably Quartet Group; sAB, mSI, wMS; PY 0.5%, trace CP to 151.7m; below this only wSI and trace PY
155.7 - 164.5 m FAULT ZONE (FLTZ): interval includes metasomatized sediments from 159.4-161.1m.
164.5 - 166.7 3m WERNECKE BRECCIA (bht): sSI; PY 1%. E.O.H

From	To	Rocktype & Description
0.00	3.05	OVBN CASING. No core recovered.
3.05	7.75	bht HETEROLITHIC WERNECKE BRECCIA. Mottled red, dark green with some grey and off-white. Chloritic matrix; locally clasts discrete, pebble-sized, subrounded, elsewhere clast outlines are less obvious. Majority of clasts are a reddish hue, generally a salmon-red (kspar?). Unit is moderately silicified, increasing slightly in intensity towards lower contact. « Silicification 2.00*» Strong chlorite « Chlorite 3.00*» ; strong potassium feldspar « K-feldspar 3.00*» ; weak carbonatization (calcite) « Calcite 1.00*» . Fine-grained « Specularite 0.50%» disseminated and in calcite-qz stringers; trace « fine Pyrite 0.01%» (?). Minor « calcite>qtz veining 0.1%», highly reactive to HCl, as stringers and rare veinlets, randomly oriented; many of these have dark dirty brown fe-oxide (limonite?) selvages. Trace « white Quartz veining 0.01%»; predominant orientation « white Quartz veining 70°»; appear to predate calcite-qz veining.
7.75	30.25	bht WERNECKE BRECCIA (HETEROLITHIC?). Brick-red; chaotic appearance. Individual clasts difficult to make out, particularly in the upper half of the unit. Much less chlorite compared to unit above, but still present as irregular stringers; slightly more abundant in lower half of unit. Strong to intense kspar alteration, strong silicification. Significant amount of calcite>qz vein material, generally randomly oriented/irregular/discontinuous, many with Specularite / mg. Range from stringers to veinlets. Selvages/wallrock contacts typically dirty brown (limonite?). « calcite>qz veining 4%». « 7.75- 16.80 K-feldspar 4*» « Silicification 3.00*» « 7.75- 22.50 Chlorite 1*»« 22.50- 29.50 Chlorite 2*»« Calcite 2.00*» Trace disseminated « Pyrite 0.01%». To approximately 12.0m 1% Specularite with veining and disseminated; below this 1% magnetite. Magnetite has been replaced by Specularite by supergene oxidation?

From	To	Rocktype	& Description
			« Silicification 2.00*» « Albite 2.00*» « Calcite 2.00*»
			0.5% disseminated pyrite. « Pyrite 0.50%».
			Crackle-breccia matrix composed of calcite plus limonite. « Limonite 3.00%»
45.45	49.15	slts	METASOMATIZED SILTSTONE(?).
			Pale salmon-pink, (locally darker red, or greyish), with a stockwork of dark green stringers. Very strongly altered, protolith difficult to be sure of.
			Locally it seems like some chloritic stringers roughly follow remnant bedding planes.
			Upper contact gradational; lower contact sharp < @ 49.15 lower contact 65.00° >.
			Strong silica and potassic alteration. 10% chlorite stringers Minor local short zones of disseminated magnetite, with associated pyrite and calcite.
			« Silicification 3.00*» « K-feldspar 3.00*» « Chlorite 2.00*» « Calcite 1.00*» « mg 1.00%»
			« Pyrite 0.50%», disseminated and also in chlorite stringers; more abundant in magnetite-rich zones.
			Trace qz-calcite stringers; appear to predate chlorite stringers.
49.15	53.30	bht	HETEROLITHIC WERNECKE BRECCIA.
			Dark grey, locally dark red-brown. Clasts generally clearly visible, discrete, subrounded, probably polymictic. Appears to be clast-supported, with matrix a mixture of carbonate, sericite, chlorite. silica. (Only weakly reactive to HCl so carbonate either not calcite, or calcite content relatively low.)
			Strongly silicified. Weak probable hematite staining, strongest in upper half of unit. Moderate patchy salmon-pink probable kspar alteration near upper contact.
			« Silicification 3.00*» « Calcite 1.00*» « Sericite 1.00*» « Chlorite 1.00*»
			« Hematite 1.00*»
			« 49.15- 49.70 K-feldspar 2.00*»
			Disseminated « Pyrite 0.20%», probable trace « Chalcopyrite 0.01%».
			Trace qz-calcite veinlets.

From	To	Rocktype	& Description
			Locally a striped appearance, representing remnant bedding.
			< @ 76.50 bedding 45° >< @ 77.20 bedding 60° > < @ 77.50 bedding 65° >< @
			81.60 bedding 50° > < @ 81.00 lower contact 50° >
			Intensely metasomatized, with strong magnetite-carbonate (dolomite?)
			alteration, weak to moderate silicification. Magnetite is typically
			disseminated, coarse-grained, anhedral, and tends to occur in zones of higher
			and lower concentrations.
			« mg 10.00%» « Dolomite 3.00*» « Silicification 2.00*» « Sericite 1.00*» «
			Specularite 0.50%» « Pyrite 0.50%»
			Would have expected more pyrite associated with magnetite, but only minor;
			disseminated, medium-grained.
			At 78.34 a 6cm section of 30% coarse platy spec hem, surrounded by a section of
			40% magnetite... looks like spec hem is replacing the magnetite (photographed).
			From « 77.22- 78.17 K-feldspar 3*» (probably kspar, not earthy hematite).
81.00	85.00	bht	
			METASOMATIZED HETEROLITHIC (WERNECKE) BRECCIA.
			Similar to unit between 70.27 to 76.46. Slightly more magnetite, higher
			sulphide content.
			« Silicification 2.00*» « Albite 3.00*» « Sericite 2.00*» «suspected
			Ankerite 1.00*» « mg 4.00%»
			« Pyrite 3.00%» « Chalcopyrite 0.50%»; both sulphides disseminated and as part
			of veinlets.
			Albite (probable) present as distinct bands/veins up to 4cm wide at various
			orientations up (as well as pervasive).
			Unit contains trace « Calcite > Quartz - Pyrite > Chalcopyrite veining »
			predominantly as hairline stringers. Minor Hematite associated with veining.«
			Hematite 1 .00*»..
85.00	97.95	dol	
			DOLOMITE. Pale green, almost apple-green; from 91.5 to 94.8 interbedded with
			light grey.
			Unit wide and quite homogeneous compared to rest of hole. Locally bedded on a
			1cm scale. Bedding angles gradually steepen with depth.
			Entire unit weak « Silicification 1.00*»; from « 85.00- 91.50 Sericite 3*»,
			remainder of unit « 91.50- 85.00 Sericite 2*».

From	To	Rocktype & Description
		Unaltered, except towards lower contact, where it is moderately silicified and probably albitized. « 110.75- 111.43 Silicification 2» « Albite 2.00°» In unit « qtz-li>py>chalco veining 0.3%» Overall « Pyrite 0.50%», disseminated, blebby and in veining; more abundant in lower half of unit..
111.43	118.02	vn
		QUARTZ VEIN. Smoky qz, looks to have been cut by 10% irregular later milky qtz with hazy edges/contacts. Locally short pale grey-green sections with irregular/gradational outlines that represent altered and partially absorbed wallrock fragments. « Silicification 4.00*» qz vein is weakly crackle-brecciated. Minor limonite associated with the crackle-brecciation. Unit contains 2% coarse disseminated anhedral pyrite, (clots up to 10mm in diameter). Minor earthy hematite deriving from the pyrite grains (photograph). « Pyrite 2.00%» « Limonite 1.00*» « Hematite 1.00*» Sharp upper contact at 65°; lower contact also sharp but irregular. It is possible that instead of a Quartz vein, this section is merely almost totally silicified sediments.
118.02	138.27	slts
		SILTSTONE. Medium grey. Bedding visible locally to 122m, more massive below this. Entire unit moderately silicified, with weak to moderate pervasive silicification plus dark irregular silica-rich patches that resemble vein material of above unit. « Silicification 2.00*» « 128.10- 128.58 Albite 3.00*», bleached. « 132.80- 138.27 Albite 1*» Significant pyrite content, both disseminated and in hairline irregular stringers (many of them oxidized) that may also contain qtz+/- calcite. Trace disseminated chalco. Hematite predominates in upper half of unit; below this limonite is the dominat Fe-oxide. « li/he+/-py+/-qtz+/-ca veining 2%» « Pyrite 2.00%» « 118.02- 138.27 Chalcopyrite 0.03%» « 118.02- 138.70 Hematite 1*» « 129.00- 138.27 Limonite 1»

