LIST OF PLATES

<i>Plate 1: Thick and thin bedded quartzite (QRZT) with phyllitic partings, showing typical blocky fracture, Spire Creek.</i>	14
<i>Plate 2: Phyllitic quartzite (QRZT phy) with pyritic layers producing jarosite staining, North Star Creek (458350E/7083200N).</i>	14
<i>Plate 3: Variable weathering in QRZT ca, thin calcareous beds with recessive weathering and slightly gossanous surface. Goethite and Manganese oxides occur on fractures (458000E/7083115N).</i>	15
<i>Plate 4: Chlorite to chlorite-sericite schist of the metavolcanic member (Dmv), Earn Group (455343E/7085066N).</i>	15
<i>Plate 5: Typical foliated diorite (DIOR, right), with feldspar evident in groundmass, intrudes quartzite section and is cut by an unfoliated intermediate, biotite porphyry dyke (left), Spire Creek area (457925E/7084540N).</i>	16
<i>Plate 6: Massive to thin bedded quartzite, deformation (foliation, isoclinal folding) is concentrated in thinner, phyllitic beds (457765E/7083960N). Foliation is largely axial planar cleavage, dipping shallowly southeast. Photo to right contained in box on left photo.</i>	17
<i>Plate 7: Main Zone, looking across zone to east. Outcrops in background are in the footwall to zone and central outcrop contains a mineralized pyrolusite-rich breccia striking roughly perpendicular to the main trend (200°). Chip sample from outcrop in lower left corner returned 223 g/t Ag over 3.6 metres.</i>	18
<i>Plate 8: Sample S193113, in float at the north end of North Star soil anomaly. Strongly fractured quartzite with manganese and iron oxides in fractures, weak sericite and silica alteration (459010E/7083965N).</i>	19
<i>Plate 9: Sample S193103, from altered phyllitic quartzite with abundant iron and manganese oxides in fractures. Sample taken from roadcut near the western margin of the Bighorn Soil Anomaly (454065E/7084252N). No historical work has been recorded in this area.</i>	22

1.0 SUMMARY

The Haldane property is a structurally-controlled, silver vein prospect located within the Keno Hill silver district in the central Yukon. The Keno Hill silver deposits produced over 200 million ounces of silver in a long history of mining from 1913 to 1989, with production recommencing in 2011. The Haldane property is located about 25 km west of the main Keno Hill deposits. Mineralization is controlled by northerly trending vein-faults, and consists of galena, sphalerite and tetrahedrite-tennantite in quartz-siderite gangue. The best mineralization occurs where the mineralized structures cut the Keno Hill quartzite unit, below the Robert Service Thrust. These features are almost identical to the setting for mineralization at the Keno Hill mining camp.

Between June 29th and July 23rd, 2018, a field program of soil sampling, geological mapping and rock sampling, and minor trenching was completed on the Haldane property. The main objective of the program was to identify areas of potential mineralization outside of the Mt. Haldane Vein System ("MHVS"), a well-mineralized structural corridor that crosses north-south through the centre of the property. A crew of 5 people, 2 mappers and 3 samplers were involved in the program, which was based from a small, road accessible tent camp central to the property. A total of 1210 soil and 53 rock samples were collected.

The 2018 program was successful in defining a new Pb-Ag-Zn-Sn soil anomaly, here named the Bighorn Anomaly, in an area with no known previous work located 2.8 km west of the MHVS. This anomaly lies within quartzite and trends north-northeast, similar to other mineralized vein-faults on the property.

In the south part of the property, detailed soil sampling extended the Ross Anomaly another 300 m north and so effectively doubled the strike length outlined in 2011. As well, anomalous samples indicate the possible presence of two other parallel structures in the area. The Ross Anomaly lies 1.8 km along strike south of the Middlecoff Zone of the MHVS. If continuous, this indicates a total strike of more than 3.5 km for the MHVS from the Main Zone to the Ross Anomaly.

Several other areas returned anomalous soil results from the 2018 program. Of these, the North Star Anomaly in the north part of the property, looks the most like a typical mineralized structure on the Haldane property. This moderate to highly anomalous Pb-Ag-Sn-Zn anomaly stretches about 1 km north-south on the north side of North Star Creek and is associated with manganese and iron oxides in highly fractured quartzite host rocks. The Strebchuk Showing lies south of North Star Creek, another 0.7 km south along strike from the North Star anomaly.

Geological mapping in 2018 primarily filled in details and refined the geological framework for the property. Rock samples collected during mapping did not return significant results outside of the MHVS. Two small excavator trenches were completed near the end of the program. The first of these comprised a 65 m long trench across the central part of the Ross Anomaly that failed to reach bedrock, although samples of soil spoil from the east half of the trench returned highly anomalous Pb, Zn, and Ag that further enhance the anomaly. Within the MHVS corridor, a second trench was done to clean out and extend a historic trench on the Main Fault, west of the Johnson Adit, that contained historical high-grade rock samples. This trench exposed a fault zone with schistose rocks that are anomalous in Pb and Ag. Unfortunately, the trench flooded before it could be sampled in its entirety.

Additional geological mapping, structural interpretation, soil sampling and trenching could be done to enhance the known showings and geochemical anomalies prior to diamond drilling on the Haldane property. However, diamond drilling should be done on the Ross Anomaly as trenching did not prove effective due to the deep overburden present in the area. There are several structures known to host mineralization within the MHVS but specific ore controls are still uncertain. Diamond drilling should focus on defining the plunge control on ore grade mineralization within the vein-faults. Additional field work (Mapping and sampling) plus a possible total of 1000 m trenching, primarily on soil anomalies, and 2000 m diamond drilling, has been outlined for the next exploration program. Depending on the scope, up to 6.5 kms of road upgrades and new trails will need to be completed in support of this program.

2.0 INTRODUCTION

This report has been prepared by Equity Exploration Consultants Ltd. (“Equity”) for Alianza Minerals Ltd. (“Alianza”), which has a purchase agreement to acquire 100% of the Haldane Claims from Equity and 100% of the contiguous “Ross Claims” from the estate of John Peter Ross. The report is based on a field exploration program that was completed in the period from June 29th to July 23rd, 2018 by Equity and on previous work from private company files, publicly available assessment reports and government publications. The author both supervised and participated in the 2018 field program.

3.0 RELIANCE ON OTHER EXPERTS

Other than data gleaned from previous reports on the property and government geological and geochemical survey reports, the author has not relied upon other experts for the information in this report.

