INTRODUCTION

The Hooch and Moraine claims are referred to collectively as the Hooch property, which lies in southwestern Yukon. The property covers the Moraine Showing; a copper, gold, silver, molybdenum and tungsten skarn occurrence, as well as geochemical and geophysical anomalies. The property is wholly owned by Strategic Metals Ltd.

This report describes geochemical sampling, prospecting and geological mapping completed from June 10 to 21, 2013 by Archer, Cathro & Associates (1981) Limited on behalf of Strategic Metals. The author participated in and interpreted all data results from this work and her Statement of Qualifications is provided in Appendix I. A Statement of Expenditures is located in Appendix II.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The Hooch property comprises 326 contiguous mineral claims, which are located on NTS map sheets 115A/15 and 115H/02 at latitude 61°02' north and longitude 136°65' west (Figure 1). The property covers an area of approximately 6500 ha (65 km²). The claims are registered in the name of Archer Cathro, which holds them in trust for Strategic Metals. Details concerning the claims are listed below, while their locations are shown on Figure 2.

* Expiry dates do not include 2013 work that has not yet been filed for assessment credit.

The Hooch property lies 14 km east of the Aishihik Lake Road, at a point 20 km north of its junction with the Alaska Highway. Previous access to the property was via helicopter or by a bulldozer trail that leaves the Alaska Highway at Cracker Creek (km 1529). The Alaska Highway is usable in all seasons by two wheel drive vehicles. The community of Haines Junction is the nearest supply centre and is situated 60 km southwest of the property.

HISTORY AND PREVIOUS WORK

The first recorded work at the Moraine Showing was in 1934 or 1935 when Chief Hutshi Joe and Hutshi Jackson staked the Moosehide claims. Six hand pits, a four metre shaft and four, four metre long open cuts were completed. No results were reported and the claims were allowed to lapse following this work.

The showing was restaked by independent prospectors as the Fox claims in 1947 and the Ox claims in 1954. Work programs from that era comprised only a minor amount of trenching. No assessment reports were filed for this work.

In 1961, the showing was restaked by independent prospectors as the Ball claims. Bulldozer trenching was performed that year, and hand trenching was completed from 1964 to 1966. No assessment reports were filed.

View of Moraine Showing outlined in red (facing northwest).

In 1966, Empress Mines Limited (Atlas Exploration Limited and Nippon Mining Limited) staked the AH claims immediately west of the Ball claims. Minor prospecting was done before the ground was allowed to lapse.

In 1967, the Ball claims were optioned by two prospectors who performed trenching before dropping their option. In 1968, Union Carbide Mining Limited optioned the Ball claims and performed bulldozer trenching, geochemistry, magnetic surveys and mapping. In 1972 and 1975 the prospectors who staked the Ball claims completed additional hand trenching. No assessment reports were filed to document this work. The Ball claims lapsed following the 1975 trenching.

In 1978, Whitehorse Copper Mines Limited restaked the showing as the Coot claims, and then formed a joint venture with Hudson Bay Exploration and Development Company Limited. Work performed by the joint venture comprised geochemical and magnetic surveys, as well as mapping (Downing, 1979). The magnetic survey identified two parallel magnetic highs that were interpreted to reflect magnetite and pyrrhotite skarn horizons. In 1981, Hudson Bay Exploration performed mapping, geochemical sampling, hand trenching and VLF-EM surveys. Results from this exploration program were not published.

In 1985, the Geological Survey of Canada (GSC) conducted a regional geochemical survey (RGS) consisting of low-density stream sediment and water samples on NTS map sheet 115H (Friske et al., 1985). Four samples were taken from creeks draining the Hooch claims. The results are listed in Table I.

Relative to other samples collected from NTS map sheet 115H, these samples returned an 80th percentile value for silver, but less than 50th percentile results for gold, arsenic, copper, mercury and zinc.

In 1989, the Moraine Showing was restaked by Aurora Gold Limited. Work performed included a magnetometer survey and geological mapping (Stephen, 1990). Chip sampling across an epidote skarn exposure returned 2.06 g/t gold, 2.48% copper, 56.9 g/t silver, 693 ppm molybdenum and 366 ppm tungsten over 3.4 metres. A specimen of rusty, garnetiferous limestone assayed 2.47 g/t gold and 0.17% copper. The magnetic survey identified a number of broad magnetic highs, which were thought to correspond to magnetite-rich granodiorite, and a narrow linear high, that corresponds to a mapped skarn zone. The most interesting magnetic anomaly was reportedly located east of the known skarn zone in an area with thick overburden and vegetation cover. The claims later lapsed.

In 1993, the GSC conducted a regional geochemical survey consisting of low-density stream sediment and water samples on NTS map sheet 115A (Friske et al., 1994). Two samples were collected from creeks draining the Moraine claims. The results are listed in Table II.

Samples draining the Moraine claims returned strongly anomalous values relative to other samples taken from the same map sheet. Silver and copper were in the 99th percentile range while arsenic and mercury were in the 95th percentile and gold was in the 90th percentile. Zinc and other elements were below the 80th percentile threshold.

In 2009, Strategic Metals staked the Hooch 1 to 30 claims, and in summer 2010 it performed one day of prospecting and soil sampling. Results from this work included a 4.5 m chip sample of skarn that returned 0.391 g/t gold, 10.6 g/t silver, 0.32% copper, 340 ppm molybdenum and 350 ppm tungsten. Soil samples dug into overburden on the floors of old trenches returned strongly anomalous results up to 636 ppb gold (average 50 ppb), 23.6 ppm silver (average 2.25 ppm), 13,350 ppm copper (average 1016 ppm), 170 ppm molybdenum (average 18 ppm) and 1680 ppm tungsten (average 134 ppm). Grid soil sampling in undisturbed areas yielded much weaker values up to 19 ppb gold, 0.4 ppm silver, 148 ppm copper, 47 ppm molybdenum and 10 ppm tungsten (Smith, 2011).

