## 1.0 summary

A diamond drill program, structural mapping exercise and an induced polarization geophysical ground survey was conducted on the Plateau Property between May 28 and September 4, 2018. The property is owned 100% by Goldstrike Resources Ltd. and consists of 3167 contiguous quartz claims situated in the Mayo Mining District. It is located 131 kilometers east of Mayo, Yukon Territory, along the Hess River within the Russell Range. Access to the project is by fixed wing float plane and by helicopter from Whitehorse and Mayo. There is an airstrip located 4 kilometers south of the property at Russel Lake.

The Plateau Property is underlain by the Vendian-Cambrian aged Yusezyu Formation of the Hyland Group and forms part of the Selwyn Basin of the Omineca Belt (ca. 580 Ma). The Yusezyu Formation consists of metamorphosed metasedimentary rocks with minor metavolcanics, intruded by a variety of intrusives. The supracrustal rocks underlying the claims are situated between major thrust faults with the Hess, MacMillan, and Robert Service Faults to the north and a series of thrusts characterizing the Moose Lake Fault to the south. Recent mapping has observed the Robert Service Thrust cross cutting the northeastern portion of the Plateau property.

Lower greenschist facies siliciclastic sandstones and pebble conglomerates account for 65% of the stratigraphy underlying the Plateau Property. Clastic argillaceous metasediments account for 25% and reflect a turbidite sequences consisting of well bedded argillaceous (argillite/shale/slate) metasediments with finer arenaceous (siltstone) metasediments. Interformational limestone (1%) occurs within the clastic metasediments with the most extensive and thickest units located in the western part of the Plateau property south of the Hess River. There are two major Mayo Suite Intrusions (ca. 95.5 Ma) located in the project area that are of granite to granodiorite in composition accounting for the remaining 9%. Both metavolcanics and metasediments have undergone several deformation events.

The property is structurally divided into two domains: The Hess Domain and the Armstrong Domain. The Hess Domain is stratigraphically lower and is characterized by shallow-dipping bedding and dominant S1 foliation. The Hess Domain is structurally overlain by the Armstrong Domain and is observed hosting steeply dipping features. At least 3 compressional events have been recorded on the property. D1 is responsible for features with top-to-southwest asymmetry in Hess Domain and for isoclinal and recumbent folds in Armstrong Domain. D2 is equated with regional top-to-northeast thrusting recognized throughout the Yukon Cordillera. D3 is mainly observed in the Hess domain consisting of steeply to moderately dipping crenulation cleavage and small scale folds in argillite packages. Fold axes resulting from all compressional events are coaxial with gentle to sub horizontal plunges to the southeast or northwest. The combined domains were subjected to late orogen-parallel extension resulting in conjugate faulting and quartz-vein emplacement.

The 2018 mapping program supplemented work completed in 2017. The program's primary focus was north of the Hess River. The area represents the lowest stratigraphy on the property and is comprised of sandstone, siltstone and lesser argillite and granitoid intrusives. Isoclinal to recumbent folding is observed throughout the area with gentle to sub horizontal plunges to the southeast and northwest. The region is most similar to the Hess structural domain defined in 2017

displaying shallow to moderate dipping features and dominant S1 foliation. The D1 strain intensity appears greater than in areas to the south of the river; strain is commonly partitioned into argillaceous beds and the main foliation is commonly north of the Hess River.

A small induced polarization geophysical ground survey was conducted over the Goldstack area. The survey was performed in the Goldstack area directly above known mineralization. The aim of the program was to examine the effectiveness of IP for targeting mineralization, identifying mineralized lithologies, and identifying marker horizons. Several areas of interest were identified and the strongest target was tested by diamond drilling.

The 2018 diamond drill program tested six zones. Twenty-six NQ2 drill holes were completed from May 28 to August 21 totaling 7,753 meters. Four drill holes targeted the Goldstack totaling 1,070 meters, 7 drill holes were located at Goldrush totaling 2,383 meters, 8 drill holes were undertaken at Gold Dome totaling 2,507 meters, 4 holes were drilled at Big Bang East totaling 867 meters, 2 drill holes (695 meters) were completed at Goldbank, and 1 drill hole, 230 meters, targeted Bonanza North.

## **2.0 Introduction**

In March of 2017, Goldstrike Resources Ltd. and Newmont Canada FN Holdings ULC, a fully owned subsidiary of Newmont Mining Corporation, entered into an “Earning and Venture Agreement”. The earn-in agreement allows Newmont Canada to earn up to 75% in the Plateau Project. The agreement is structured over several years and consists of two phases. Phase 1 includes exploration expenditure requirements and cash payments. Under the agreement Goldstrike remained operator in 2017 and Newmont will assume operatorship in 2018 for the duration of the agreement. Newmont Canada’s 2018 exploration requirements is \$4.0 million USD.

Exploration activities undertaken during the 2018 season include: a diamond drill program, a structural mapping program, a geophysical survey, and soil and outcrop sampling. The diamond drill program consisted of 26 drill holes testing 7 zones of interest. The mapping program continued building on efforts completed by Stubleby Geosciences in 2017 with a primary focus lying north of the Hess River. A small 3.8 kilometer induced polarization geophysical ground survey was completed over Goldstack mineralization. A small soil grid was completed in the northeastern portion of the property and outcrop sampling was completed concurrently while structural mapping.

This report has been prepared by Newmont Canada FN Holdings ULC on behalf of Goldstrike Resources Ltd. of Vancouver, BC in order to fulfill the assessment requirements of the Mayo Mining Recorder. Field exploration work for the 2018 season was performed by Druid Exploration Inc. of Dawson City, YT and various consultants. Drilling was performed by Geotech Drilling Services Ltd. of Prince George, BC. The ground geophysical survey was completed by Aurora Geosciences of Whitehorse, YT. Alkan Air Ltd. of Whitehorse, YT provided fixed wing support for the project and Great Slave Helicopters of Calgary, AB provided helicopter support for drill and exploration crews.

### 3.0 Property Location and Access

The Plateau Property is located 131 kilometers east of Mayo, Yukon Territory within the Russell Range. It is located within the Mayo Mining District (Figure 1), on NTS map sheets 105N06, 105N05, 105N03 and 105N04. The Hess River anastomoses through the property, trending east-west, dividing the project into a northern and southern block. The property is best accessed by floatplane or helicopter from Mayo, YT. There is an airstrip located 4 km to the south of the property at a camp on Russell Lake. Once on site, all activities requiring transportation are completed via rotary aircraft.

Goldstack Camp was utilized as the main camp during the 2018 season. The camp was constructed in 2017 and was upgraded and permitted for up to 49 people in May 2018. Spit Camp was decommissioned and dismantled during the summer and awaits further reclamation. Goldstack camp was accessed from both Mayo and Whitehorse by float plane provided by Alkan Air Ltd. of Whitehorse, YT. All movements within the property boundaries from Goldstack camp was by helicopter. Great Slave Helicopters Ltd. was contracted to provide onsite transportation and drill support. No access roads were constructed during the season.

## **4.0 Topography, Vegetation, and Climate**

The Plateau Project lies within the Stewart Plateau physiographic subdivision area within the Lansing Range (Mathews, 1986). This area lies within the McConnell Cordilleran Ice Sheet (28 ka to 15 ka), where there is at least one generation of glacial deposits above the valley floor (Murphy, 1997). The height of land ranges from 584 meters to 1987 meters above sea level. Inferred thickness of overburden varies from bedrock exposure on steep slopes and topographical rolls with the thicker overburden cover not known. The overburden cover consists of unconsolidated boulder-rich, silty clay to clay, and gravel deposits in major creeks/rivers. Colluvium in the form of felsenmeer or frost-heave debris material, loose boulder size talus, and regolith characterize the terrain in higher relief areas with thick organic matter/moss covered areas on relatively gentler slopes. Local clay-rich soils are characteristic in relatively stagnant, poorly drained areas. There are several glacial lakes and ponds, particularly in the western part of the property. Relief on the property is generally steep with moderate to rolling topography towards the lower relief of the Hess River. The west-flowing Hess River is the main drainage in the region, as a tributary from the Stewart River.

The property is characterized by variable outcrop exposure with <5% in the lower tree-covered areas to 25% in the higher mountainous terrain. Outcropping areas occur as intermittent exposures along steep slopes and topographical rolls/ledges in higher elevations. Frost heave, slope creep, and talus boulders and sub-outcrop are prevalent on higher ground slopes. Vegetation in higher relief areas are characterized by a thick moss cover, relatively thin soil cover, reflected by boulder-rich and felsenmeer-type colluvium. Vegetation located at lower elevations consists of spruce balsam, poplar willows, and low lying brush, with alders following drainage systems. There are a number of restricted burn areas in the lower relief areas towards the Hess River.

## **5.0 Property Description**

The property consists of 3,167 contiguous quartz claims in the Mayo Mining District covering 662 square kilometers. The property is divided into 5 claim groups, Group 2 through Group 6 (Figure 2). The Hess River is used to demarcate the boundary between Plateau North and Plateau South. Plateau South refers to the claims falling south of the Hess River, while Plateau North refers to the claims north of the Hess River. The claims are located on NTS map sheets 105N05, 105N06, 105N03, 105N04, 105N07, and 105M08. The claims are owned 100% by Goldstrike Resources Ltd. of Vancouver, BC. A complete list of the mining claims and location map that comprises the Plateau Property and their status can be found in Appendix I.

## **6.0 Property History**

### **6.1 Historical Exploration**

There is no documented historical exploration work on the Plateau Property prior to Goldstrike

Resources Ltd. in 2010. The nearest historical exploration work is located south of the property. The work was carried out by Atlas Explorations Limited in 1967, as part of a broader program covering the Lansing Range (105 N), Nidday Lake (105 O), Tay River (105 K), and Sheldon Lake (105 J) map sheets. The focus of exploration was on base metal (copper-lead-zinc) mineralization. The Lansing Range had undergone limited regional mapping, soil sampling, and silt sampling by Atlas.

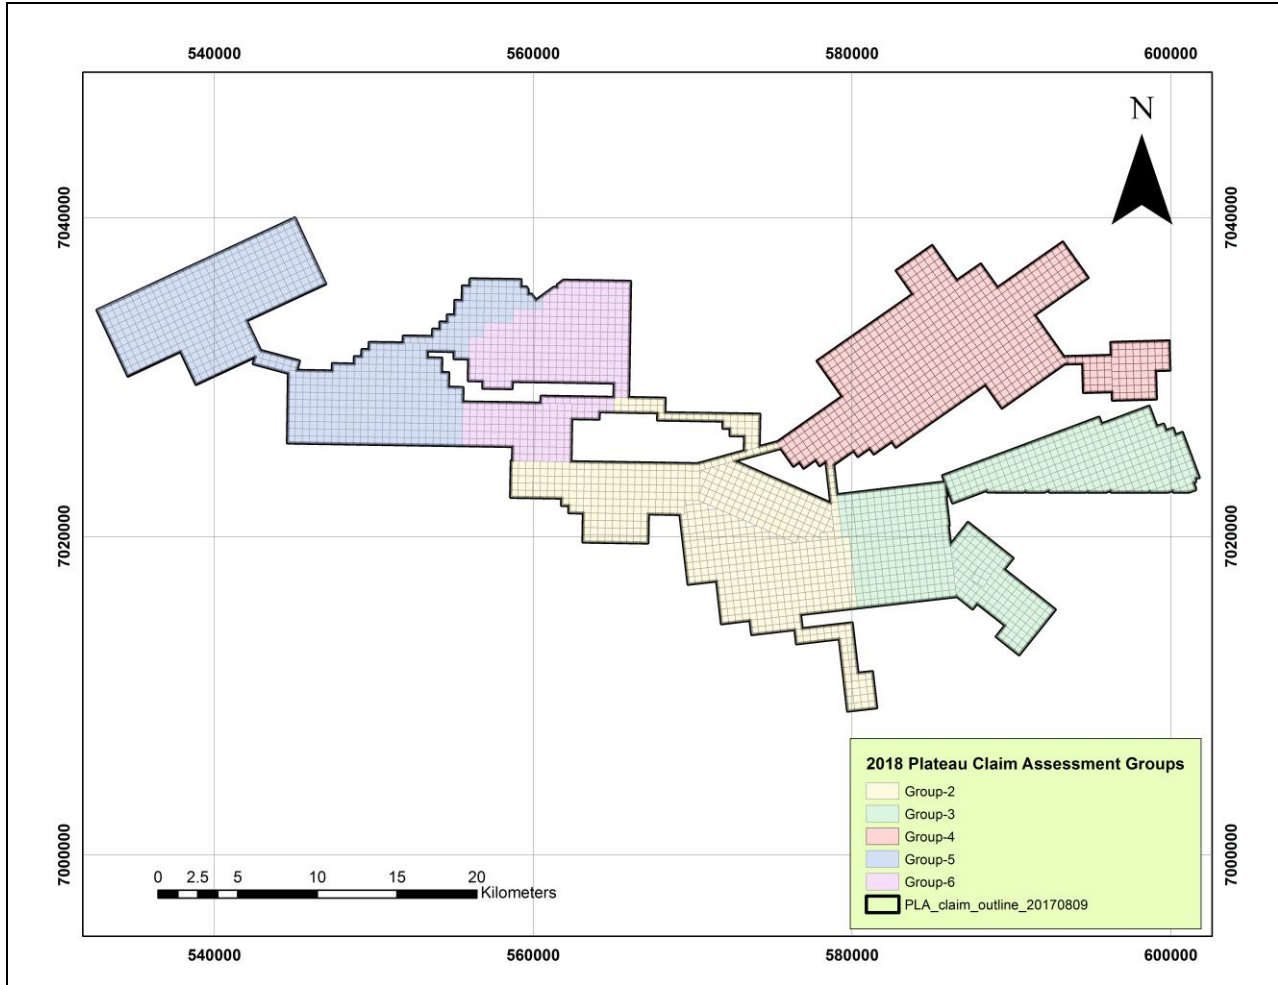

Figure 2) A map displaying the breakdown of claims and claim groupings for assessment filing on the Plateau Project.

The exploration work did encroach on the northern boundary of the Mount Armstrong Intrusive within the Plateau Project area. In 1975, Union Carbide Exploration Corporation conducted exploration in the Mount Armstrong area, approximately 10 kilometers south of the Plateau Project. Union Carbide focused on tungsten-copper exploration in a skarn-type geological environment. Exploration work consisted of geophysical surveys including: very low frequency-electromagnetics, magnetics, and a horizontal loop EM-17. This was followed up by a 1,495.6 meter drill program distributed over five drill holes. Drilling intersected the Mount Armstrong Intrusive (quartz-monzonite/granodiorite) and skarn-type host rocks, which consisted of metamorphosed, hydrothermally altered arenaceous and argillaceous metasediments, schist, and marble. Numerous thin zones of varying disseminated and blebby fracture-fill pyrrhotite-chalcopyrite-pyrite-(scheelite) were intersected. The best results were returned from drill hole 5, which assayed 0.13% tungsten and 0.10% copper over 1.0 meter.