4.0 PROPERTY DESCRIPTION AND LOCATION

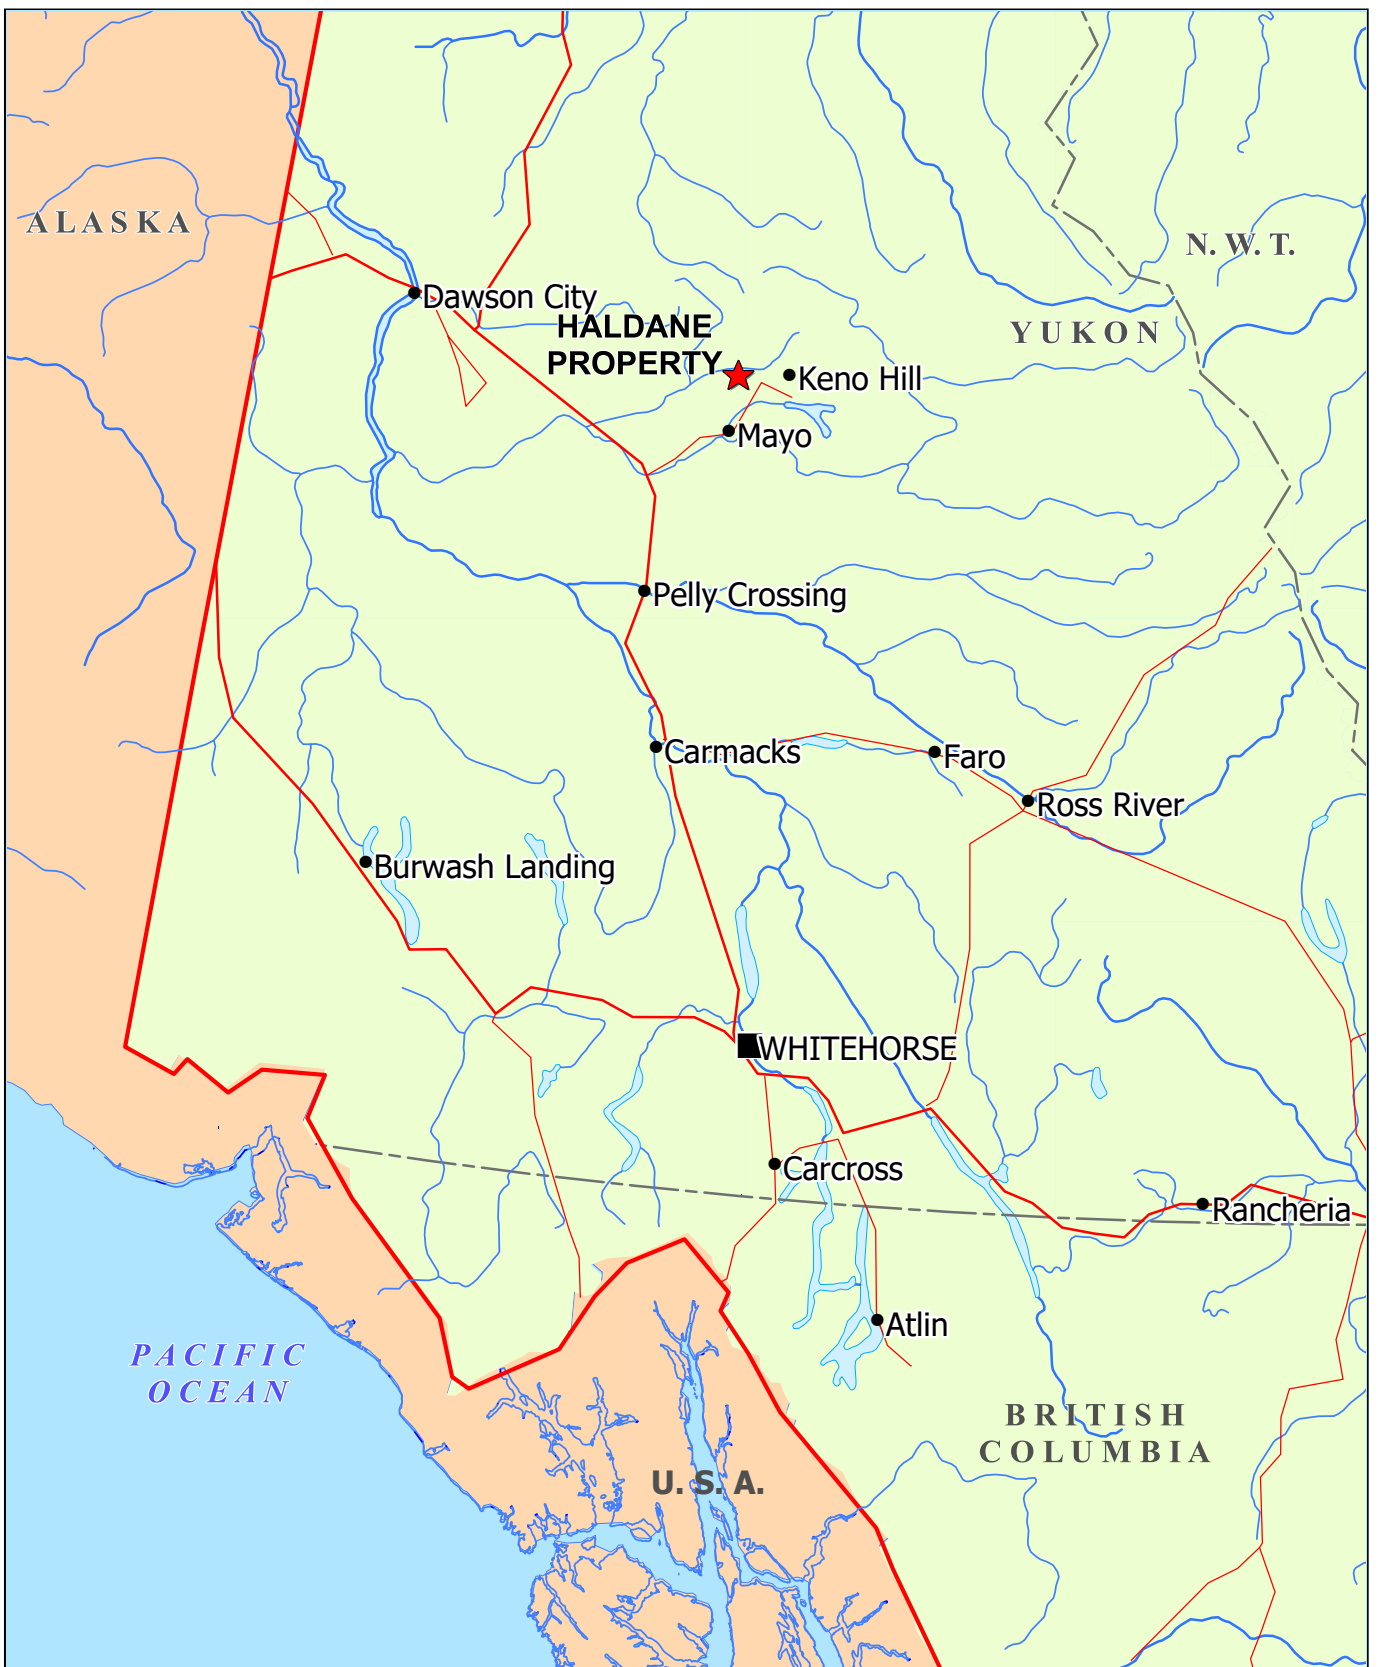

The Haldane property is approximately 30 km north of Mayo, Yukon and about 2 km west of Highway 11, which runs between Mayo and Keno City (Figure 1). The main Keno Hill mining camp lies approximately 20 km to the east. The Haldane property (Figure 2) consists of 432 contiguous quartz mineral claims for a total of 8,579 hectares (21,198 acres) in the Mayo Mining District of the Yukon (Table 1).

The Haldane and HAO claims are registered to Equity Exploration Consultants Ltd. of Vancouver, BC. The adjacent “Ross Claims” (Nur, Clarkston and Fara claims) are registered to Alianza Minerals Ltd. Alianza has a purchase agreement to acquire 100% of the Haldane claims from Equity and 100% of the Nur, Clarkston and Fara claims from the estate of J.P. Ross. The claims are centred at 63°52’N latitude and 135°52’W longitude on the National Topographic System 105M/13 map sheet.

5.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, PHYSIOGRAPHY

A rough four-wheel drive road leaves Highway 11 at Halfway Lakes and passes through the southern part of the Haldane property. An existing branch off this road and along Bighorn Creek was re-habilitated to the property in 2011, to provide access to underground workings and trenches along the MHVS. Accessing the property from the east can be accomplished along largely overgrown bulldozer trails. Ten kilometres northeast of Halfway Lakes along Highway 2 is a turn-off for the Dublin Gulch road that crosses the northern portion of the property. Charter helicopter service is generally available in Mayo throughout the summer field season. Elevations on the Haldane property range from 790 to 1838 m. Outcrop exposures are good on ridges but most slopes are extensively talus covered.

Climate is classified as sub-arctic with long cold winters and short, cool summers. Average temperature can range up to 20°C from June to August, with the greatest amount of precipitation falling during the same time period.

6.0 HISTORY

6.1 Previous Exploration

Prospectors entered the Keno Hill area as early as the 1890's and there is some evidence that they located silver mineralization on Mt. Haldane but the earliest documented work on the Haldane property dates to 1918 in a GSC report by Cockfield (1919) that describes two adits on the Middlecoff Zone on the south side of Bighorn Creek (Figure 3). The mineralized veins were traced over 600 m on surface and the underground development produced 24.7 tonnes of hand-sorted ore that graded 3102 g/t Ag and 59% Pb. At the same time, work was taking place on the Johnson Vein on the north side of Bighorn Creek, including a short adit. In 1926 and 1927 the Johnson Vein produced a total of 2.1 tonnes of hand-sorted ore at 4602 g/t Ag and 57.9% Pb. Both of these workings are on the MHVS, lying on the west slopes of Mt. Haldane.