In July 2011, Bonaparte Resources Inc. optioned the Hooch claims from Strategic Metals. Bonaparte performed a small geochemical sampling program comprising 16 rock and 119 soil samples. Grid soil samples yielded a few moderately anomalous values for gold (up to 27 ppb), silver (up to 1.1 ppm), bismuth (up to 5 ppm), copper (up to 118 ppm) and molybdenum (up to 23 ppm). Values for iron and tungsten were low. Trench floor soil samples yielded locally strong to very strong values for gold (up to 205 ppb), silver (up to 10.5 ppm), bismuth (up to 8 ppm), copper (up to 3570 ppm), iron (up to 16.7%), molybdenum (up to 130 ppm), and tungsten (up to 1780 ppm). Skarn samples yielded values up to 2.1 g/t gold, 425 g/t silver, 55 ppm bismuth, 7.22% copper, 38.6% iron, 804 ppm molybdenum and 930 ppm tungsten, while a quartz vein sample returned 13.7 g/t gold, 9.9 g/t silver, 21 ppm bismuth and 1.8% copper with low molybdenum and tungsten values (Smith, 2011).

In November 2011, Strategic Metals staked the Moraine 1 to 72 claims to cover the probable source area of the anomalous 1993 RGS samples.

In December 2011, Bonaparte contracted Geotech Ltd. of Aurora, Ontario to perform helicopter-borne VTEM and magnetic surveys over the Hooch 1 to 30 claims, Strategic Metals' Moraine 1 to 72 claims and open ground between them.

In February 2012, Strategic Metals staked the Hooch 31 to 254 claims to cover the geophysical survey area, thereby connecting the original Hooch and Moraine claim blocks.

In September 2012, Strategic Metals performed a soil and silt geochemical sampling program comprising 561 grid and contour soil samples and 72 silt samples in the southeast part of the property. Grid soil sampling outlined a 1000 by 1000 m area with elevated silver, arsenic, copper and molybdenum, but low gold and bismuth values. In the northwest corner of the soil grid three isolated moderately to strongly anomalous gold values (up to 263 ppb) were returned; however, these samples lack pathfinder element support. Contour sampling south of the grid highlighted three zones of anomalous soil geochemistry. The first is an isolated very strongly anomalous gold (368 ppb) value near the southern property boundary. The second is a gold (29 ppb) and arsenic (21.5 ppm) anomaly that is also situated near the southern property boundary, while the third is a copper (253 ppm), silver (0.15 ppm) and arsenic (82.8 ppm) anomaly located about 800 m south of the main soil grid (Montague, 2013).

In January 2013, Bonaparte dropped its option with Strategic Metals.

GEOMORPHOLOGY

The Hooch property is located at the southeastern end of the Ruby Range within the Kluane Plateau. It is drained by creeks that flow into the Nordenskiold River, part of the Yukon River watershed. Elevations on the property range from 950 to 1750 m above sea level (asl), and tree line is approximately 1500 m asl. The property is forested by spruce, willow and birch with an understory of buck brush, moss and lichen. Alpine areas are characterized by grasses and moss. Outcrop is locally abundant on knolls above approximately 1050 m asl.

This part of Yukon was glaciated during the Late Pleistocene (26,000 to 10,000 years ago) McConnell glaciation. Glacial features commonly include glacial lakes, drumlins, and moraines. In the Hooch area, the ice sheet generally moved in a northwesterly direction; however, local meltwater channels flowed northeasterly.

The climate in the Hooch area is typical of northern continental regions with long, cold winters, truncated fall and spring seasons and short, mild summers. The property is mostly snow free from late May to late September.

REGIONAL GEOLOGY

In 1973, the GSC published a geological map of the Aishihik Lake area (NTS map sheet 115H) at 1:250,000 scale (Templeman-Kluit, 1974) and in 1992, it published a geological map of the Dezadeash area (NTS map sheet 115A) at a 1:250,000 scale (Dodds, 1992). Gordey and Makepeace (2003) later completed a Yukon-wide geological compilation, which updated the main lithological unit names.

The Hooch property is located within the Yukon-Tanana Terrane (YTT) as shown on Figure 3. The YTT represents a continental arc that developed along the ancient Pacific margin of North America from Late Devonian to Permian. Figure 4 illustrates regional geology as presented by Yukon Geological Survey (2013). The main lithological units are described in Table III.

The Hooch property area is underlain by the Nisling Assemblage, which is unconformably overlain by a sliver of the Pelly Gneiss Suite immediately southeast of the property. This package has been intruded by numerous plutons of the Ruby Range Suite and one of the Aishihik Suite. Four plugs of the Ruby Range Suite have been inferred on the property through geophysical interpretation, and will be discussed in the Geophysics section below. Quaternary sediments blanket much of the south-central and eastern parts of the property. North-trending regional faults cut both the Nisling Assemblage and Ruby Range Suite to the south of the property.

