1 Introduction

White Gold Corporation commissioned Groundtruth Exploration Ltd. (“Groundtruth”) of Dawson, Yukon to perform Soil Sampling, Dighem and XCAM aerial survey programs on their Pedlar Gold Property (the “Property, located in Yukon’s White Gold district, approximately 130 km southeast of Dawson, YT in the Dawson Mining District on NTS Map Sheet 115O/13 north of the Yukon River near the confluence with Britannia Creek (Figures 1, 2).

2564 Soil samples, 360km² of XCAM survey (28cm resolution) were collected on the property during the 2016 field program.

8126 Soil samples and 226.3 line km of Dighem were collected on the property during the 2017 field program. The Dighem survey was contracted to CGG Global of Toronto.

Results and interpretation of these surveys form the basis of this report. Appendices to this report are attached as digital files.

2 Property Description, Location, Accessibility, Climate

The Pedlar Gold Property is located in the central-western part of Yukon, approximately 130km southeast of Dawson (Figure 1) near the confluence of the Yukon River and Britannia Creek. The center of the property is located at Latitude 62°56’N and Longitude -138°35’W.

The property is located in an unglaciated region of the Dawson Range. Elevations range from 440m to 1130m. Vegetation is typical of the Boreal forest, with mixed white and black spruce forests in valley bottoms, stunted black spruce and moss matt forests underlain by permafrost on north facing slopes and as elevation increases, transitioning into moss, talus and felsenmeer with increasing elevation. The typical climate of the area is moderate precipitation, warm summers, and cold winters.

Access to the property is by helicopter from Dawson City or via fixed wing aircraft to one of 4 airstrips within 20km of the property. Dawson is the nearest supply center and 538km by paved highway from Whitehorse, Yukon Territory (Figure 1).

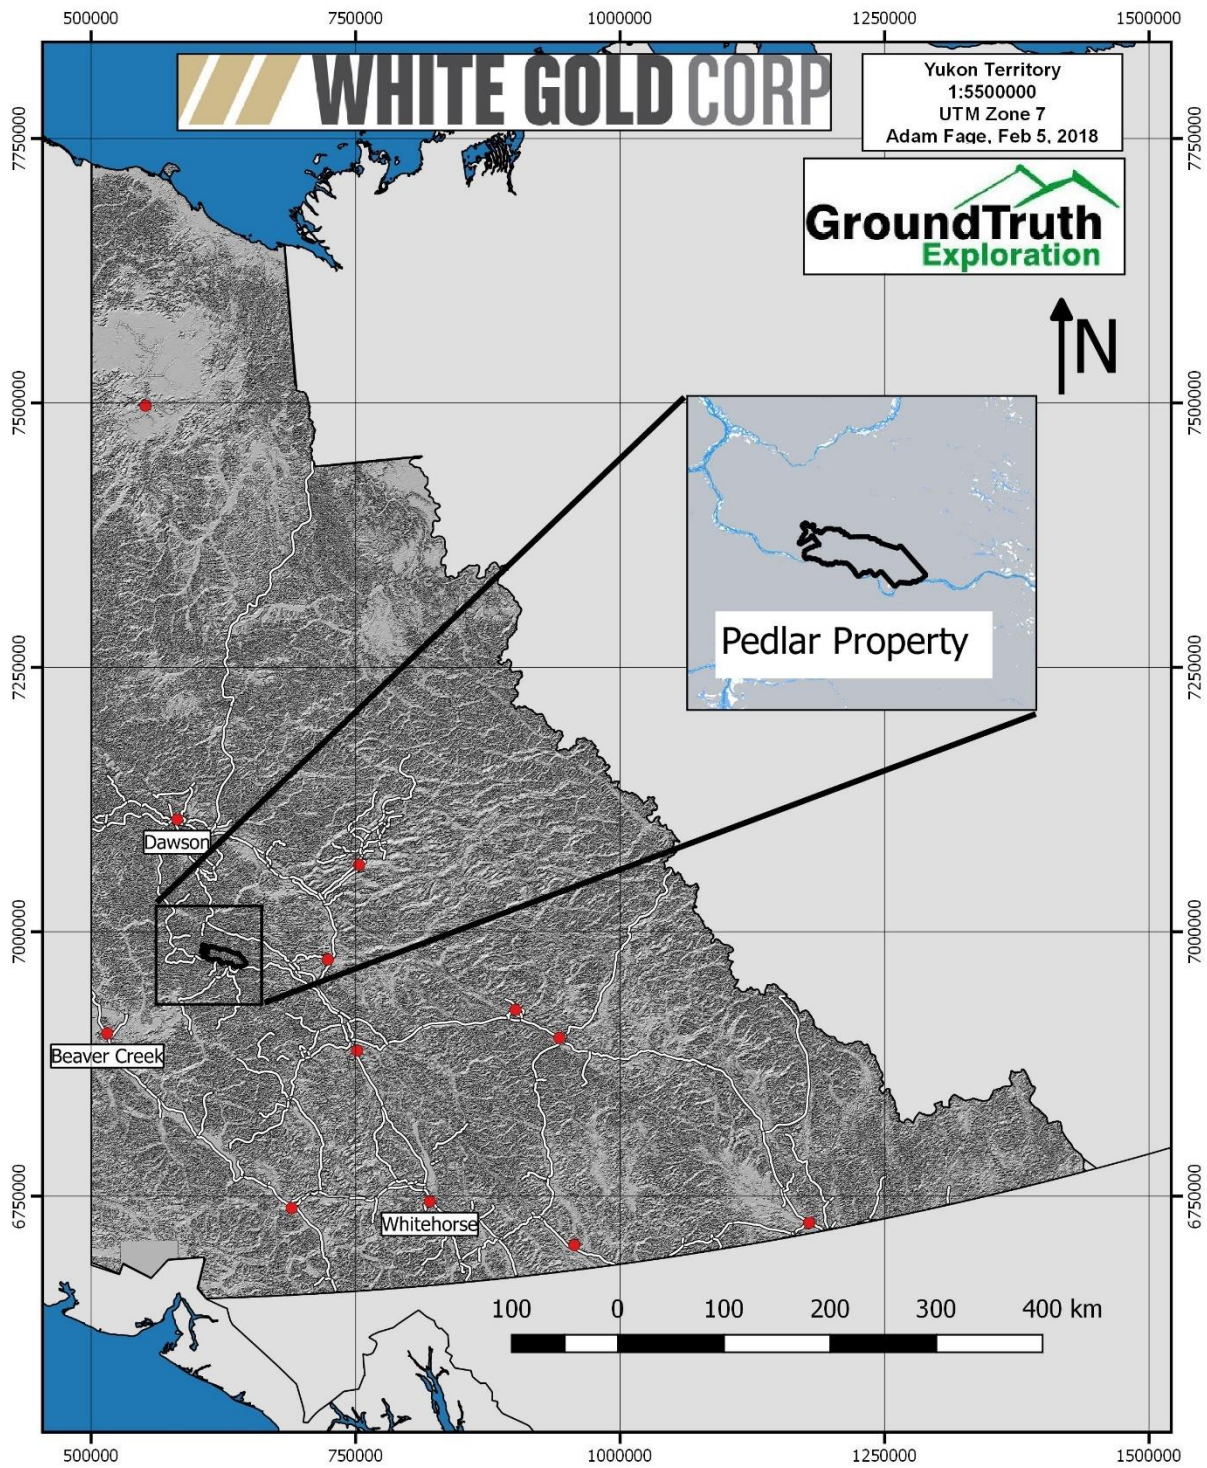

Figure 1: Location of the Pedlar Property, Yukon, Canada

3 Claim Information

The Pedlar Gold Project is registered in the Dawson Mining district on mapsheet 115J/15,16. (Figure 2, Appendix A) It encompasses 42879 hectares and is composed of the following 2187 claims:

Claim name	Grant Number	Owner	Operator
Bridget 1-8	YC35402-409	White Gold Corp. - 100%	White Gold Corp. - 100%

4 History

The Pedlar property covers the Scroggie and Baja, Minfile occurrences (staked as porphyry copper targets following the Casino discovery) and the Onasick uranium Minfile occurrence, all in the central property area (Minfile Numbers 115J 072, 073, 093) as documented by the Yukon Geological Survey. In the Pedlar Project area, Scroggie and Mariposa Creeks are major placer producing streams and Pedlar and Cripple Creeks have seen some placer production.