Subsequently, very little work was recorded in the area until 1963, when the property was acquired by Silver Titan Mines, a company controlled by the well-known Dr. Aaro Aho. Silver Titan rehabilitated the old Middlecoff workings, drilled one surface drill hole for 61.6 m and discovered additional mineralization through minor soil sampling and extensive bulldozer trench work (private company reports). The property was optioned to Haldane Silver Mines in 1966 and they carried out 701 m overburden drilling in 43 holes, and 487 m underground drifting in the Lower Johnson adit, and 518 m of underground drilling around the Middlecoff Zone. Continuing in the MHVS, the Mayag Syndicate did a small soil grid in 1979, consisting of 232 samples, upslope south of the Middlecoff adits to try to trace mineralization on the vein system to the south (Way, 1979). Weakly elevated lead values indicated the trace of a structure to the ridge top. In 1989, a brief prospecting and mapping program was initiated but not completed or filed, including additional geological mapping and confirmation rock sampling on the MHVS (company files).

East of the MHVS, United Keno Hill Mines staked the H claims on the east half of Mt. Haldane - based on stream geochemistry released by the GSC in 1964 - and in 1966 conducted geological mapping, soil sampling and some chip sampling (Heard, 1966). The soil survey covered an area of 1700 by 2500 m to the north and east of North Star Creek, with 1552 soil samples on a 300' by 100' grid. The soil samples were analysed for Ag, Pb, Zn and Cu at a field lab in Calumet (Keno Hill). The survey defined a strong Pb-Zn soil anomaly over 300 by 50 m in the southwest corner of the grid, roughly coincident with a select sample of mineralized fault breccia from the Strebchuk Showing that assayed over 1600 g/t Ag and 70% Pb (Table 2). Additional spotty Pb-Zn geochemical anomalies (defined by 50 ppm Pb and 100 ppm Zn) are present in the north part of the grid, near the lower contact of the quartzite unit where they correspond well with the projection of known structures and mineralized zones. Chip sampling on a 200 m long quartz vein with scattered sulphide mineralization on the ridge east of Mt. Haldane's peak returned up to 6206 g/t Ag over 0.38 m (the "Peak Vein", Table 2). Silver Spring Mines Ltd. did a very minor amount of soil and silt sampling in the area in 1968 (Sadler-Brown, 1968).

In the late 1970's, exploration attention shifted slightly east with the discovery of Sn-W mineralization associated with Cretaceous-aged intrusions on the east slopes of Mt. Haldane. Work by the CCH Syndicate (Woodsend, 1978; 1979) and Billiton (Paul and Rota, 1982) in the late 1970's to early 1980's identified two showings, the Fed and Pro (Figure 3), with cassiterite mineralization. However, geochemical surveys and rock sampling showed that Fed and Pro also have potential for Ag, Pb, Zn and Au mineralization. Recognition of gold mineralization associated with Cretaceous intrusions in the McQuesten River area, such as at the nearby Wayne Property, led to more work in the late 1980's by M.J Moreau Enterprises Ltd. on the east side of Mt. Haldane (Hulstein, 1989). Highlights of this work include elevated Au-Ag values in talus fine soil samples (10-172 ppb Au, 1.0-19.6 ppm Ag) and similar numbers in rocks in the upper Fortune-Aldis Creeks area. But this sample coverage was very limited with only 21 rocks, 34 soils, and 1 silt taken in only 3 or 4 days work. In his report, Hulstein (1989) notes that local prospector Louis Beauvette (pre-1920?) reported the "best mineralization" in an upper branch of Aldis Creek - possibly referring to silver mineralization given the intense activity at Keno Hill at the time - but this was not followed up in detail.