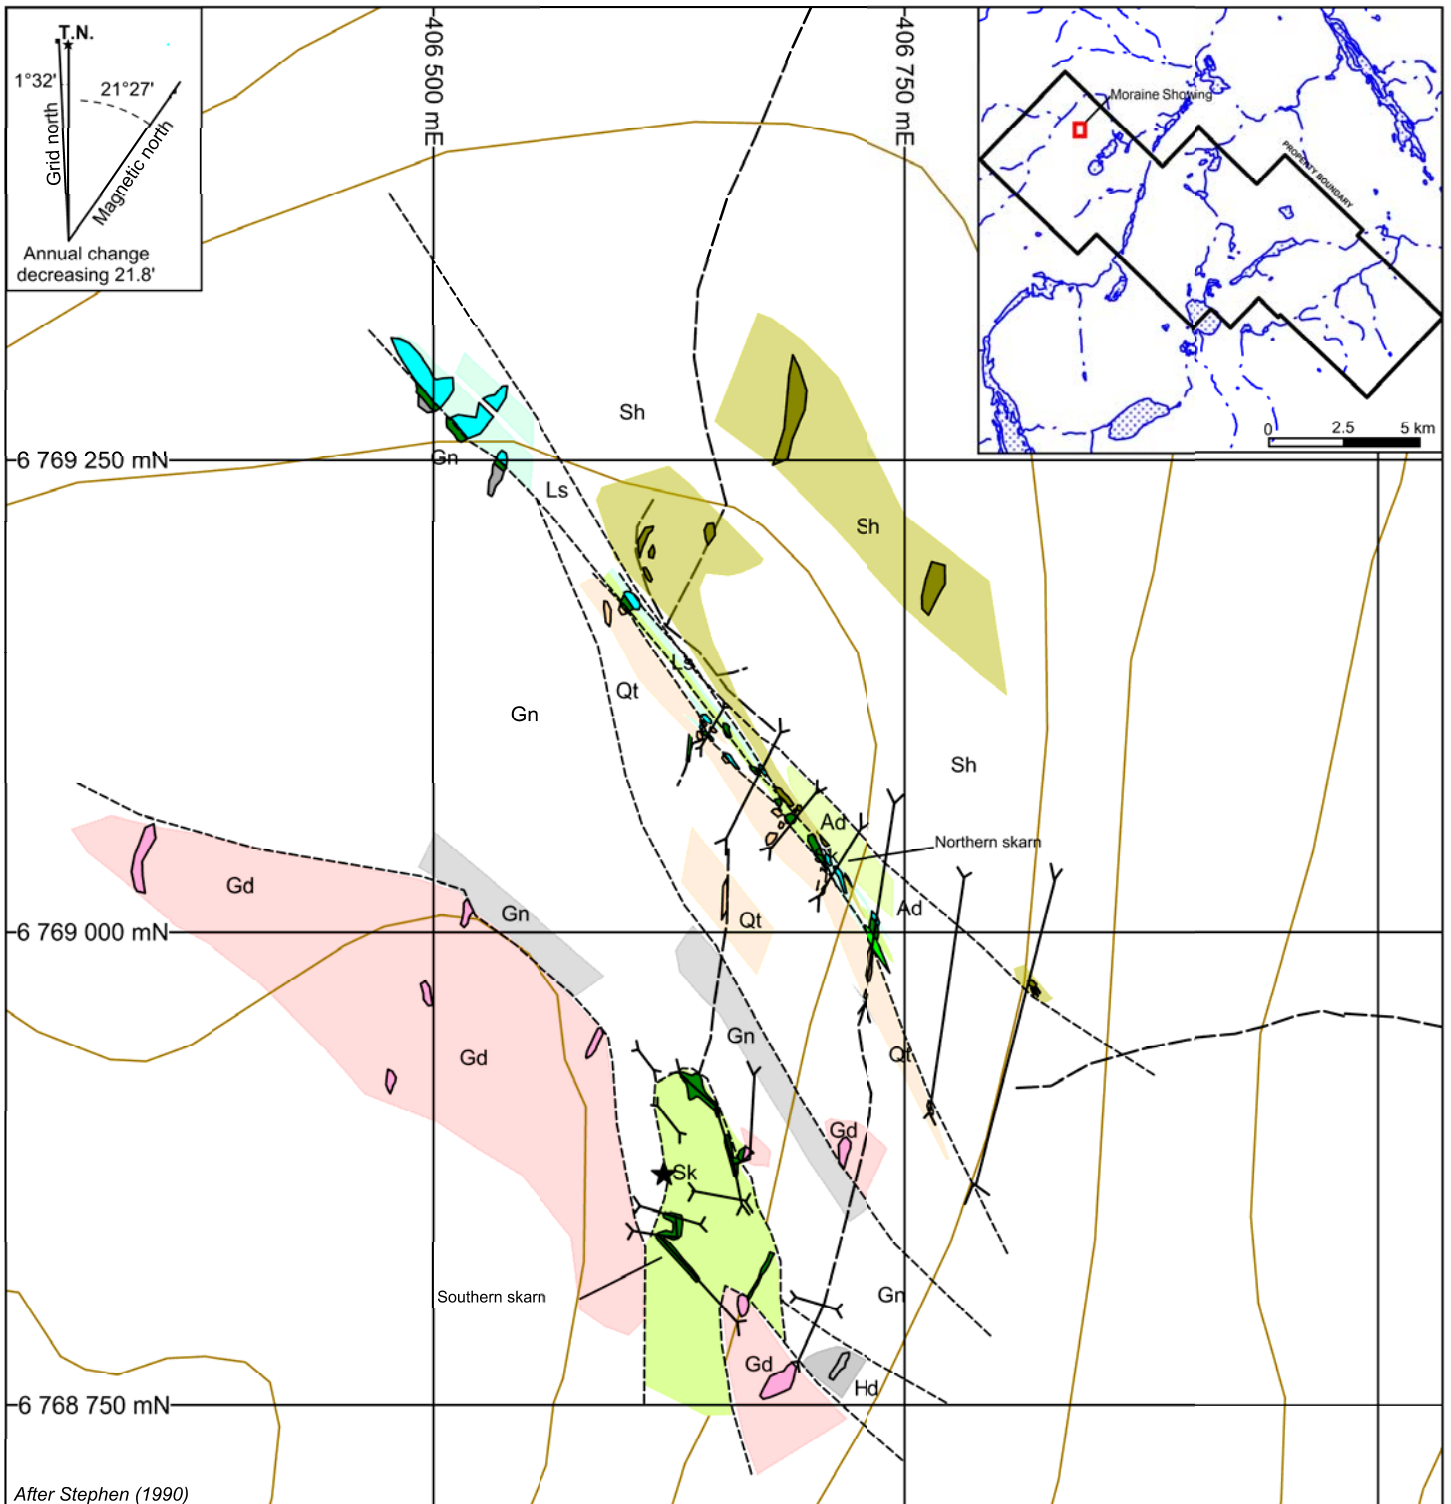

PROPERTY GEOLOGY

Detailed geological mapping on parts of the Hooch property was completed by Stephens in 1990 and Strategic Metals in 2013. Due to limited outcrop exposure the mapped areas are restricted to the northwestern (Moraine Showing), central and southeastern parts. The area of the Moraine Showing has been mapped at 1:2000 scale (Figure 5), while the central and southeastern parts of the property have been mapped at 1:2500 scale (Figures 6 and 7, respectively). Each of these areas are described in the following paragraphs.

Moraine Showing

Mapping of the showing focused on the trenched area where bedrock was exposed. Five metasedimentary and three intrusive sub-units have been identified in the vicinity of the Moraine Showing, as described in the following paragraphs (Stephen, 1990). Metasedimentary units form a stratigraphic package with northwesterly strikes and dips ranging from 30° and 70° to the northeast. The Moraine Showing area is floored by a sub-unit composed of quartz-biotite gneiss and minor micaceous schist, which has a mapped thickness of about 250 m. This sub-unit is overlain by a 75 m thick package of quartz-rich gneiss to relatively clean quartzite, which is well fractured and generally rusty. The quartzite package is conformably overlain by a 50 m thick section of white to grey limestone with thin bands of disseminated garnets. There are two skarn horizons within the mapped area (North and South).