The work completed by various operators as documented in Yukon Minfile (*Deklerk, 2010*) and the Geological Survey of Canada and company publications is summarized below.

1969-70: Reconnaissance soil sampling on Baja (Cripple claims) in 1970 by Selco Exploration Company Ltd under option from Dawson Range Mines Ltd. following the discovery of the Casino copper porphyry deposit to the south (*Deklerk, 2010*). Results were not reported.

1970-72: Grid soil sampling, mapping, hand trenching and a VLF-EM survey by Dawson Syndicate (Silver Standard Mines Ltd. and Asarco Exploration Company of Canada Ltd.) in Scroggie area (Bridget claims) outlined a molybdenum and lesser copper soil anomaly, traces of chalcopyrite, molybdenite, pyrite and magnetite and weak skarn alteration (*McMichael, 1973*).

1977-80: Soil sampling, radiometric surveys and limited pits and trenches for uranium were conducted in the Onasick area (U claims) by a joint venture between Eldorado Nuclear Ltd. and Canadian Occidental Minerals Ltd., and by N. Burmeister on adjacent claims (*Burmeister, 1980*). Maximum values of 535 ppm uranium were obtained in soil and brecciated and clay altered rock chips were obtained from soil pits (*Riley, 1978 and Olsson, 1979 and 1980*).

1980: Geological mapping, geochemical sampling (160 soil, 70 rock, 52 stream sediment) and IP and magnetic surveys in Scroggie area by Amax of Canada Ltd. in 1980, under option from N. Burmeister targeted anomalous tungsten from reanalysis of previous sample splits. A 300 by 600m coincident copper-molybdenum soil anomaly open to the south, a broad induced polarization and a separate magnetic anomaly were outlined, but only very low tungsten.

2004-08: Prospecting and soil sampling in Scroggie area in 2005 with detailed magnetometer (38 line km) and soil (595 samples) surveys in 2008 by Shawn Ryan outlined a 750m long, >200 to 711 ppm copper \pm molybdenum (to 322 ppm) soil anomaly with flanking tungsten values, bismuth (up to 155 ppm), and up to 62 ppb Au. The magnetic survey outlined two regional northwest trending magnetic highs separated by a broad magnetic low (*Ryan, 2009*). The results suggest similarities with the Minto and Lucky Joe areas of mineralization.

Staking of U claims and soil sampling by Shawn Ryan was conducted in the Onasick area in 2005, followed by reconnaissance soils (*Hibbitts and Nillos, 2007*) and an airborne magnetic and radiometric survey (*Sheldrake, 2007*) by International KRL Resources Corp. under option. A 100m by 500m long uranium in soil anomaly (maximum 408 ppm U) was delineated (*Ryan, 2006*).

2011: Ethos Gold Corp. carried an exploration program on the Bridget property during the 2011 field season. The objective of 2011 exploration on the Bridget property was to screen the property, primarily using ridge-and-spur soil sampling, to detect geochemically anomalous areas that would suggest a substantial zone of gold mineralization. The 2011 exploration on the Bridget property included collection and analysis of 9,457 soil samples, pit trenching, 296 prospecting and rock samples, 4,812 line kilometers of airborne magnetic and radiometric surveying, and ~150 airphotos to create 45 orthophotos of the Bridget property. A total of 385 man-days work was completed during the 2011 field season plus work by contractors up to September 30, 2011 (*Tallman, 2012*).

4.1 Regional Geology

Regional and Property Geology of the Pedlar Property is summarized below from Paulter, 2011.

The following regional geology is primarily summarized from Gordey and Ryan (2005) for the Stewart River map sheet (115 N-O) and integrated with the older geology for map sheet 115 J by Tempelman-Kluit (1974).

The Pedlar Projects occur within the unglaciated Yukon Plateau portion of the Paleozoic Yukon Tanana Terrane, southwest of the Tintina Fault, dominated in the regional area by Devonian to Mississippian metasiliciclastic rocks (DMps), which interfinger with, and are stratigraphically overlain by, intermediate to mafic amphibolite (DMA). The metasiliciclastic rocks include metamorphosed fine clastic rocks, quartzite and conglomerate. The above lithologies include marble horizons (DMc) and are metamorphosed to amphibolite grade. Devonian to Mississippian metasedimentary rocks (quartzite and metapelite) of the Nasina Assemblage (DMq) lie structurally above and/or may partly be equivalent to the above metaclastic unit.

Abundant orthogneiss bodies of Devonian to Mississippian (DMog - undivided, DMogg, DMoga, DMogt, DMogta) and Permian ages (Pog - undivided, Pogg, Poga), with compositions ranging from granite (g) to K-spar augen bearing (a), to tonalite and diorite (t), occur within Yukon-Tanana Terrane. DMogta represents undivided DMogt and DMA. Narrow bodies of Paleozoic ultramafic rocks (mPum), commonly serpentinized (mPums) also occur within the area.

On map sheet 115 J the above units are generally undifferentiated with the Devonian-Mississippian, and possible minor Permian, felsic and lesser mafic orthogneiss, with interlayered amphibolite and metasedimentary basement rocks represented as the Pelly Gneiss (DMgPW). Unit DMN3 is dominated by Devonian-Mississippian metasedimentary quartzite ± chlorite schist, locally with feldspar augen bearing orthogneiss.

The above units are interpreted to represent two arcs, an older Devonian to Mississippian arc consisting of amphibolite (DMA) and associated subvolcanic intrusions (DMogg, DMoga, DMogt) built on a siliciclastic basement (DMps, DMq, DMcg, DMNq) and a Permian arc of granitic orthogneiss (Pogg, Poga) and coeval metavolcanic rocks (PKs) built on the Devonian-Mississippian arc.

The above lithologies are intruded by small plugs and stocks of Cretaceous aged quartz monzonite and granodiorite (Kg), Late Cretaceous Prospector Mountain suite felsic, commonly quartz and/or feldspar porphyries (LKp) and Jurassic aged granodiorite (eJgd,

eJgA), and unconformably overlain by massive andesite flows and breccias of the Late Cretaceous Carmacks Group (uKcV), locally with Early Cretaceous coarse clastic to conglomerate sedimentary rocks (IKTcg) at the base of the sequence. Early

Tertiary feldspar ± quartz porphyry stocks and dykes (Tg) intrude the above. All of the above lithologies are overlain by small, isolated occurrences of Quaternary basalt (Qb).

Northwest trending faults predominate on the map sheet, locally with more northerly trends (particularly in the central map area) and fewer (or more poorly documented) northeast trends (Figure 3).