Expatriate Resources Ltd. did a 6-day, 3-person exploration program around the Sundown Showing in 2000 (Becker, 2000). The Sundown is located on the southern portion of the MHVS (Figure 3). The showing is not well described but centres on a sericite-altered felsic dyke with disseminated arsenopyrite mineralization. A chip sample on a quartz vein at the margin of this dyke in host phyllite returned 402 g/t Ag, 0.115% Pb, and 0.14% Zn over 1.4 m. A small 50 by 100 m sample-spacing soil grid over a 500 by 800 m area around the Sundown showing indicated a north trending Pb-Zn-Sb-Ag anomaly that is open to the north. Additional soil sampling at 150 m spacing along claim lines (about 900 m apart) picked up numerous spot anomalies (likely due to the wide spacing used) including a Au-As anomaly located along a north-south structure west of the Middlecoff Zone on the Ross claims. This structure projects to the soil anomaly outlined around the Sundown Showing. No prospecting was done outside of the Sundown Showing.

Prior to a small program by J.P. Ross in 2003, silts on the Nur claims were found to have anomalous As (up to 1000 ppm), Sn (up to 20 ppm) and W (up to 100 ppm) with no gold analyses. In 2003, J.P. Ross took 93 soils along claim lines with about 900 m spacing. Eleven float samples were also collected during this program. Soil assays were encouraging with highs of 63 ppb Au, 9785 ppm As, and 11.1 ppm Sb, whereas the highest assays for the float samples were 7 ppb Au, and 5281 ppm As. Numerous Au-As or Au trends, up to 1800 m long and open in both directions, were noted (Ross, 2004). In 2004, Klondike Gold Corp. entered into an option agreement with J.P. Ross on the Fara and Clarkston claims and he was also hired to work the claims. He collected 194 soil samples and 47 rock samples on the claims. Soil lines were spaced about 225 m apart with samples taken at 45 m intervals. The work outlined two anomalous Au soil samples to the north of the claims, though Ag-Pb-Zn values are generally low (Stirling, 2005).

In 2008, Equity performed field work on the Haldane claims that confirmed the presence of high-grade Ag mineralization on the main MHVS (Jones, 2008). Grades up to 5030 g/t Ag and 55.5% Pb were found in select hand specimens from the Middlecoff adit dumps, and generally samples have a silver (in grams/tonne) to lead (in percent) ratio of 50 to 100. A grab sample of strongly oxidized float below the Johnson Adit returned 16.9 g/t Au, 955 g/t Ag and 42.1% Pb and the samples from the Johnson Adit area have a silver to lead ratio

of 20 to 180. The work indicated that additional unrecognized and mineralized structures may be present, both within and on the east side of the MHVS.

Following the option of the Haldane, Clarkston, Fara and NUR claims by Habanero in the winter of 2010, Habanero conducted a 2010 work program undertaken by Equity consisting of 406.89 m diamond drilling in three holes, plus minor geological mapping and rock sampling (Branson, 2010). Two of the three holes were drilled to completion, one in the Johnson Adit area and the other in the Middlecoff Lower Adit area. The third hole was abandoned. Mineralization was encountered down dip from the adits in both holes with the best result being 101 g/t Ag over 2.0 metres in HLD10-02 at the Middlecoff Zone (Table 3).

In 2011, Habanero completed a 2-phase field work program. The first phase consisted of geological mapping, prospecting (40 rock samples) line cutting and soil sampling (282 samples) on the MHVS and the access road was rehabilitated. This work defined significant Pb-Zn-Ag-Sb-Sn soil anomalies coinciding with known mineralized structures but also detected mineralization east and west of the main MHVS corridor and a few kilometres to the south adjacent to the access road in Black Creek valley. In the second phase, 9 drill holes for a total of 1404.5 metres were completed with six holes in the Main Zone, one hole in the Johnson Adit area, and two holes in the Middlecoff area. Drill core recovery was very good where the ground was not broken but quite bad in fault zones, which tended to be associated with the mineralized structures. A total of 419 core samples (including blanks, standards and duplicates) and one rock sample were collected during the course of the second phase of the program. Despite poor recovery in the mineralized zones a significant mineralized intersection was encountered in hole HLD11-09 at depth on the West Fault, a previously unexplored target on the west side of the MHVS corridor.

A small drill program was completed in 2013 between August 26 and September 2, 2013. Two HQ diamond drill holes were cored from two sites for a total of 125.35 metres. A mud program was put in place during the drilling to try to improve the poor core recovery within the MHVS corridor with minimal success. The holes intersected narrow mineralized zones but the targets were disrupted by faulting in HLD13-12 and a diorite dyke at target depth in HLD13-13. Results from this drilling are summarized in Table 3.

Table 3: Significant Drill Results from the Mt. Haldane Vein System (2010-2013)

6.2 2018 Work Program

A geological mapping, rock, silt, and soil sampling, and minor excavator trenching program was conducted in the summer of 2018. Field work was done between June 29 and July 23, 2018 by a 4-5 person crew, including 2 geologists and up to 3 samplers. The crew stayed in a tent camp on the property close to the Main Zone. The program was designed to investigate under-explored areas of the property outside of the MHVS, particularly north of Bighorn Creek and in the North Star Creek drainage basin. Additional work was focused on areas underlain by the Keno Hill quartzite. A total of 115 person/days were spent in camp. In the course of the program 52 rock samples and 1210 soil samples were collected, including blanks and duplicates (~1 of each, every 40 soil samples).