The North Skarn horizon formed at the quartzite-limestone contact and occurs as discontinuous, calc-silicate altered lenses within limestone. The North Skarn is overlain by micaceous schist,

which varies from massive quartz-rich gneiss to highly sheared mica schist. The South Skarn horizon is globular in shape (120 by 70 m) and lies near the granodiorite-gneiss contact. Both skarn horizons contain calcite, epidote, actinolite and garnet with local concentrations of magnetite, pyrrhotite, pyrite, chalcopyrite, molybdenum and molybdo-scheelite.

The metasedimentary package has been intruded by three sub-units: granodiorite, hornblende diorite and andesite. The extents of these sub-units are not known and most contacts have been inferred.

Granodiorite is grey to light pink and comprises fine to medium grained feldspar, hornblende, quartz and biotite. It is massive and forms a stock and dyke with north-trending, steeply dipping joints. The stock intrudes gneiss in the southwestern part of the Moraine Showing while the dyke lies within the gneiss near the quartzite contact.

Hornblende diorite is fine to medium grained with porphyritic hornblende crystals. It lies immediately north of the granodiorite and may be a border phase to the granodiorite stock.

Andesite occurs as massive to fine grained, greenish to dark grey dykes on the edge of the North Skarn. The dykes are slightly fractured and feature minor malachite staining.

Central Mapping Area

Outcrop in the Central mapping area is confined to a prominent north-trending knoll. This area is mostly underlain by micaceous schist of the Nisling Assemblage. The schist is interbedded with limestone horizons that vary in thickness from less than 1 m to 15 m. Foliations within the schist strike northwest and dip steeply from 50° to 80° to the northeast. A Ruby Range Suite pluton intrudes the metasedimentary package in the northern part of the mapped area and is cut by minor hornblende diorite dykes. Andesite dykes with variable orientations cut the metasediments in the centre and south of the map area. Minor white quartz veins run sub-parallel to metasedimentary foliation and flank the andesite dykes.

Southeast Mapping Area

Mapping in this low-lying area was hindered by Quaternary cover and limited outcrop. Most of the mapping was carried out near the southern property boundary, where outcrop is more abundant. Outcrop comprises Nisling Assemblage metasediments that are intruded by Skukum andesite dykes and Ruby Range Suite dykes.

MINERALIZATION

Moraine Showing

Both skarn and vein type mineralization have been identified in the northwestern part of the property. There are two skarn horizons (North and South) which have varying mineralization, but are typically composed of pyrrhotite, chalcopyrite, magnetite and pyrite with minor molybdenum and molybdo-scheelite.

The North Skarn has been discontinuously sampled over a 30 by 100 m area. Samples collected in 2011 yielded values up to 0.391 g/t gold, 25.2 g/t silver, 1.06% copper, 38.6% iron, 804 ppm molybdenum and 930 ppm tungsten. The North Skarn is open to the southeast where historical trenches were excavated, but did not reach bedrock. The South Skarn spans a 70 by 120 m area. Skarn samples collected in 2011 returned values up to 2.1 g/t gold, 425 g/t silver, 55 ppm bismuth, 7.22% copper, 37.3% iron, 178 ppm molybdenum and 740 ppm tungsten.

Rusty, mineralized quartz vein felsenmeer was discovered in a shallow trench near the South Skarn. The vein comprised pale grey to white dusty quartz with up to 30% vugs hosting a fine grained disseminated black mineral (chalcocite?). A sample from it returned 13.7 g/t gold, 9.9 g/t silver, 21 ppm bismuth and 1.8% copper with low molybdenum and tungsten values. The vein float was exposed over one metre, and no attempt was made to trace it.

Secondary copper minerals, such as malachite, occur on fractures in some sub-units, notably the andesite dykes. The Moraine Showing was not revisited in 2013.

In 2013, a total of 31 rock samples were collected from the central and southeastern parts of the property. Sample locations are illustrated on Figure 8, while rock sample descriptions and certificates of analysis appear in Appendix III and IV, respectively. All rock samples were sent to ALS Chemex in North Vancouver where they were crushed to 70% passing 2 mm before a 250 g split was pulverized to 85% passing 70 microns. A split of the pulverized fraction was then dissolved in aqua regia and analyzed for 35 elements using the inductively coupled plasma-atomic emission spectroscopy technique (ME-ICP41). An additional 30 g charge was further analysed for gold by fire assay and inductively coupled plasma-mass spectroscopy finish (Au-ICP21).

Central

Sixteen rock samples were taken of rusty quartz veins, calc-silicate altered limestone horizons and pyritic andesite dykes. Although trace malachite was observed, results from this sampling were low.

Southeast

Fifteen rock samples were collected from float or hand pits dug to follow up very strong gold-in-soil values. Trace disseminated pyrite mineralization was noted within dykes, quartz veins and quartz-mica schist. Semi-massive magnetite and euhedral magnetite crystals were found within sub-rounded quartz-rich float. All 15 samples returned background values for the elements of interest.

SOIL GEOCHEMISTRY

In 2013, a total of 952 grid and contour soil samples were taken at 50 to 100 metre spacing in the central and southeastern parts of the property. A soil grid was completed across the knoll in the central part of the property, while a larger grid was completed in the southeast corner of it.

Locations for 2012 and 2013 soil samples are plotted on Figure 9. Thematic results for 2010 to 2013 samples for gold, silver, arsenic, copper, molybdenum, tungsten and zinc are plotted on Figures 10 to 16, respectively.

All soil sample locations were recorded using hand-held GPS units. Sample sites are marked by aluminum tags inscribed with the sample numbers and affixed to 0.5 m wooden lath that were driven into the ground. Most of the soil samples were collected from 20 to 60 cm deep holes using hand-held augers. They were placed into individually pre-numbered Kraft paper bags. The soil samples were sent to ALS Minerals in Whitehorse where they were dried, screened to -180 microns, dissolved in aqua regia and then shipped to North Vancouver where they were analyzed for 35 elements using the inductively coupled plasma-atomic emission spectroscopy technique (ME-ICP41). An additional 30 g charge was further analyzed for gold by fire assay with inductively coupled plasma-atomic emission spectroscopy finish (Au-ICP21). Certificates of Analysis are given in Appendix IV.

Table IV lists anomalous thresholds and 2013 peak values used to describe the soil sample results in the following paragraphs.