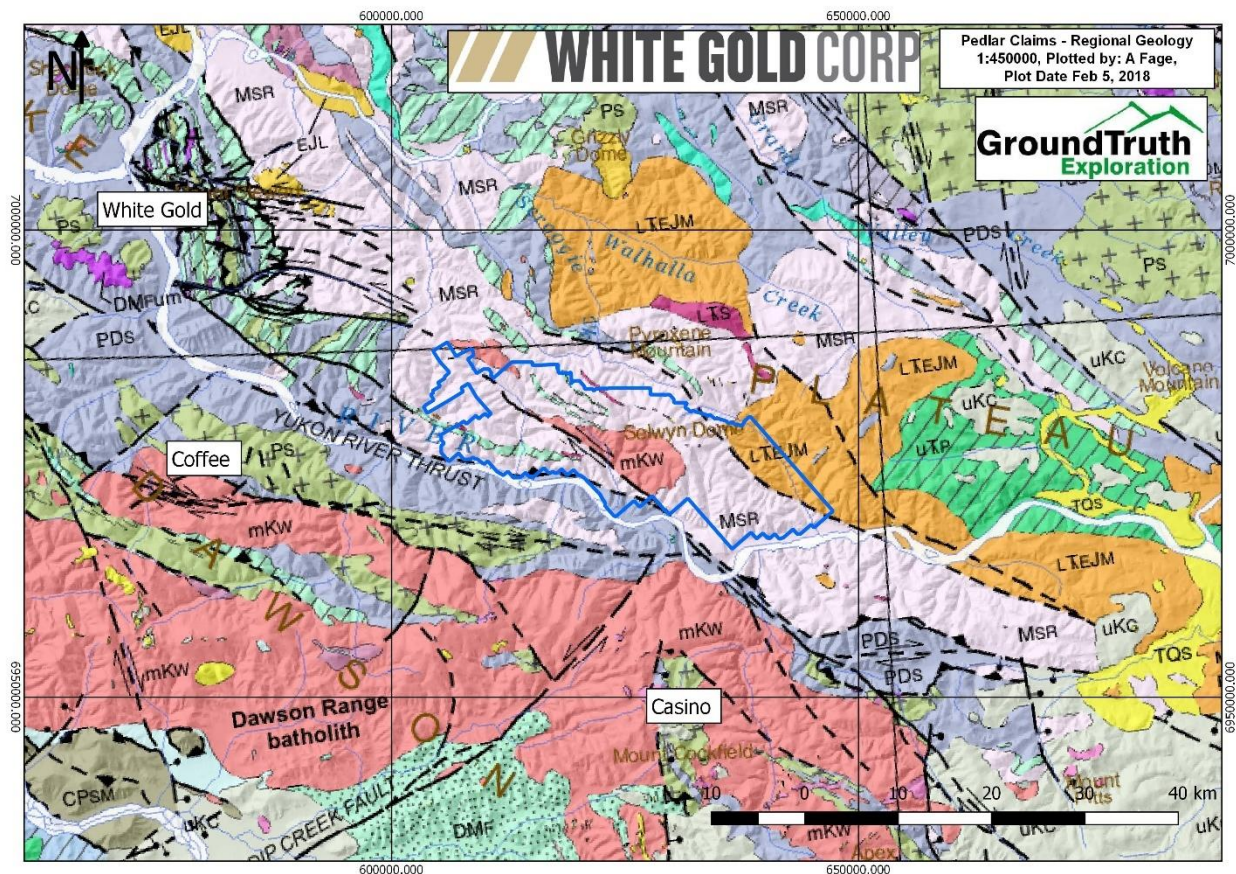

Figure 3: Regional Geology of the Pedlar Property (From Colpron et al., 2016)

4.2 Property Geology

The Bridget Project is primarily underlain by undifferentiated Devono-Mississippian, and possible minor Permian, felsic and lesser mafic orthogneiss, with interlayered amphibolite and metasedimentary basement rocks (DMgPW – Pelly Gneiss) of the Yukon-Tanana Terrane (Figure 4). This unit lies on trend of similar lithologies that underlie the White property, which includes the White Gold deposit, of Kinross Gold Corporation.

The lithologies have been mapped in more detail on the Stewart River map sheet (115N-O).

The northern Pedlar claims and southern U claims are underlain by Devonian-Mississippian metasedimentary basement rocks (DMN3) of the Yukon-Tanana Terrane (including quartzite, micaceous quartzite and quartz-muscovite \pm chlorite schist), locally with feldspar augen bearing orthogneiss. A marble band, with minor skarn alteration has been mapped in the northern Bridget grid area (Booth et al., 1980).

The Pelly Gneiss is intruded by a stock classified as Early Tertiary Nisling Range sugary textured alaskite (eTqN). Microporphyrific rhyolite to coarse grained quartz feldspar porphyry was reported in previous work in the Bridget claim area (Booth et al., 1980). The stock was mapped as Tertiary (now considered to be Cretaceous) Coffee Creek granite, by Tempelman-Kluit (1974) and described as a medium grained, and locally fine grained quartz monzonite by Olsson, (1980). During the site examination by the author an aphanitic quartz eye porphyry of alaskite composition was observed to the east on Selwyn Dome, similar to quartz eye porphyries of the Late Cretaceous Prospector Mountain Suite (LKqp). Mineralization within the southeastern portion of the Dawson Range copper-gold belt (Freegold to Casino) is intimately associated with rocks of the Prospector Mountain Suite. The Patton porphyry at Casino, the main host to the porphyry gold-copper-molybdenum mineralization, has been dated at 74-75 Ma (Bennett et al., 2010).

The Dawson Range Batholith lies 6 km to the south of the southernmost Bridget Project and primarily consists of the Casino granodiorite phase (mKgW) in this area. Early Jurassic granodiorite of the Aishihik Suite (eJgA) at the north end of the Carmacks copper-gold belt lies just east of the Project.

A strong northwest trending aerial and magnetic lineament, noted by Burmeister (1980a), traverses the southern Pedlar and U claims and may represent a major splay of the Big Creek Fault.

The Bridget Project is located 40 km east of the Coffee Project, 55 km southeast of the White Gold deposit and 25 km northeast of the Casino gold-copper-molybdenum deposit of Western Copper Corporation

Source: GSC (Jim Ryan, et al, 2013)

5 Geochemical Sample Preparation and Analysis

Samples were shipped to Bureau Veritas (BV) sample preparation facility in Whitehorse. Prepared samples were shipped by BV to Vancouver where final analysis was completed.

Soil samples are prepared using the SS80 method. Samples are dried at 60 degrees Celsius and sieved until up to 100 grams of material passes 180 microns (80 mesh). The samples are then analyzed by the AQ201+U method which involves dissolving 15 grams of material in a hot Aqua Regia solution and determining the concentration of 37 elements of the resulting analyte by the ICP-MS technique.

6 Soil Sampling Program

6.1 Introduction

The 2016 soil program consisted of sending a 9 man crew from Dawson City for a 13 day detailed sampling program to collect 2563 soil samples with the objective of sampling ridges and spurs throughout the property.

2016 sampling took place on May 11, September 22-29, October 1-2, 4-5 2016.

The 2017 soil program consisted of sending a 19 man crew from Dawson City for a 26 day detailed sampling program to collect 8126 soil samples with the objective of sampling grids over anomalous gold in soil anomalies encountered during ridge and spur sampling programs throughout the property.

2017 sampling took place on June 8, 10-12, 14-30, July 1-4, 11, 2017.

6.2 Personnel

The 2016 survey was conducted by the following GroundTruth Exploration personnel:

1. Braeden Paun-Burnett
2. Brian Hyde
3. Dan Brown Hozjan
4. Jack Taforo
5. Luke Severinsen
6. Mark Severinsen
7. Matt Emmett
8. Phil Severinsen
9. Yoann Voyer

The 2017 survey was conducted by the following GroundTruth Exploration personnel:

1. Alexander Arbery
 2. Alan Binger
 3. Andrew Truax
 4. Brian Hyde
 5. Cosenti Graf-Smith
 6. Dan Brown-Hozjan
 7. Griffin Schroff
 8. James Alexander
 9. Julian Moore
 10. Jordan Siewnarine
 11. Keaton Markham
 12. Luke Severinsen
-

13. Norbert Kapa
14. Patrick Dunbar
15. Pawel Kapa
16. Riley Dean
17. Sean Babcock
18. Tom Lacey
19. Veronica Valdron

6.3 Soil Sampling Survey Procedure

The survey is completed in the field according to the following procedure:

All sampling traverses are pre-planned, with pre -specified sampling intervals, typically 50m. Field technicians navigate to sample site using handheld GPS units. The soil sampler arrives at each sample site, identifies the most appropriate location to collect the sample and lays out a sheet of plastic (12"x20" ore bag). The soil sample is taken using an Eijkelkamp brand hand auger at a depth of between 20cm and 110cm. Samplers strive to consistently collect C-Horizon sample material. Where necessary (rocky or frozen ground) a prospector's pick ('mattock') is used to obtain the sample.

The soil is laid out on the sheet of plastic in the order it was recovered from the sample hole. Two Standardized photos are taken at each sample site- 1) Sample Location photo: across slope, 5m from sample hole with auger inserted and 2) Sample Profile photo: Close up of sample laid out on ore bag with barcode tag and munsell color chart in photo.

The sampler places the necessary amount of soil (400-500 grams) from the bottom of the hole into a kraft sample bag. The bag labeled with the 3-letter project and tagged with a plastic barcode ID tag containing a unique 7 digit sample identification number is inserted. A plastic barcode ID tag with the sample identification number is attached to a rock or branch in a visible area at the sample site along with a length of pink flagging tape.