Project: Werneckes **Hole Number:** UT07-10

From	To	Rocktype & Description
		SHALE. Dark grey. Locally pale orange, light grey and pale green. Locally altered by silica, kspar, albite and sericite. 5-30cm quartz veins crosscuts shale at several locations. 3- 5% quartz+/-calcite+/- pyrite veinlets and stringers common throughout unit. Locally large (1-3cm) blebs of pyrite within veining blowouts.
		Locally brecciated, with no chlorite altreration, unlike monolithic breccia in upper unit.
		« 118.52- 118.87 quartz+/-kspar+/-chlorite+/-pyrite vein 37cm» Kspar within vein maybe altered host rock grains hosted within veining. Disseminated« Pyrite 5%» associated with chlorite alteration.
		Strong silicification« 118.87- 121.70 Silicification 3*» with associated quartz+/-chlorite+/-pyrite stringers and veinlets« quartz+/-chlorite+/-pyrite veining 10%». 1-3 cm kspar alteration halos commonly form around veinlets, and less commonly sericite
		,
		« 118.87- 121.70 K-feldspar 2*», « Sericite 2*», « Chlorite 1*», « Pyrite 3%»
		< @ 119.10 blebby Pyrite 3cm >, associated with quartz veining.
		Less common quartz veining and associated kspar alteration halos from 121.70-128.95, but still moderately silicified.
		« 121.70- 128.95 Silicification 2*».
		Graphitic coating along fracture surfaces « Graphite 0.10%»
		Irregular « calcite veinlets 3% 1-3mm» common
		< @ 125.65 quartz+/-chlorite vein 36° 6cm > with associated kspar and silica alteration. Chlorite forms as selvage and within the vein. No pyrite hosted within the vein, but is present as 1% within alteration zone.
		« Pyrite 0.1%» over entire interval(121.70-128.95)
		Moderately silicified
		« 128.95- 139.00 Silicification 2*», weakly albitized« Albite 1*», chloritized« Chlorite 1*», with 5-10% quartz+/-calcite veinlets« quartz+/-calcite veining 5-10% 1-5mm». Locally larger quartz vein systems present, < @ 132.00 quartz vein 5cm >, < @ 132.50 quartz+/-pyrite+/-brannerite veining 1cm 20 deg>.
		Locally scintillometer reading reaches 455cps due to tiny brannerite crystals with characteristic red halo< @ 132.50 Beryl 0.1%>

Project: Werneckes **Hole Number:** UT07-10

From	To	Rocktype & Description
		Alteration halos not as strong as higher up the hole, with no pale pink alteration, instead it is light grey, likely albite alteration.
		Intense quartz alteration, with strong kspar alteration with 1% pyrite « 139.00- 140.20 qtz 4*», « K-feldspar 3*», « Pyrite 1%»
		Moderate silicification« 140.20- 141.61 Silicification 2*», with calcite veinlets and stringers« calcite veinlets 1%» hosting « trace Pyrite ». Graphitic coating along fractures« Graphite 0.1%» < @ 141.30 fault zone 30cm >
		Transition into strong sericite, moderate silicification, weak chlorite alteration over 0.65m from fault contact with mottled mixing of moderate sericite, chlorite, kspar and quartz. with « 0.5% Pyrite » « 141.61- 142.26 Silicification 2*», « K-feldspar 2*», « Sericite 2*»« Chlorite 2*»
		Strong sericite « 142.26- 154.54 Sericite 3*» and irregular quartz« qtz 2*» alteration/veining « quartz veining 5.00% 2.00-10.00mm» with trace pyrite « Pyrite 0.01%» hosted within veins. Weak limonite crusting along fractures « Limonite 1.00*»
		Faulted lower contact < @ 154.54 faulted contact 10° > < @ 122.00 bedding 50° > < @ 128.00 bedding 25° > < @ 137.50 bedding 28° > < @ 154.00 bedding 15° >
154.54	159.00 mts	METASOMATIZED SEDIMENTS. Light pink to grey to pale orange. Locally strong potassic, siliceous, sericitic, while weakly chloritic throughout« 154.54-158.80 Chlorite 1*»; locally hosts chlorite altered andalusite porphyroblasts.

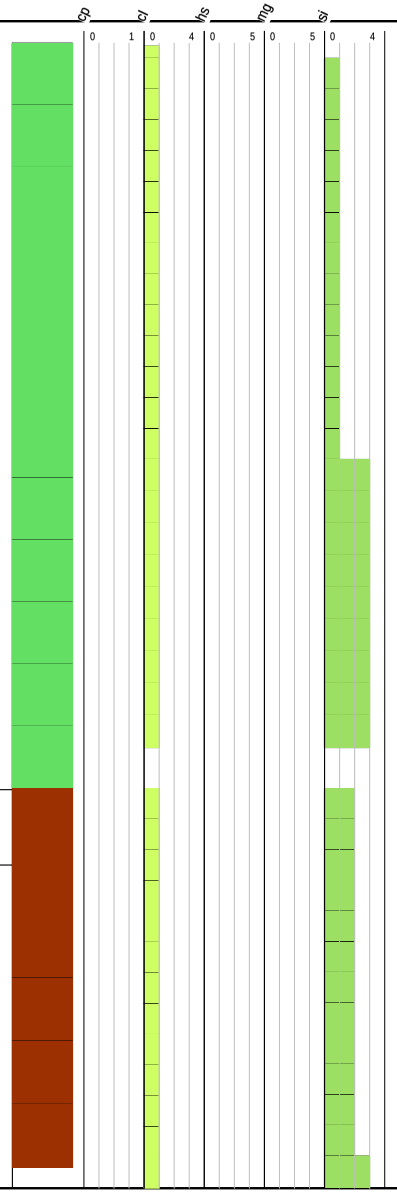
Project: Werneckes **Hole Number:** UT07-10

From	To	Rocktype & Description
		Uppermost part of unit is strongly altered by kspar « 154.54- 154.70 K-feldspar 3*» and quickly grades into moderately siliceous « 154.84- 155.30 Silicification 2*» and earthy hematite« Specularite 2*»altered matrix with 1% magnetite« mg 1%». The matrix appears to be weakly banded but it is not likely bedding. A small interval (15cm) of what appears to be breccia cuts the unit < @ 155.30 brecciation 48.00° >. Same appears and alteration as previously logged Wernecke Breccia higher up in the hole. Another cuts across < @ 155.98 brecciation 61° 2cm >. Possible siltstone protolith from 155.45m with strong albite « 155.45- 157.40 Albite 3*» and weak chlorite« Chlorite 1*», silica« Silicification 1*», sericite« Sericite 1*» alteration, hosting « andalusite porphyroblasts 1-3% 0.5-1cm» and « trace Pyrite ». Alteration qucikly grades into strong pale orange kspar « 157.40- 158.80 K-feldspar 3*», silica« Silicification 3*» and weak chlorite, sericite« Sericite 1*» alteration with 0.1% pyrite hosting quartz veinlets« quartz+/-pyrite veinlets 0.1% 2mm». Lower contact is a possible fault zone « 158.80- 159.00 fault zone 75° 20cm». Rock is grinded and after the zone bedding is visible and continuous.
159.00	171.37	slts
		METASOMATIZED SILTSTONE. Grey to pale orange. Moderate to strong silica alteration, weak to moderate albite alteration, weak chlorite « 159.00- 171.37 Chlorite 1*», and locally strongly sericitic and potassic. Hosts 1-5% chlorite altered andalusite pophyroblasts and trace pyrite « trace Pyrite ». Moderate silicification, « 159.00- 163.80 Silicification 2*», turning into strong silicification « 163.80- 165.00 Silicification 3*». Small fault zone < @ 165.00 fault zone 5cm > cuts off strong silicification, changing it to moderate silica « 165.00- 171.37 Silicification 2*» alteration until end of hole. < @ 161.35 quartz vein 39° 2cm > nearly perpendicular to bedding.



From	To	Width	Sample	Au ppm	Ag ppm	Cu ppm	U ppm	Mo ppm

Project: Werneckes **Hole Number:** UT07-10

From	To	Rocktype & Description
		Moderate pale orange kspar « 159.00- 162.18 K-feldspar 2*», sericite« Sericite 2*» alteration effects the top of the interval and gradually grades out as albitization picks up. Moderate albite alteration begins at « 161.63- 162.18 Albite 2*», altering alternating beds with sericite and kspar and gradually increases in intensity until it becomes dominant alteration type « 162.18- 165.00 Albite 3*». Same fault cuts off strong albitization as silicification, changing it to weak albitization until end of hole « 165.00- 171.37 Albite 1*».
		Chlorite altered andalusite porphyroblasts « 162.18- 171.37 andalusite porphyroblasts 1-5%» appear when albitization alteration becomes strong and continues to the end of hole.

From	To	Rocktype & Description
0.00	5.18	OVBN CASING. No core recovered.
5.18	11.24	OVBN OVERBURDEN. Probably a mix of subcrop and true overburden - 10% soil, 50% rubble, 40% 4-15cm sections of solid rock. The latter vary in appearance, but many look to be magnetite-rich kspar altered siltstone (subcrop?).
11.24	11.74	bht HETEROLITHIC BRECCIA (WERNECKE). Clasts red-brown, black, off-white, minor brownish-yellow; groundmass dark grey-green. High clast content (60%) but matrix-supported. The black shale clasts are angular and cobble- to pebble-sized; the other clasts are subrounded and pebble-sized. Matrix probably composed of fine-grained carbonate (non-reactive to HCl), chlorite, silica. Essentially unaltered. 0.5% fine specular hematite « Specularite 0.50%» . Lower contact abrupt but not measurable.
11.74	17.00	slts SILTSTONE. Dark green, faintly, finely speckled very dark green (chlorite grains). No bedding planes noted. Approximately 50% of the unit is strongly fractured, particularly towards the lower contact. Strong chlorite alteration « Chlorite 4.00*» « Silicification 1.00*» . Roughly 5% irregular black chorite-silica bands locally brecciating unit. These are in turn cut by calcite-qtz-red hematite stringers. « chlorite-silica veining 5%» « 11.74- 17.00 calcite-qtz-hematite veining 2%» 0.5% disseminated chalco, trace pyrite, spec hem. « Chalcopyrite 0.50%» « Pyrite 0.10%» « Specularite 0.10%»