Other surveys completed by the Geological Survey of Canada (GSC) include:

- 1) Aeromagnetic Survey (1968)
- 2) Regional Stream Sediment and Water Geochemical Data (Friske et al., 1990)
- 3) Various Geological Progress/In Current Reports and Maps by GSC, Indian and Northern Affairs, and Yukon Geological Survey (Roots et al., 1994, 1995, 1997, 1998, and 2003)

## 6.2 Exploration Performed by Goldstrike Resources Ltd.

## 7.0 Geology

### 7.1 Regional Geology

The supracrustal rocks underlying the Lansing Range region are mid Cambrian aged rocks forming part of the Selwyn Basin in the Omineca Belt. The Selwyn Basin consists of metamorphosed Late Proterozoic-Paleozoic metasedimentary rocks with minor metavolcanics, intruded by a variety of intrusive complexes (Figure 3). The supracrustal rocks have undergone lower greenschist facies metamorphism, with amphibolite facies metamorphism near mid-late Cretaceous aged intrusions. The Selwyn Basin rocks are characterized by the older Cambrian to Vendian rocks of the Hyland Group, which consists of the Yusezyu Formation and lesser Arrowhead Lake Member, both of the Narchilla Formation. There are zones of uplift creating disconformity where Ordovician and Lower Devonian Elmer Creek and Duo Lake Formation of the Road River Group are observed at surface. The Yusezyu Formation (ca<580 Ma [Moynihan, 2015]) is predominantly comprised of clastic metasediments consisting of arenite (sandstone, psammite, and siltstone) and carbonaceous phyllite and shale/slate, along with minor inter-formational limestone and marble which account for 90% of the underlying rocks on the Plateau South Project. It has been traced over 90 kilometers and thickness cannot be determined, as a result of stratigraphic and structural tops being unknown. The younger Road River Group comprises of two conformable units; the basal Duo Lake Formation and the upper Elmer Creek Formation, which is a lateral equivalent to the Steel Formation. Both formations consist of black shale and chert, with minor argillaceous limestone, and have an aggregate thickness ranging from 450 to 550 meters.

There are two major late Cretaceous Mayo Suite intrusions (granite to granodiorite) in the area. Originally mapped as Tombstone Suite, this series of intrusions was recently reclassified to Mayo Suite. The smaller intrusion to the west is termed the Russell Stock and the larger body to the east is the Mount Armstrong Intrusion. Recent age dating (U-Pb zircon, chemical abrasion - thermal ionization mass spectrometry [CA-TIMS]) indicates an age of 95.5 Ma for both intrusions (P. Sack, pers. comm 15/02/2018). Both intrusions are part of a 75 kilometer southern regional trend of multiple late Cretaceous intrusions and associated metamorphic aureoles.

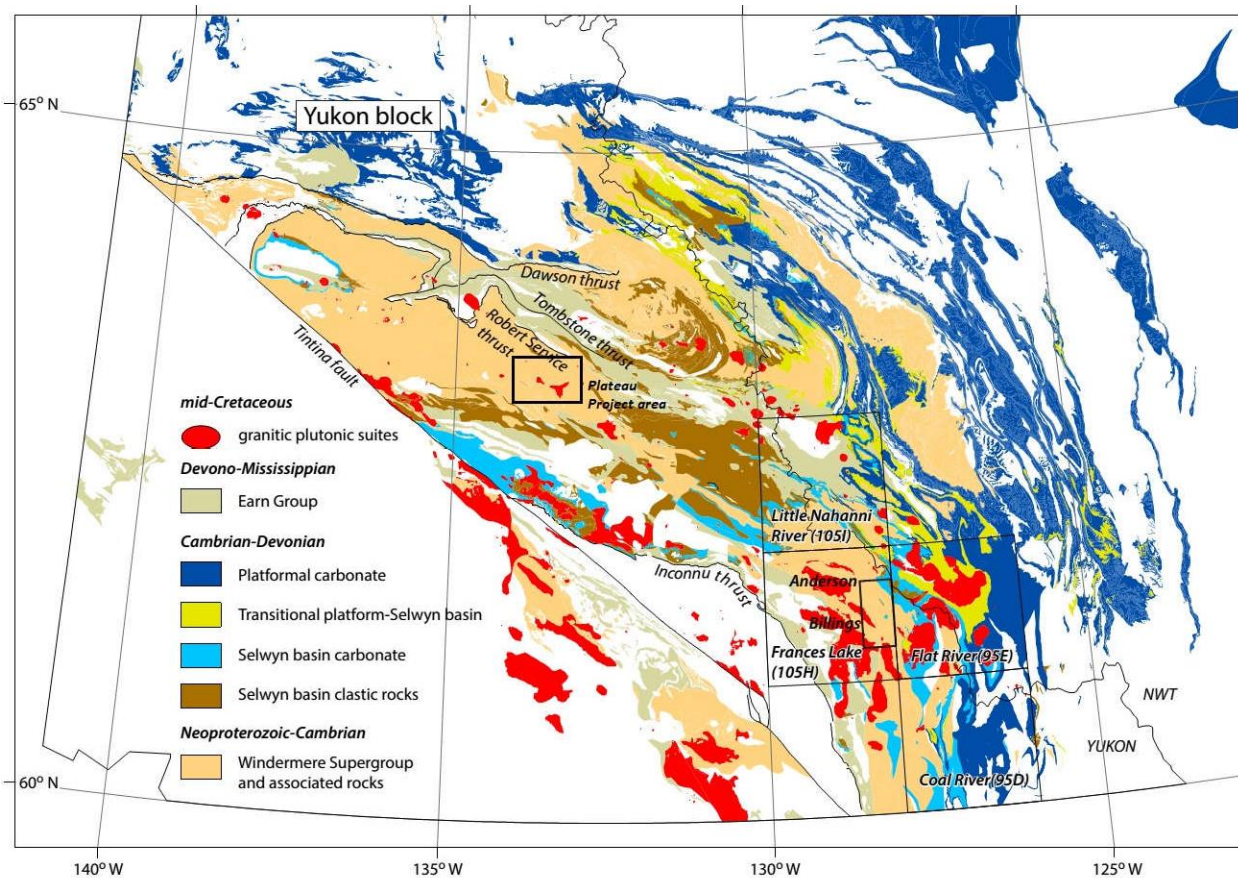

Figure 3) Simplified geology of the Selwyn fold and thrust belt with the Plateau Project area outlined (modified from Moynihan, 2016).

The Plateau Project lies within a region with multiple stacked thrust sheet faults and imbricate structures in the Lansing Range and Russell Range. The prominent structures in the region are the Hess and MacMillan Faults and the Robert Service Fault, located north of the property. The Moose Lake Thrust Fault is a major fault to the southwest from the property. These thrust faults occupy northwest trending valleys. The Tombstone Strain Zone has overprinted the Yusezyu Formation east of the Russell Range (Plateau Property) and is characterized by highly deformed rocks and strain fabrics (Murphy, 1997). It extends for approximately 200 kilometers and is several kilometers thick.

## 7.2 Property Geology

The Plateau Property is dominantly underlain by supracrustal siliciclastic metasedimentary rocks described variably as arenite, sandstone, grit, psammite, and siltstone or carbonaceous phyllite and shale/slate (Figure 4). Historical mapping has also identified several in-folded felsic to intermediate meta-volcanic or volcanoclastic units. Texturally the interpreted metavolcanics and siliciclastic metasedimentary units' grade into one-another and considerable debate has taken place as to the provenance of these rocks.

Prior to 2016, property-scale mapping completed by Goldstrike had indicated a significant departure from the regional lithologies mapped by Roots (2003). This had to do with the reclassification of metamorphosed siliciclastic rocks to metamorphosed crystal tuff and sub-volcanic quartz porphyry intrusive, which account for 60% of the underlying rock types on the property (Roach, 2013). Using a volcanic protolith these rocks classify as F1 calc-alkaline rhyolite, with the more intermediate varieties being atypical. Due to the nature of the chemistry and textures of such rocks, petrographic studies by Shandl (2012), Franklin (2013), and Richards (2015) all failed to confidently identify a protolith. The intense silica overprinting in many areas added further complication. As such all mapping, sample descriptions, and core logging were done with a volcanic setting in mind. When viewing property-scale maps, reports and core logging prior to 2016, the terms felsic metavolcanic, crystal tuff, and quartz porphyry may be interchangeable with sandstone, grit, and quartz pebble conglomerate. During 2016 and 2017, more regional studies and an expanded data set have led the company to view the area more in line with the regional mapping completed by Roots.

Non-silicified clastic metasediments account for 30% of the rocks underlying the property and reflect a turbidite sequence. They consist mainly of well bedded argillaceous (argillite/shale/slate) metasediments with arenaceous (siltstone) metasediments and are up to 4 kilometers thick. The main clastic sequence wraps around, as well as being cut-off, by both Mayo Suite Intrusives, and arises as inter-formational units within the siliciclastic units to the north. In the western part of the property, a 1.5 kilometer long northwest trending limestone (1%) unit is up to 300 meters wide. Other thin limestone and skarn units have been observed near the Mount Armstrong Intrusive as inter-formational units within the clastic metasediments. The prominence of limestone and arenaceous metasediments to transitionally argillaceous metasediments in the eastern part denotes a transition to a deeper water environment to the east. The two large Mayo Suite intrusives are located in the southern part of the property and account for the remaining 9% of the rocks underlying the property. Age dating has placed the intrusives as late Cretaceous (ca 95.5 Ma) in age and lithogeochemistry has designated a granitic composition. Multiple other small late Cretaceous intrusions are mapped in the area as well as unmapped intrusions which have presented themselves in the airborne magnetic data such as located at Goldrush.

The stratigraphic sequence is observed to young to the southwest while strain intensity decreases, and lithological diversity increases, higher stratigraphy. Stratigraphy is divided into the Hess and Armstrong structural domains. The stratigraphically lower Hess Domain is characterized by shallow dipping structural features whereas the overlying Armstrong Domain displays steeply dipping features (Stubley 2017). A D2 thrust fault with multi-kilometer displacement is inferred to have juxtaposed the two domains. At least three compressional events are recorded in Hess Domain,

and the earlier two of these are also apparent in Armstrong Domain (Stubley 2017). The early D1 event is responsible for features with top-to-southwest asymmetry in Hess Domain and for quasi-symmetrical steeply inclined folds in Armstrong Domain. D2 is equated with regional top-to-northeast thrusting recognized throughout the Yukon Cordillera. Fold axes resulting from all compressional events are coaxial with gentle to sub-horizontal plunges to the southeast or northwest (Stubley 2017). The project area was subjected to late extension resulting in conjugate faulting and extensive quartz-vein emplacement (Table 2).

## 8.0 Deposit Types

The metallogenic province of the Tintina Gold Belt extends from Alaska to Central Yukon and hosts a number of intrusive-related and orogenic gold deposits. These deposits account for approximately 40 million ounces of gold produced from deposits such as Fort Knox, Donlin Creek, Pogo, Brewery Creek, Red Mountain, and Dublin Gulch. They are hosted by both Cretaceous aged granitic intrusions and the surrounding country rock. Gold mineralization in the Yukon shows evidence of a similar pattern of a diverse array of characteristics with the Plateau Property:

- Quartz-arsenopyrite ± galena fault controlled veins in a late brittle environment
- Orogenic lode-gold quartz vein and wallrock replacement environment
- Au-Mo with Bi-Te-W-(Cu-Sn) in granitoid South Mayo/Tombstone Intrusive
- Au in aureole of contact metamorphosed clastic metasediments and limestone

Mineralization at Plateau is associated with quartz vein and veinlet developed in a late extensional environment. Quartz vein emplacement is related to a brittle conjugate fault set associated with dextral movement along a northwest regional fault system. There is an interpreted spatial and genetic relationship between the gold mineralization and the Mayo Intrusives suite. Gold Dome and Goldstack au mineralization is observed to be associated with As ± Sb while further outboard au showings such as Bonanza and Goldbank are typically observed to be associated with Pb-Zn±Te±Bi. A summary of showings can be found in Table 3.

## 9.0 Geophysical Program

### 9.1 Ground Geophysics

A 3.8 kilometer induced polarization geophysical ground survey was completed over the Goldstack showing. The survey was performed by Aurora Geosciences of Whitehorse, YT over a 7 day period in early June. The purpose of the survey was to characterize the mineralization in order to assess its usefulness as an exploration tool for targeting mineralization on the Plateau Property. Two northeast trending corridors, spaced 100 meters apart, were used as survey lines. The most southerly corridor, Line 0N was 2,550 meters in length and crossed immediately north of mineralization at Goldstack. The second corridor, L 100N, is located north of 0N and is 1250 meters in length and is situated directly over the mineralization previously encountered in drill core (Figure 4). Both corridors traversed the northwest-southeast trending Goldstack Fault.

The petrophysical interpretation conducted by Aurora Geosciences supports the use of chargeability as a targeting tool for the mineralization at Goldstack (Hildes 2018). Five targets were identified using the above criteria and the top target was drill tested. A complete report is located in Appendix II.

The following excerpt is derived from Hildes 2018.

*“Based on the petrophysics and the positive correlation of recovered chargeability with the Goldstack Zone, high chargeability was used as the primary criterion for targeting. Low chargeability ratio is advantageous, and resistivity is also used as a secondary tool”* (Hildes 2018).

## 10.0 Diamond Drill Program

### 10.1 Summary

A diamond drill program was completed between May 28, 2018 and August 21 2018. The program consisted of 26 drill holes accounting for 7,753 meters of NQ2 drill core (Table 4). Drilling was performed under contract by Geotech Drilling Ltd. of Prince George, BC. All drill holes collars were located using a handheld Garmin GS 62 or GS 64 gps device. All drill holes were aligned using the Reflex TN-14 and all down holes survey were completed using Reflex North seeking interlocking Gyro. A down hole survey was recorded in the casing an every 50 meters down hole following the initial test. A final survey was recorded when the hole attained its final depth. All drill core intervals were oriented using the ACT III core orientation tool.

A total of ten targets were tested in six areas (Big Bang East, Bonanza North, Goldstack, Goldbank, Gold Dome and Goldrush). Eight drill holes were completed at Gold Dome totaling 2,507 meters, 7 drill holes were located at Goldrush totaling 2,383 meters, 4 drill holes were completed at both

Goldstack and Big Bang East accounting for 1,070 meters and 867 meters respectively, a total of 695 meters of drill core was completed in two holes located at Goldbank, and one drill hole was completed at Bonanza North (230 meters).

All core samples were selected and sampled by the logging geologist. A QAQC protocol was followed with regards to sampling, cutting, bagging, and the insertion of blanks and standards. Analytical samples were shipped via chain of custody to ALS Whitehorse, YT for sample preparation and forwarded for gold and multi-element lithogeochemistry analysis at ALS North Vancouver, BC. As of December 2018, the core from the 2017 and 2018 drill programs is stored at Goldstack Camp on the Plateau Property. All 2016 core is stored at the Spit Camp. Drill holes PSGS-15-01, PSGS-15-02, PSGS-15-03, PSVG-15-06, and PSVG-15-08 from the 2015 program are located at the Druid Exploration yard in Dawson City, YT while the 6 remaining 2015 holes are cross-piled on the Plateau Property at the Gold Dome showing (UTM E581194, N7018113).

## 10.2 Sample Preparation, Analysis, and QA/QC

### 10.2.1 Sample Preparation

#### Sampling

All core samples were selected and sampled at the discretion of the logging geologist.

- Maximum sample length is 1 meter in mineralized domains and 2 meters in non-mineralized domains.
- Minimum sample length is 50 centimeters.
- Sample breaks occurred at lithologic, alteration, mineralization, and vein contacts.
- A red wax crayon is used to draw the geologic sample breaks on the core
- A QC sample (standard or a blank) is inserted, alternating, on every 10<sup>th</sup> sample
- A field duplicate sample is completed on every 26th sample

#### Core Sample Cutting

Core is cut at the sample interval (red line), and split along the cut line. The left hand portion of the core is placed back into the box

- A portion of the sample tag (one short bar code with date label and remarks) is stapled in the bottom of the core box at the start of the sample interval
- The right hand portion of the core is placed into a corresponding pre-labelled poly ore bag
- A portion of the sample tag (2 pieces; marked assayers copies) is put in the sample bag
- The bag is securely tied with a zap strap and placed on the counter in sequential order for later packing into rice bags

### Field Duplicate Preparation

- When a field duplicate is required, the remaining left hand portion of the core is put into a pre-labelled poly ore bag.
- The assayers copy of the sample tag (2 pieces; marked assayers copies) is placed in the sample bag
- The remaining portion of the sample tag is stapled in the bottom of the core box
- The bag is securely tied with a zap strap and placed on the counter in sequential order for later packing into rice bags

### Standard Preparation

- Standards are stored in sealed Tupperware containers in the cutting room
- Each sample tag will have a standard number identified
- The corresponding standard is collected from the Tupperware container
- The identification sticker is removed from the standard and the sticker is applied to the split list
- The standard is placed in the pre-labelled poly ore bag
- The assayers copy of the sample tag is put into the sample bag
- The remaining portion of the sample tag is stapled in the bottom of the core box
- Secure the sample bag with a zap strap and place it on the counter in sequential order for later packing into rice bags

### Blank Preparation

- Blank material is stored in Rubbermaid bin in the cut shacks
- Put the assayers copy of the sample tag into the sample bag
- Staple the remaining portion of the sample tag in the bottom of the core box
- Secure the sample bag with a zap strap and place it on the counter in sequential order for later packing into rice bags

### Sample Shipments

- The pre-labelled rice bags are filled poly ore bags by teams of two
- Weigh, and record the weight, of the filled rice bag
- Close the rice bag with a zap strap
- A security tag is added and recorded on the sample split list
- Paperwork is completed and the shipment is sent via chain of custody

### 10.2.2 Sample Analysis

All analytical samples were shipped to ALS Laboratories in Whitehorse for sample preparations. Fire assay and litho geochemistry analysis was performed at ALS Laboratories in North Vancouver. Flow chart figures summarizing the analysis protocol for core, outcrop rock, and soil samples are

located in Appendix III. Also, a description of sample preparation and analysis methodology is located in Appendix III.