A field duplicate sample is taken once for every 25 samples. Both samples are given unique Sample identification number. The data for both samples is recorded and a note is made indicating the duplicate and its corresponding sample identification number. At client's discretion, standard reference material is inserted into the sample stream at an interval of 1:50.

The GPS location of the sample site is recorded with a Garmin GPSMap 60cx or 76cx GPS device in UTM NAD 83 format, and the waypoint is labeled with the project name and the sample identification number. A weather-proof handheld device equipped with a barcode scanner is used in the field to record the descriptive attributes of the sample collected. This includes: sample identification number (scanned into device at sample

site), soil colour, soil horizon, slope, sample depth, ground and tree vegetation and sample quality and any other relevant information. As well, the GPS coordinates are entered into the handheld device as a secondary backup in case of GPS failure.

6.4 Soil Survey Results

A location map of soil samples collected in 2016 and 2017 is shown below in Figure 5.

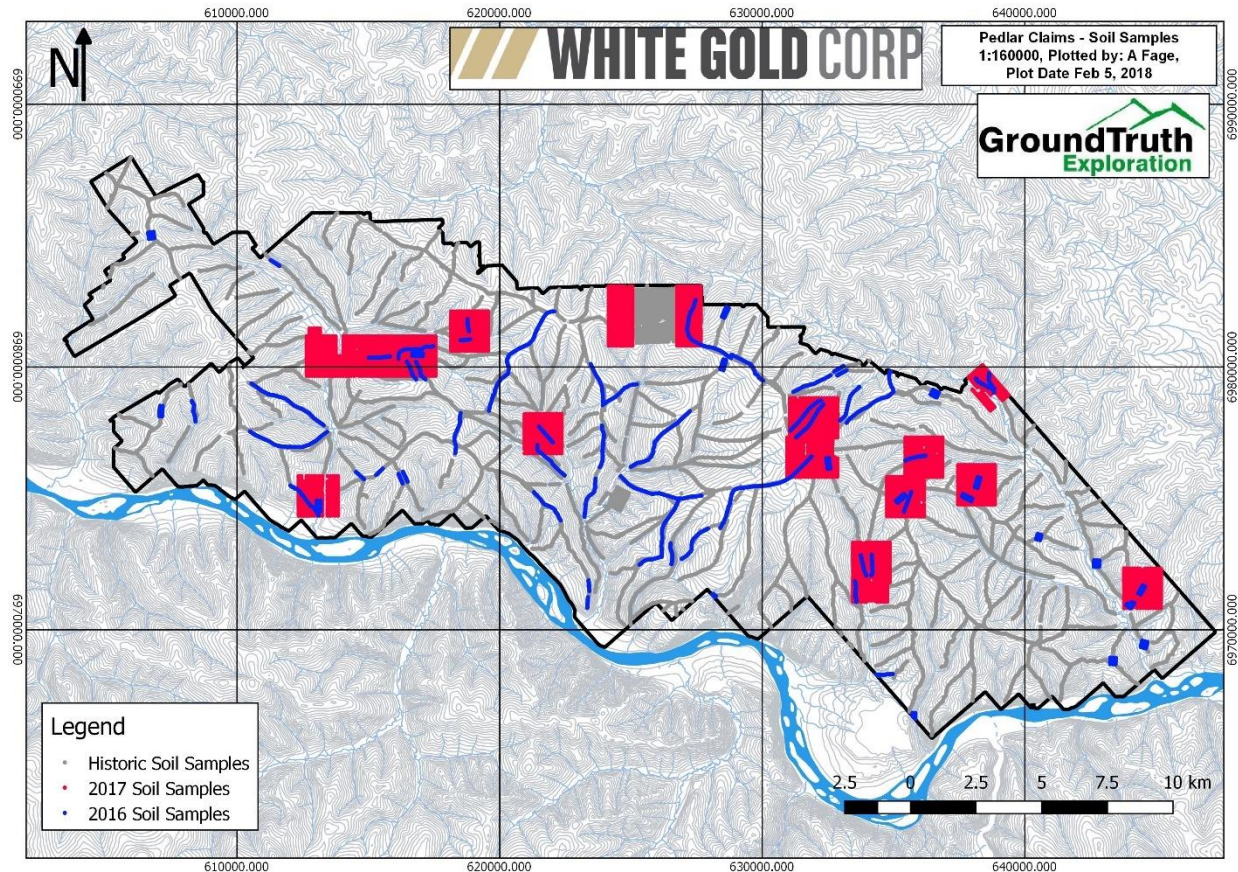

Figure 5: Location of 2016, 2017 Soil Samples

Maps shown below in Figures 6-10 are plotted with break points at 80th, 90th, 95th, 98th and 99th percentile for all samples on the property. Several low-tenor gold in soil anomalies and multielement (Ag/Mo/Cu/Pb/Zn) anomalies were identified in the ridge and spur sampling programs that were later followed up with grid sampling programs.