From	To	Rocktype & Description
17.00	22.92	bht
		WERNECKE BRECCIA.
		Distinctive unit with bright red hematitic clasts. Matrix-supported; clast content ~50%; most clasts are red, a few are light grey. Below 19.68m clasts are large, pebble-size, subrounded, discrete. Matrix is dark grey-green, locally speckled white, and is probably composed of abundant chlorite, with medium- to coarse-grained dolomite (? white-ish non-reactive carbonate) and minor cryptocrystalline silica. Minor carbonatized (HCl-reactive) patches occur locally, perhaps part of a later metasomatizing event.
		To 19.00m, the breccia lithology is not obvious - the bright red hematite occurs more as irregular patches. This section is also cut by 5% low-angle qtz-calcite veinlets, and contains « coarse euhedral disseminated Pyrite 3.00%». « 17.00- 19.68 qtz-calcite veining 5%» « veining 25°»
		Over entire unit weak patchy silicification.
		« Silicification 1.00*» « Chlorite 3.00*» « Dolomite 1.00*» « Calcite 1.00*»
		Disseminated chalco « Chalcopyrite 0.50%». « Specularite 0.10%»
22.92	25.07	bhm
		MONOLITHIC BRECCIA.
		Mauve, speckled, off-white; locally brecciated by white-ish matrix material. Very strange unit. Contacts are quite sharp. Possibly a section of siltstone that has been locally brecciated by qtz-carbonate+/-albite vein-type material and also silicified and speckled with medium subhedral dolomite grains. Locally there are islands of mauve silicified rock that are unaffected by the carbonate speckling, but I would not call them clasts. Two small areas where heterolithic breccia (red clasts) can be seen, probably earlier breccia dykes.
		« Silicification 3.00*» « Dolomite 3.00*» « Quartz 1.00*» « Albite 1.00*» « Chlorite 1.00*» « Specularite 0.01%»
		Upper< @ 22.92 contact 45° >, lower < @ 25.07 contact 43° >
25.07	33.72	bht
		WERNECKE BRECCIA.
		Somewhat similar to the breccia described between 17.0 to 22.92m, with bright red-brown and minor grey/pink clasts supported in a chloritic matrix. However,

From	To	Rocktype & Description
		in this unit there are also sections with darker red-brown, more angular, monolithic (siltstone?) clasts. The matrix of these sections has greater amounts of carbonate(dolomite?)-quartz(white) than chlorite. This is perhaps due to compositional variations in the brecciating fluids, and/or possibly due to separate events (if so, the carbonate-qtz might be the earlier event, as it looks like an in-situ brecciation, whereas the chloritic breccia appears to have undergone some transportation). ...Or it could also be the opposite, with the interval originally composed of siltstone cut by breccia dykes, and then weakly brecciated by qtz-carbonate vein-like (but highly irregular) material. Am tending to lean toward the latter explanation. The entire unit has also undergone moderate pervasive silicification. « Silicification 2.00*» « Chlorite 2.00*» « Dolomite 2.00*» « Quartz 2.00*» « Hematite 3.00*» Unit contains nil sulphides; « Specularite 1.00%» as coarse blades associated with carbonate-qtz-rich matrix material.
33.72	44.15	bhm
		MONOLITHIC BRECCIA. Dark red-brown (altered siltstone?) clasts weakly brecciated by off-white quartz-carbonate (dolomite?) material comprising roughly 25% of unit. Rare bedding noted. Moderate to strong earthy hematite content present in clasts; matrix material contains medium- to coarse specular hematite. Fine disseminated chlorite also present in clasts. Towards the lower contact (below 42.10m) chlorite is a constituent of the matrix, and the breccia may be heterolithic within this interval; it is almost definitely heterolithic in the bottom 15cm of the unit. Lower contact sharp but irregular. Unit weakly silicified. « Silicification 1.00*» « Dolomite 2.00*» « Quartz 2.00*» « Chlorite 2.00*» « Hematite 2.00*» « Specularite 1.00%» Nil sulphides. < @ 36.97 bedding 45° > < @ 36.94 micro-fault 85° >< @ 38.81 bedding 26° >

From	To	Rocktype & Description
44.15	49.86	slts
		SILTSTONE(?).
		Dark grey-red-brown becoming more red-brown downhole; lightly speckled white.
		Bedding rare.
		Cut by 7% irregular quartz-dolomite-albite(?)-specular hematite vein material, similar to that occuring in units above.« Qtz-dol-albite(?)-spec hem veining 7.00%» « Specularite 1.00%»
		White speckles are likely medium-grained subhedral to euhedral (rhombohedral) dolomite - possibly calcite that has subsequently altered to dolomite. They may be a fluid-alteration product, related to the vein material, but it is odd that they occur as well-formed disseminated crystals. Finer-grained chlorite also occurs as disseminations, and is present in the vein material towards the lower contact.
		Unit is strongly pervasively silicified and hematized. « Silicification 3.00*» « Hematite 3.00*» « Chlorite 2.00*» « Dolomite 2.00*» « Albite 1.00*»
		Nil sulphides.
		< @ 49.25 probable bedding 35° >
49.86	54.17	bht
		WERNECKE BRECCIA.
		Chaotic appearance, mottled bright red-brown, red-brown (clasts), white/off-white, dark green (matrix). Generally discrete, possibly heterolithic clasts supported by a carbonate-albite-chlorite+/-qtz matrix.
		Upper contact broken, < @ 54.17 lower contact 60° >.
		Entire unit is moderately pervasively silicified.
		« Silicification 2.00*» « Quartz 2.00*» « Dolomite 2.00*» « Albite 2.00*» « Chlorite 2.00*» « Hematite 2.00*»
		« Specularite 0.50%» associated with matrix material.
		Nil sulphides.
		Lower 30cm appears to be a section of hematized bedded siltstone, only weakly brecciated.
		« 53.87- 54.17 slts »
54.17	54.87	bht
		HETEROLITHIC BRECCIA.
		Wernecke breccia, with a mix of red hematized subrounded clasts and larger (predominantly cobble-size) black Quartet shale clasts (their first appearance in this hole). Breccia is clast-supported.
		< @ 54.87 Lower contact 30° >

From	To	Rocktype & Description
		Lower contact of unit is gradational, and sheared over 0.5m. No shale clasts are visible here, presumably, with shale's ductility, they have been incorporated into the shear. « 72.54- 73.10 shear 52°»
73.10	78.38	bhm MONOLITHIC (SILTSTONE) BRECCIA. Medium grey, with pale pinkish-brown-grey patches/clasts. A siltstone weakly brecciated at its contact with heterolithic Wernecke Breccia. Both upper and lower contacts are gradational. Pinkish-brown-grey clasts may originally have been siltstone beds of a slightly different composition; they appear to be slightly coarser-grained than the other grey-only clasts. Breccia is clast-supported. Matrix (15% of unit) consists of chlorite, carbonate (dolomite?), possible albite+/-quartz, minor spec hem. Small sweats of probable partially-hematized albite occur throughout the unit. « Hematite 1.00*» « Albite 2.00*» « Chlorite 1.00*» « Dolomite 1.00*» « Specularite 0.20%»
78.38	111.85	slts SILTSTONE. Medium grey; a few cm-scale beds that have a weak pink tinge. The latter are slightly coarser than the rest of the siltstone and may have been preferentially weakly hematized. Very weak pervasive silicification; strong pervasive (calcite) carbonatization to 97.45m. Minor « qtz-calcite>specular hematite veining 1.0%», with trace chalcopyrite. Minor albite(?) sweats/irregular vein material. The former predominate in the upper half of the unit, the latter in the lower half. Trace disseminated pyrite. « Silicification 1.00*» « 78.38- 97.45 Calcite 3.00*» « Albite 1.00*» « Specularite 0.10%» « Chalcopyrite 0.01%» « Pyrite 0.01%» « 97.45- 111.85 Calcite 1*» < @ 84.83 bedding 53.00° >< @ 88.00 bedding 45.00° > < @ 88.80 bedding 42.00° > < @ 93.92 bedding 43° > < @ 98.30 bedding 40° > < @ 102.20 bedding 50° > Some of the pinkish beds look to be fining downhole - unit overturned? From	To	Rocktype & Description
		black shale and tan or grey chert clasts also present. Clasts are poorly sorted, ranging from large cobbles to small pebbles and are predominantly subangular. Matrix is chlorite, silica, carbonate > specular hematite; matrix constitutes approximately 30% of unit. Weak pervasive silicification. Overall moderate earthy hematite staining. « Silicification 2.00*» « Chlorite 2.00*» « Dolomite 2.00*» « Hematite 2.00*» « Specularite 0.50%» Minor pyrite, fine-grained in matrix, also as disseminated coarse clots. « Pyrite 0.50%». From « 150.80- 151.15 fine-grained Pyrite 3%». A couple of white albite-qtz veins within unit.< @ 142.45 white albite grey qtz veining 60.00° > < @ 145.65 15 cm albite-qtz vein 53.00° >
152.60	154.42	slts
		SILTSTONE. Grey, uniform, bedding planes not observed. Upper contact very sharp at < @ 152.60 contact 40.00° >, lower contact indistinct. Minor irregular « 152.60- 154.42 qtz-dolomite(?) veining 1%» with minor spec hem « Specularite 0.5%» (overall). Locally disrupted. Minor hematite-stained patches/clasts/disrupted beds. « Hematite 1.00*». Otherwise little alteration in unit. « Pyrite 0.01%»
154.42	156.15	dol
		DOLOMITE Light tan-grey-green with pale to dark red-brown patches/sections, some of which are bedding conformable - locally colour-banding.