Soil lines were established using Garmin hand-held GPS instruments to maintain line azimuth and to locate stations (+/-3 m accuracy). The lines were oriented northwest-southeast to test for both east-west and north-northeast-south-southwest trending, potentially mineralized structures. Sampling on reconnaissance style lines was done at 50 m spacing and the lines were spaced 200 or 400 m apart. Detailed lines, with sampling at 25 m spacing, were done in the vicinity of the Ross Anomaly (with 100 m line spacing), to the west-northwest of the Middlecoff Zone, and downslope from the Strebchuk Showing. Two ridge-spur traverses, with samples at 50 m spacing, were completed between the headwaters of Bighorn Creek and Aldis Creek. Samples were taken using a narrow-nosed shovel from B-horizon soil wherever possible but by necessity, talus fines and colluvium make up a large proportion of the sampled material. All sample sites were indicated with orange flagging and a Tyvek tag marked with the sample tag number affixed to a tree branch or established brush where available. At all soil sample sites, the UTM coordinates were collected and notes describing the sample site and sample material were recorded. Back in camp, the samples were hung to dry before being organized for shipping. One duplicate and one blank sample were included in every 40 samples. Silica sand with an established composition was used for blank material.

Geological data and observations, including lithological and structural data, were collected by geologists in the field on GPS-equipped, Toughbook computers using MapInfo software. Rock samples were collected during geological mapping on the property. Data pertaining to the nature of the rock sample and its geological context were also collected on digital forms on the computer. All rock samples were bagged and given a sample number from a series of sample tags. A representative hand specimen was also collected for each sample for future reference. The sample sites were marked in the field using blue and pink flagging plus an aluminum tag inscribed with the sample number, sampler's initials, date, and type of sample. Given the reconnaissance nature of the work, no blanks or duplicates were included in the rock samples.

All samples were packaged and sealed in rice sacks for shipment to the lab. The sacks were closed using a security strap with a unique identifier and recorded on a form that was sent to the lab for verification.

The sealed sample sacks were delivered to ALS Minerals' sample preparation in Whitehorse, Yukon via Haldane Services and Small's Expediting. Rock samples were analysed for gold, by fire assay-atomic absorption (FA-AA) on a 30 g aliquot, and for 35 elements by induced coupled plasma-atomic emission spectroscopy (ICP-AES) using an aqua regia digestion. Over-limit results were re-assayed for Ag, Cu, Pb and Zn by a modified ICP-AES procedure for higher grade materials (OG46). Soil samples were analysed for 51 elements including gold by (AuME-TL43) whereby a 25g aliquot was digested using aqua regia. The larger aliquot allows for quantitative results for gold using an ICP-MS analytical technique.

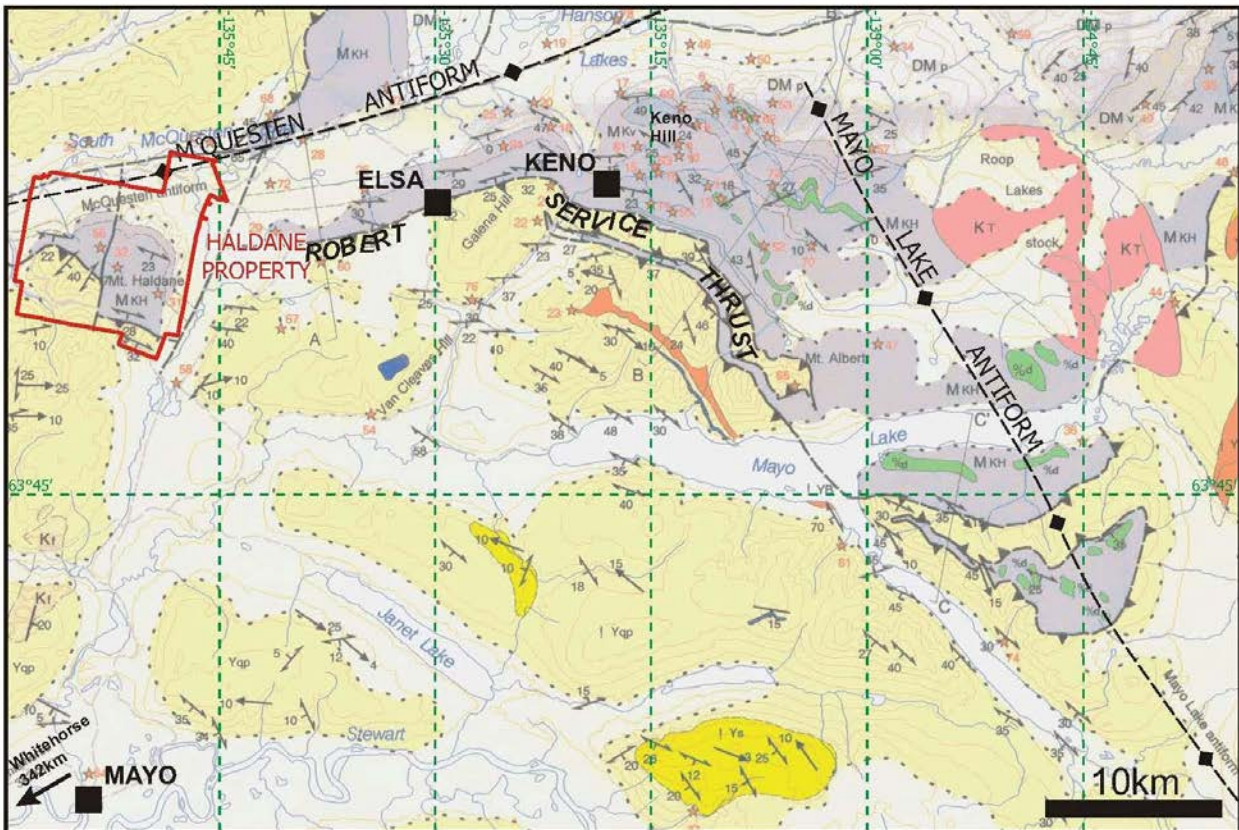

A magnetic declination of 20° E was used for all compass measurements. Structural measurements are all reported utilizing the right-hand rule. All maps and UTM coordinates are referenced to the 1983 North American Datum (NAD83; Zone 8).

Rock sample descriptions are found in Appendix C and analytical certificates in Appendix E. Data recorded digitally is also included in Excel files (Appendix F).

7.0 REGIONAL GEOLOGY AND MINERALIZATION

7.1 Geology

The Keno Hill area (Figure 4) is primarily underlain by a >1 kilometre thick quartzite unit, the early Carboniferous Keno Hill quartzite (MKH). This unit overlies the metavolcanic member (MKV) of the mid to late Devonian Earn Group consisting of quartz- and feldspar-phyric chloritic phyllite with minor limestone horizons (Roots, 1997). Greenstone sills intrude the section and are concentrated in the lower part of the quartzite unit. The sills are Triassic-aged, foliation-concordant, and dioritic to gabbroic in composition. Carbonaceous phyllite and siltstone with rare greywacke, conglomerate and felsic volcanic units (DMv, DMp) of the Earn Group underlie the metavolcanics member and represent the structurally lowest stratigraphy exposed in the area. The top of the Keno Hill quartzite is in thrust contact with overlying micaceous and siliceous phyllite and schist of the upper Proterozoic Hyland Group. This thrust is known regionally as the Robert Service Thrust and the surface trace meanders from Mt. Haldane in the west through the Keno Hill area and off to the east near Mayo Lake. Lake.