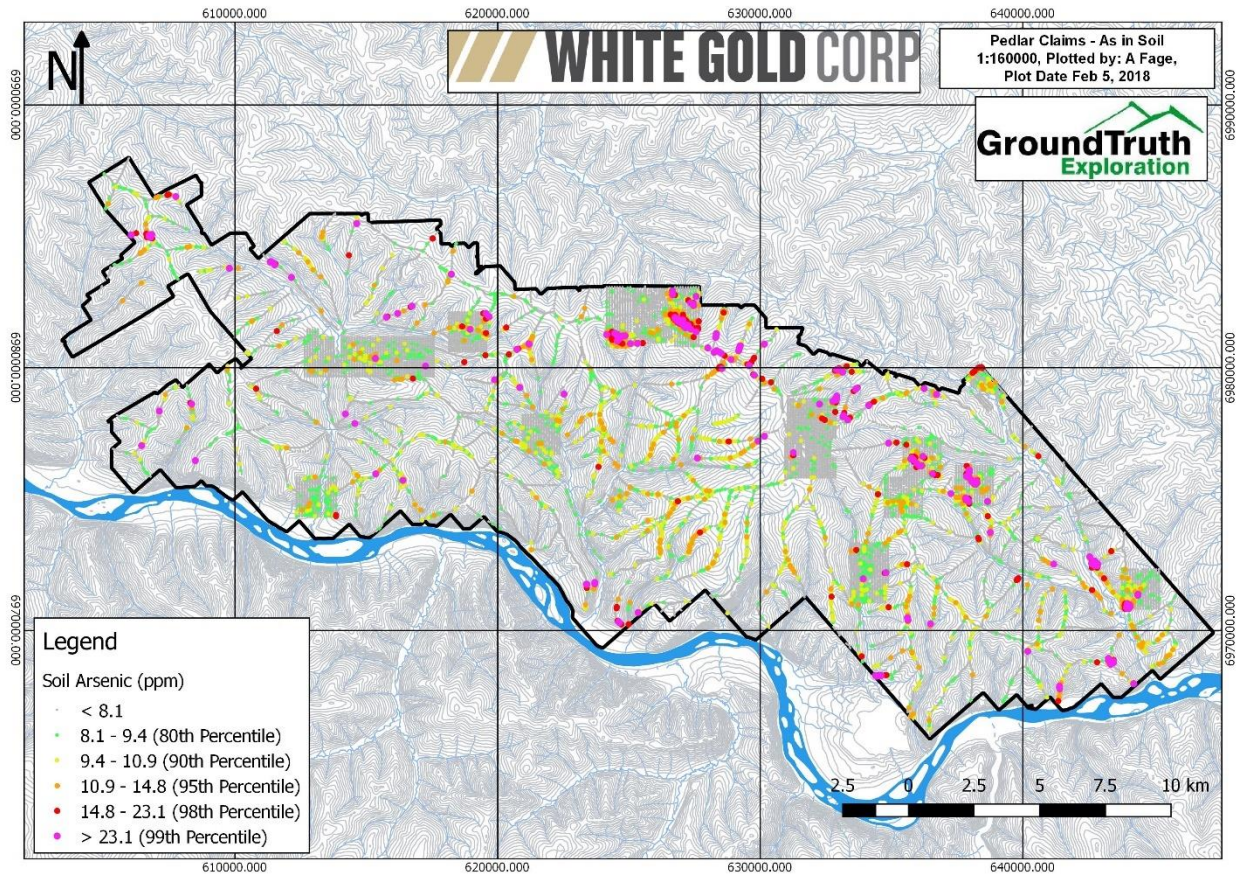

Figure 7: Arsenic-in-soil, Pedlar Property

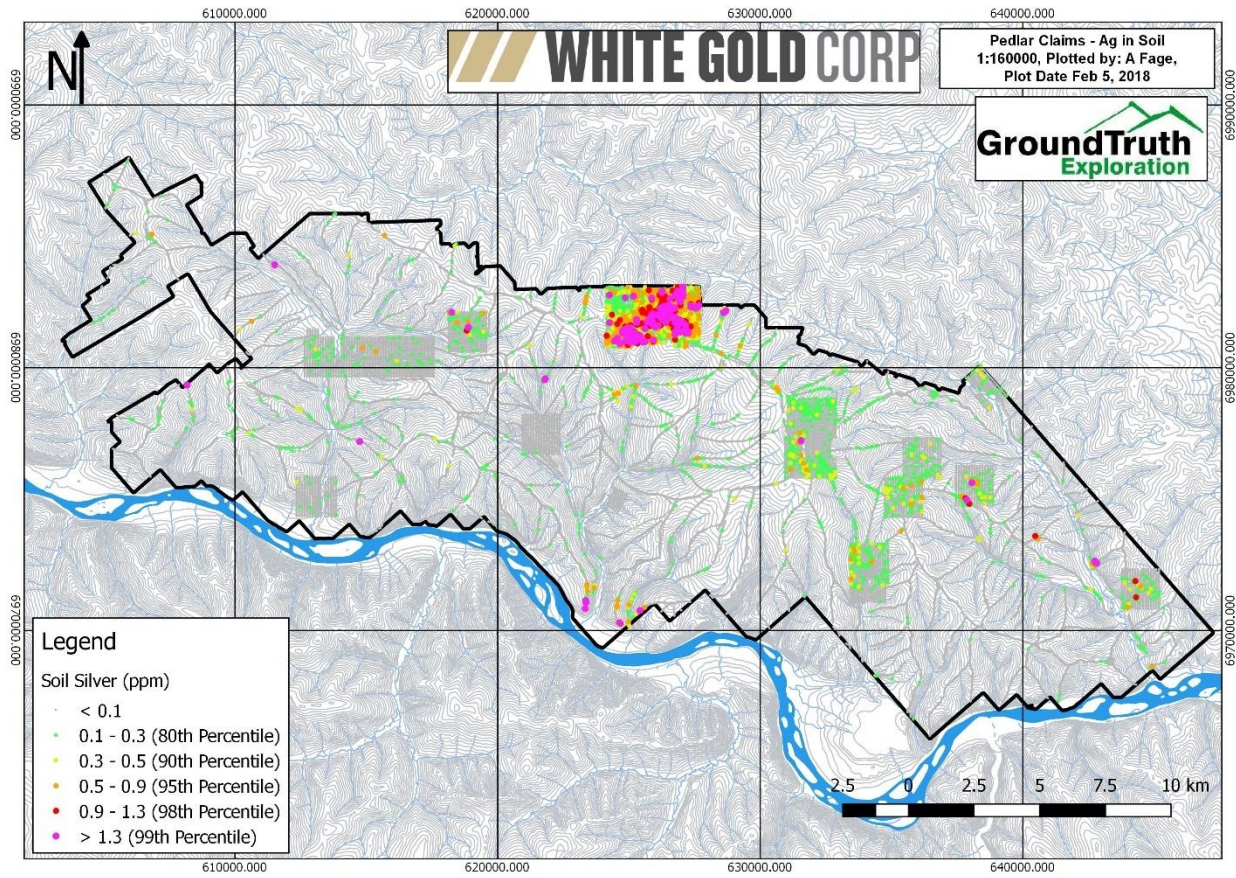

Figure 8: Silver-in-soil, Pedlar property

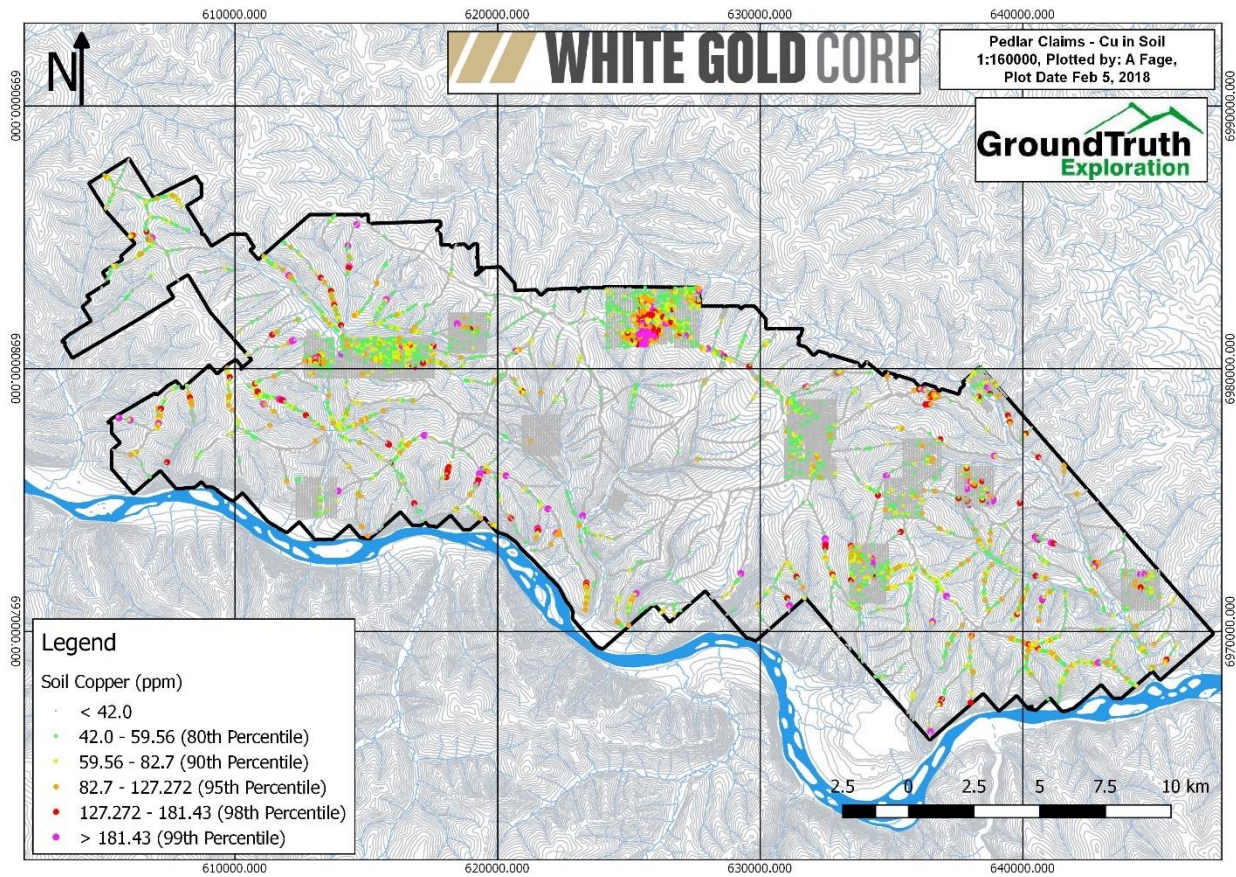

Figure 9: Copper-in-soil, Pedlar property

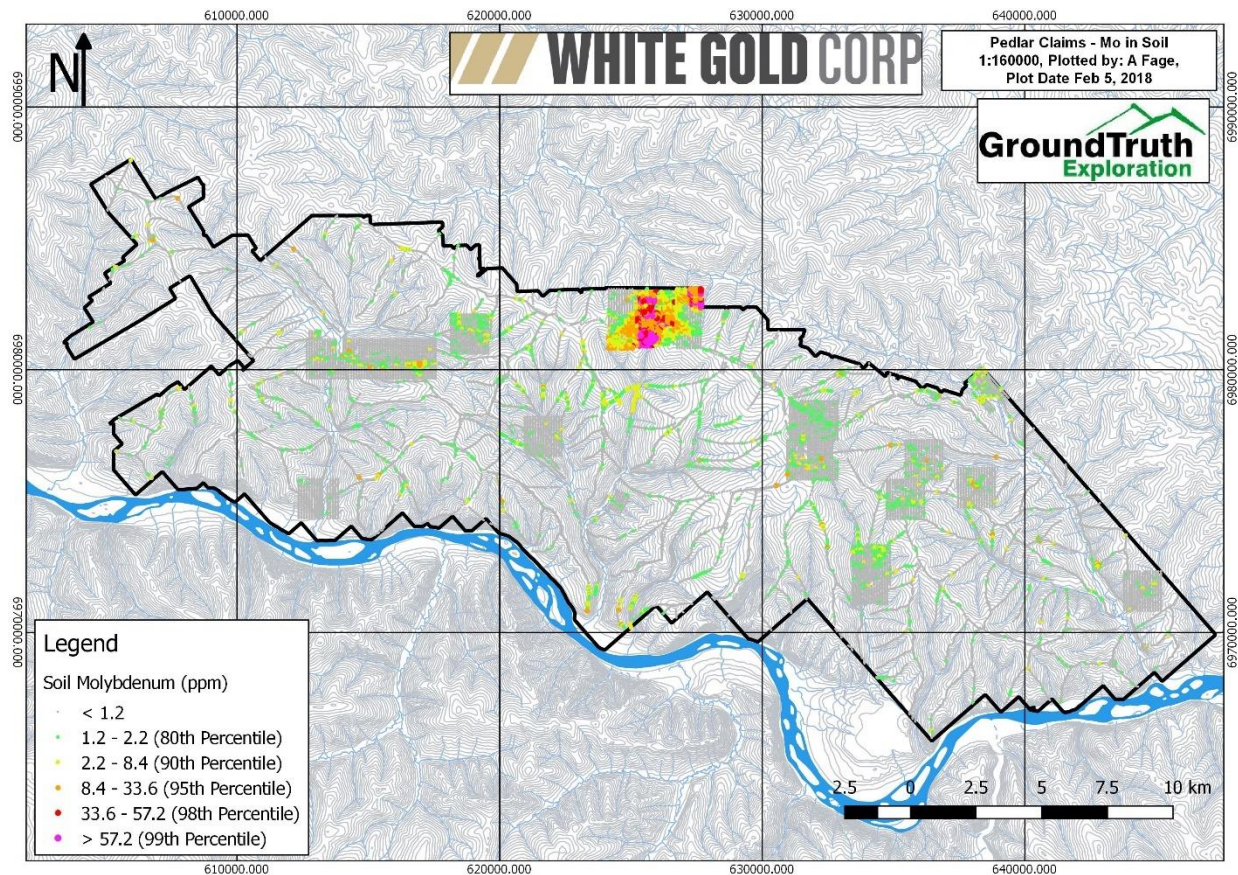

Figure 10: Molybdenum-in-soil, Pedlar Property

7 XCAM Survey Program

7.1 Introduction

360km² of XCAM survey at 28cm resolution was completed on October 20, 23, 24, 2016. This survey produced an orthophoto and terrain elevation model over the property.

The XCam pod is a plastic pod containing two cameras set to capture a panoramic shot. The pod is mounted onto a bar attached to a strut on the plane (Figure 11). The bar is parallel to the wing, which will be parallel to ground in flight, but angled slightly upwards on the ground since the plane is a tail-dragger. The pod is attached with two rings to a curved metal plate on the bar.

Figure 11: XCAM Mounted to airplane strut.

Inside the pod are two Canon cameras and a single usb hub. The cameras are both connected to the hub which is connected to a microcontroller to the rear ports. These ports connect cables (usb and coaxial) to the external GPS unit mounted to the top of the wing, the external batter, and the tablet: the latter two situated inside the plane. The GPS is connected to the microcontroller first to provide location data for the photo metadata.

Inside the plane is the tablet, two external camera batteries, and in inverter. The pod does not have an internal power source and can not run off power from the plane, instead custom batteries are used.

The tablet contains software to create and view missions live as they are being surveyed. It has software to utilize the external GPS and provide heading corrections to ensure correct coverage and overlap of photos. It is also possible to view the camera image live via the tablet and Canon software. All the mission parameters (ie. target area, elevation, flight lines) are chosen with mission creation and can not be changed during a mission. The only settings that can be altered without creating a new mission are camera settings (ie. shutter speed, f-stop, and ISO).

7.2 XCAM Survey Results