Project: Werneckes

Hole Number: UT07-11

From	To	Rocktype & Description
		Weak pervasive sericitization may be lending green hue to rock - locally wispy sericite can be noted. Not silicified, easily scratched. Cut by irregular « qtz-carb-chlor-spec hem veining 5%», stringers and veinlets. « Specularite 0.30%» Bedding is ~perpendicular tca. < @ 155.10 bedding 86.00° > < @ 155.95 bedding 87° >. Some late micro-faulting with beds and veinlets offset/truncated.
156.15	156.40	di
		DIABASE DYKE? Very dark green, fine-grained, faint salt-and-pepper appearance. Contacts sharp; post-dates both sediments above and Wernecke Breccia below. Chlorite-rich; minor earthy specks/tiny patches (remnants of absorbed wallrock inclusions?). Upper < @ 156.15 contact 42° >; lower < @ 156.40 contact 80° >. « Pyrite 3.00%», fine- to medium-grained, disseminated. This could conceivably be an intensely chloritized siltstone (with chlorite derived from matrix of adjacent breccia), but if so one would not necessarily expect such a sharp (and unconformable) contact between it and the dolomite above, which is not chloritized at all. Nor does this unit display any bedding. Nor are there any clasts of this unit in the breccia, although another probable dyke can be seen in the Wernecke Breccia, approximately 0.8m further downhole.
156.40	157.92	bht
		WERNECKE BRECCIA. Nice-looking breccia with predominantly reddish clasts and a dark green matrix. Clasts are very discrete, angular, and make up 65% of unit; rare clasts are slightly coarser-grained, some are light grey, one is possibly a hematized diorite. One quartz fragment also noted Matrix is mostly chlorite, with minor discrete silica-carbonate. Similar to diabase above, it contains significant medium-grained pyrite. Overall, « Pyrite 2.00%». Could it be that the above diabase is merely breccia matrix material with no clasts in it?? Clasts are weakly silicified, moderately hematized. « Silicification 1.00*» « Chlorite 3.00*» « Hematite 2.00» Lower contact is a fault.
157.92	162.50	slts
		SILTSTONE.

Project: Werneckes **Hole Number:** UT07-11

From	To	Rocktype & Description
		dolomite clasts present (with andalusite porphyroblasts), also rare black shale clasts.
		This breccia somewhat unusual in that matrix content is very high - 60%.
		Chlorite>carbonate (dolomite? non-reactive to HCl). Also minor earthy hematite disseminated throughout matrix.
		Unit is weakly pervasively silicified.
		« Chlorite 4.00*» « Silicification 1.00*» « Dolomite 2.00*» « Hematite 2.00*»
		« Specularite 0.05%» « Pyrite 0.01%»
		Minor « qtz-albite(?) veining 0.5%» « veining 55°».
184.76	192.20	bht
		WERNECKE BRECCIA.
		Mottled red-brown, dark purple-red, off-white, with dark green stringers (red hues predominate). Chaotic-looking, clasts generally hard to discern.
		Strongly silicified « Silicification 3.00*» « Hematite 3.00*». Matrix composed of chloritic stringers plus finely intermixed silica+carbonate (dolomite?) and minor spec hem. « Chlorite 2.00*» « Dolomite 2.00*» « Specularite 0.50%».
		Below 188.36m highly irregular « 188.36- 192.20 albite>chlorite veining 5.00%», or sweats with chlorite occurring along selvages. In this part of the unit the overall colour is much darker - wine coloured, possibly a change in the hue of hematite.
		Lower contact very gradational.
		Trace disseminated medium-grained « Pyrite 0.05%».
192.20	200.57	bht
		WERNECKE BRECCIA.
		To 197.5m very mottled dark green, dark purple-brown, clasts difficult to distinguish; below this clasts quite visible, discrete, clearly heterolithic.
		Most of unit is cut by a fault which runs parallel to the core axis, and which has weakly silica-clay-calcite altered wallrock immediately adjacent to it.
		< @ 194.00 mid-pt of mm-wide fault 0° >
		Patchy « Silicification 1.00*» « Clay 1.00*» « Calcite 2.00*» « Chlorite 3.00*» « Hematite 1.00*» « Specularite 0.50%»

From	To	Rocktype & Description
200.57	221.85	bht

WERNECKE BRECCIA.
Chloritized a dark green, matrix plus predominantly dark green clasts - also but some pinkish and tan-grey-green clasts which decrease in abundance downhole, as the unit approaches a wide, similarly chloritized, siltstone unit and the breccia clasts become increasingly derived from this unit. Clasts change from being predominantly subrounded to being subangular downhole. Weak patchy silicification. Possible weak sericite. Very little qtz-carb/ab vein material « veining 0.2%» (irregular).
« Chlorite 4.00*» « Silicification 1.00*» « Dolomite 1.00*» « Sericite 1.00*» « Hematite 1.00*»
Nil spec hem, sulphides.

From	To	Rocktype & Description
221.85	245.85	slts

SILTSTONE.
Dark green, massive,. homogeneous. Locally a faint light-coloured speckling.
Bedding planes rare.
Contacts gradational over 0.5m and 0.2m respectively.
Intensely chloritized. Not silicified. Probable weak dolomitization+/-sericitization and clay alteration. « Chlorite 4.00*» « Sericite 1.00*» « Dolomite 1.00*» « Clay 1.00*»
< @ 233.10 bedding 45.00° > < @ 231.40 bedding 45.00° > < @ 253.90 probable bedding 60.00° >
Rare « qtz veining ».

METASOMATISED SEDIMENTS.
Mottled dirty pale yellow, grey; semi-translucent appearance. Remnant bedding visible in many parts of the unit. Very distinctive unit.
Intensely albitized, strongly silicified. Albite is generally cryptocrystalline (and yellowish) but locally occurs as clusters of coarse anhedral laths (best example from 258.45m to 258.60m (photographed); this section includes an albite veinlet that has albite laths radiating out at right angles from it). Grey silica occurs in bedding-parallel bands (probably alteration rather than veining). Minor sericite. Rock non-reactive to HCl.
Protolith probably dolomite; minor coarse andalusite (chiastolite?) porphyroblast laths. < @ 257.60 andalusite >
« Albite 4.00*» « Silicification 3.00*» « Sericite 2.00*»
Disseminated fine-grained « Pyrite 1.00%» and « Chalcopyrite 0.20%».
Bedding is at roughly right angles tca. < @ 257.10 bedding 82° > < @ 245.85 bedding 90° > < @ 259.75 bedding 85° > < @ 261.50 bedding 80° >.
No veining except < @ 258.15 white semi-translucent qtz vein 45° >.
From « 255.10- 255.72 fault », fractured core with minor fault gouge.
Contacts gradational.

From	To	Rocktype & Description
262.03	280.93	slts

SILTSTONE.
Light grey, slight bleached look. Locally bedding visible on a cm scale.
Strongly silicified, moderately to strongly albitized. Moderate pervasive alteration (silica+albite?), as well as bands of intense silica, often bedding-parallel, and irregular patches and randomly-oriented veins of albite (plus rare hazy laths). Weak sericitization.
Silica often has a dirty brown tinge, particularly in lower half of unit.
« Silicification 3.00*» « Albite 2.00*» « Sericite 1*»
Disseminated throughout unit and in albite-veining « Pyrite 1.00%» « Chalcopyrite 0.05%». < @ 272.20 6cm qtz with minor py, trace Chalcopyrite vein 50° >

Project: Werneckes **Hole Number:** UT07-11

From	To	Rocktype & Description
		< @ 268.30 bedding 75° > < @ 266.70 bedding 80° > < @ 272.85 bedding 85° > < @ 276.65 bedding 80° >.
280.93	286.73	mts
		METASOMATISED SEDIMENTS. Medium grey, yellowish patches, lath-clusters. Similar to above altered siltstone, but albitization stronger, with clusters of subhedral laths (up to 3cm long) occurring locally. Also silicification more uniform, pervasive, and - like albite - slightly more intense. « Silicification 3.00*» « Albite 3.00*» « Sericite 1*» Unit contains « Pyrite 3.00%», fine- to coarse-grained, disseminated, less often in stringers. Also « irregular white qtz+ab veining 5%», similarly pyrite mineralized. From 278.75 to 278.95 driller's rod grease coats core.
286.73	287.06	vn
		QUARTZ VEIN. Off-white, minor pale yellow patches (probably albite). Non-reactive to HCl. Minor fine chlorite. « Silicification 4.00*» « Albite 1.00*» « Chlorite 1.00*» Disseminated « Pyrite 2.00%». < @ 286.73 Upper contact 80° >, < @ 286.73 lower contact 80° >.
287.06	294.74	mts
		METASOMATISED SEDIMENTS. Light grey going to medium dark grey downhole. Mottled appearance locally. Intensely silicified, a mix of pervasive silicification and qtz veining. What little albite there is seems to be associated with probable later veining (with qtz). « Silicification 4.00*» « Albite 1.00*» « Chlorite 1.00*» « Sericite 1.00*»

Project: Werneckes **Hole Number:** UT07-11

From	To	Rocktype & Description
		To 290.92 core is weakly crackle-brecciated by pyrite, chlorite, sericite. Overall « Pyrite 5.00%», as stringers, clots, disseminations. Between « 289.92- 290.21 white qtz>>ab>>py vein 65°», upper contact irregular.
294.74	298.25	slts
		SILTSTONE. Medium grey, massive, relatively unaltered, very weak calcite carbonatization. « Calcite 1.00*». Minor chloritized medium- to coarse-grained andalusite porphyroblasts. « Chlorite 1.00*» Overall « Pyrite 3.00%» , disseminated and in qtz-sericite veins. « Qtz>>sericite veining 5.00%». Veining is predominantly as veinlets and veins (up to 6cm) at relatively low angles tca (20-40), but some vein material is also irregular. < @ 295.40 vein 25.00° >, ~6cm. Upper < @ 294.74 contact 20° > intense silicification/qtz veining (belonging to unit above).
298.25	306.30	bhm
		MONOLITHIC BRECCIA. Medium grey with 20% darker subangular pebble-sized clasts. Unit is moderately to strongly silicified; matrix is silica plus probable sericite; clasts are strongly silicified. A few clasts have tiny patches of sericite. Brecciation probably in-situ, with matrix material more a replacement than a brittle, vein-type event. Many clasts are irregular in shape. « Silicification 3.00*» « Sericite 2.00*» « Pyrite 3.00%», euhedral, disseminated and in medium to coarse clots. From « 294.74- 298.66 moderate shear 53°», representing upper contact. Lower contact gradational. Minor « white qtz veining 15-20°», with minor pyrite.
306.30	315.50	slts
		SILTSTONE. Medium grey, locally a banded appearance. Bedding locally visible. Locally coarse andalusite laths present/visible. Moderate, patchy silicification; some patches conformable to bedding. Moderate carbonatization (calcite). Weak sericitization. « Silicification 2.00*» « Calcite 2.00*» « Sericite 1.00*» « Pyrite 3.00%» 3% pyrite in coarse anhedral clots, most abundant in lower half of unit.