---	---

Figure 4: Regional geology around the Haldane Property. The Keno Hill mining district stretches from west of Elsa to east of Keno Hill. The Haldane property is outlined in red.

Cretaceous granite, monzonite and granodiorite stocks intrude the section, such as the Roop Lakes stock east of Keno Hill. These intrusions range from dyke-sized to batholithic.

The overall structure of the area is dominated by two open antiforms: the broad, northwest-trending Mayo Lake Antiform with Keno Hill lying on its west limb, and the smaller, west-trending McQuesten Antiform which is superimposed on the west limb of the Mayo Antiform (Roots, 1997). The McQuesten Antiform extends west from Keno Hill to Mt. Haldane and both areas are situated on its southern limb, where bedding dips 30° south on average. The folds affect the stratigraphy above and below the Robert Service Thrust.

The Mt. Haldane area lies within the Tombstone Strain Zone, a shallow southerly-dipping shear zone with a penetrative structural fabric related to the underlying Tombstone Thrust (Roots, 1997). The penetrative fabric has overprinted previous structural features and bedding is commonly obscured. Deformation related to the Tombstone Thrust has affected the rocks above the overlying Robert Service Thrust, as well. The Tombstone Thrust sheet and the underlying, less strained rocks have been folded by open folds and cut by north-east trending faults. Some of the late, brittle faults host mineralized veins in the Keno Hill camp. The veins may be related to a northeast trending, brittle shear zone (Lynch, 1989), and subparallel faults are present under Haldane Creek and cut the Robert Service Thrust at Bighorn Creek.

The upper slopes of Mt. Haldane were not affected by the most recent glaciation event (~10,000 years ago), other than by local alpine glaciers. The area was last inundated by glaciers in the Reid glaciations that occurred more than 200,000 years ago (Lebarge, 1996). As a result, weathering and oxidation in bedrock on Mt. Haldane has penetrated to substantial depths. This is particularly true of areas underlain by the Keno Hill quartzite that is susceptible to blocky fracturing and forms abundant talus on steeper slopes.

7.2 Mineral Deposits

The Keno Hill Silver Mining Camp produced over 200 million ounces of silver through a mining history that began in 1913 and ended in 1989; production by Alexco Resources' Bellekeno Mine began in 2011 and has continued sporadically to 2018. Production statistics show 4.87 million tonnes were mined to 1989 with an average grade of 1389 g/t Ag, 5.62% Pb, and 3.14% Zn (Yukon Minfile, 2003). Alexco Resource Corp. is developing and exploring a very large land package in the Keno Hill mining camp that includes their Bellekeno mine. Current indicated resources can be found on Alexco's website (www.alexcoresource.com/).

All the ore in the Keno Hill mining camp comes from the south limb of the McQuesten Antiform, where northeast-striking, steeply southeast-dipping, normal "transverse" faults cut the Keno Hill quartzite. These faults show complex histories, including multiple episodes of mineralization, and have sinistral displacement ranging from a few metres to more than a kilometre. Related, east to east-northeast trending "longitudinal" faults, likely representing linking structures between the transverse faults, also host vein mineralization. The veins may be offset by unmineralized NW-striking cross faults, which commonly have moderate southwest dip and generally right-hand displacement of 10's of metres to a kilometre or more.

Keno Hill mineralization is simple open space filling, with no obvious chemical controls and minimal wall rock alteration. Grade and tonnage records indicate Pb/Zn ratio and Ag content decrease with depth (Roots, 1997), based on early mining of near surface ore shoots. Work by Alexco has shown that additional shoots are commonly present at depth (Ghaffari et al, 2009). Ore controls are structural, with veins filling available open space related to host rock competency, vein intersections, and proximity to cross faulting. The main ore mineralogy consists of galena, sphalerite, tetrahedrite and pyrargyrite, with gangue of manganiferous siderite, pyrite, arsenopyrite and quartz.

Lynch (1986) hypothesizes a district scale lateral zonation pattern in ore and gangue minerals based on proximity to an intrusive source (Roop Lakes Stock) for the Keno Hill Mining District and age dates on the mineralization and the intrusions (~90 Ma.) are similar (Roots, 1997). The intrusion-centred mineral zonation is similar to the plutonic-related gold deposit model (Thompson et al, 1999) that is described in the area. Deposits such as Eagle (Dublin Gulch) would represent the proximal, Au-rich end member of Lynch's model. Eagle is a sheeted-vein gold-tungsten deposit that is directly related to the local intrusion. The deposit has a N.I. 43-101-compliant resource of 222 Mt at 0.70 g/t Au in the Indicated category and 78 Mt at 0.63 g/t Au in the Inferred category with a 0.35 g/t Au cut-off grade (Mosher and Triebel, 2011). The association of Sn-W

mineralization in the plutonic gold model is also consistent with Lynch's mineral zoning model. In the Keno Hill area, tin-tungsten veins and skarn are located in the contact zones of Cretaceous intrusions, particularly in the intrusion carapace (Emond, 1986). Significant tin is present in sphalerite in the Keno Hill deposits (Watson, 1986) and Lynch (1986) suggests the potential for tin-tungsten mineralization at depth below Keno Hill.

8.0 PROPERTY GEOLOGY AND MINERALIZATION

8.1 Geology

Figure 5 depicts the geology of the Haldane property. Mapping in 2018 covered much of the property save the lower eastern, northern and western slopes overlooking Haldane Creek and the South McQuesten River. Bedrock exposure on Mt. Haldane is generally poor with large areas inundated by talus cover and or thick bush. Generally, the ridges and very steep slopes have some bedrock exposure.