### 10.2.3 QAQC Results

In order to verify the quality of the sample results a QAQC program was completed simultaneously during analysis. Certified reference Material(s) (CRM) was sourced from CDN Resource Laboratories Ltd. of Langley, BC, Canada. A blank or standard was inserted every 10th sample into the sampling stream alternating between the blank and one of the gold standards. The standard was selected by the geologist and was based on the assumed grade of the surrounding core samples. A total of 159 pulp blank samples, 36 CDN-GS-P6B/CDN-GS-P6 (0.625 g/t au and 0.626 g/t au), 48 CDN-GS-2S (2.38 g/t au) and 2 CDN-GS-6E (6.06 g/t au) standards were analyzed during the program (Figure 5 and Figure 6).

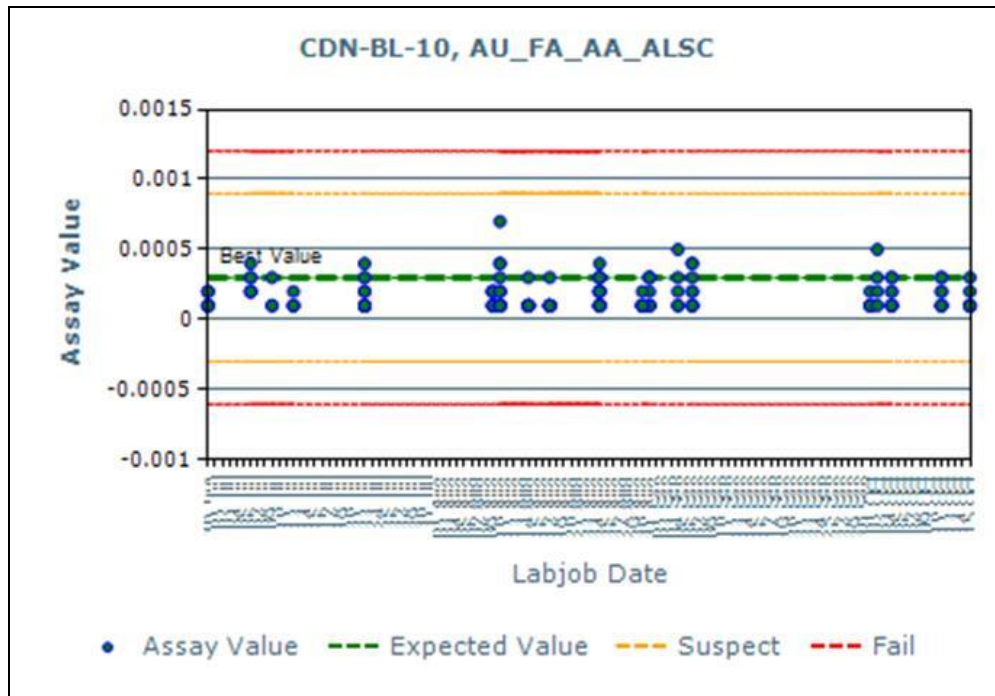

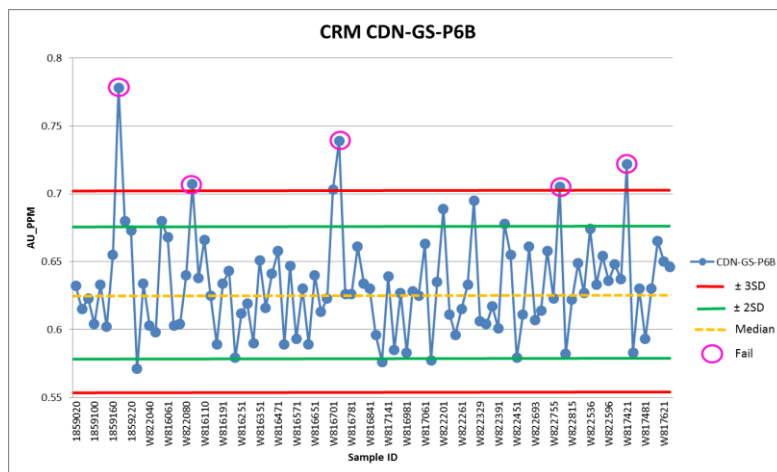

Figure 5) A graph displaying the CDN-BL-10 blank performance (oz/t).

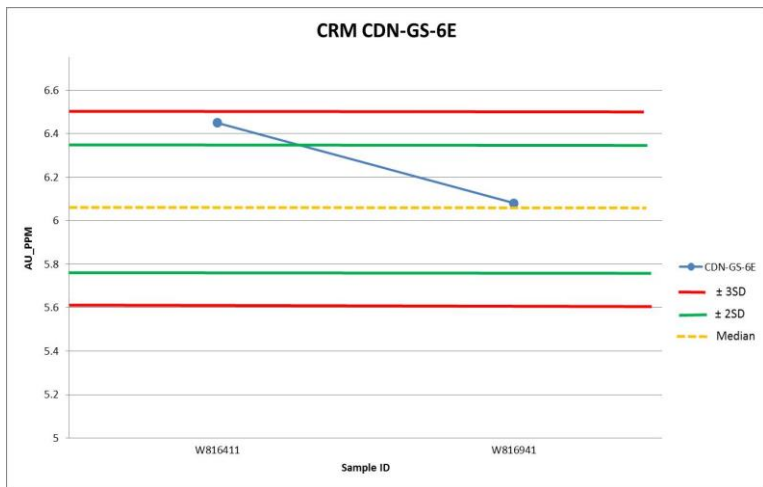

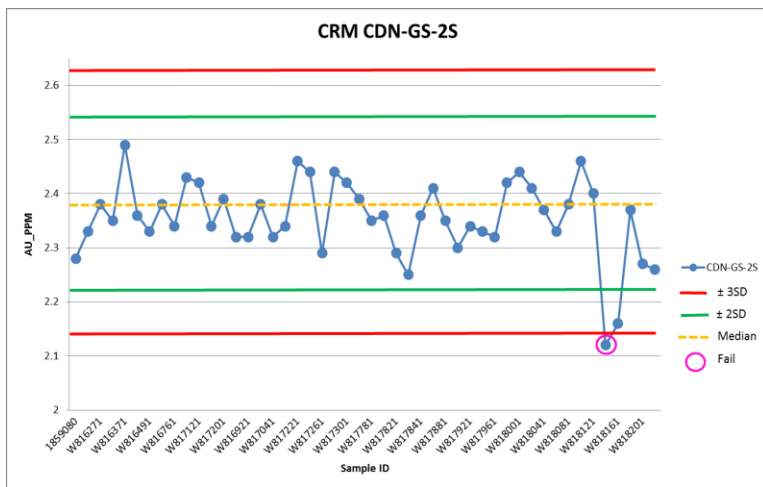

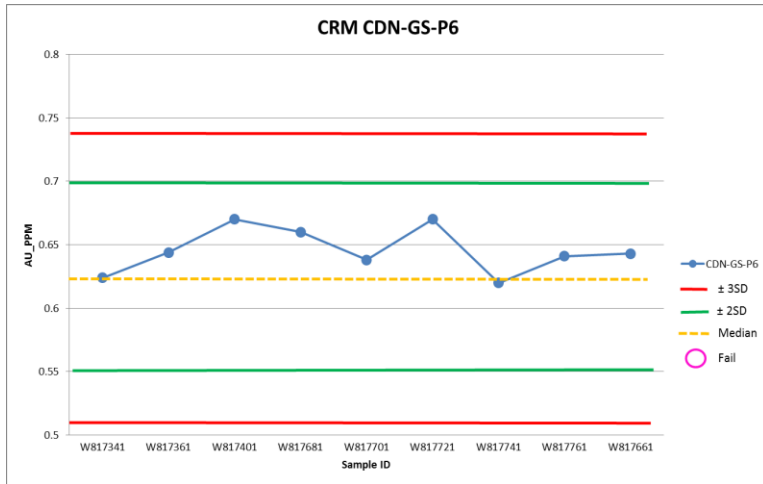

Figure 6) A series of four graphs displaying the performance of the various CRM materials.

Based on the series of samples no obvious indicators of sample contaminations or incomplete digestion errors were noted. The accuracy and precision of the data was determined by the analysis of CRMs. One blank and one standard were used during analysis along with internal checks by ALS. The CRM gold values were plotted with respect to  $\pm 2$  and  $\pm 3$  standard deviations of the CRM mean to show any failed CRM samples. Samples that are located beyond the 3 sigma

error lines signify a CRM sample failure. For within lab CRM quality analysis, 80% of the samples within the 3 sigma lines are considered acceptable and is dependent upon the detection limit values of each element (Tetra Tech 2012). Failed CRM values may be related to instrumental drift, an increase or decrease in the element value with a rebound back to the mean after the drift correction, and are dependent on the assay's limits of detection. The data is considered to be satisfactory. The certificates for the CRM's are located in Appendix IV

Recommendations moving forward include:

- 1) Using locally sourced reference material that closely matches onsite samples to allow checks on digestion inconsistencies.
- 2) Using a coarse blank material to check for cross-contamination during crushing and pulverizing.

### 10.3 Drill Results

The following is a summary of the drill program results by area (Table 5). Drill logs, analytical results, and drill sections (plan and Vertical) can be found in Appendices V, VI, and VII.

#### 10.3.1 Goldstack Zone

Drilling at Goldstack consisted of 4 drill holes (PTU-00003, PTU-00006, PTU-00007, and PTU-00026) accounting for 1,070 meters. The program was designed with two intentions. The first aim of the program was to perform two 150 meter step outs to the southwest testing mineralization along strike for 300 meters. The two step outs would then be undercut by a single drill hole in order to test the plunge orientation of mineralization. The second goal was designed to follow up on mineralization intercepted in PGS-17-09 (3.13 ppm over 1.0 meter) testing continuity at depth to the south.

Drill holes PTU-00003 and PTU- PTU-00007 tested along strike at 150 meter intervals. PTU-00006 was drilled to undercut PTU-00007 creating a fence across the section. Unfortunately a second drill hole could not be drilled to complete a fence with PTU-00003 at the step out located 150 meters from mineralization due to topography. Typical basin stratigraphy consisting of sandstone, pebble conglomerate and argillite was intercepted in core along with patchy silica and sericite alteration. The core was strongly fractured and faulted and hematite staining is prevalent in the upper portions of the drilling. Sulphides observed throughout the sequences include pyrite and pyrrhotite. A small zone containing quartz-arsenopyrite veinlets was observed in PTU-00007 at approximately 40 meters down hole. All drilling cross cut the mineralized horizon interpreted in previous programs. No significant assays were returned.

PTU-00026 was designed to test the system at depth to the south below PGS-17-09. PGS-17-09 returned 3.13 grams per ton gold over 1 meter during the 2017 campaign. Lithologies intercepted include pebble conglomerates, sandstone, siltstone and minor argillite. Silica alteration was regularly noted and multiple zones of quartz veining were encountered. The main sulphides present include pyrite and pyrrhotite and minor arsenopyrite. Drilling attained a final depth of

~398 meters. No significant assays were returned.

### 10.3.2 Gold Rush

Seven drill holes were completed at Goldrush accounting for 2,383 meters. Drill holes PTU-00016, PTU-000017, PTU-00018 and PTU-00019 targeted a kilometer scale geochemical soil anomaly and coinciding kilometer scale alteration anomaly, and bedding parallel faults. Drill holes PTU-00021,

00023, and 00024 focused on a conceptual target observed in geophysical data sets and in recent surface mapping. The concept involves the movement along 060° trending faults the interactions between D<sub>2</sub> structures and Cretaceous Aged Intrusions.

Drill holes PTU-00016 through PTU-00019 all intercepted similar lithologies consisting of shallow west dipping fine to medium grey sandstone units interbedded with occasional decimeter scale argillite and siltstone units. Alteration noted included minor sericite, silica, and chlorite. Pyrrhotite was observed located in micro fractures, along the margins of quartz veins, and along bedding and foliation planes. Pyrite was also present in smaller amounts in similar locations. Arsenopyrite was noted as rare fine grained disseminations accompanied by blebby pyrite along foliation surfaces. Three faults zones were noted associated with of increased pyrite and carbonate content. Assay results include 0.596 g/t au over 1 meter in PTU-00017.

Drill holes PTU-00021, PTU-00023, and PTU-00024 were drilled on the northern slope of the Goldrush area. Targets were based on the interpreted geometry created between granitoid intrusions observed in geophysical surveys and 060° trending faults interpreted to interact and create interference patterns with interpreted D<sub>2</sub> structures. The concept showed the development of “space” at this junction point. Stratigraphy intercepted included greywacke and unsubdivided sedimentary rocks (sandstone, argillite and siltstone). Carbonate rich units were encountered in the upper levels of drilling. Chlorite alteration was observed throughout with occasional zones of sericite alteration along with rare silicification. Two strongly bleached zones of silica and sericite alteration accompanied by an increase in arsenopyrite were noted in PTU-00021 (at approx. 38 meters depth) and PTU-00023 (at approx. 125 meters depth). Both zones returned assay results of 2.41 g/t au over 0.72 meters in PTU-00021 and 3.23 g/t au over 0.61 meters in PTU-00023. Minor pyrrhotite was encountered throughout located along foliation planes.

### 10.3.3 Gold Dome

A total of 2,507 meters of diamond drilling in eight drill holes was completed at Gold Dome. All targets were selected based on geochemical anomalies derived from soil sample interpretation (PTU-00010 through to PTU-00015) along with historical drilling results (PTU-00020 and PTU-00022). All drilling was completed on an azimuth of 155° as core orientation measurements and structural mapping from past programs indicated a preferred mineralized vein orientation of 65°.

Drill holes PTU-00010 through PTU-00013 were designed as a fence of hole testing the western margin of the plateau at Gold dome. PTU-00014 and PTU-00015 formed a fence sequence 370 meters to the east-northeast along the eastern margin of the plateau. Although the pluton contact was not intercepted observations noted a transition from biotite to cordierite to the south. Overall an increase in silica alteration + sericite ± chlorite is observed to the south. Pyrite and pyrrhotite are located throughout the entire sequence with a minor increased in arsenopyrite noted to the south. Visible gold was observed in drill hole PTU-00015 located within a quartz vein associated pyrite. Further details are obscured by broken core and strong hematite staining. Numerous subgram au intercepts were returned along with 1.26 g/t au over 1 meter in PTU-00011 and a 7.17 g/t au over 0.85 meters in PTU-00015.