Project: Werneckes **Hole Number:** UT07-11

From	To	Rocktype & Description
		In vein « Pyrite 3.00%», generally associated with inclusions (but also in quartz); medium- to coarse-grained, anhedral to subhedral. « Chlorite 1.00*» Contacts irregular.
325.90	333.21	slts
		SILTSTONE. Various shades of grey, chaotic-looking due to patchy alteration that locally resembles brecciation. Andalusite/chiastolite porphyroblasts locally visible. Strong « Silicification 3.00*», probable moderate non-reactive carbonatization « Dolomite 2.00*». « 325.90- 333.21 irregular qtz veining 0.2%» « 325.90- 327.65 very coarse clots of Pyrite 6.00%» « 327.65- 333.21 Pyrite 3.00%». From « 332.20- 332.33 intense chloritic shear 60°». Lower contact abrupt but not sharp.
333.21	343.45	bhm
		HEMATIZED MONOLITHIC BRECCIA. Red-brown (hematized probable siltstone), brecciated by 20% irregular chloritic stringers and veinlets. « Chlorite 2.00*» Upper half of unit (to 338.14m) anomalous on scint, averaging ~190cps and up to 225cps locally (at 334.92, point value). « 333.21- 338.14 190cps » In lower have of unit scint averages ~1540cps. Overall, in unit « Chalcopyrite 0.50%» and « Pyrite 0.20%», with the chalco occurring in the matrix and the pyrite in the matrix and also inside magnetite clots. Matrix also contains fine specular hematite « Specularite 2.00%»; and locally magnetite is present (perhaps spec hem is replacing mag), in matrix and also in disseminated clots « mg 2.00%». Unit is weakly silicified « Silicification 1.00*». « Hematite 2.00*»; fairly confident hematite rather than kspar due to variations in intensity of red hue (the deepest red may actually be burn haloes from fine-grained brannerite, but no brannerite observed in interval). Upper contact sheared « 333.21- 333.41 shear 55°». Lower contact very gradational. Minor « qtz veining 0.4%», in narrow discontinous gashes, favouring matrix material; some of these contain minor chalco.

From	To	Rocktype & Description
343.45	354.61	bhm

CHLORITIZED MONOLITHIC BRECCIA.

Somewhat similar to above hematized monolithic breccia, but less strongly hematized (very patchily) and chlorite component much stronger. Also, more chaotic in appearance. Chlorite is strongest between 347.22 and 349.63.

« 343.45- 347.22 Chlorite 3*» « 347.22- 349.63 Chlorite 4*» « 349.63- 354.61 Chlorite 3*»

« Hematite 1.00*»

Unit contains « mg 6.00%», in disseminated clots and in matrix, locally being replaced(?) by « Specularite 3.00%». Some clots of magnetite have spec hem cores.

Unit contains « Pyrite 3.00%», primarily medium-grained, anhedral, associated with magnetite. It also contains « Chalcopyrite 4.00%»; some of this is also associated with magnetite, but vast majority is major component of « 343.45- 354.61 qtz-carb (dol?) veining 4%» which is somewhat irregular and variously oriented but generally at low angles tca. Perhaps this is same chalco-qtz veining mapped on surface at ~160 Az.

« 346.52- 346.76 Chalcopyrite 12%», associated with vein « 2cm chalco-qtz-carb vein 8°».

Near upper contact is a band of « 343.96- 344.10 semi-massive Specularite 75%». This could conceivably represent a very narrow spec hem unit such as the ones mapped on surface.

Weakly anomalous with the scint « 343.45- 354.61 weak uranium mineralization 140», strongest counts in the lower half of the unit. At 350.60 230cps, looks like a weak low-angle narrow (2cm) shear expressed by chlorite « 350.40- 350.70 shear 10°». There also seems to be a weak relationship between stronger hematite staining and elevated scint counts.

Contacts of unit gradational.

From	To	Rocktype & Description
411.35	424.90	mts METASOMATISED SEDIMENTS. Mottled black (speckled), white, greyish-white, yellow-white, metallic yellow-green, rarely pinkish. Locally laminated, suggesting protolith probably sediments. Intensely altered (silica, albite, carbonate, possible weak sericite) and magnetite/spec hem-pyrite mineralized. Silica tends to be cryptocrystalline white to greyish-white, locally intermixed with fine probable carbonate (non-reactive to HCl), patchy and in vein form. Albite is yellowish, patchy, generally with qtz vein material. Magnetite occurs in clusters of medium to coarse anhedral grains; some clusters so heavily populated that magnetite is semi-massive. Magnetism is not as strong as would be if some of the magnetite were not being replaced(?) by spec hem. Pyrite occurs as large anhedral clots and masses, or as irregular, discontinuous veinlets (which tend to parallel laminations). « Silicification 3.00*» « Dolomite 3.00*» «ab 2.00*» « Sericite 1.00*» « Hematite 1.00*» « Pyrite 10.00%» « mg 12.00%» « Specularite 5.00%» < @ 412.70 laminations 60.00° >< @ 412.05 laminations 61.00° > < @ 417.00 laminations 57.00° > < @ 423.00 laminations 58° > From « 418.52- 419.70 mg 35%» « Specularite 15%» semi-massive magnetite/spec hem.
424.90	431.70	bht METASOMATISED WERNECKE BRECCIA. Dark grey to grey-green. Breccia texture only locally visible. Probably matrix supported; clasts generally pebble-sized, subrounded, ranging in colour from dark grey, grey, reddish, grey-green, dark green. The latter two colours seem to be a factor of later alteration (sericite/chlorite; the sericitic ones tend to be the same colour as the matrix). Strongly sericitized and chloritized, possible weak carbonate. « Chlorite 3.00*» « Sericite 3.00*» « Dolomite 1.00*» . Throughout unit « qtz-albite-pyrite veining 5%», random orientations but predominantly « veining 40-60°», 1 to 3cm wide. Overall, « Pyrite 3.00%» , disseminated and in veining. Trace « Chalcopyrite 0.01%», disseminated near lower contact. At upper contact « Pyrite 10.00%» as clots. « 424.90- 425.86 Silicification 1.00*»

From	To	Rocktype & Description
		Near lower contact laminated/sheared(?) « 430.70- 431.70 weak shear 65°». Contacts gradational.
431.70	440.88	bht
		SERICITIZED WERNECKE BRECCIA.(?) Tan grey-green to grey-green. Intensely pervasively sericitized, such that clasts (when visible) are often the same colour as matrix. Similar to breccia unit above but alteration slightly different and clasts less obvious. « Sericite 4.00*» « Chlorite 2.00*» « Silicification 1.00*» « Pyrite 2.00%», disseminated, medium-grained, many have silver-metallic iridescent tarnish. Minor « qtz>ab>py>cp veining 2%». From « 439.60- 440.15 weak shear(?) 63°». Lower contact abrupt but not measurable.
440.88	443.32	slts
		SILTSTONE. Medium dark-grey, homogeneous, bedding locally visible. « Pyrite 6.00%» in clots and smears. Weak pervasive silicification « Silicification 1.00*». < @ 441.50 bedding 57.00° > < @ 443.20 bedding 67.00° > < @ 443.20 bedding 80.00° >
443.32	445.53	slts
		SILICIFIED SILTSTONE. Various shades of grey. Bedding locally visible. Strong but patchy silicification. « Silicification 3.00*» « Sericite 1.00*» « Pyrite 3.00%», medium-grained, disseminated. < @ 444.50 bedding 68° >
445.53	452.78	mts
		METASOMATISED SEDIMENTS. Mottled shades of grey, dirty yellow-brown. Probably totally altered siltstone. Intensely silicified; weak sericite, calcite. Weakly crackle-brecciated.

DRILL LOG

Project: Weneckes	**Collar Elevation (m):** 1820.0
Hole UT07-12	**Azimuth (º):** 125
Location: 7200900 m North, 534449 m East	**Dip (º):** -45.0
Logged by: S.Boyce	**Length (m):** 206.70
Drilled by: Cabo	**Horizontal Projection:**
Assayed by: ALS Chemex	**Vertical Projection:**
Core Size: NQ2	
Date Started: 2007/09/11 **Date Completed:** 2007/09/23	
Dip Tests By: No	
Objective To test for structurally controlled mineralization within the HEM Zone.	