Table IV – Soil Geochemical Thresholds

At the **Moraine Showing** numerous auger samples were collected in 2010 and 2011 from the floor of old trenches. These samples returned strongly anomalous values for gold, silver, copper, molybdenum, tungsten and zinc; however, they cannot be directly compared to 2012 and 2013 sampling because they were collected from much deeper in the soil profile. Deep auger soil samples taken around the Moraine Showing in 2010 and 2011 returned weak to moderate values for elements of interest. These values are in-line with the values returned from 2012 and 2013 sampling elsewhere on the property.

The **Central** grid returned elevated values for arsenic, gold, copper and zinc, but low values for silver, molybdenum and tungsten. Arsenic-in-soil values form a linear northwest-trending anomaly near the highest point on the knoll. This anomaly parallels the mapped foliation within the Nisling Assemblage mica schist and also contains weak to moderate gold values. Copper-in-soil values are strongest within the Ruby Range Suite intrusion, to a peak of 235 ppm. Zinc-in-soil values are elevated peripheral to the Ruby Range Suite intrusion and on top of the knoll in areas mapped as schist.

The **Southeastern** grid returned strongly anomalous values for gold, copper and zinc. In most instances the anomalies occur as isolated high values or small clusters and exhibit weak correlation between elements of interest. Five very strongly anomalous gold-in-soil values (up to 356 ppb) lie in the south-central part of the grid. A number of moderately to strongly anomalous values correlate with a northeast-trending creek. One very strongly anomalous sample (248 ppb gold) was returned from the bottom of a two metre deep soil pit located in the northern part of the area. Three very strongly anomalous and three strongly anomalous copper values (up to 313 ppm) lie in the east-central part of the grid. Strongly anomalous zinc values (up to 161 ppm) are randomly distributed in this area.