The geology of the Haldane property is dominated by an up to 2000 m thickness of Keno Hill quartzite, possibly structurally thickened, forming a wide band across most of Mt. Haldane (as per Hunt et al, 1996). This unit is characterized by thin to medium-bedded quartzite (**QRTZ**) with minor sericitic to biotitic phyllitic to schistose partings (Plate 1). The rock is grey to bluish-grey to, rarely, greenish in colour and strongly fractured resulting in blocky talus that inundates the surface. Within the quartzite section there are several phyllite (**QRZT phy** or **PHYL**), or dominantly phyllite, sections that are grey to tan and locally pyritic (Plate 2), siliceous and/or carbonaceous. A phyllite-dominant section outcrops in North Star Creek northwest of the Strebchuk Showing. There is also a calcareous quartzite component (**QRZT ca**), characterized by recessive weathering and weak gossan on the more calcareous layers (Plate 3). Strong goethite and manganese oxides occur locally on fracture surfaces, primarily in close association with mineralized zones. Abundant quartz veins are common, typically <10 cm in width, and locally covered by weak to moderate manganese oxides. Veining is mostly foliation-parallel, but does cut foliation locally, particularly associated with faulting.

Table 4: Lithologic/Stratigraphic Legend for the Haldane Property

STRATIGRAPHIC UNIT	Description
Cretaceous	
GRNT	biotite granite
FELS	feldspar porphyritic, fine grained felsic dyke, locally quartz phyrlic
Triassic	
DIOR	medium green to blackish, foliated diorite, feldspar phyrlic
GBBR	gabbro, weak foliation, dark, locally pyroxenite
Early Carboniferous, Earn Group	
QRTZ	Keno Hill quartzite, grey weathering, thin to thick bedded quartzite (QRTZ), grey to black phyllitic (QRZT phy), brown to buff weathering calcareous (QRZT ca), with graphitic partings or interbeds
PHYL	phyllite, tan to grey, locally carbonaceous
Devonian, Earn Group	
SCHS CL, MS PHYL	chlorite to chlorite-sericite schist, grey to green, sericitic phyllite, strongly foliated, highly deformed
Upper Proterozoic, Hyland Group	
SCHS, PHYL	micaceous phyllite to schist, phyllitic quartzite, thin bedded

Attempts to define a consistent stratigraphic sequence within the Keno Hill quartzite section on the property have not succeeded to date. There is commonly phyllitic quartzite close to the lower and upper contacts and calcareous quartzite occurs near the middle of the section. But the specific lithologies appear to be highly variably distributed.

The Keno Hill quartzite is underlain by sericitic phyllite (**PHYL**) and chlorite+/-sericite schist (**SCHS (CL-MS)**) of the metavolcanic member (Plate 4) that is, in turn, underlain by carbonaceous sediments of the Earn Group (not mapped). Hyland Group, sericitic, chloritic, and graphitic phyllite and schist, hosting interbeds of quartzite and grit, lie above the Robert Service Thrust in the south half of the property (Figure 5).

Plate 1: Thick and thin bedded quartzite (QRZT) with phyllitic partings, showing typical blocky fracture, Spire Creek.

Plate 2: Phyllitic quartzite (QRZT phy) with pyritic layers producing jarosite staining, North Star Creek (458350E /7083200N).

Plate 3: Variable weathering in QRZT ca, thin calcareous beds with recessive weathering and slightly gossanous surface. Goethite and Manganese oxides occur on fractures (458000E/7083115N).

Plate 4: Chlorite to chlorite-sericite schist of the metavolcanic member (Dmv), Earn Group (455343E/7085066N).

Diorite (**DIOR**) and gabbro (**GBBR**) sills intrude the Keno Hill quartzite on the Haldane property, as they do in the Keno Hill camp. Dark to medium green, chloritic and well-foliated to schistose diorite sills are concentrated in the lower part of the Keno Hill quartzite section on the north and west side of Mt. Haldane. The diorite commonly has relict feldspar phenocrysts (Plate 5). The sills are quite variable in thickness and are locally sericite and carbonate altered. They are generally recessive and were observed primarily in talus and subcrop and as such are probably more restricted than indicated on the geology map.

Felsic dykes (**FELS**), commonly feldspar porphyritic and with local quartz phenocrysts, cut through the section and are normally seen in float. These dykes are fine-grained and tan to grey in colour. An 800 by 200 m granite pluton (**GRNT**) that is elongated east-west has been mapped in the upper part of the Fortune Creek drainage (Paul and Rota, 1981). This stock has a proliferation of small dykes that emanate from it, cutting the sedimentary units and diorite sills on the east side of Mt. Haldane. Other similar smaller intrusions are scattered

to the south and southwest. The Sundown Showing is centred on an altered quartz porphyry dyke with disseminated arsenopyrite mineralization (Woodsend, 1979). Rare occurrences of a massive biotite-phyrlic intermediate dyke have also been seen (Plate 5).

Plate 5: Typical foliated diorite (DIOR, right), with feldspar evident in groundmass, intrudes quartzite section and is cut by an unfoliated intermediate, biotite porphyry dyke (left), Spire Creek area (457925E/7084540N).

The bedding on the Haldane property generally strikes east-west, varying from 060° to 120° . The units dip shallowly to moderately (20° to 40°) south although in the north part of the property, east of Spire Creek, bedding is almost horizontal ($<15^{\circ}$). Foliation in the diorite tends to parallel the dominant layering orientation (S_1) in the enclosing quartzite (Jones, 2008). Bedding trends in the schist and phyllite above the Robert Service Thrust are generally northeast-southwest with moderate dips to both the northwest and southeast. Cleavages vary considerably more with dips to the north and west. The variable nature of the foliation orientation is reflective of variable strain history associated with the Tombstone Thrust (Roots, 1997). Isoclinal folding is common, particularly in phyllitic interbeds in massive quartzite (Plate 6). Fold hinges generally indicate north to northwest directed, relatively flat-lying, thrusting. A later phase of northeast-directed deformation produced shear planes that broke up foliation and attenuated compositional layers (Roots, 1997). Flat-lying structures, commonly filled by younger quartz veins like the Peak Vein in the east part of the Haldane property, may be related to this phase of deformation (Jones, 2008).

Faulting is prominent on the Haldane property. There are large scale off-sets apparent on the regional geology map by Hunt et al (1996). The kilometre scale, apparent dextral offset of the Robert Service Thrust, south of the Middlecoff Zone, is related to primarily normal off-set (west side down) on a relatively young fault known as the Ewing Fault, oriented at $175^{\circ}/55-60^{\circ}W$ (Aho, 1964). The Ewing Fault appears to form the west boundary to the MHVS south and north of Bighorn Creek. Subparallel faults occur on the east side of Mt. Haldane, most evident where they off-set diorite sills.