The 2016 drone survey covered the entire Pedlar claim block. The orthorectified image resulting from the drone survey is shown below in Figure 12.

Figure 12: Orthophoto from the 2016 XCAM Survey of the Pedlar Property.

8 Dighem Survey Program

8.1 Introduction

This report describes data acquisition and preliminary data processing results of 2017 airborne frequency domain electromagnetic FDEM and magnetic survey. The survey has been carried out by CGG Canada Services. GroundTruth Exploration was commissioned by White Gold Corp, Toronto, ON to plan airborne survey and process the data.

Between June 10 and July 7, 2017, airborne-electromagnetic (AEM) and airborne-magnetic (AM) surveys were completed over Pedlar claims located in the Yukon Territory. This survey is a part of comprehensive airborne FDEM and magnetic survey in order to target future exploration on the property. Dawson City, Yukon was the base of operations. The airborne-geophysical surveys were undertaken using DIGHEM frequency-domain system.

8.2 Purpose and Scope

The primary purpose of completing AEM and AM geophysical surveys is to determine the spatial distribution of subsurface electrical and magnetic properties of rocks. This, in turn, will allow to characterize geophysical signatures for zones of mineralization and support geological models and structural mapping.

8.3 Survey Description

The Block 602997-13 of DIGHEM 2017 survey covers Bridget target area on Pedlar property. Total coverage of the survey block amounted to 226.3 km.

Data were acquired using a multi-coil, multi-frequency electromagnetic system, supplemented by a high-sensitivity cesium magnetometer. A GPS electronic navigation system ensured accurate positioning of the geophysical data with respect to the base map coordinates. The outline of survey areas and layout of flight lines are shown in Figure-13.

Block-13 was flown in an azimuthal direction of NE-SW (NE25°) with line spacing of 100m and SE-NW (NE115°) with tie lines spacing of 1250m. Survey coverage consisted of 206.0 km of traverse lines and 20.3 km of tie lines. The coordinates of the corner points of the survey blocks are presented in Table 1. Planned flight lines and total line-kilometers are summarized in Table 2 (after CGG report #602997, Oct. 6, 2017).