Drill holes PTU-00020 and PTU-00022 were completed as a fence immediately west of the historic drilling completed at Gold Dome. Lithology intercepted includes sandstone and argillite, with minor silty limestone and limey mudstone/sandstone at depth. Biotite alteration was noted in sections of increased intercalations of argillite in sandstone lithologies. Alteration zones of moderate to strong silicification and weak sericite along with trace amounts of disseminated pyrite and pyrrhotite were located throughout both drill holes. Trace chalcopyrite and rare arsenopyrite were noted at 49 meters, 133-136 meters, and 189 meters respectively. Assays results include 0.61 g/t au over 1 meter in PTU-00022.

#### 10.3.4 Big Bang East

Four drill holes, 867 meters, were completed at Big Bang East across two fences (PTU-00004, PTU-00005 and PTU-00008, PTU-00009). Both fences were designed to test geochemical anomalies, historic outcrop sample, and large east-north-east trending faults. All drill holes were drilled on a 000° azimuth and at an inclination of -48°. PTU-00008 and PTU-00009 were located 400 meters to the north-northwest of PTU-00004 and PTU-00005.

PTU-00004 and PTU-00005 tested a soil anomaly and several surface samples from quartz veins which returned au assay results up to 6.6 g/t au. The fence was designed to intercept a large 70° fault the preferred orientation of mineralization quartz veining. PTU-00008 and PTU-00009 was created to intercept an interpreted fold hinge, a large east-north-east trending fault, and a soil sample anomaly. Drilling in both fences intercepted basin stratigraphy consisting of pebble conglomerate, sandstone, siltstone and minor argillite weakly altered by sericite ± chlorite. Both faults were intercepted along with multiple vein sets in the upper portion of the drilling. Pyrite was the main sulphide observed throughout the sequences with minor arsenopyrite being noted near surface in both PTU-00004 and PTU-00009. Assay results include 0.702 g/t au over 0.50 meters in PTU-00009.

#### 10.3.5 Goldbank

One drill hole, PTU-00001, was designed to test geophysical interpretations from the 2017 induced polarization ground survey and the SkyTEM electromagnetic survey. PTU-00002 was completed from the same set-up as PTU-00001 but on a steeper inclination. The purpose was to test favorable alteration and sulphides mineralization observed in PTU-00001. Both holes, PTU-00001 and PTU-00002, were drilled on an azimuth of 030° and attained a depth of 477 meters and 218 meters respectively.

PTU-00001 was targeting a near surface chargeability high and resistivity high and a conductivity high at depth observed in the electromagnetic data. Stratigraphy intercepted consisted of shallow dipping sandstone, siltstone, and interbedded argillite all of which were variably altered by silica and sericite. Sulphides consisting of pyrite and pyrrhotite were the most prevalent. Quartz-arsenopyrite veinlets were observed between 30-45 meters and at 225 meters associated with bleached areas and silica-sericite alteration. A fine-grained cluster of galena was observed between 372.6-372.8 meters.

The induced polarization anomaly was interpreted as being caused by pyrite and pyrrhotite along with silicification. The EM anomaly at depth was due to pyrrhotite, up to 5%, hosted within intercalated argillite units and minor siltstone and sandstones. PTU-00002 did not intersect the visual indicators observed in the previous drill hole. All gold results were returned from PTU-00001 and include 0.595 g/t au over 1 meter at 34 meters, 0.965 g/t au over 0.5 meter at 203 meters, and 0.597 g/t au over 1 meter at 421 meters. No significant results were returned from PTU-00002.

### 10.3.6 Bonanza

One drill hole was completed at on the Bonanza North in order to follow up on drilling completed in 2017 which returned gold values of 1.23 and 3.08 g/t au in drill hole PSBZ-17-02. PTU-00025 was drilled 170 meters to the west-north-west of PSBZ-17-02 along strike to a depth of 230 meters. Medium to coarse-grained, grey siliceous sandstone was found throughout accompanied by minor argillite, siltstone, and limey-sandstone. Trace disseminated pyrite was noted throughout the hole. Pyrite stringers were intersected between 180-182 meters and 191.9-193.5 meters. No significant assays were returned.

## 11.0 Soil Sampling

A 315 sample soil program was completed over the Devil’s Gate area. Previous exploration work in the area included limited prospecting and minor soil sampling. The program was initiated to follow up on geochemical interpretation work completed in early 2018. Factor analysis of historical data highlighted favourable areas of lithologies associated with high Au, As, and Sb (Figure 7).

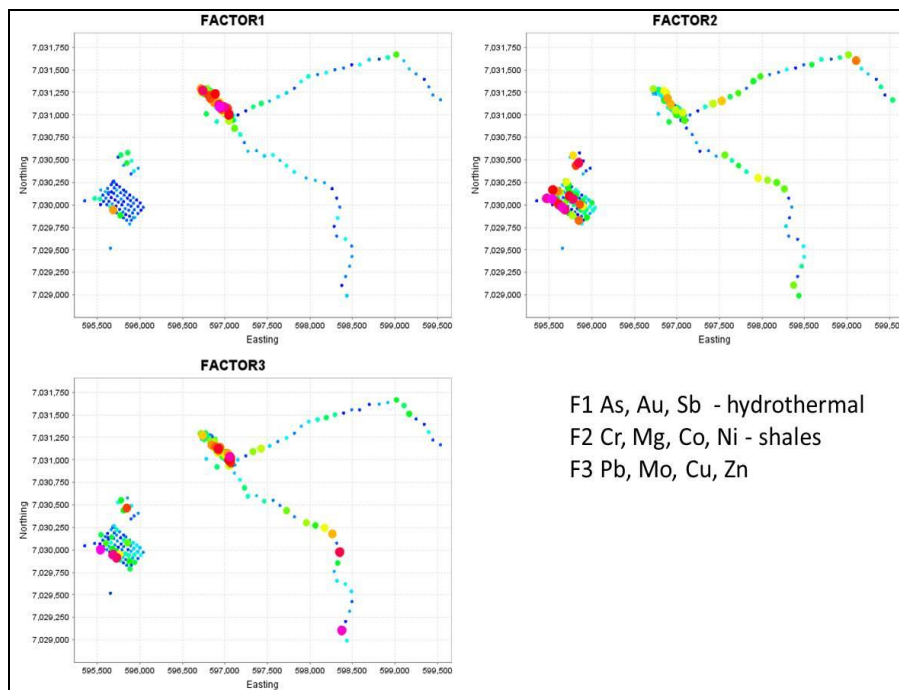

Figure 7) Factor analysis of historical soil results displaying Au, As, and Sb anomaly in the Devil's Gate area.

The program was completed over a six day period at the end June with samples being collected on a 100 x 100 meter grid. Results show the development of a weak au anomaly in the northwest corner of the grid with support from an overlapping as anomaly. Weak cu is present but displays more sporadic trend. Overall, results show the development of patchy pattern with no overall strong au anomaly (Figure 8). Several follow up site visit to the area were completed in order to further evaluate the area for economic potential. Mapping and rock sampling in the area were unsuccessful in identifying large scale veins and or a strong hydrothermal alteration system. Analysis results are located in Appendix VIII.

## 12.0 Mapping and Prospecting

A structural mapping program and concurrent outcrop sampling was conducted on the Plateau Property, Central Yukon, between June 1 and August 22, 2018. The exercise focused on five areas located north of the Hess River: West Plateau, Central Plateau, Southwest Gold Rush, Northeast Gold Rush and Devil's Gate (Figure 9). The 2018 mapping program supplements the structural framework completed by Mike Stublely in 2017. The classification of structural events and lithologic units from that work were utilized during the 2018 program. A short description of each area is located below except Central Plateau which falls outside the scope of this report.

Lithologies observed during the exercise included unsubdivided siliciclastics, quartzite and siliceous grits, Cretaceous biotite granite and rare mafic to intermediate volcanogenic rocks. This classification was adopted from Mike Stublely (2017). The unsubdivided siliciclastic unit is comprised of interbedded grits, sandstones, siltstones and argillites. This sequence of rocks is observed in all areas exposed along ridgelines. The area has undergone low-grade regional greenschist metamorphism in the form of sericite-chlorite. Amphibolite facies is attained along the contacts of the Cretaceous aged intrusions.

## 12.1 West Plateau

The West Plateau area is dominated by unsubdivided siliciclastics with intermittent centimeter scale argillite units and turbidite sequences. Local quartz veining range from millimeter scale veinlets to centimeter scale veins associated with minor sulphides. Regional greenschist alteration is noted throughout the area.

Bedding is observed dipping shallowly to the northeast  $\sim 310^\circ/18^\circ$ . The prominent structural feature is an  $S_1$  foliation dipping shallowly north-northeast  $338^\circ/22^\circ$  (Figure 10). The area features large scale Isoclinal, to recumbent folding. Parasitic folding is noted at the centimeter scale within finer grained units. Fold axes plunge shallowly to the north-northwest with occasional fold axes noted plunging to the south-southeast. The average fold axis for the area plunges  $8^\circ$  and strikes  $357^\circ$ . A conjugate joint set striking north-south and east-west with variable dips were observed cross cutting bedding and foliation.

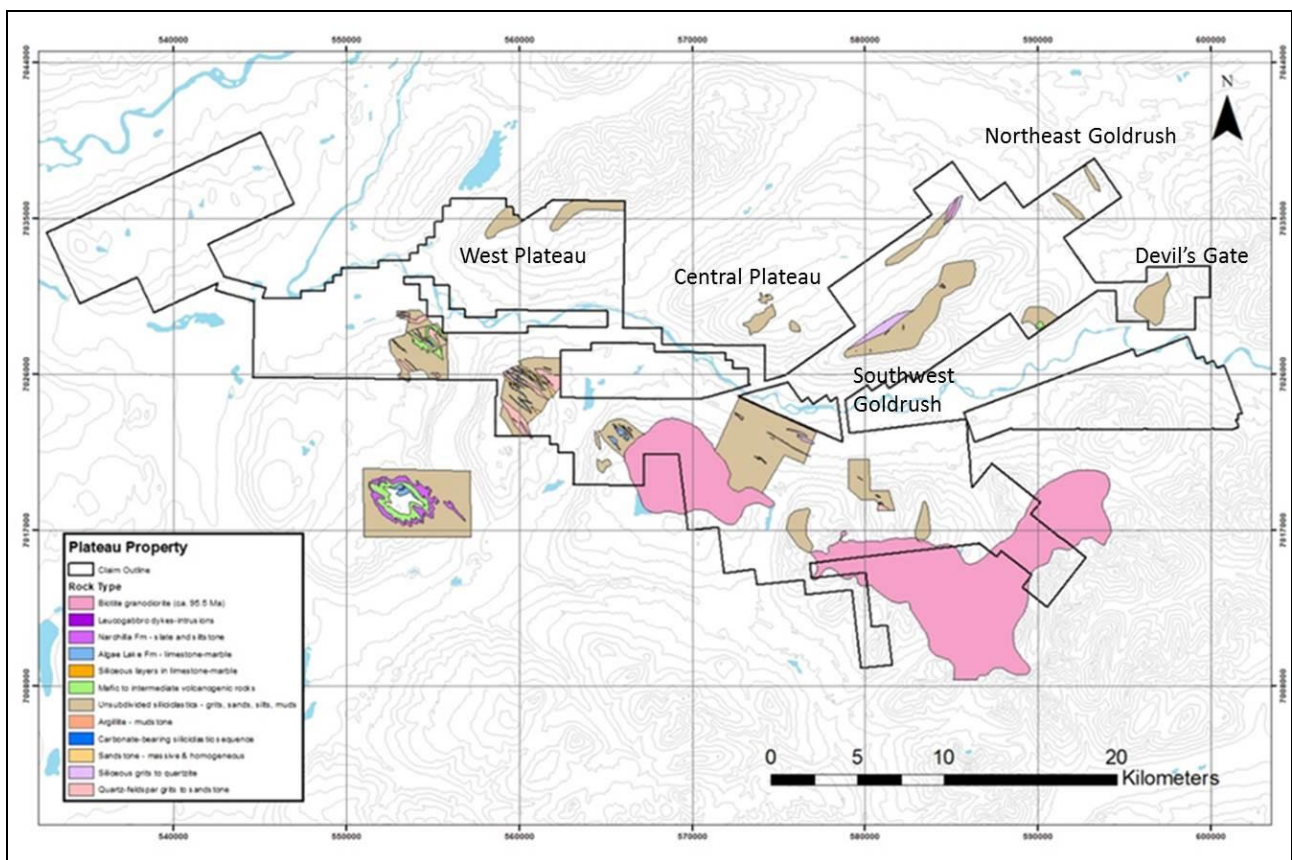

Figure 9) Areas examined during the of the 2018 Plateau mapping program.

## 12.2 Southwest Goldrush

The Southwest Gold Rush area is dominated by unsubdivided siliciclastics. Intermittent carbonate units (limey siltstone/mudstone) are observed interbedded within the stratigraphic sequence. Although discontinuous in nature, quartz veining is observed throughout the sequence ranging from small veinlets to large blowouts. Early veins are observed folded by a  $D_1$  event and later

quartz veinlets are observed to cross cut all structural features.

Bedding is observed moderately dipping to the west-southwest ( $\sim 150^\circ/31^\circ$ ). Foliation is subparallel to bedding moderately to shallowly dipping with local variations ( $\sim 142^\circ/27^\circ$ ). Large scale isoclinal and sub-horizontal to inclined folds are observed plunging shallowly to the northwest and to the southeast. A conjugate joint set trending northwest-southeast and northeast-southwest is prevalent throughout the area.

Figure 10) Bedding-cleavage relationship observed at West Plateau

### 12.3 Northeast Goldrush

Northeast Gold Rush lithology is dominated by unsubdivided siliciclastics with lesser massive quartzite units. A medium grained biotite granite unit is observed intruding into the sequence. Quartz veining in the area is noted as early folded veins and late veins nucleating at the mudstone-siltstone contact extending into the sandstone units. Extensional veins are observed cross-cutting bedding and the dominant foliation. These veins are observed propagating into the more competent units of quartzite and sandstone (Figure 11).

Bedding dips sub-horizontally to the northwest with foliation being noted sub-parallel to bedding dipping shallowly to the west. Pervasive east-northeast to north-northwest jointing is regularly

observed throughout the area.

#### 12.4 Devil's Gate

The area is heavily vegetated and outcrop on safe terrain is limited. Unsubdivided siliciclastics was the main lithology identified. Bedding is observed dipping steeply to the northeast and the dominant foliation is subparallel to steeper than bedding. The foliation dips moderately to steeply approximately northeast and may represent a  $D_2$ - $D_3$  deformation event. Conjugate joints sets measuring  $049^\circ/72^\circ$  and  $347^\circ/82^\circ$  were noted on limited data points. A major thrust fault interpreted by Stubley (2017) and Valli (Pers comms. 2018) is evident in LiDAR and electromagnetic survey is observed to cross cut the area. The fault runs through the center of Devil's Gate area, and may have been reactivated during a later deformation event.

Figure 11) Quartz vein propagating into the sandstone unit cross cutting the dominant foliation.

#### 12.5 Prospecting

Simultaneous outcrop sampling was conducted during the course of the mapping exercise. Mapping crews were instructed to take representative samples of the various lithological units and of veining and mineralization when encountered. The focus of the sampling was directed north of the Hess River with a minor focus south of the Hess around Spit Camp and south of Goldstack

Camp. A total of 310 samples were collected and sent for analysis (Figure 12). Results include several low grade au values and a single high grade au value of 6.56 g/t. The high grade sample was float obtained from the Gold Dome area.

### 13.0 Discussion and Observation

The main focus of the 2018 program was to drill test the top priority targets. Target selection was completed in conjunction with Goldstrike Resources Ltd. and was based on compiled results from previous exploration programs. Over the course of the exploration seasons a number of observations have been made on various relationships at Plateau.

- Mineralization at Plateau is associated with a late extensional event(s). The development of mineralization is located in conjugate fault sets associated northwest-southeast trending faults.
- Quartz veins are observed nucleating at the argillite-sandstone contact and propagating into the sandstone units. The vein walls are sharp showing little to no deformation.
- The area has undergone regional greenschist metamorphism in the form of sericite-chlorite

± carbonate. The presence of a hydrothermal alteration system is discrete and limited in extent.