GEOPHYSICS

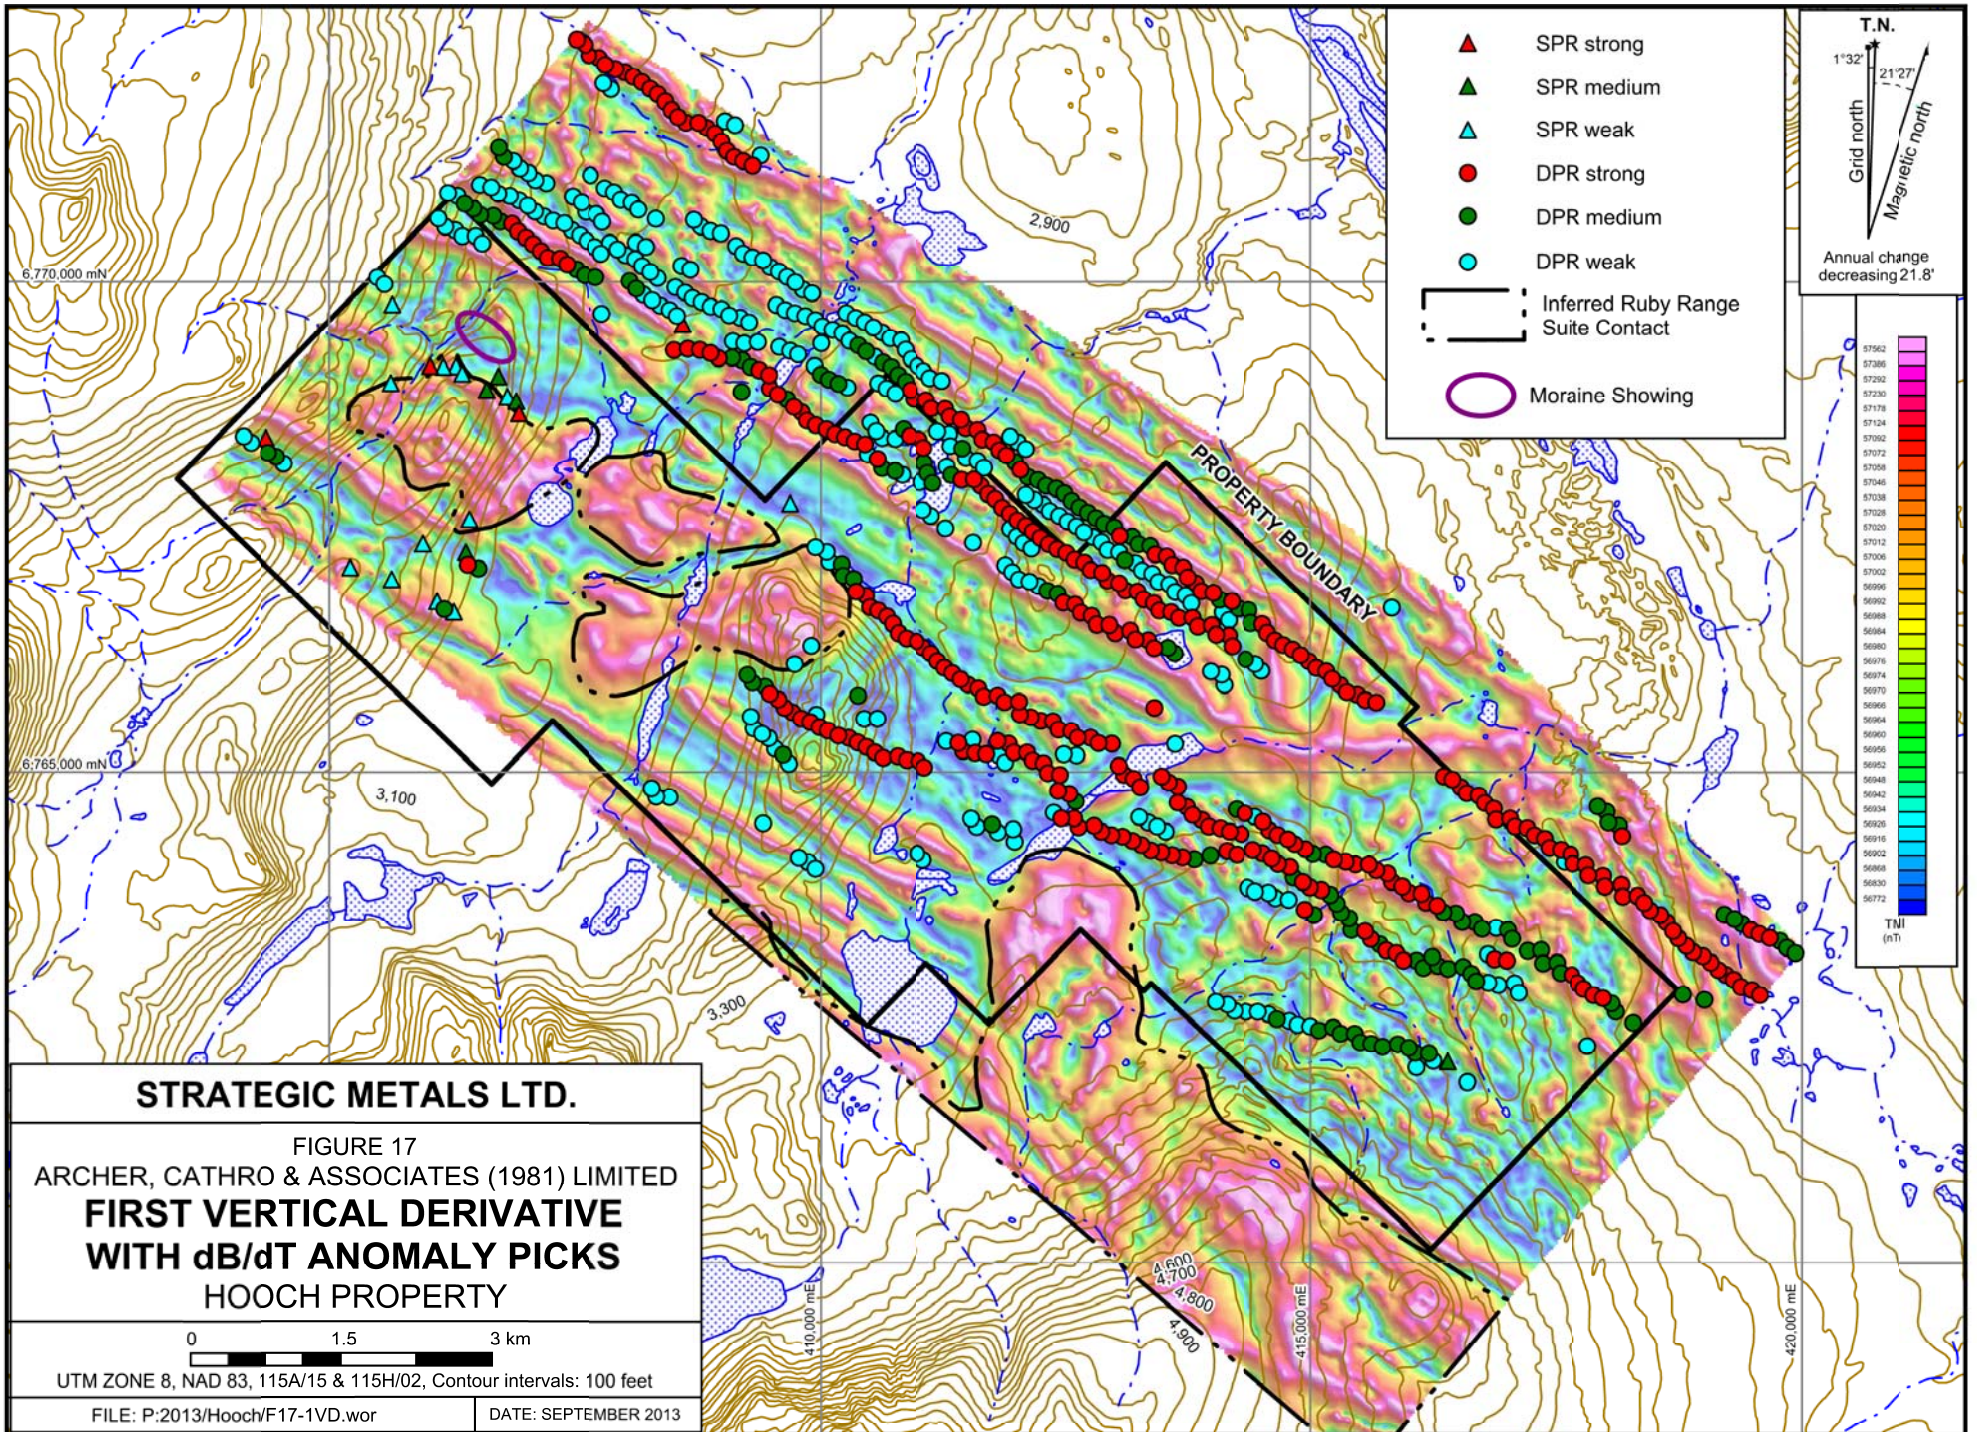

In late 2012, Strategic Metals commissioned Condor Consulting, Inc. to carry out processing and interpretation of the VTEM and magnetic survey data obtained by Geotech in 2011. The total magnetic intensity (TMI) response varies dramatically across the Hooch Property. The margin of the main magnetic high is irregular and roughly parallels the contact between the Ruby Range Suite granodiorite and the Nisling Range metasediments. This strong magnetic feature extends from the Moraine Showing to the southeast corner of the property. The North Skarn lies immediately north of this magnetic high and the South Skarn occurs within it. The magnetic signature across the remainder of the property is relatively subdued; however, a second, but weaker northwesterly-trending magnetic high lies along the northern edge of the survey area, close to the property boundary. Figure 17 illustrates numerous northwesterly-trending linear magnetic features, which were determined using tilted first vertical derivative data. These features have been interpreted by Condor as magnetic dykes or skarns within the metasediments. The tilted data also identified northerly-trending glacial features and a series of easterly-trending magnetic lows, which may represent demagnetized alteration zones.