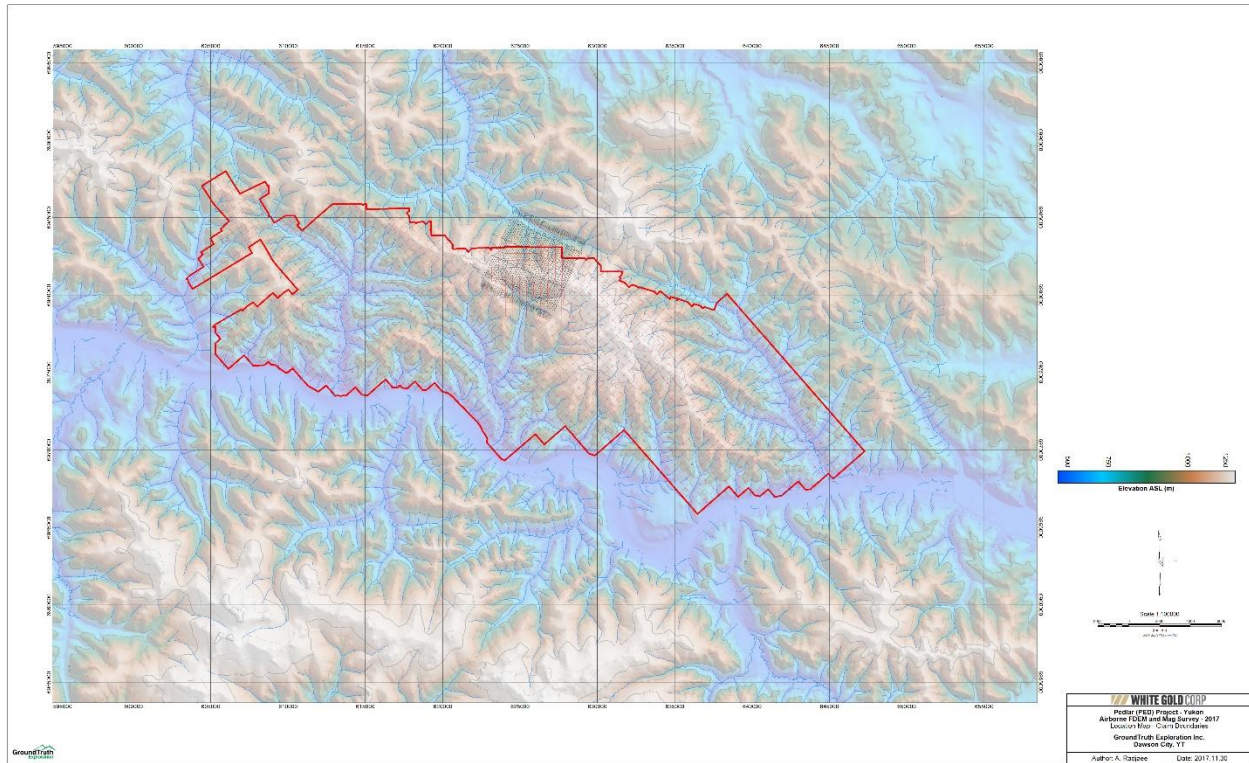

Figure 23: Location of airborne FDEM and Mag survey 2017 on Pedlar property.

Table 1: The coordinates of the corner points of the survey blocks.

8.4 Survey Theory

8.4.1 Electromagnetic surveys

Electromagnetic (EM) methods can be used to map subsurface variability in electrical properties caused by changes in lithology, structure, alteration, and contamination due to mining activity. These methods are sensitive to low resistivity targets and thus can be used to map the location and moderately conductor bodies. The depth of investigation can range from less than a few tens through hundreds of meters depending on amounts of subsurface conductivity and applied frequency. Resolution of targets and detectability tend to decrease with increasing depth of burial.

The data include in-phase and quadrature components for each frequency. The electrical conductivity of rocks can be modeled by inversion of electromagnetic data. 2D grids and derivative products provide information for mapping lithological and structural features or linear conductors.

In EM surveys, a transmitter does generate a time-varying electromagnetic field in the earth, known as the primary field. This field gives rise to small time-varying voltages in the earth. Where the earth is conductive, the voltages drive small time-varying flows of current, which give rise to electromagnetic fields of their own called secondary fields. EM surveys measure the earth's willingness to conduct electricity, or conductivity in siemens/m. The higher the conductivity, the more current will flow in the earth for a given electrical field strength.

Any time-harmonic signal can be expressed by an amplitude factor times an oscillating term of a sinusoidal function. We denote the transmitter current as $I_0 \cos \omega t$, which indicates a peak current I_0 and a fixed angular frequency ω . According to Biot-Savart's law, the primary magnetic field generated by this current is $H_p \cos \omega t$, where H_p can be determined using the distance from the transmitter to an observation point in the whole-space, and the primary field is entirely in-phase with the transmitter current. Then the primary field induces eddy currents in the subsurface. In most cases, this induced current is no longer in-phase with the primary and usually bears a phase lag ψ . So the secondary magnetic field due to the induction has the form $H_s \cos(\omega t - \psi)$, where the amplitude H_s is determined by the distance and geometric coupling. Finally, at the location of the receiver, we can observe the primary field $H_p \cos \omega t$ the phase-lagged secondary field $H_s \cos(\omega t - \psi)$.

An FDEM system in practice only measures the secondary field $H_s \cos(\omega t - \psi)$. The convention in FDEM is to use the primary field $H_p \cos \omega t$ as the reference to describe the secondary field data. First, the secondary field is considered as a linear combination of two orthogonal sinusoidal signals

$$H_s \cos(\omega t - \psi) = H_s \cos(\psi) \cdot \cos(\omega t) + H_s \sin(\psi) \cdot \sin(\omega t)$$

where $\cos(\psi) \cdot \cos(\omega t)$ represents a signal in-phase with the source and $\sin(\psi) \cdot \sin(\omega t)$ represents a signal out of phase with the source. The first term is also called “real” and the second term “imaginary” or “quadrature”. Next, the amplitudes of the two sinusoidal signals are normalized by the amplitude of the primary field at the receiver to obtain the data in real and imaginary components. Figure 14 shows primary and secondary fields, transmitter and receiver. The normalization provides significant convenience, as it eliminates the need for timing the measured signals and the effect of the transmitter and receiver's dipole moments. Because the data are relative quantities, they are expressed in percent or most often in parts per million (ppm).

Figure 14: A time varying electrical current generates a primary magnetic field which induces secondary currents in the subsurface, and creates secondary magnetic field. Both the primary and secondary fields reach the receiver (2017, GeoSci Developers).

8.4.2 Magnetic surveys

Magnetic is the most commonly used geophysical method for gold, diamond, platinum group metals and base metal exploration. Measurements of the magnetic field contain information about subsurface variations in magnetic susceptibility. Data can be acquired in the air (planes, satellites), on the ground (stationary, moving platforms, marine) and underground (boreholes, tunnels). The measurements record the sum of Earth's field and fields induced in magnetic materials. More

magnetic (i.e. susceptible) materials have stronger induced fields. Removing Earth's field from the observations yields anomalous fields that can be interpreted in terms of where magnetic material lies and also its susceptibility and shape. Processed data are presented as maps or profiles, and advanced processing, involving inversion, yields parametric structures or 3D models of the subsurface susceptibility distribution.

Magnetic surveying is extremely versatile and can be applied in many areas in the geosciences including geologic mapping and mineral exploration. In gold exploration, magnetics helps in direct detection of associated mineralization and for mapping large- and local-scale structure (faults, dikes, and shear zones).

To a first approximation, Earth's magnetic field resembles a large dipolar source with a negative pole in the northern hemisphere and a positive pole in the southern hemisphere. The dipole is offset from the center of the earth and also tilted. The north magnetic pole at the surface of the earth is approximately at Melville Island. The field at any location on the Earth is generally described in terms described of magnitude $|B|$, declination D and inclination I as illustrated in Figure 15.

When the magnetic source field is applied to earth materials it causes the material to become magnetized. Magnetization is dipole moment per unit volume. This is a vector quantity because a dipole has a strength and a direction. For many cases of interest, the relationship between magnetization M and the source H (earth's magnetic field) is given by:

$$M = \kappa H$$

where κ is the magnetic susceptibility. Thus the magnetization has the same direction as the earth's field. Because Earth's field is different at different locations on the earth, then the same object gets magnetized differently depending on where it is situated. As a consequence, magnetic data from a steel drum buried at the north pole will be very different from that from a drum buried at the equator.

The magnetic field that results from the magnetized earth is evaluated with the equation:

$$B_A = \frac{\mu_0}{4\pi} \int_V M \cdot \nabla^2 \left(\frac{1}{r} \right) dV$$

where μ_0 is the magnetic permeability of free space, M is the magnetization per unit volume V , and r defines the distance between the object and the location of the

observer. This magnetic field is referred to as the “secondary” field or sometimes the “anomalous” field B_A . For geological or engineering problems, these anomalous fields are the data to be interpreted, and this is what we seek to measure.

When the magnetization is governed by the linear relationship (1) then the above anomalous field can be written as:

$$B_A = \frac{\mu_0}{4\pi} \int_V \kappa H_0 \cdot \nabla^2 \left(\frac{1}{r} \right) dV$$

where (\cdot) is a vector inner product. This means that B_x is the projection of the vector B onto a unit vector in the x -direction. Similar understandings exist for B_y and B_z .

Figure 15: Earth’s magnetic field, declination (D) and inclination angles (2017, GeoSci Developers).

8.5 Field Survey

Details of system information and survey parameters including aircraft, geophysical equipment, quality control and in-field data processing are presented in Appendix-A of this report.