Summary Log:

0 – 1.44 m CASING
1.44 – 79.0 m WERNECKE BRECCIA (bht,m): generally with red hematitic clasts; interval also contains siltstone units.
79.0 – 116.4 m SILTSTONE (slts): lower portion of unit silicified and potassically(?)-altered; interval between 87.5 and 88.4m moderately anomalous on scint (up to 400 cps in corebox); strong magnetite mineralization begins at 83.5m and continues to EOH; 5% quartz-carbonate-chalcopyrite veining below 87.5m to base of unit (most veins at low angles to core axis).
116.4 – 117.6 m SEMI-MASSIVE MAGNETITE (mxMG)
117.6 – 128.7 m SILTSTONE (slts): intensely hematized; locally weakly anomalous on scint.
128.7 – 130.9 m MASSIVE MAGNETITE (mxMG)
130.9 – 149.8 m SILTSTONE (slts): hematized; 15% pyrite in bottom 15m.
149.8 – 154.9 m MONOLITHIC BRECCIA (bhm): minor pyrite, trace chalcopyrite.
154.9 – 191.4 m METASOMATISED SILTSTONE: earthy hematite / sericite / dolomite / weak silica / possible weak potassium feldspar alteration; top 3m of unit anomalous on scint (up to 300 cps in box).
191.4 – 194.9 m SEMI-MASSIVE PYRITE (MXSX)
194.9 – 200.1 m SEMI-MASSIVE MAGNETITE (mxMG)
200.1 – 206.7 m METASOMATISED SEDIMENTS (mts): silica / albite / carbonate / potassium feldspar alteration; abundant pyrite and minor chalcopyrite.
206.7m = EOH (abandoned)

Downhole surveys:

Depth	Dip	Azimuth
0.00	-45.00	125.00

Project: Werneckes **Hole Number:** UT07-12

From	To	Rocktype & Description
0.00	1.44	OVBN CASING. No core recovered.
1.44	29.47	bht WERNECKE BRECCIA. Bright red hematitic clasts, dark green matrix with small patches of white. 60% discrete subangular clasts, mostly some shade of red, but also occasional black Quartet shale clasts. Matrix chlorite plus carbonate (probably dolomite); the later generally forms discrete masses up to 1cm in diameter; some clasts also carbonatized. Unit not silicified. « Chlorite 3.00*» « Dolomite 3.00*» « Hematite 3.00*» Disseminated fine- to medium-grained specular hematite « Specularite 1.00%» Trace limonite, on fracture surfaces. « Limonite 1.00*» Nil veining. « 15.66- 16.80 Pervasive Hematite 4*» < @ 29.47 Lower contact 60° > « 5.88- 6.55 fracture zone »
29.47	33.48	slts HEMATIZED SILTSTONE. Dark red brown. Locally faint probable bedding visible, on a cm-scale, expressed by slight variation in colour. Locally brecciated by chlorite stringers. « Hematite 3*» « Chlorite 2.00*» « Dolomite 1.00*» < @ 29.80 bedding 65.00° >< @ 32.10 bedding 55.00° > < @ 29.75 microfault 10° >

Project: Werneckes **Hole Number:** UT07-12

From	To	Rocktype & Description
33.48	42.38	bht
		WERNECKE BRECCIA. Very similar to breccia unit at top of hole, with bright red hematitic clasts, dark green matrix with small patches of white. Except upper contact gradational, and top 2m are clearly monolithic, with chlorite stringers brecciating the above siltstone unit. Lower down in unit clasts are generally more discrete; however no black shale clasts were found and only one clast was distinctly different from the red, siltstone clasts, being grey-green, more siliceous. So difficult to say whether heterolithic or not. « Chlorite 3.00*» « Dolomite 3.00*» « Hematite 3.00*» Disseminated fine « Specularite 1.00%». Trace chalco « Chalcopyrite 0.01%». Between 37.94m and 38.55m no clasts are present and rock is a mix of chlorite, carbonate and earthy hematite. From « 35.50- 42.38 Silicification 1*».
42.38	46.36	slts
		SILTSTONE. Grey, with pink-grey patches. Contacts gradational. Patchy weak hematization, carbonatization, strongest in the upper half of the unit. Some of this looks to have followed bedding planes but been subsequently disrupted by microfaulting. « Hematite 1.00*» « Dolomite 1.00*» « 42.38- 42.48 fault »; minor gouge. Trace chalcopyrite.
46.36	55.06	bht
		WERNECKE BRECCIA. Mottled red, grey-green, off-white (yellowish), orangy-brown. Not a typical Wernecke Breccia in terms of colouration, and also in terms of wide range of clast sizes, which range from 3mm to 20cm in diameter. Orangy-brown due to limonite, which is obvious on fracture surfaces but also pervades matrix and clasts locally (mostly near the upper contact). Matrix-supported (chlorite + carbonate > sericite); clasts subangular to subrounded and heterolithic (predominantly probable siltstone, rare black shale). Moderate earthy hematite, mostly in clasts but also occurring in matrix. « Chlorite 3.00*» « Dolomite 3.00*» « Sericite 2.00*» « Limonite 1.00*» « Hematite 2.00*»

From	To	Rocktype	& Description
			Trace fine « Specularite 0.30%».
			< @ 52.60 fault 5° >; 5mm wide, subparallel tca; fault gouge.
55.06	58.08	slts	SILTSTONE.
			Medium dark grey, locally speckled off-white. Bedding not observed.
			Strong carbonatization « Dolomite 3.00*».
			Both contacts gradational.
58.08	63.17	bht	WERNECKE BRECCIA.
			Mottled dark green, off-white; with pale green also, particularly toward the lower contact.
			Clasts in many places difficult to make out; these may be sections of monolithic (siltstone) breccia where the matrix material is more of a patchy alteration than a brecciation.
			Matrix is predominantly carbonate (non-reactive - dolomite?), plus chlorite and sericite. Stronger sericitization has occurred near the lower contact, along with weak silicification.
			Little earthy hematite present in this unit.
			« Dolomite 3*» « 58.08- 63.17 Chlorite 2*» « 62.07- 63.17 Sericite 3*» « 58.08- 62.07 Sericite 2*» « 62.07- 63.17 Silicification 1*»
63.17	65.95	slts	SILTSTONE.
			Dark grey. Essentially unaltered except for moderate patchy carbonatization (dolomite) which makes a very fine salt-and-pepper appearance; some of which probably conforms to bedding.
			« Dolomite 2.00%»
			Trace « fine Specularite 0.10%».
			Upper contact is a narrow fault (broken over 3cm, minor fault gouge); lower contact also broken up but not thought to be a fault.
			< @ 63.17 fault >
			< @ 64.70 probable bedding 56.00° >
			< @ 64.30 2cm white qtz>>calcite vein 83.00° >

From	To	Rocktype & Description
65.95	68.56	bht
		WERNECKE BRECCIA. Mottled pale green, green, cream-coloured, locally reddish. Probably monolithic but hard to say for sure due to alteration. Clasts are generally intensely sericitized and patchily chloritized, subangular, probable metasomatized siltstone (bedding can be seen in some clasts). Matrix is predominantly carbonate (dolomite?), with minor sericite, grey silica and possible albite. « Sericite 4.00*» « Dolomite 4.00*» « Chlorite 2.00*» « Silicification 1.00*» « Albite 1.00*» « Hematite 1.00*» Unmineralized. Upper contact abrupt, lower gradational over 10cm.
68.56	74.98	slts
		SILTSTONE. Dark grey, somewhat mottled appearance. Bedding not observed. Moderate patchy sericitizationa and carbonatization; weak pervasive silicification and chloritization. « Sericite 2.00%» « Dolomite 2.00*» « Silicification 1.00*» « Chlorite 1.00*» Unit includes « qtz-carbonate>>spec hem veining 4.00%»; veins are 1-4cm width, at various orientations; quartz has a weak brownish tinge. Overall « Specularite 0.10%», in veins and trace disseminated. No sulphides seen. Contacts gradational.
74.98	79.00	bht
		WERNECKE BRECCIA. Mottled red, dark grey, lesser off-white.Irregular in appearance, with sections with discrete clasts, and other sections with clasts difficult to make out, possibly monolithic sections, siltstone patchily altered/brecciated by fluids related to the more obvious breccia sections. « Hematite 3.00*» « Dolomite 2.00*» « Chlorite 1.00*» « Specularite 0.50%», mostly associated with carbonate (dolomite?) which occurs as vein material as well as matrix material. « 74.98- 79.00 carbonate-qtz veining 1%» Contacts gradational.
79.00	83.49	slts

From	To	Rocktype & Description
128.68	130.86	mxMG
		SEMI-MASSIVE MAGNETITE.
		Black with dark red undertone; heavy core. Intensely magnetite-altered probable sediments. Some of magnetite replaced(?) by specular hematite. Moderate earthy hematite.
		« mg 50.00%» « Specularite 15.00%» « Pyrite 2.00%» « Dolomite 2.00*» « Hematite 2.00*»
		Contacts gradational.
130.86	135.47	slts
		SILTSTONE.
		Similar to unit between 111.58 - 128.68.
		Massive; bedding planes very rare.
		« Hematite 3.00*» « Silicification 1.00*» « Dolomite 1.00*» « mg 7.00%» « Pyrite 3.00%»
		No chalcopyrite noted in unit.
		Minor « qtz-carb>mag-spec hem-py veining 3%» at low core axis angles. Magnetite and Pyrite tend to favour selvages. < @ 133.91 5cm vein 20° >
		< @ 134.50 bedding 60° >
		NB. Bit contamination between 130.86 and 135.1.
135.47	149.84	slts
		SILTSTONE.
		Mottled red-brown and grey; more chaotic colouration than siltstones above.
		Bedding present only locally.
		Magnetite is generally finer-grained than noted above in hole. Minor sericite present in this unit.
		Trace chalcopyrite, in rare low-angle qtz-carb veins.
		« Hematite 2.00*» « Dolomite 2*» « Silicification 1.00*» « Sericite 1.00*» « mg 6.00%» « Pyrite 3.00%» « Chalcopyrite 0.01%»
		Poorly-defined short intervals of Wernecke Breccia (vague red-brown pebble-sized clasts) within this unit. « 140.44- 140.88 bht,m » « 142.35-142.65 bht,m »
		Upper contact abrupt; lower contact gradational.
		« 138.42- 138.85 Hematite 3*» « Sericite 2*»
		< @ 138.33 5cm qtz-dol>>mag-hs-py>cp vein 23° >
		« 146.41- 146.85 mg 20.00%» « Pyrite 12.00%» « 147.88- 148.04 mg 20.00%»
		< @ 137.50 probable bedding 50° >< @142.75 bedding 55° >< @ 149.70 bedding 50°