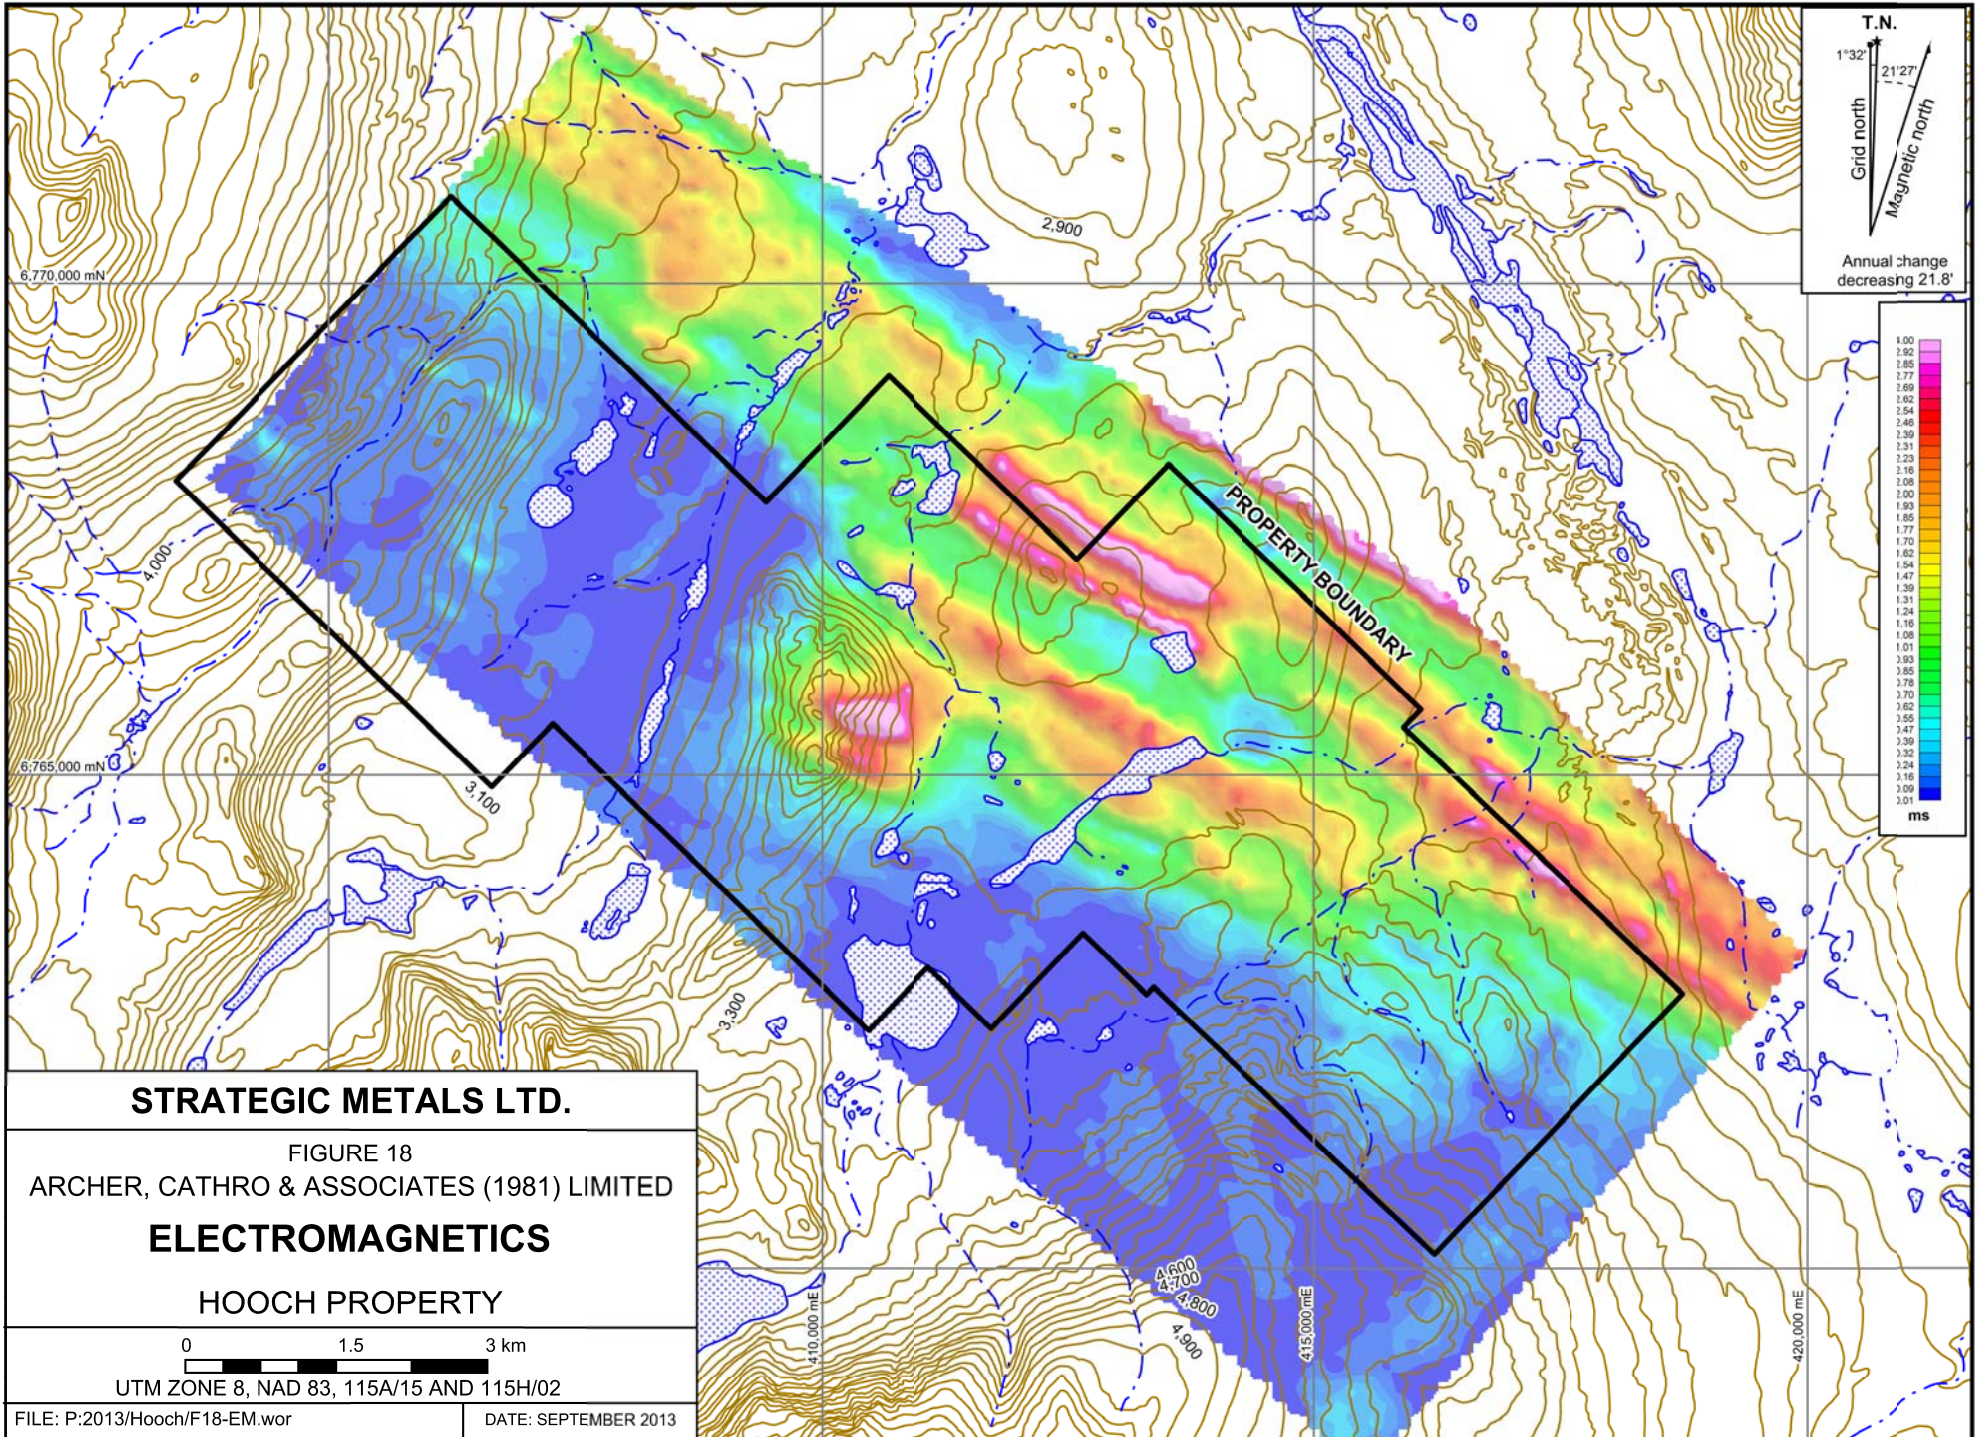

The VTEM data revealed strong northwesterly-elongated conductive bodies on the northeastern side of the survey region, but none on the southwestern side (Figure 18). The conductive linears may represent graphite-rich beds within the metasediments. A 1500 by 1000 m strong electromagnetic conductor correlates with the topographic high in the centre of the property. Geological mapping of this area in 2013 did not identify the source of the conductor due to limited outcrop exposure.

DISCUSSION AND CONCLUSIONS

The Hooch property is favourably situated in the southern part of the Dawson Range Gold Belt, about 25 km south-southeast of Strategic Metals' Hopper property where drilling has identified high-grade copper-gold skarn zones flanking a porphyry copper prospect. Detailed geochemical, geological and geophysical studies performed on the Hooch property have identified two copper, gold, silver, molybdenum and tungsten skarn horizons and a gold-rich quartz vein, which collectively comprise the Moraine Showing.

Preliminary geochemical and geological mapping programs in previously unexplored parts of the property have highlighted additional areas with skarn and/or porphyry potential. The central soil grid returned elevated copper-in-soil geochemistry within a Ruby Range Suite intrusion, which is

encouraging for porphyry-style mineralization. Although most of the southeastern part of the property covers glaciated and heavily vegetated terrain, cursory soil sampling returned significant gold, arsenic, copper and zinc anomalies. At present time the control of mineralization in this area is not known; however, due to the close proximity of some of the high gold-in-soil values to creeks that coincide with magnetic lows, it is possible that the gold is structurally controlled.

Follow up work in the covered southeastern corner of the property should include digging hand pits in the vicinity of strongly anomalous gold-in-soil values. Additional studies should be completed to determine the extent of down-ice and/or downhill dispersion.

Future exploration at the Moraine Showing should include deepening existing trenches with the goal of sampling bedrock. Pending encouraging results from trench sampling, self-propelled reverse-circulation percussion drilling or helicopter-supported diamond drilling should be performed to test the extent and continuity of both skarn and vein style mineralization.