- Au mineralization observed in drill core mainly corresponds to quartz-arsenopyrite veinlets. Veinlets are observed to cross cut all structural features and develop along a similar orientation to the trends observed on surface. Mineralization at Gold Dome and Goldstack is situated in both quartz veins and veinlets. Large meter scale veins (brecciated at Goldstack) are observed at the argillite-sandstone rheological contact. Quartz-arsenopyrite veinlets are observed to cross cut all other structural features and appears to cross cut the larger veins at some locations.
- Cretaceous Aged Intrusions are spatially and possibly genetically related to Au mineralization at Plateau. The Armstrong Pluton is located immediately south of Gold Dome and the Russell stock is located immediately south of Goldstack. Rock samples of granitic composition were accrued immediately northwest of the Goldrush area of interest.
- Variations in structural observations in Northwestern Plateau may be caused by a large D2 thrust structure observed to be cross cutting the area and its potential reactivation during later deformation events.

## 14.0 Conclusions

Previous deposit models have favoured an Orogenic Gold model over an Intrusive Related Gold model. Gold mineralization at Plateau is noted to occur as gold bearing quartz veinlets and as meter scale quartz veins. Gold showings display various mineral assemblages depending on location with regards to Cretaceous Aged Intrusions. Showings located near the Cretaceous aged intrusions are observed to be associated with As ± Sb in the form of arsenopyrite as observed at Gold Dome and Goldstack. Gold showings further outboard to the intrusions are observed to be associated arsenopyrite but also Sb-Pb-Zn (Goldbank and Ron Stack) and occasionally Te (Goldbar and Ron Stack).

Three to four compressional deformation events have been identified on the property and structural features north of the Hess River are most similar to the shallow dipping Hess Domain. The compressional structures and fabrics are overprinted by a late extensional event an emplacement of large volumes of quartz veining and gold mineralization.

A case for orogenic mineralization can be argued the intrusion related gold model is preferred due timing of the mineralization, the zonation of gold mineralization and associated assemblages along with the lack of development of a strong hydrothermal alteration system. It is recommended that the entire data set be analyzed and re-interpreted using various deposit models.

# 1 SUMMARY

Petrophysical analysis of 20 samples from drill holes at the Goldstack Zone on the Goldstrike Plateau project indicate that chargeability and an early-to-late-window chargeability ratio are both effective tools to identify similar in-situ mineralization. Two lines were surveyed using direct current resistivity – induced polarization (DC-IP), which did identify a nearly coincident chargeability high with the Goldstack Zone. Following from these results, five target areas are identified and illustrated in Figure 1.

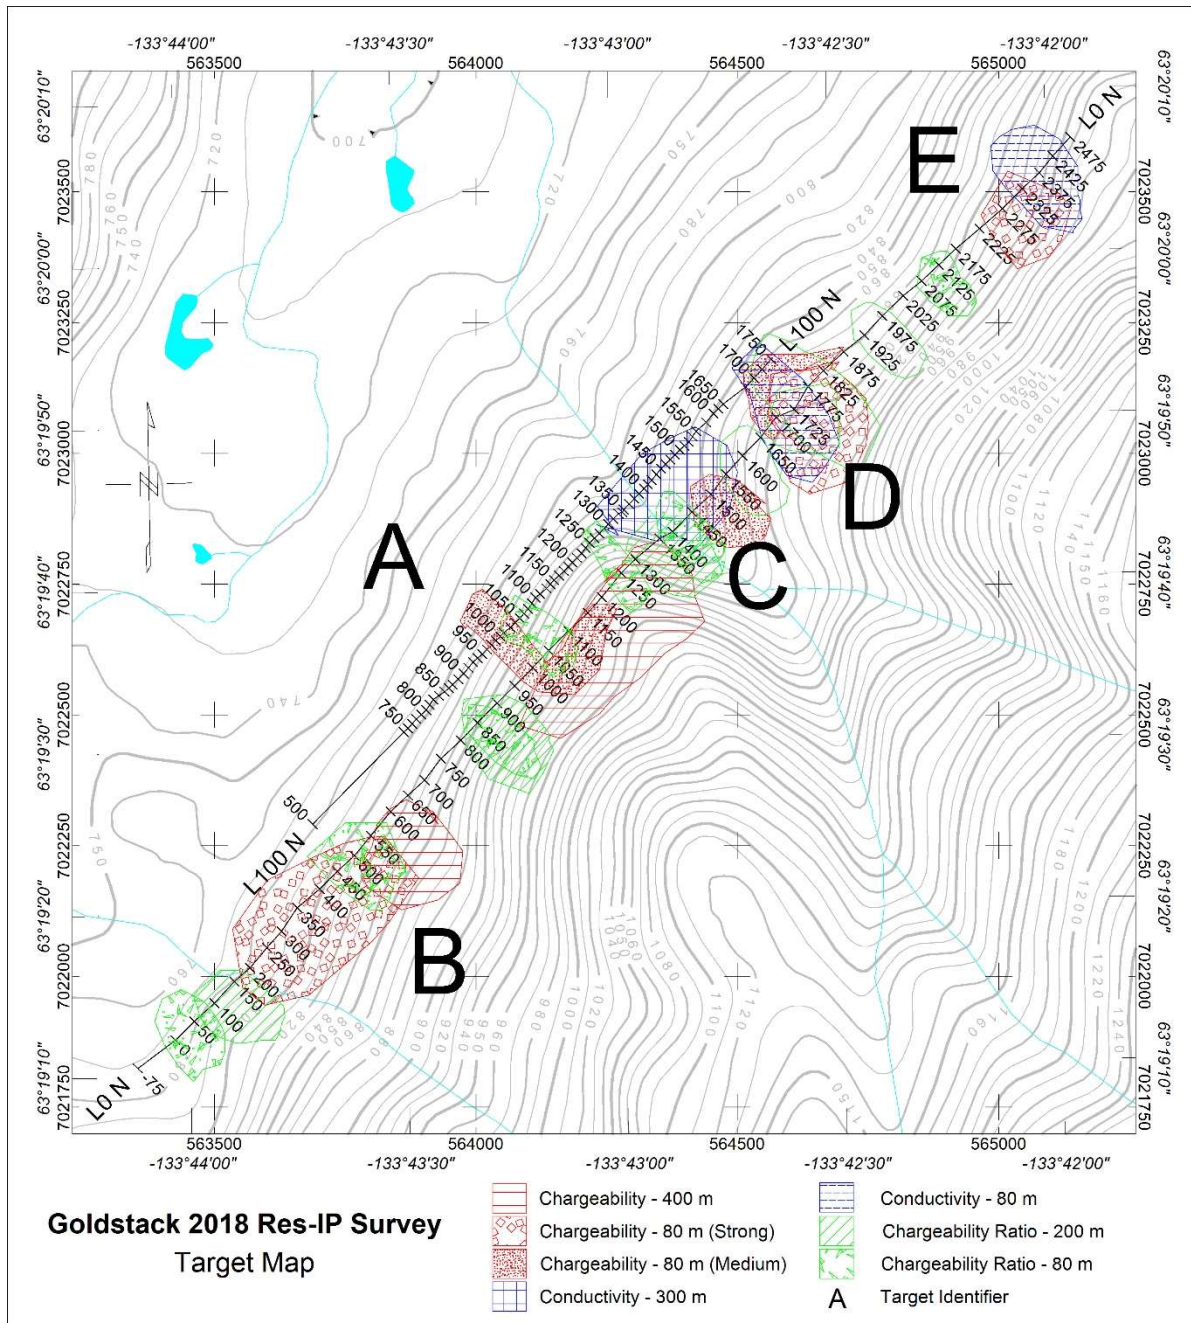

Figure 1: Target Map

Targets A and B are relatively shallow chargeable highs, coincident with favorable early-to-late chargeability ratios. The chargeability anomalies extends to depth (400 m). Target C is a shallow (80 metres below surface) chargeability anomaly on the eastern flank of a deep conductive zone. These are the top ranked targets.

Targets D and E are strong chargeability anomalies associated with conductive zones, and at Target D is coincident with a mapped argillite unit. These are therefore interpreted as argillite and are secondary ranked targets.

## **2 PETROPHYSICS SUMMARY**

A total of 20 samples were analyzed for their petrophysical properties. All consist of drill core samples from the Goldstrike Plateau project, from drill holes PSGS -15-01, PSGS -15-02 and PSGS -15-03. The samples were selected to represent both mineralized as well as host country rock units found at the Goldstack Zone. A full report including petrological descriptions was submitted to Goldstrike Resources Ltd. on May 25, 2018; a summary of results are shown in Figure through Figure 4.

Remanent magnetization was measured on samples 1553356 (grit), 1552257 (grit + HyBx) and 1553360 (argillite); however the core was not oriented, so only the intensity of remanent magnetization could be measured and not the direction.

Figure 2: Petrophysics summary – specific gravity.

Figure 3: Petrophysics summary – magnetic susceptibility.

The Koenigsberger ratio (Q) indicates the relative strength of remnant magnetization. From the petrophysical analysis, Q was determined to be 0.63, 1.01 and 1.43 for the grit, mineralized grit and argillite respectively. However, as can be seen in Figure 3, the mineralized and unmineralized grits are not separated in their magnetic susceptibility. Thus, magnetic surveying is not likely to be a fruitful exploration tool at Goldstack, regardless of the remanent magnetization. Magnetic surveys may be useful to identify areas of argillite, however the argillite sample had significant remanent magnetization; this would complicate a magnetic interpretation, particularly without knowing the direction.

Figure 2 shows a summary of the specific gravity measurements that, similar to magnetic susceptibility, do not show a strong separation between mineralized and unmineralized zones. However, the argillite samples again separate out well. This would suggest that although a gravity survey would not be useful to identify mineralization, it could help to identify argillitic areas.

Figure 2: Petrophysics summary – chargeability.

Figure 3: Petrophysics summary – chargeability ratio.

The chargeability results (Figure 2) are more encouraging from a targeting perspective, with a clear grouping of more chargeable samples with mineralized stockwork, brecciation and less chargeable barren grits. The argillite samples are variable, but generally exhibit higher chargeability.

The ratio of early time chargeability (the mean of chargeability windows 2, 3 & 4) to late chargeability (the mean of chargeability windows 18 & 19) for each sample is shown in Figure 3. Similar to the chargeability petrophysical results, the chargeability ratios separate unmineralized grit from the mineralized grit samples well, while the argillite again shows variable results.

Figure 4: Petrophysics summary – resistivity.

The resistivity results (Figure 4) of the mineralized samples are not distinct from the barren samples, however the argillite samples are in general less resistive than the grits.

### 3.2 Survey Location

The survey grid, shown in Figure 5, is centered at approximately 564225, 7022825 on the Goldstack Zone. All coordinates in this report are UTM Zone 8N coordinates in the NAD83 (CSRS) datum. The crew accessed the grid daily by helicopter from the Goldstack Lake camp, a few kilometers to the north of the survey area. Mobilization and demobilization to and from Goldstack Lake was by float plane from Whitehorse.

The lines were cut in advance of the IP crew by Druid Exploration personnel but were not picketed, so the station locations in Figure 5 are not marked on the ground. The area is topographically challenging and many electrode placements in talus slopes or bare rock were anticipated; in preparation for this, a rock drill and many bags of kitty litter were brought to the survey area to act as an electrode binder in talus. However, suitable placements were found in almost all electrode locations without requiring these measures.

### 3.4 Data Processing

Resistivity-IP and GPS data were downloaded nightly from the receiver and archived. Data were imported into the Geosoft Oasis Montaj IP package and inspected. Poor quality readings and those which did not repeat were rejected from the database. The apparent resistivity was recalculated using a four-electrode equation assuming a homogeneous earth, and georeferenced coordinates. The apparent resistivity and total chargeability were averaged for repeated stations.

The data quality is in general very high. Some conductive ground on the northeast end of L100 N precluded sufficient signal for useable IP data on the long offset dipoles.

Elevations were determined from a digital elevation model for NTS 1:50 000 map sheet 105 N/05.

Averaged apparent resistivity and chargeability are presented as pseudosections in Figure 6 and Figure 7.

Both QA/QC databases (where all data appear) and final databases (where only the accepted, averaged data appear) are appended to this report. Channel descriptions are detailed in Table 1.

## 4 MODELLING

Block earth models of chargeability and resistivity were created using the Geosoft VOXI package. Data were rotated 45 degrees counter-clockwise around the point 564250, 7022800 to increase inversion efficiency.

A variable mesh was used to adequately capture the detail of L100 (surveyed with 12.5 metre dipoles) while still retaining a reasonable number of cells for efficiency on the longer L0 (surveyed with 50 metre dipoles). The rotated mesh comprised of 2X15, 2X13, 11, 10, 9, 8.25, 15X7.5, 8.25, 9, 19, 11, 2X13, 2X15 metre cells, for a total of 40 active cells over 436 metres in the (rotated) x direction and 60X15, 2X13, 11, 10, 9, 8.25, 145X7.5, 8.25, 9, 19, 11, 2X13, 48X15 metre cells for a total of 265 active cells over 2836 metres in the (rotated) y direction. Dimensions in the z direction start with 6.25 cells at the top of the model (932 m) and increase with an expansion ratio of 1.08 until a linear-log transition at 748.5 m for a total of 59 active vertical cells over a total of 850 metres.

Additionally, there are 10 padding cells in each horizontal direction and 7 padding cells at depth, all with an expansion ratio of 1.5.

Following the inversions, the active area of the model was unrotated and regridded with a cell size of 7.5 metres using a kriging algorithm. Finally, each model was clipped to topography using the NTS 105N/05 DEM downloaded from NRCAN's webpage.

### 4.1 Resistivity Modelling

Primary voltages as recorded by the GDD receiver and currents, as reported from the GDD transmitter, were used as inputs for the inversions. An error for the primary voltage is reported from the receiver and errors of 3% of the primary voltage or the reported error, whichever was greater, were used for the inversions. Inversions were run with starting and reference models of 1350 and 350 Ohm-m. Predicted and observed data are shown in Figure 8 (L0) and Figure 9 (L100).