		NB: Core-Box 26 was dropped before logging (140.44 - 146.33m). Core in this box was quite competent so it was replaced in roughly the correct order; however it is possible that some pieces may be in the wrong place.
149.84	154.86	bht
		WERNECKE BRECCIA. Mottled red-brown, grey, blue-grey-green, black. Very chaotic and clasts (pebble-sized, subangular, red) discernible only locally. Moderate hematite staining; moderate sericitization (patchy, from weak to strong); moderate carbonate (non-reactive, dolomite); possible weak feldspar (kspar?) alteration. Nil to very weak silicification. « Hematite 2.00*» « Dolomite 2.00*» « Sericite 2.00*» « K-feldspar 1.00*» Magnetite, pyrite and chalco mineralization present: mag and Pyrite typically fine-grained, disseminated or in clusters/clots, and chalco in rare medium-grained concentrations and in low-angle qtz-carbonate veins. Trace malachite, in a vein and on one fracture surface (vein contact). « mg 8.00%» « Pyrite 5.00%» « Chalcopyrite 0.50%» « Malachite 0.01%» « qtz-carb (dol)>cp>hs-mag(selv) veining 4%»« veining 10-25°» « 154.70- 154.86 ~15cm qtz-dol w 3% chalco vein 25°»
154.86	157.59	bhm
		WERNECKE BRECCIA. Mottled deep red-brown, black, metallic grey-green, pale yellowish-grey. Clasts difficult to make out but seems to be more of an in-situ breccia that has been brecciated by py, mag, sericite, carbonate. Strong to intense hematite, moderate silicification (somewhat patchy), moderate patchy sericite, weak dolomite. Strong pyrite-magnetite>>chalcopyrite mineralization. Pyrite occurs in fine-grained irregular clots, magnetite is in fine- to medium-grained clusters, chalco is medium-grained and generally associated with magnetite (not in veins). « Hematite 4.00*» « Silicification 2.00*» « Sericite 2.00*» « Dolomite 1.00*» « mg 6.00%» « Pyrite 10.00%» « Chalcopyrite 0.30%» Unit is anomalous on scintillometer, with 250- 300 CPS (in box) from « 156.30- 156.70 U mineralization ». This section is a particularly deep red hue and

Project: Werneckes **Hole Number:** UT07-12

From	To	Rocktype & Description
		Contacts reasonably sharp. < @ 188.34 Upper contact 65° >
188.72	191.45	mts
		METASOMATIZED SEDIMENTS(?).
		Predominantly dark grey, with light grey, speckled black, yellow-brown,
		metallic greenish-yellow patches/sections.
		Intensely altered, impossible to be sure of protolith. Occasional laminations
		that are probably remnant bedding. But also, rare possible clasts noted,
		suggesting that this unit is transitional to a breccia.
		Intense silica, strong pyritization; bottom 0.5m of unit magnetite-bearing.
		« Silicification 4.00*» « Sericite 1.00*» « Dolomite 1.00*» « Albite 1.00*»
		« Pyrite 17.00%» « 190.95- 191.45 mg 20.00%» « Limonite 1.00*» « Chalcopyrite
		0.01%» (chalco in qtz vein only)
		< @ 190.05 Bedding 75.00° > < @ 191.37 Bedding 65.00° >
		< @ 188.72 Upper contact 70.00° >
		< @ 190.20 3cm qtz-pyrite>>cp vein 15.00° >
191.45	194.88	MXSX
		SEMI-MASSIVE PYRITE.
		Mottled metallic greenish-yellow, grey.
		Pyrite in large irregular clots. « Pyrite 50.00%» « Chalcopyrite 0.30%»
		« Silicification 3.00*» « Dolomite 2.00*» « Sericite 1.00*»
194.88	200.13	mxMG
		SEMI-MASSIVE MAGNETITE.
		Densely speckled black on off-white. Moderately increasing to strongly
		silicified downhole, probable albitization. Pyrite in large fine-grained
		clots.
		« suspected Albite 2.00*» « Dolomite 1.00*» « Sericite 1.00*» « 194.88- 199.35
		Silicification 2.00*»
		« mg 40.00%» « Pyrite 10.00%» « Specularite 1.00%» « 194.88- 199.35
		Chalcopyrite 0.20%»
		Minor supergene Fe-oxidation « Limonite 1.00*» « Hematite 1*»
		To 199.35 « 194.88- 199.35 qtz+/-dol+/-chalco veining 3%»; chalco prefers qtz
		veinlets oriented « 55-70°».
		Below 199.35 « qtz-chalco veining 7%» « veining 55-75°»« 199.35- 200.13
		Silicification 3.00*»« Chalcopyrite 2.00%». Veining as veinlets <1cm width.

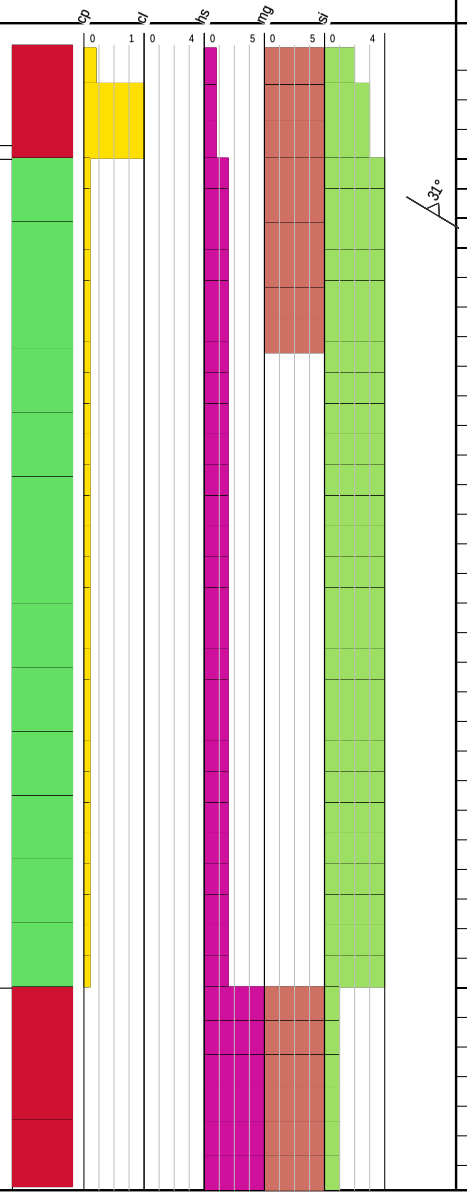
Project: Werneckes **Hole Number:** UT07-12

From	To	Rocktype & Description
		Some chalco also medium-grained, disseminated; mineral most abundant in upper portion of unit. < @ 198.35 micro- fault 75.00° >
200.13	202.13	mts
		METASOMATIZED SEDIMENTS. Mottled mixture of dark grey, dark reddish purple, orange to pale yellowish orange. Intensely silicified throughout, with moderate earthy hematite alteration and weak dolomite. Orange yellow alteration mainly associated with quartz replacement of host sediments, forming as halos or hosted within the quartz, and stronger orange is commonly related to pyrite mineralization. Pyrite mineralization, locally up to 25% and as 1% disseminated pyrite, is associated with carbonate(mainly ankerite replacement) veinlets and veins, also hosting 5% chalco within veinlets. Mineralization: « mg 10.00%» , « Chalcopyrite 0.1%» , strongest near bottom and top of section, with little chalcopyrite hosted in central region. « Pyrite 1.00-5.00%» hosted as disseminations, with semi massive pyrite replacement of carbonate veins and veinlets < @ 200.65 vein replacement Pyrite 25% >, and < @ 201.80 vein replacement Pyrite 20% > Alteration: « Silicification 4.00*», « Specularite 2.00%» « Dolomite 1*» Veining: « carbonate veinlets 2% 1-3mm», erratic in nature, hosting pyrite and chalco in varying amounts, mentioned above. < @ 200.25 carbonate+/-chalco veinlet 31° 1mm > Lower contact is defined by increase in magnetite and dolomite alteration, with a brecciated texture.
202.13	202.61	mxMG
		SEMI MASSIVE MAGNETITE. (Logged by T. Branson to EOH) Dark grey. Massive magnetite with carbonate+/-quartz veins hosting pyrite creating brecciated texture of magetite+/-hematite clasts. Mineralization: « mg 40.00%» , « Specularite 5.00%» replacement of host sediment