Comments: Dominately quartz-mica schist with pervasive reddy/orange alteration. Rock is weakly quartz veined with veins up to 1 cm. Sample was float (represents about 1% of subcrop) taken from a 10- 15 m high 50 degree slope taken from the plain of a landslide/slump. The sample was taken below an andesite-aplite? dyke, which may be responsible for the alteration. The outcrop is approximately 10 x 4 m.

Sample Number: L865554 Grid East: E Grid North: N Type: **Grab** Dimension:

Comments: A continuous 50 cm wide chip sample was taken from the footwall of country rock adjacent to a 10 cm wide alkali-feldspar quartz dyke. The sample consists of medium green and white/beige banded (varies from mm to cm scale) comprising medium grained chalcedony? and alkali-feldspar and quartz, respectively. Interfingered alkali-feldspar and quartz dyke (1 cm to 2 cm- 4 per 0.5 m) occurs pervasively throughout these rocks. Footwall is up to 80 cm thick (may be thicker - trends into vegetation cover) and trends into vegetation along strike east and north (trace is approxiamtely 2.4 m long). The

LITHOLOGICAL UNITS

EARLY TERTIARY

ETgN: RUBY RANGE SUITE
 Biotite-hornblende granodiorite (locally K-feldspar megacrysts), quartz monzonite, quartz diorite, minor granodiorite-gneiss; hornblende and biotite-hornblende diorite, biotite-quartz-feldspar porphyry and porphyritic biotite-quartz monzonite.

LOWER EOCENE

IES1: SKUKUM
 Flow banded rhyolite and andesite flows and breccia, tuff, pyroclastic and epiclastic rocks, granite conglomerate; rhyolite feldspar porphyry domes, plugs and laccoliths; feldspar ± hornblende ± quartz-phyric felsite dykes and plugs.

LATE PROTEROZOIC AND PALEOZOIC

PPN: NISLING ASSEMBLAGE

PPN1: Dark grey to brown, biotite-muscovite-quartz-feldspar schist, quartzite and micaceous quartzite, garnetiferous, felsic chlorite-biotite orthogneiss; rare amphibolite, minor(?) two-mica gneiss and hornblende diorite gneiss.

PPN2: Bleached white-weathering, white to grey, coarsely crystalline, flow banded, feld marble; graphite, chert, metabasite and calc-silicate lamina are common.

SYMBOLS

--- Contact; known and inferred
 - - - Linear
 Chl - chlorite alteration QFP - Quartz feldspar porphyry
 Ep - epidote alteration ● Outcrop
 Sil - silicification
 # Bedding orientation
 # Foliation measurement
 # Fracture orientation
 # Quartz vein