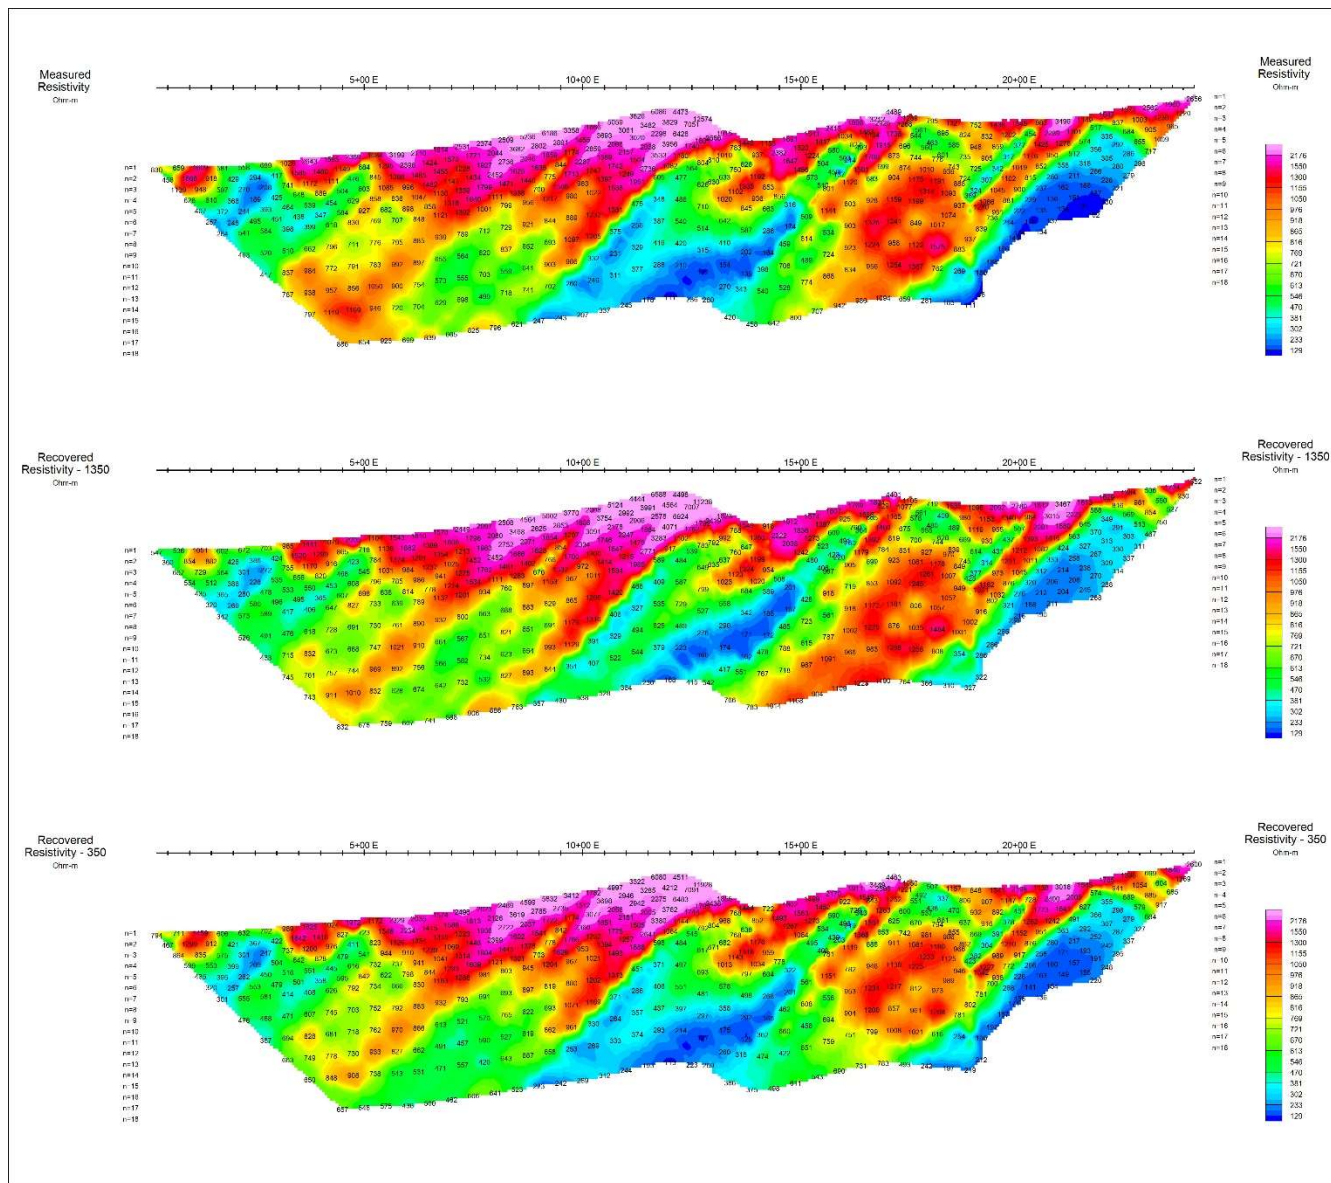

Figure 8: L0 observed resistivity (top panel), recovered resistivity using starting and reference models of 1350 Ohm-m (middle panel) and 350 Ohm-m (bottom panel).

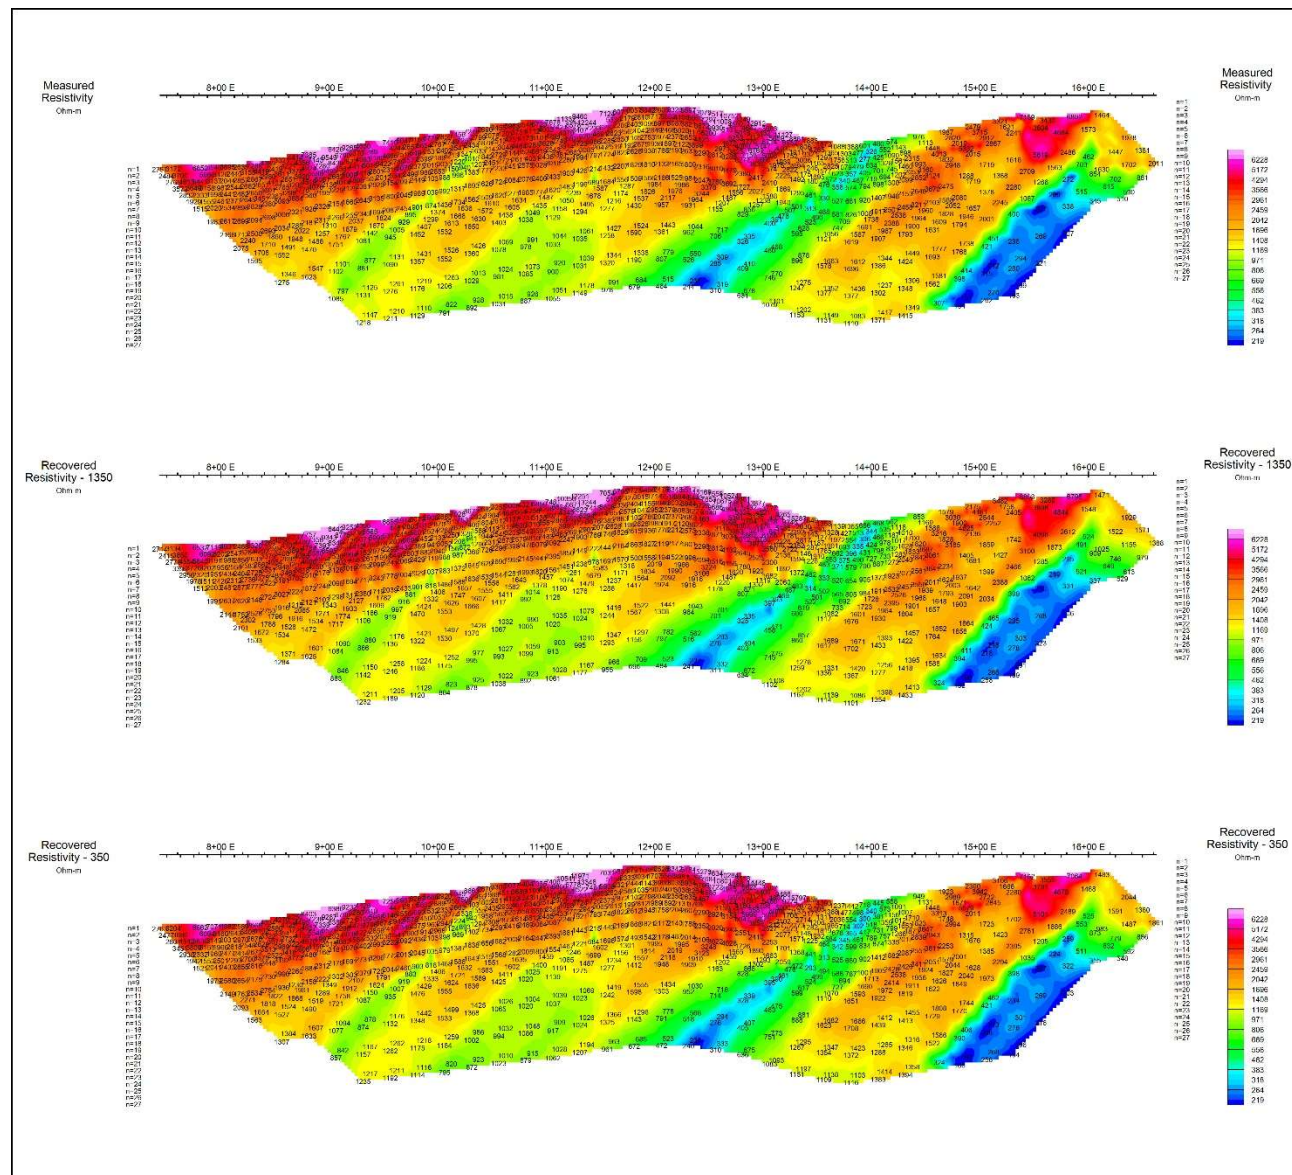

Figure 9: L100 observed resistivity (top panel), recovered resistivity using starting and reference models of 1350 Ohm-m (middle panel) and 350 Ohm-m (bottom panel).

## 4.2 Chargeability Modelling

Averaged chargeabilities over the 20 windows were used as inputs for the inversions. Initial inversion runs using errors of 3% of the measured chargeability or the reported error, whichever was greater, produced results that either did not sufficiently capture the distinct and important chargeability high at the Goldstack Zone on L100 or did not sufficiently capture the high chargeability areas on L0. A modified error scheme is used with 0.5% error (or measured, whichever is greater) in the area around the Goldstack Zone, 1% error (or measured, whichever is greater) anywhere the observed chargeability is greater than 25 mV/V, and 3% error (or measured, whichever is greater) elsewhere. This scheme produces predicted data that honors the observed data and models without excessive complexity.

All chargeability models use a starting resistivity model of 1000 Ohm-m and a lower bound of 0 mV/V. To mitigate high spatial variation close to surface, a 4-layer below surface y-direction smoothing weighting voxel of 16-8-4-2 and an 8-layer below surface x-direction smoothing weighting voxel of 16-12-8-6-4-3-2-1.5 were used. Inversions were run with initial and reference models of 0 and 20 mV.V. Observed and predicted data are shown in Figure 10 (L0) and Figure 11 (L100).

Analysis of the chargeability curves from the petrophysics suggest that in addition to the integrated chargeability, a ratio of early-to-late window chargeability can also be used as a targeting tool. It should be noted that the inherent quality of the integrated chargeability data from all twenty windows is expected to be higher than the ratio of early-to-late windows; however as the data quality is in general excellent this is not a serious concern.

The ratio of the mean of chargeability windows 2, 3 and 4 to chargeability windows 18 and 19 was calculated and used as input for a heuristic IP-ratio inversion. An error scheme of 1% of the chargeability ratio in the vicinity of the Goldstack Zone and 3% elsewhere is used.

All chargeability ratio models use a starting resistivity model of 1000 Ohm-m, a lower bound of 2 and an upper bound of 6. To mitigate high spatial variation close to surface, a 4-layer below surface y-direction smoothing weighting voxel of 16-8-4-2 and an 8-layer below surface x-direction smoothing weighting voxel of 16-12-8-6-4-3-2-1.5 are used. Inversions were run with initial and reference models of 3.5 and 4. Observed and predicted data are shown in Figure 12 (L0) and Figure 13 (L100). The predicted fit is not good in the station 1400 to 1800 area.

## 5 RESULTS AND TARGETING

The petrophysics indicate chargeability as a primary targeting tool for the mineralization and host rock setting at Goldstack. The tight dipole line (L100) over the Goldstack Zone was designed to test the response of the mineralized zone in-situ.

Sections of the recovered chargeability in the vicinity of the drill holes show a reasonable, but not perfect, correlation of mineralization with a small, distinct and robust chargeability high, as seen in Section 4 (Figure 15), Section 5 (Figure 16) and Section 6 (Figure 17). The location of these sections relative to topography and the surveyed lines is shown in Figure 14. The chargeability high associated with the known mineralization is also clear in the gridded recovered chargeability drape in Figure 18 at a constant depth of 40 metres below surface. There is no associated resistivity response (Figure 19), nor associated chargeability ratio response (Figure 20).

Based on the petrophysics, and the positive correlation of recovered chargeability with the Goldstack Zone, high chargeability is considered the primary criterion for targeting. Low chargeability ratio is advantageous, and resistivity is also used as a secondary tool. Figure 21 is a target map that shows recovered chargeability highs, chargeability ratio lows and resistivity lows at various depths. The letters are target identifiers.

## 5.1 Targets

### 5.1.1 Target A

Target A is a relatively shallow (80 m below surface) & modest chargeability high at station 1000 on both lines 0 and 100, although the anomaly is better developed on L100. There is a chargeability ratio low immediately to the north on both lines, but again better developed on L100. A slight resistive low is also

immediately to the north of the chargeability high. It is at the southern end of a deep chargeable zone. This is a top ranked target.

### **5.1.2 Target B**

A strong chargeability anomaly 80 m below surface extends from station 200 to station 550 on L0. The northeastern part of the target is preferred (at station 500) because of more favorable chargeability ratio and a greater depth extent to the chargeability anomaly. L100 did not extend far enough to the southwest to cover Target B. This is a top ranked target.

### **5.1.3 Target C**

Target C is a relatively shallow (80 metres below surface) and modest chargeability anomaly on Line 0 at Station 1500. The chargeability ratio is not spatially cohesive in this area, casting doubt on the reliability of this metric at Target C. It is on the eastern flank of a deep conductive zone. The Goldstack mineralization is on the southwestern flank of the same deep conductive zone, suggesting that it may represent a feeder system. This is considered a top ranked target.

### **5.1.4 Target D**

A strong chargeability zone at a depth of 80 metres on Line 0 and a modest chargeability zone on Line 100 at Station 1725 comprise Target D. The chargeability ratio is not spatially cohesive in this area, casting doubt on the reliability of this metric at Target D. A coincident resistivity low does not dismiss this target, but it is coincident to mapped “clastic metasediments”, which is assumed to be the equivalent of argillite. This is therefore classified as a secondary target.

### **5.1.5 Target E**

Target E is a strong chargeability zone at a depth of 80 metres on Line 0 at Station 2300. Line 0 did not extend far enough to the northeast to cover this anomaly. There is not a favorable chargeability ratio. A coincident resistivity low does not dismiss this target, and Target E is outside of the area of surface mapping, but the tenure of conductivity is similar to that of Target D and is therefore interpreted to also represent argillite. This is a secondary target.

# Sample Preparation

---

Sample preparation is designed to produce a representative, homogenous sub-sample from the original raw sample. Many variations on the methods and packages in the following pages are available, and sample preparation schemes can be customized to suit any particular project requirement. We have a wide range of expertise available within ALS to help you with any questions you might have.

Samples may be submitted to any of the locations listed on the back pages of this schedule. We can also offer advice on shipping to any of our laboratories by ground, air cargo and air express.

**Sample submission forms are available on request.**

---

## Sample Submission

Confidence and security in the chain of custody for your samples as they pass through our system are paramount. Your samples are given a barcode and logged into our proprietary global laboratory information management system on receipt. We encourage clients to barcode samples prior to sending them to our laboratories. Our system will accommodate all major barcode formats.

# Precious Metals Analysis

---

The unique chemical properties of gold, silver, and the platinum group elements pose challenges in geochemical analysis. They often occur inhomogeneously in geological materials, at scales ranging from micron-sized inclusions in minerals to large nuggets. As a result, large analytical charge weights are required to accurately represent content in the overall sample. Solvent digestions can also lose gold to adsorption on the original sample when certain forms of carbon and sulfide minerals are present, in a process called preg robbing.

ALS has decades of expertise in reliable and reproducible precious metals analysis by fire assay, cyanide leach and aqua regia digestion at parts per billion to percent levels.

**Please submit at least three times nominal sample weight for efficient service.**

## Gold by Fire Assay

An optimal fire assay flux recipe and rigorous quality control program easily handle problem materials including chromite, base metal sulfides and oxides, selenides, and tellurides.

Choice of crushing fineness, splitting technique and pulp size can all affect the analytical outcome of fire assay gold methods. Discuss with your local ALS laboratory for more information.

## Silver

Trace level and low-grade silver samples may be analyzed by acid digestion for maximum sensitivity and precision. Multi-element packages including Ag are listed in the Targeted Exploration section.

Because silver can suffer from nugget effect, occasional duplicate analysis may help detect sampling error at these low levels. At higher grades, fire assay with larger nominal weights may be preferable.