From	To	Width	Sample	Au ppm	Ag ppm	Cu ppm	U ppm	Mo ppm

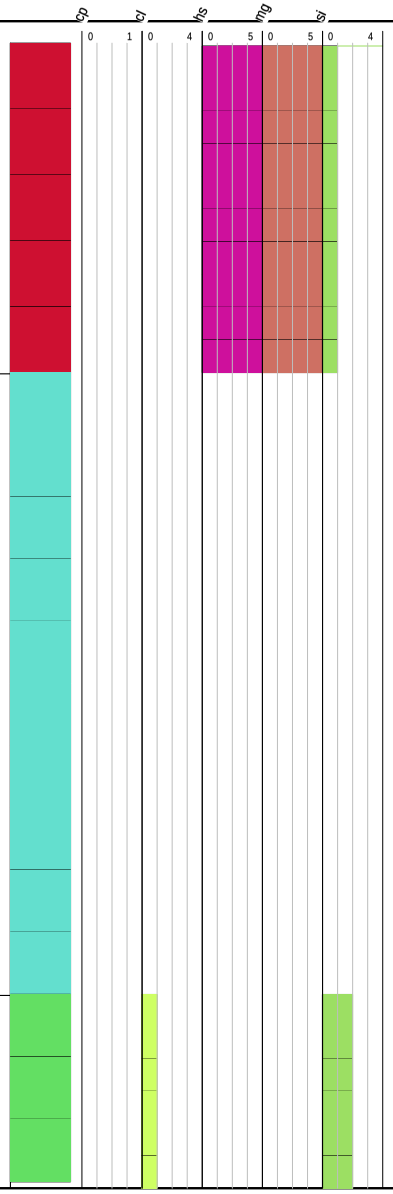
Project: Werneckes

Hole Number: UT07-12

From	To	Rocktype & Description
		« Pyrite 1.00-3.00%», forms as selvage of veining and as disseminations throughout. Pyrite at bottom contact totally replaces veins. Alteration: « Silicification 1.00*» Veining: « carbonate+/-quartz veining 10.00% 2.00-10.00mm» Lower contact is characterized by change in colour and is moderately sharp. Appears as if it may be a carbonate vein cutting through seds.
202.61	203.50	dol
		CARBONATE VEIN? Light orange. Coarse-grained carbonate vein with pyrite selvage. Microfracturing throughout along cleavage planes. Pyrite is more abundant at the bottom portion of section with up to 20% hosted as selvage. Mineralization: « Pyrite 2-10%» Alteration: « carbonate (ankerite?) 3.00*» , weakly fizzes with HCl Structure: < @ 202.70 fault 47° 5cm >, gossannous fault gouge < @ 202.90 fault 43° 2cm > Lower contact is characterized by change to gossanous rock grading into albitized sediments
203.50	204.90	mts
		METASOMATIZED SEDIMENTS. Orange to pale yellowish green. Highly gossanous at top of section grading into strong albite, moderate silica, weak chlorite. Brecciated appearance « breccia texture » for 50cm from 204.40, with moderate sericite alteration. Mineralization:



From	To	Width	Sample	Au ppm	Ag ppm	Cu ppm	U ppm	Mo ppm
202.60	203.75	1.15	244221	0.009	0.52	174	30.3	35.00
203.75	204.90	1.15	244222	0.005	0.08	278	23.7	4.71

Project: Werneckes **Hole Number:** UT07-12

From	To	Rocktype & Description
		« Pyrite 0.01%» ,trace Alteration: « Albite 3.00*», « Silicification 2.00*», « Chlorite 1.00*», chlorite mainly forms along fractures, whereas albite is pervasive. « 204.40- 204.90 Sericite 2.00*» Structure: < @ 204.15 fracture 50° > < @ 204.20 fracture 65° > Lower contact is heavily fractured, but semi-discrete < @ 204.90 contact 55° >
204.90	206.70 mts	
		METASOMATIZED SEDIMENTS. Locally dark grey, purplish red, dull pinkish grey to light grey. Locally massive magnetite< @ 204.90 massive magnetite 80% 20cm > and hematite< @ 205.25 massive hematite 80% 15cm >. Locally strong potassic and albitic alteration. Mineralization: « 205.10- 205.25 Pyrite 10.00%», « Chalcopyrite 0.25%» « 205.40- 205.95 Chalcopyrite 0.5%», forming in carbonate veinlets « 205.40- 206.70 Specularite 5.00%» Alteration: « Albite 3.00*» , between massive magnetite and hematite « 205.40- 205.95 K-feldspar 3.00*» , « Chlorite 1.00*» Structure: < @ 206.12 Flow banding texture 50.00° >, with hematite grains forming along bands. Could be original bedding? Veining: « 205.40- 206.70 carbonate+/-quartz veinlets 1% 2-5mm», hosts chalco, mentioned above. E.O.H.

CERTIFICATE TR07054308

Project: Werneckes

P.O. No.: FRG07-01

This report is for 85 Drill Core samples submitted to our lab in Terrace, BC, Canada on 5-JUN-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
LOG-24	Pulp Login - Rcd w/o Barcode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES
Cu-OG62	Ore Grade Cu - Four Acid	VARIABLE
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS	

To: **EQUITY ENGINEERING LTD.**
ATTN: EQUITY ENGINEERING GENERAL

CERTIFICATE TR07058520

Project: Werneckes

P.O. No.: FRG07-01

This report is for 68 Drill Core samples submitted to our lab in Terrace, BC, Canada on 6-JUN-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	DAVID MCKEE
MARK O DEA	NEIL P	

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
LOG-24	Pulp Login - Rcd w/o Barcode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS	

To: **EQUITY ENGINEERING LTD.**
ATTN: EQUITY ENGINEERING GENERAL
700 - 700 PENDER ST
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR07058522

Project: Werneckes

P.O. No.: FRG07-01

This report is for 23 Drill Core samples submitted to our lab in Terrace, BC, Canada on 9-JUN-2007.

The following have access to data associated with this certificate:

DARCY BAKER WES HODSON NEIL P	IAN DUNLOP DAVE KURAN	QUITY ENGINEERING GENERA CHRIS LEE

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS

CERTIFICATE TR07061031

Project: Werneckes

P.O. No.: FRG07-01

This report is for 162 Drill Core samples submitted to our lab in Terrace, BC, Canada on 16-JUN-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES
Cu-OG62	Ore Grade Cu - Four Acid	VARIABLE
U-XRF10	Fusion XRF - U Ore Grade	XRF
OA-GRA06	LOI for ME-XRF06	WST-SIM
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-MS61	48 element four acid ICP-MS

CERTIFICATE TR07062900

Project: Werneckes

P.O. No.: FRG07-01

This report is for 66 Drill Core samples submitted to our lab in Terrace, BC, Canada on 18-JUN-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
U-XRF10	Fusion XRF - U Ore Grade	XRF
OA-GRA06	LOI for ME-XRF06	WST-SIM
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS

CERTIFICATE TR07065306

Project: Werneckes

P.O. No.: FRG07-01

This report is for 140 Drill Core samples submitted to our lab in Terrace, BC, Canada on 25-JUN-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES
Cu-OG62	Ore Grade Cu - Four Acid	VARIABLE
U-XRF10	Fusion XRF - U Ore Grade	XRF
OA-GRA06	LOI for ME-XRF06	WST-SIM
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-MS61	48 element four acid ICP-MS

CERTIFICATE TR07065308

Project: Werneckes

P.O. No.: FRG07-01

This report is for 95 Drill Core samples submitted to our lab in Terrace, BC, Canada on 26-JUN-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
U-XRF10	Fusion XRF - U Ore Grade	XRF
OA-GRA06	LOI for ME-XRF06	WST-SIM
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-MS61	48 element four acid ICP-MS	

To: **EQUITY ENGINEERING LTD.**

CERTIFICATE TR07086401

Project: Werneckes

P.O. No.: FRG07-01

This report is for 121 Drill Core samples submitted to our lab in Terrace, BC, Canada on 7-AUG-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES
Cu-OG62	Ore Grade Cu - Four Acid	VARIABLE
U-XRF10	Fusion XRF - U Ore Grade	XRF
OA-GRA06	LOI for ME-XRF06	WST-SIM
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-MS61	48 element four acid ICP-MS

CERTIFICATE TR07086403

Project: Werneckes

P.O. No.: FRG07-01

This report is for 117 Drill Core samples submitted to our lab in Terrace, BC, Canada on 7-AUG-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES
Cu-OG62	Ore Grade Cu - Four Acid	VARIABLE
Zn-OG62	Ore Grade Zn - Four Acid	VARIABLE
U-XRF10	Fusion XRF - U Ore Grade	XRF
OA-GRA06	LOI for ME-XRF06	WST-SIM
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-MS61	48 element four acid ICP-MS

CERTIFICATE TR07088980

Project: Werneckes- E

P.O. No.: FRG07-01

This report is for 71 Drill Core samples submitted to our lab in Terrace, BC, Canada on 14-AUG-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS	

To: **EQUITY ENGINEERING LTD.**
ATTN: EQUITY ENGINEERING GENERAL

P.O. No.: FRG07-01

This report is for 138 Drill Core samples submitted to our lab in Terrace, BC, Canada on 27-AUG-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS	

To: **EQUITY ENGINEERING LTD.**
ATTN: EQUITY ENGINEERING GENERAL
700 - 700 PENDER ST
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR07091753

Project: Werneckes

P.O. No.: FRG07-01

This report is for 105 Drill Core samples submitted to our lab in Terrace, BC, Canada on 21-AUG-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
ME-OG62	Ore Grade Elements - Four Acid	ICP-AES
Cu-OG62	Ore Grade Cu - Four Acid	VARIABLE
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM
U-XRF10	Fusion XRF - U Ore Grade	XRF
OA-GRA06	LOI for ME-XRF06	WST-SIM
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-MS61	48 element four acid ICP-MS

CERTIFICATE TR07092548

Project: Werneckes - E

P.O. No.: FRG07-01

This report is for 65 Drill Core samples submitted to our lab in Terrace, BC, Canada on 22-AUG-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS	

To: **EQUITY ENGINEERING LTD.**
ATTN: EQUITY ENGINEERING GENERAL
700 - 700 PENDER ST
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR07093494

Project: Werneckes - E

P.O. No.: FRG07-01

This report is for 65 Drill Core samples submitted to our lab in Terrace, BC, Canada on 27-AUG-2007.

The following have access to data associated with this certificate:

DARCY BAKER	MARK BAKNES	ROB DUNCAN
IAN DUNLOP	QUITY ENGINEERING GENERA	WES HODSON
DAVE KURAN	CHRIS LEE	NEIL P

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA23	Au 30g FA-AA finish	AAS
ME-MS61	48 element four acid ICP-MS	

To: **EQUITY ENGINEERING LTD.**
ATTN: EQUITY ENGINEERING GENERAL