8.6 Results and Interpretation

Survey flight lines of DIGHEM 2017 are shown in Figure 4, apparent resistivity maps for different frequencies are presented in Figure 5 through Figure 9. Residual magnetic intensity map is presented in Figure 9. The data can be processed in advanced levels using inversion techniques, and be presented in 3D formats for detail analysis and visualization. This will ensure that 3D geological models respect a consistent structural, stratigraphic, and topological framework in addition to ensuring consistency between different geophysical models.

The combination of geophysical models and geological information allows some general correlations to be made. Commonly, geologic setting of epithermal deposits includes faulted, fractured, and brecciated rocks. Predominantly, geophysical signatures of epithermal deposits for electrical resistivity and magnetic susceptibility can be characterized as:

- Short-wavelength magnetic anomalies are common over volcanic terranes because of variable magnetizations and polarizations. This pattern may contrast with an area of moderate to intense alteration that will display a longer-wavelength low, often linear in the case of vein systems, caused by the destruction of magnetite. Local magnetic highs may be associated with intrusions. Magnetic lows will be associated with alteration, however, discriminating such lows from the background may be difficult on a deposit scale.
- Regional resistivity is generally low for weathered and altered rocks as compared to high resistivity typical of buried intrusions. A resistivity high flanked by resistivity lows is characteristic of a simple and idealized quartz vein system with associated argillic to propylitic alteration. However, there may be geologic structures and petrologic complications that distort this ideal picture. More generally, resistivity lows will be associated with: 1) Sulfides when concentrated and connected at about 5-percent volume or more, 2) argillic alteration, and 3) increased porosity related to wet, open fractures and brecciation. Resistivity highs will be associated with zones of silicification, intrusion, or basement uplifts.

Advanced inversion modeling and interpretation of EM and magnetic data is recommended for detailed and property scale explorational targeting works.

9 Discussion and Interpretation

9.1 Soil Sampling Program

The tenor of gold in soil anomalies encountered at the Pedlar property is much lower than at other properties within the area which contain recent gold deposit discoveries such as White Gold and Coffee (99th percentile quantiles are calculated at 18.8ppb). The higher tenor gold in soil samples are also found sporadically throughout the property and do not comprise linear gold in soil anomalies.

However, several robust multielement soil anomalies are emerging from the various soil sampling grids throughout the property; many of which were originally targeting anomalous gold in soil anomalies. For example, the Bridget grid is composed of a >1km x 2km Ag-Cu-Zn-Pb-Mo-Cd-W soil anomaly with 251 samples containing 1 g/t or greater silver in soil (max 6 g/t Ag). This anomaly is hosted within Simpson Range orthogneiss adjacent to a small sliver of Finlayson Assemblage amphibolite, an intrusion of Pyroxene Mountain pyroxenite and a plug of Rhyolite Creek rhyolite (Figure 23).

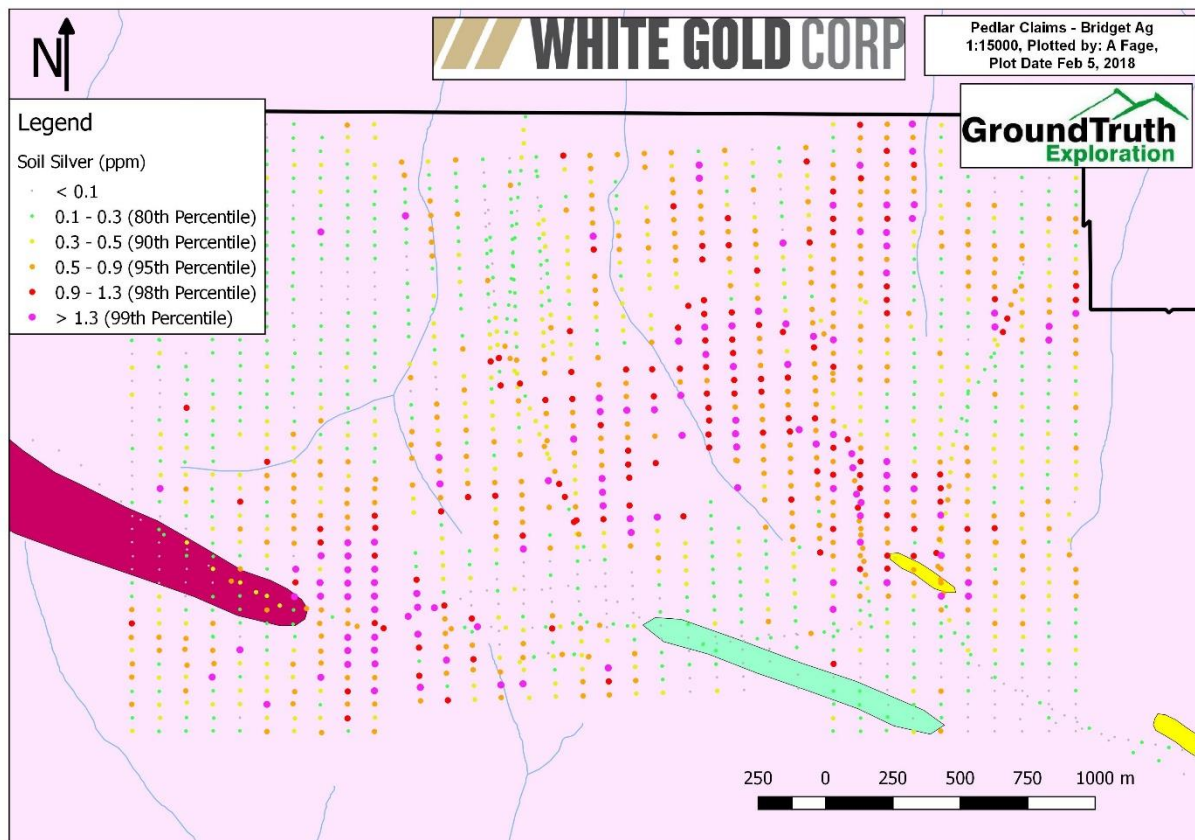

Figure 23: Silver in Soil, Bridget Anomaly, Pedlar property.

9.2 XCAM Survey

The XCAM image provides an excellent basemap for exploration and infrastructure planning and baseline environmental surveys.

9.3 Dighem Survey

The lineament interpretations of EM and magnetic results can better identify lithological and structures features as well as the fracture zones. Advanced inversion modeling and

interpretation of EM and magnetic data is recommended for detailed and property scale explorational targeting works.

9.4 Interpretation

Soil anomalies encountered thus far at the Pedlar Property are different in character than recent discoveries in the White Gold Camp (White Gold, Coffee, QV). The multielement soil anomalies host potential for several deposit types discovered throughout the Tintina Gold Belt such as porphyry (Casino), copper-gold (Minto), shear zone hosted gold (Fort Knox), quartz vein hosted (Donlin Creek, Pogo).

10 Recommendations

It is recommended that a comprehensive desktop study be undertaken combining all of the available geochemical, geophysical, and geological data available for the Pedlar property in order to determine a deposit, structural and exploration model for the multielement geochemical soil anomalies encountered to date. Once an exploration model is in place, further work can be planned.

11 Costs

Pedlar Expenditures	
2016 Soil Sampling 2563 Samples	\$179,483.55
2016 XCAM Survey	\$18,270.00
Total 2016 expenditures on the Pedlar Property	\$197,753.55

PED 1 Grouping Expenditures	\$191,420.48
PED 2 Grouping Expenditures	\$277,563.50
Ped 3 Grouping Expenditures	\$92,196.90
Total 2017 expenditures on the Pedlar Property	\$561,180.88

13 Qualification

I, Adam Fage have continuously been involved in Mineral Exploration since 2004. I graduated from Dalhousie University with an Honours Bachelor of Science (Earth Science) in 2008. I graduated from Lakehead University with a Master's of Science (Geology) in 2011.

Dated this 5th day of February, 2018.

Respectfully submitted

Adam Fage

A handwritten signature in black ink on a light green rectangular background, reading "Adam Fage".

Fixed Wing	Amount	Description
Islander, 206, Skyvan, etc.	\$ 2,764.15	GRA: Dawson - Ballarat strip
Total Logistical Support	\$ 28,539.90	

Total Project Expenditures \$ 92,196.90

Total 2017 expenditures on the Pedlar Property	\$561,180.88
---	---------------------

Appendix C: Soil Sample Location, Description and Assay Certificates