# Generative Exploration

---

Every method listed in the following four pages involves some aspect of our innovative methodology for super trace analysis on the ICP-MS. Detection limits have been pushed orders of magnitude below average crustal abundance for the majority of elements, enabling excellent precision at geochemical background levels and clearly defined geochemical anomalies. Digestion methods appropriate for any sample medium are available - soils, sediments, regolith, vegetation, water, rocks, and drill core. ALS remains committed to solving long-standing analytical challenges in exploration geochemistry by making use of new instrumentation and fresh ideas from our team of expert analytical chemists and geochemists.

**Please submit at least three to four times the nominal sample weight for efficient service.**

## Aqua Regia for Soils and Sediments

Aqua regia digestion with super trace ICP-MS analysis provides extremely low detection limits useful for regional and deep cover exploration.

The rare earth elements and lead isotope concentrations add new dimensions to super trace data. REEs may be useful pathfinders despite reflecting only the labile component, while Pb isotopic signatures can be used in fingerprinting and hydrothermal fluid history.

## Biogeochemistry

Plants may be viewed as large-scale geochemical sampling devices, with root systems that can selectively absorb elements from a large volume of soil, groundwater, and even bedrock. Careful selection of plant species is important as biological effects control geochemical response.

ALS provides additional vegetation preparation services such as separating the plant parts of interest from waste material. Please contact your local lab to discuss your specific project goals.

## Four Acid Super Trace Analysis

This super trace package is suitable for regional drilling, trenching and hand samples in unmineralized rocks, and can also be used effectively in areas of thick regolith for bedrock mapping. ALS has lowered the detection limits on key pathfinder elements such as As, Sb, Se and Tl to near or below average crustal abundance, revealing anomalous patterns at levels previously unattainable due to technical limitations.

The rare earth elements and lead isotopes are available as add-ons to expand the utility of the method in greenfields exploration.

# Targeted Exploration

---

No single method covers all types of geological materials for all geochemically-relevant elements at all concentrations. Sample type, commodity of interest, geochemical pathfinders and expected concentration of target elements should all be considered when selecting appropriate methods for your project.

Broadly, aqua regia readily dissolves many sulfide, oxide and carbonate minerals, as well as retaining mercury, a particularly volatile element. Four acid digestions quantitatively dissolve nearly all minerals, but it may sometimes be necessary to use even stronger techniques such as fusions in order to fully digest barite, rare earth oxides, and tin, tungsten, niobium and tantalum minerals.

The choice between various instrument finishes should be informed by the expected concentrations of the elements of interest in the sample.

**Please submit at least four times  
the nominal sample weight for  
efficient service.**

## Aqua Regia With ICP-MS Finish

Method selection can be key to achieving exploration success. Sample type, target commodity, and pathfinder elements should all be considered when selecting the most appropriate method for your project.

Aqua regia is an excellent exploration tool for various deposit types that involve gold, silver and base metals hosted in sulfide and carbonate minerals.

## Four Acid Digestion With ICP-MS Finish

Four acid digestion quantitatively dissolves nearly all minerals in the majority of geological materials. However, barite, rare earth oxides, columbite-tantalite, and titanium, tin and tungsten minerals may not be fully digested.

Despite the potentially incomplete digestion of REEs, the leachable portion of these elements may hold important exploration vectoring information and can be chosen as an add-on.

## Portable XRF For Indicative Analysis

Portable XRF may be used to screen large volumes of samples for intermediate to ore grade elements when the standard lab test is relatively costly and time-consuming. The pXRF method must be calibrated for a specific sample suite on an individual project basis. Submitting samples not represented in the calibration suite creates a high risk of inaccurate results, including false positives.

ALS offers custom calibration for pXRF on project-specific sample suites, with our rigorous quality standards and XRF expertise ensuring accurate, reliable results. The pXRF instrument can be located in the prep lab nearest your project, or on-site if the project is remote. Contact your local client services team for more information.

### **ORIGIN OF REFERENCE MATERIAL:**

Standard CDN-BL-10 was prepared using a blank granitic material.

### **METHOD OF PREPARATION:**

The granitic material was dried, crushed, pulverized and then passed through a 270 mesh screen. The +270 material was discarded. The -270 (<53 micron) material was mixed for 5 days in a double-cone blender. Splits were taken and sent to 12 commercial laboratories for round robin assaying. Round robin results are displayed on the next page.

**DATE OF CERTIFICATION:** October 19, 2016

### **ORIGIN OF REFERENCE MATERIAL:**

Standard CDN-GS-P6B was prepared using 800 kg of blank granite and 6 kg of a high grade gold ore..

### **METHOD OF PREPARATION:**

Reject ore material was dried, crushed, pulverized and then passed through a 270 mesh screen. The +270 material was discarded. The -270 material was mixed for 5 days in a double-cone blender. Splits were taken and sent to 15 commercial laboratories for round robin assaying. Round robin results are displayed below:

### APPROXIMATE CHEMICAL COMPOSITION (by whole rock analysis):

	Percent		Percent
SiO <sub>2</sub>	62.2	Na <sub>2</sub> O	3.2
Al <sub>2</sub> O <sub>3</sub>	16.4	MgO	2.6
Fe <sub>2</sub> O <sub>3</sub>	6.0	K <sub>2</sub> O	1.6
CaO	6.0	TiO <sub>2</sub>	0.5
MnO	0.1	LOI	1.2
Total S	<0.1	Total C	<0.1

**Statistical Procedures:**

The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. Data from any one laboratory was removed from further calculations when the mean of all analyses from that laboratory failed a t test of the global means of the other laboratories. The mean and standard deviation were calculated using all remaining data. Any analysis that fell outside of the mean  $\pm 2$  standard deviations was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data. This method is different from that used by Government agencies in that the actual "between-laboratory" standard deviation is used in the calculations. This produces upper and lower limits that reflect actual individual analyses rather than a grouped set of analyses. The limits can therefore be used to monitor accuracy from individual analyses, unlike the Confidence Limits published on other standards.

Our certified gold values are based on 30 g Fire Assay determinations. For optimal results, we strongly recommend you assay our standards with similar methods using "at least" 30 g of material. Using a smaller sample weight may result in erratic values.

Standards with an RSD of near or less than 5% are certified; RSD's of between 5% and 15% are Provisional; RSD's over 15% are Indicated. Provisional and Indicated values cannot be used to monitor accuracy with a high degree of certainty.

Please note that the certified value and between lab 2SD calculated for each element are done so for a specific analytical procedure. It is inappropriate to apply them to other techniques (eg. geochemical analyses).

**INDEPENDENT GEOCHEMIST:** Dr. Barry Smee., Ph.D., P. Geo.  
**DATE OF CERTIFICATION:** September 5<sup>th</sup>, 2017

### ORIGIN OF REFERENCE MATERIAL:

Standard CDN-GS-2S was prepared using 17 kg of high grade ore by Teuton Resources from their Clone gold property in B.C., Canada blended with 783 kg of granite.

Mineralization of Clone gold property is localized within highly silicified semi-massive to massive specular hematite.

Gold occurs as fine disseminations and is associated with the oxide mineralization. The major lithology is light grey to green andesitic pyroclastic intercalated with fine grained to aphanitic andesite. Clasts are sub angular to angular, matrix supported, and range in size from 1-3cm. Quartz-calcite stockwork pervades the unit in moderate abundance.

### METHOD OF PREPARATION:

Reject ore material was dried, crushed, pulverized and then passed through a 270-mesh screen. The +270 material was discarded. The -270 material was mixed for 5 days in a double-cone blender. Splits were taken and sent to 15 commercial laboratories for round robin assaying.

### ASSAY PROCEDURES:

**Au:** Fire assay pre-concentration, AA or ICP finish.

Whole rock analysis and 30 element ICP analysis (4-acid digestion) was also conducted on 5 samples.

### APPROXIMATE CHEMICAL COMPOSITION (by whole rock analysis):

	Percent		Percent
<b>SiO<sub>2</sub></b>	59.4	<b>Na<sub>2</sub>O</b>	3.1
<b>Al<sub>2</sub>O<sub>3</sub></b>	16.5	<b>MgO</b>	2.9

### STATISTICAL PROCEDURES:

The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. Data from any one laboratory was removed from further calculations when the mean of all analyses from that laboratory failed a t test of the global means of the other laboratories. The mean and standard deviation were calculated using all remaining data. Any analysis that fell outside of the mean  $\pm 2$  standard deviations was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data. This method is different from that used by Government agencies in that the actual "between-laboratory" standard deviation is used in the calculations. This produces upper and lower limits that reflect actual individual analyses rather than a grouped set of analyses. The limits can therefore be used to monitor accuracy from individual analyses, unlike the Confidence Limits published on other standards.

Our certified gold values are based on 30 g Fire Assay determinations. For optimal results, we strongly recommend you assay our standards with similar methods using "at least" 30 g of material. Using a smaller sample weight may result in erratic values.

1.10	16.00	3J Sandstone	coarse		grey	light	Light grey sandstone with sections of greenish-grey sandstone. Limonite is disseminated in wallrock and concentrated on fractures. Fault fracture zones are common throughout sandstone unit. Thin quartz veins(+/- carbonate) <1cm wide are common (<1%) at a variety of orientations. Quartz-carbonate veins often occur perpendicular tca.
16.00	20.34	3H Conglomerate	fine		green	medium	Polymictic pebble conglomerate with clasts upto 1cm long set in a medium-green siliceous matrix
20.34	29.00	3J Sandstone	fine		grey	medium	Medium-grey, Fine-medium-grained sandstone. Limonite is concentrated on fractures and in fracture zones, often displaying cm wide alteration halos on fracture contacts. Fault fracture zones are common throughout sandstone unit. Interval contains a ~4m fault zone with small sand size pieces, rubble and bigger more competent pieces. The end of the fault zone also seems to have occurred through a quartz vein due to the abundance of small quartz pieces.
22.00	39.26	3L Siltstone Arenaceous – Arenite	fine		black	dark	Fine grained Siltstone with thinly bedded mudstone. Interval near fault zone resulting in many fractured pieces and minor amounts of gouge. Fracture infill of pyrite at 29.21.

0.00	1.82	OB Overburden					OVERBURDEN
1.82	3.44	3J Sandstone	medium		grey	medium	Grey-green siliceous sandstone, highly fractured with limonite on fracture surfaces.
3.44	15.25	3E Argillite/Mudstone	fine		black	medium	Black argillite with interbedded siltstone. Cordierite porphyroblasts throughout unit. Limonitic fractures.
15.25	18.15	3J Sandstone	coarse		grey	medium	Grey siliceous sandstone, some limonitic fractures and quartz veining.
18.15	20.58	3E Argillite/Mudstone	fine	Up-hole	black	medium	Black and grey argillite (60%) interbedded with coarse grained siliceous sandstone (40%). Alternating sequence of argillite and sandstone between 1.5cm and 19cm thickness. Flame structure in argillite at 20.17m shows younging up hole.
20.58	51.60	3B Sandstone Arenaceous – Arenite	coarse		grey	medium	Grey siliceous sandstone. Medium to very coarse grained sandstone with pebble conglomerate sections (clasts up to 0.5cm in size). Occasional muddier sandstone beds contain cordierite porphyroblasts. Zone from 34.44m to 34.84m appears brecciated. Some argillite beds (up to 4cm thick) from 49.75m
51.60	77.20	3K Limey/Sandstone	coarse		grey	medium	Grey medium to coarse grained sandstone with a limey matrix and interbedded sections of argillite (25%). Section within fault zone has been decalcified. Silicified zones don't react with HCL.
77.20	112.52	3K Limey/Sandstone	coarse		grey	medium	Grey medium to coarse grained sandstone with a limey matrix. Rare fine beds of argillite (1%). Section within fault zone has been decalcified. Silicified zones don't react with HCL.
112.52	187.07	3K Limey/Sandstone	coarse		grey	medium	Grey medium to coarse grained sandstone with a limey matrix and interbedded sections of argillite (25%). Silicified zones don't react with HCL. Some graphitic zones in the argillite between 125.9 and 129m. Matrix becoming gradually less limey from approximately 173m to base of unit. Mostly graphitic argillite from 185.04 to base of unit.
187.07	205.45	3B Sandstone Arenaceous – Arenite	coarse		grey	medium	Grey-green siliceous sandstone. Slightly limey unit from 192.60 to 193.18m. Light green zones from approx. 190-201m and from 209.5-213.3m.
205.45	227.70	3D Greywacke	medium		brown	medium	Brown-grey siliceous greywacke. Gradual contact with arenite sandstone beds above. Some argillite rip up clasts from 209.60-209.70m. Light green zone from approx 209.5-213.3m.
227.70	231.63	3E Argillite/Mudstone	fine		black	medium	Black argillite with interbedded siltstone and greywacke (30%). Cordierite porphyroblasts throughout unit.
231.63	257.48	3K Limey/Sandstone	coarse		grey	medium	Grey medium to coarse grained sandstone with limey matrix and interbedded sections of argillite (20%). Calcite infill along fracture surfaces.
257.48	272.55	3B Sandstone Arenaceous – Arenite	coarse		grey	medium	Grey fine to coarse grained sandstone with sections of pebble conglomerate (clasts up to 0.8cm in size). Some interbedded argillite up to 260.70m (30%).
272.55	307.00	3D Greywacke	coarse		brown	medium	Brown-grey siliceous greywacke with beds of coarse grained sandstone/pebble conglomerate (40%). Argillite bed from 287.87 to 288.03m. Some cordierite porphyroblasts are visible in greywacke and argillite. FOH.

0.00	4.03	OB Overburden					OVERBURDEN
4.03	37.60	3K Limey/Sandstone	medium		grey	medium	Grey sandstone with limey matrix material and interbedded argillite (30%). Argillite shows strong deformation and bedding is shallow dipping relative to the core axis. Some fractures have calcite infill.
37.60	57.98	3A Clastic Sediments Unsubdivided	fine		grey	dark	Dark grey interbedded siliceous sandstone, greywacke, siltstone and argillite beds. Some graphitic argillite beds between 45m and 53m. Limey sandstone beds at 47-47.70m and 49.4-50.15m.
57.98	85.50	3K Limey/Sandstone	coarse	Up-hole	grey	medium	Grey medium to coarse sandstone with limey matrix and interbedded argillite (10%). Silicified zones don't react with HCL. Flame structure at contact with underlying argillite unit shows <u>younging up-hole</u> .
85.50	96.52	3E Argillite/Mudstone	fine	Up-hole	black	medium	Black deformed argillite interbedded with grey limey sandstone (30%). Numerous flame structures in argillite and rip up clasts within sandstone show younging up-hole.
96.52	107.89	3K Limey/Sandstone	coarse		grey	medium	Grey medium to coarse sandstone with limey matrix. Occasional interbedded argillite (<5%). Silicified zones don't react with HCL. Some rip-up clasts of argillite which appear like cut-off <u>argillite beds (98-99m)</u> .
107.89	113.80	3A Clastic Sediments Unsubdivided	fine		grey	dark	Dark grey interbedded siliceous sandstone, argillite and siltstone. With bed of limey sandstone from <u>110.60-110.80m</u> .
113.80	146.72	3K Limey/Sandstone	coarse		grey	medium	Grey medium to coarse sandstone with limey matrix. Rare thin argillite (<1%) beds and rip-up clasts. Silicified zones don't react with HCL.
146.72	148.42	3E Argillite/Mudstone	fine		grey	dark	Dark grey argillite beds with interbedded limey sandstone beds (40%). Limey sandstone bed from 147.34-147.74m. Some occasional calcite veinlets (1mm) throughout.
148.42	183.04	3K Limey/Sandstone	coarse		grey	medium	Grey medium to coarse sandstone with limey matrix. Minor interbedded argillite (1%) up to 4cm thick plus thick argillite beds from 162.13-162.32m and 163.29-163.71m. Silicified zones don't react with HCL. <u>Vug/void encountered at 149.30m approx. 0.2m in size with quartz and possible anchorite crystals on surface</u> .
183.04	265.80	3K Limey/Sandstone	coarse		grey	medium	Grey coarse sandstone with limey matrix and interbedded argillite (20%). Most argillite beds are up to 2cm in size or interlaminated with limey sandstone. There are thick argillite beds from 183.12-183.45m, 222.92-230.14m and a limey mud bed from 193.33-193.55m. Sections of pebble conglomerate with limey matrix (clasts up to 0.5cm in size) from approx 189.5-194.5m. Some argillite beds are graphitic from 198.30m. Brecciated zone with vuggy quartz and pyrite fill from 253.83-254.68m. Some fractures infilled with calcite. Highly fractured and mottled appearance to rock from approx 257m-261m. Sharp contact with unit below at ~13dtca
265.80	275.54	3E Argillite/Mudstone	fine		black	dark	Dark siliceous graphitic argillite with graphitic sheen bearing round cordierite grains up to 3mm wide averaging . Fracture fill pyrite is common. Fine -medium grained pyrrhotite occurs disseminated along bedding and in 1-2cm wide quartz veins. Argillite becomes mixed with <u>sandstone hosting 10-30% rounded quartz clasts &lt;2mm wide at 269.77m</u>
275.54	355.29	3B Sandstone Arenaceous – Arenite	medium		grey	medium	Medium-grey, medium-coarse-grained sandstone is moderately-strongly siliceous. Few argillite beds and rip-up clast less than 5cm wide occur. From 297m-307m, sandstone regains its mottled appearance. 1-2 cm wide beds of deformed limey sandstone occur throughout mottled section. Below mottled zone is a strongly fractured zone from 308.46-309.96m. Green-white clay minerals are found in fractures.
355.29	356.60	3E Argillite/Mudstone	fine		black	dark	Graphitic argillite is strongly silicified
356.60	362.00	3K Limey/Sandstone	coarse		blue	light	Strongly silicified, light-blue/grey limey sandstone with quartz clasts and a silicified carbonate

0.00	7.30	OB Overburden					OVERBURDEN
7.30	201.33	3K Limey/Sandstone	coarse		blue	medium	Medium-coloured, blue-grey limey sandstone occurs massive and bedded. Porous halos up to 20cm on some near surface fractures, where carbonate has been leached from rock. Interbedded mud beds can occur finely laminated in carbonate. argillite interbedding is more deformed and strained than the host limy-sandstone. Argillite beds are rare, with few sections less than 1m.
201.33	215.54	3E Argillite/Mudstone	fine		grey	medium	Siliceous graphitic argillite interbedded and brecciated with siliceous, light-green, medium-grained sandstone and limey-sandstone. Bedding is often chaotically folded. 2-5mm wide quartz veins with grey-green alteration are common throughout mineralized consisting of disseminated
215.54	219.63	3C Arkose-Arkosic-wacke	medium		black	medium	Dark medium-grained siliceous sandstone with 15%? biotite. 0.5m of graphitic argillite interval
219.63	224.77	3E Argillite/Mudstone	fine		black		Gradation into argillite. Cordierite appears at the start of this interval, occurring 1-4mm wide, up to 25% modal percentage
224.77	227.53	3C Arkose-Arkosic-wacke	medium		black	medium	Dark medium-grained siliceous sandstone with 15%? biotite
227.53	230.00	3E Argillite/Mudstone	fine		black	dark	Graphitic argillite without cordierite
230.00	238.53	3B Sandstone Arenaceous – Arenite	medium		grey	light	Siliceous light-grey sandstone with ~15% quartz and feldspar clasts upto 3mm. Light-grey quartz
238.53	248.60	3C Arkose-Arkosic-wacke	medium		grey	dark	Dark medium-grained sandstone with 20%? Biotite. Section of argillite occur up to 20cm wide. Minor intervals of silicification
248.60	286.74	3J Sandstone	coarse		grey	medium	Siliceous, medium-light-grey(sometimes light green) sandstone with ~15% quartz and feldspar
286.74	292.55	3J Sandstone	coarse		grey	dark	Siliceous dark-grey sandstone with ~15% quartz and feldspar clasts upto 4mm wide.
292.55	304.31	3J Sandstone	medium		black	dark	Siliceous dark-grey sandstone with ~15% quartz and feldspar clasts upto 4mm wide., interbedded with graphitic argillite bearing cordierite (biotite cordierite schist), at a shallow-moderate dtca
304.31	321.00	3J Sandstone	medium		grey	medium	Dark-medium grey siliceous sandstone with abundant light-green chlorite in deformed/ sheared

2.49	4.00	3L Siltstone Arenaceous – Arenite	fine		grey	medium	Fine grained medium grey Siltstone interbedded with black mudstone up to ~3 cm thick. Thin carbonate stringers with same orientation as mudstone occur throughout interval. Yellow-orange moderate limonite alteration is apparent on core face as well as along fractures.
4.00	12.80	3J Sandstone	fine		grey	medium	Orange-red limonitic altere fine-meium grey sandstone occurs throughout a fault zone, minor amounuts of gouge. Very few quartz, carbonate, and mudstone veins observed.
12.80	19.70	3J Sandstone	fine		grey	medium	Fine-medium grained medium grey sandstone interbedded with siltstone and mudstone.
19.70	21.98	3E Argillite/Mudstone	fine		black	dark	Fine grained black argillite/mudstone interval interbeded with medium grey siltstone. ~60% argillite and ~40% siltstone. No observed quartz veining, minor carbonate stringers. ~6cm sandstone bed within the interval.
21.98	28.00	3J Sandstone	fine		grey	medium	Fine-medium grained grey sandstone with limey sandstone laminations and interbedded with argillite laminations. Some of the limey laminations appear to be leached leaving voids where grains could have been.
28.00	38.04	3E Argillite/Mudstone	fine		grey	dark	Fine grained argillite/mudstone interbedded with mostly thin laminations of siltstone and sandstone. Apparent quartz veins ranging from ~3-12cm. Small quartz-carbonate stringers. Moderate limonitic alteration observed, yellow coloration.
38.04	52.10	3J Sandstone	Fine		grey	medium	Fine-medium grained grey sandstone interbedded with thin laminations of siltstone and argillite (~20%) also with limey sandstone laminations(~5) ~1-14cm throughout, majority are small. A few smaller quartz veins and one larger quartz-carbonate vein occur within interval.
52.10	67.00	3A Clastic Sediments Unsubdivided	fine		grey	dark	Unsubdivided fairly fractured interval of fine-medium grained interbedded argillite, siltstone, and sandstone. Difficult to break out a majority litho. Light brown muddy sandstone interval from 55.92-57.45 with limonitic alteration . Moderate limonitic alteration along fractures . Chloritic alteration within quartz veins. Several fractured quartz veins displaying limonitic alteration and sulphides.
67.00	149.00	3J Sandstone	medium		grey	medium	Fine-medium grained light-medium grey sandstone interbedded with thin laminations of argillite and siltstone (~25%). Chlorite alteration observed within and along quartz vein edges. Limonite alteration observed along fractures. Several quartz veins 1-13cm through interval. A few carbonate veins mm size and stringers observed. Sharp contacts between argelite and sandstone @ 69.04 and 76.34.
149.00	232.81	3J Sandstone	medium		grey	medium	Similar unit to above interval with larger (~.5-1.5m) argillite interbedded with siltstone sections. Majority is made up of fine-medium grained light-medium grey sandstone interbedded with thin laminations of argillite and siltstone . Several quartz veins 1-20cm long at high DTCA. Minimal weak limonite alteration, weak to moderate chlorite alteration observed in and along quartz vein edges as well as possibly throughout sandstone sections. Several sharp contacts between sandstone and siltstone/argillite. Possible flame structures @ 154.88 and 183.18 indication a grading downhole.
232.81	293.37	3J Sandstone	medium		grey	medium	Fine-medium grained medium grey silty sandstone interbedded with thin laminations of argillite. ~1-3cm thick carbonate sections within sandstone paralle to bedding. Very few qtz veins ~1-5cm thick @ high DTCA. Minor thin (mm-1cm) carbonate veins. Very little alteration, occasional limonite observed.
293.37	296.69	3E Argillite/Mudstone	Fine		black	dark	Fine grained black argillite interval interbedded with siltstone and carbonate rich sandstone. Multiple small qtz veins with irregular shapes. Very rich in Pyrrhotite. Pyrr observed along bedding planes, as stringers disseminated throughout. Minor Cpy and Py observed as well. Fracturing is seen from 294.89-295.34 with larger pieces and minor gouge.
296.69	300.00	3J Sandstone	fine		grey	medium	Fine-medium grained silty sandstone. Multiple thin carbonate beds from 298.86-299.65. EOH.

0.00	3.00	OB Overburden					OVERBURDEN
3.00	14.17	3A Clastic Sediments Unsubdivided	fine		grey	medium	Highly weathered and fractured interval of sandstone and argillite. Small sections of interbedded carbonate rich sandstone and argillite. Very few qtz veins observed. Qyz filled fractures and small carbonate stringers observed. Sizes range from sand~12cm long competent pieces.
14.17	18.45	3E Argillite/Mudstone	fine		black	dark	Highly fractured interval with varying sized pieces. Medium grey-black argillite thinly interbedded with sandstone. Weathered intervals and possible weak limonite alteration along bedding. No qtz veins, small thin carb stringers.
18.45	27.76	3J Sandstone	fine		grey	medium	Highly fractured fine-medium grained grey sandstone. Occasional carb veinlets occurring within sandstone, ~1-5cm thick. A few qtz veins showing chlorite and limonite alteration. Minor carb stringers. Faulting occurs within interval with significant gouge and weathering on either end of gouge.
27.76	34.49	3E Argillite/Mudstone	fine		black	dark	grey-black argillite thinly interbedded with sandstone. Occasional larger >10cm thick section of sandstone within. Minimal qtz veining present, more qtz filled fractured observed. Yellowish-orange discoloration between bedding and along fractured seen from ~28-31.5m, possibly due to weathering or limonite alteration. Minor folding of thin beds from ~34-36m.
34.49	124.21	3J Sandstone	medium		grey	medium	fine-medium grained sandstone with 0.5m-1.5m sections of argillite. Also thinly interbedded sometimes with argillite and siltstone. 1-4cm carbonate veins within sandstone sections. Highly fractured, many small quartz and carb stringers. Qtz veins tend to contain fractures with limonite and chlorite alteration. A few faults with gouge observed. S folds of qtz veins and boudins present
124.21	195.61	3J Sandstone	medium		grey	medium	Mixed Interval of predominantly fine-medium grey sandstone with interbedded, siltstone, and
195.61	209.00	3J Sandstone	medium		grey	medium	medium grained greyish-green sandstone with a few cm thick qtz veins. Many carbonate filled fractures near end of interval. Low amount of silt and argillite unlike previous intervals.
209.00	222.00	3L Siltstone Arenaceous – Arenite	fine	Down-hole	grey	medium	fine grained grey siltstone interval thinly interbedded with sandstone and minor amounts of argillite. . May possibly be a silt rich sandstone. A few qtz veins present. Sections of many micro fractures filled with carbonates. Larger low DTCA mineralized fractures also present.
222.00	298.03	3J Sandstone	medium		grey	medium	fine-medium grained sandstone with sections of thinly interbedded argillite and siltstone. Darker sections have more argillite and a muddier sandstone. many qtz veins throughout. Carbonate beds are present throughout up to 5cm thick. significant micro fractures filled with carbonates in sections within the interval. Occasional limonite and chlorite alteration, very minimal. Asp, Cpy, Py, and Pyrr mineralization present with Pyrr being the most abundant by far. Lots of Pyrr from 271.89-275.5.
298.03	387.00	3J Sandstone	medium		grey	medium	medium grained medium grey sandstone with alternating finely interbedded argillite, siltstone

0.00	2.20	OB Overburden					OVERBURDEN
2.20	108.00	3J Sandstone	medium		grey	medium	medium grained grey sandstone with large (.5-1.5m) interbeds of argillite/siltstone. Sometimes finely interbedded aswell. Quartz veins ranging from ~2-20cm wide with weak chlorite altering wall rock inclusions. limonite alteration (mod-strong) seen on core face, within fractures/ veins and along bedding in certain areas. Fairly competent core.
108.00	146.15	3J Sandstone	fine		grey	medium	fine-medium grained grey sandstone. Occasionally interbedded with argillite. Similar to unit above but is softer and contains more siltstone (~10-15). Quartz veins present are small (~1-5cm) and not as common as above. Weak limonite alteration is present within fractures. Possible sericite alteration causing a lighter color and weak silicious alteration of select beds is present. Pyrr is present along bedding, within micro fractures, and within quartz veins, commonly in argillite rich sections. Py is found on fracture faces and disseminated within sandier areas. Cpy is present in qtz veins often with Pyrr. Small folds in quartz veins and silicious beds seen.
146.15	348.00	3J Sandstone	medium		grey	medium	medium grained grey sandstone with minimal argillite interbedding until ~216, where it is seen in more than ~1m per box. Many qtz veins over interval rangin from ~1cm-25cm wide. Mostly weak limonite alt occuring on fractured faces and within fractures (not common), chlorite alt of wall rock within qtz veins, and silicious alt of select beds.Pyrr is commonly occuring in argillite rich sections, but Cpy and Py are also found within qtz veins and within wall rock fractures. Py found in more abundance where carb filling fractures are presnt. Many areas with fracture filled qts and or carb. Fault @~201-202.30 with a lot of fracturing and alteration above,below and within. 0.00	1.55	OB Overburden					OVERBURDEN
1.55	4.85	3E Argillite/Mudstone	fine		black	dark	Highly fractured section near top of hole. Fine grained black argillite with occasional cm size sections of fine grained medium sandstone (3-5%). Larger sandstone bed from 4.09-4.20 within interval.
4.85	11.50	3J Sandstone	fine		grey	medium	fine-medium grained grey sandstone. Occasional interbedded sections with argillite and siltstone. Carbonate beds ~2-5cm thick, some leached.
11.50	61.70	3E Argillite/Mudstone	fine		grey	medium	predominately fine grained grey-black argillite and siltstone with sections of finely interbedded fine-medium sandstone. Graphitic texture present. Alteration present as limonite along fractures and along the core face, leaching of carbonate beds within sandier material. Sections containing more fractured and rubbly material. Shearing present in larger elongated qtz grains @18.30-18.55.
61.70	203.80	3J Sandstone	medium		grey	medium	medium grained grey sandstone with occasional interbedded argillite. Some of the sandstone has a pale green color. A few qtz veins and weak limonite alteration. Mineralization is mostly disseminated is the more argillite rich sections. Pyrr is the most common, then Pyrite, and a few grains of Cpy. A section from 91.79-91.87 shows Asp grains again with blebby Py, much more Asp than other holes.
203.80	285.00	3E Argillite/Mudstone	fine		grey	dark	Interval of finely interbedded approx argillite(60%),siltstone(10%), and sandstone(30%). Occasional larger interbeds of argillite and sandstone. Many qtz veins from ~2-18cm wide, mostly unmineralized with carb filled fracturing. Many intervals with qtz filled fractures that were mineralized. Occasional carb rich sandstone beds throughout. Minimal limonite alteration mostly weak seen within qtz veins. Moderate chlorite alteration over the entire interval, causing pale green coloration of the different lithologies. Main sulphide observed is Pyrr occurring within microfractures, along bedding, and within qtz fractures. Pyrite is second most abundant, occurring along fracture faces and occasionally within micro fractures. Cpy was found often with Pyrr in qtz filled fractures and veins.
285.00	362.68	3J Sandstone	medium		grey	medium	fine-medium grained medium-dark grey sandstone occasionally interbedded with argillite. Dark argillite bands often are rich in sand also. aDistinct argillite @322.43-235 and 354.79-355.75 that contain much Pyrr. Quartz veins throughout ~2-12cm wide with minimal sulphides and weak chlorite alteration within. Quartz and carb filled fracturing is many places, more severe in certain areas. Lots of deformation (shear/fracturing) from ~224-229. lots of coarse qtz carb filled