The mineralized vein-faults in the MHVS strike south to southwest ($160-200^{\circ}$) and are more steeply dipping ($65-90^{\circ}$) than the Ewing Fault, and are associated with strongly Mn-oxide stained, carbonate-rich breccia zones that are significantly mineralized (Jones and Branson, 2012; Jones, 2008). The MHVS comprises several of these subparallel faults that are very similar to the mineralized transverse vein-faults in the Keno Hill camp (Murphy, 1997). There, northeast trending transverse faults are associated with east-northeast striking "longitudinal" faults. Such longitudinal faults have not yet been mapped in the Mt. Haldane area, although there are lineaments in this orientation (Figure 5). However, small-scale, east-west faults are seen that may be

related to the east-west lineaments. Within the MHVS, these faults appear to cut off or off-set mineralization along strike at the north end the Main Zone and this is reflected in the distribution of anomalous soil geochemistry associated with the MHVS (Figures 6b-e).

Plate 6: Massive to thin bedded quartzite, deformation (foliation, isoclinal folding) is concentrated in thinner, phyllitic beds (457765E/7083960N). Foliation is largely axial planar cleavage, dipping shallowly southeast. Photo to right contained in box on left photo.

The Bighorn Fault is an interpretive feature that follows the Bighorn Creek valley and appears to be a quite late in the structural history. The fault is interpreted primarily based on a lack of obvious correlation between mineralized zones within the MHVS from the north side to the south side of the creek. The fault is similar to northwest trending, dextral, cross faults that off-set vein-faults and diorite sills in the Keno Hill camp.

8.2 Mineralization

The Haldane property hosts several zones of mineralization, the most significant being the Mt. Haldane Vein System (“MHVS”). The MHVS consists of a roughly north-south trending, steeply west dipping, vein-fault corridor on the west side of Mt. Haldane. The corridor extends at least 200 m south of Bighorn Creek (Middlecoff Zone) and 1200 m north of Bighorn Creek, where it contains at least 5 subparallel vein-faults over a width of 1000 m (McClintock, 1988), including the Johnson, South Johnson, West Fault, and Main zones. Surface mineralization within the MHVS is hosted by breccias, consisting primarily of manganese and iron oxides after galena-minor sphalerite mineralization with manganiferous siderite and quartz gangue. Thick boulder rubble covers the north side of Bighorn Creek making exploration of the recessive veins difficult.

The most developed showing is the Middlecoff Zone, located south of Bighorn Creek, with three adit levels and one sub-level in the lower adit. Mineralization at the Middlecoff Zone is similar to the rest of the MHVS except that there are commonly more remnant sulphides, primarily galena, along with iron and manganese oxides in vein and breccia zones. Samples with significant galena can assay up to 5000 g/t Ag (Jones, 2008). Similar results are found in rock samples from the Johnson Adit waste dump to the north across Bighorn Creek.

The Main Zone is the most northerly showing on the MHVS (Plate 7). Here, there is a 20 by 5-8 m phyllitic quartzite breccia with strongly oxidized matrix outcropping on the main structural zone where a 3.6 m

chip sample taken across this outcrop in 2011 returned 223 g/t Ag, 1.17% Zn, 0.62% Pb and 0.12 g/t Au (Jones and Branson, 2012). The breccia consists of manganese oxides and goethite and, possibly, iron carbonate. No sulphides were observed. The quartzite and diorite breccia clasts are locally weakly silicified and sericitized. Manganese oxide commonly fills open spaces in the breccia forming colloform and botryoidal textures and is strongly metalliferous. A select grab sample in 2011 returned 623 g/t Ag in breccia at the footwall contact. In 2018, a 1 m wide, select chip sample (S193101) of manganese-oxide breccia within the zone returned 349 g/t Ag, 2.73% Zn, 0.53% Pb and 0.166 g/t Au.

The Main South showing is located 150 m south of the Main Zone. Here, a slickensided fault scarp is exposed in a bluff with adjacent breccia and vein mineralization occurring primarily in the hanging wall. Several grab and select samples returned up to 279 g/t Ag, 1.4% Zn, and 0.16 g/t Au in strongly oxidized brecciated quartzite. To date, drilling in the Main Zone area has been largely frustrated by the difficulty in obtaining a competent core section through the fault zones that host the mineralization, exacerbated by the very deep weathering profile on the upper slopes of Mt Haldane where the Main Zone is located.

Plate 7: Main Zone, looking across zone to east. Outcrops in background are in the footwall to zone and central outcrop contains a mineralized pyrolusite-rich breccia striking roughly perpendicular to the main trend (200°). Chip sample from outcrop in lower left corner returned 223 g/t Ag over 3.6 metres.

The West Fault lies 110-125m west of the Main Zone and is another mineralized fault within the MHVS. This fault zone is unexposed but coincides with anomalous soil geochemistry and has been intersected by drilling over 300 metres strike. An intersection of 320 g/t Ag, 1.12 g/t Au, 0.67% Pb and 0.86% Zn over 2.20 m was returned from hole HLD11-09 in completely oxidized mineralization at 200 metres depth (Jones and Branson, 2012).

In 2018, a historic trench adjacent to the access road southwest of the Johnson Showing was re-opened and extended (HLT18-02) to look for the source of strong silver and lead soil results from 2011 (Jones and Branson, 2011). The east end of the trench exposed a wide section of schistose to phyllitic quartzite with abundant manganese and iron oxides. Minor float recovered from the trench contained disseminated galena. Unfortunately, water filled the more prospective west end of the trench before it could be mapped or sampled.

Rock samples from the trench only returned up to 18.6 g/t Ag and 0.17% Pb but soil samples were very highly anomalous over 35 m (up to 59.1 g/t Ag) indicating a potentially wide zone of mineralization (Figure 8).

The 2018 mapping program also located the Strebchuk Showing on the north slope of the peak of Mt Haldane. A silver assay of 1611 g/t Ag (47 opt Ag) along with 70% Pb from a select sample (pure galena?) was reported by United Keno Hill Mines from the showing (Heard, 1966). The mineralized zone was observed over a few metres on the edge of an outcrop of gossanous quartzite and phyllitic quartzite. The exposed portion of the zone was quite narrow (<1 m) and consisted of strong fracturing with abundant undeformed quartz veins and some brecciation. There is about 2-3% galena as scattered blebs and pods up to a centimetre in diameter and some stringer veinlets. A sample from this zone returned 0.43% Pb, 0.20% Zn and 8.3 g/t Ag. A sample that returned 110 g/t Ag (3.2 opt Ag) in 1965 (no dimension given) is probably from this zone. The zone appears to be oriented at $340^{\circ}/90^{\circ}$, although only one irregular side of the zone was visible. The zone was not traceable to the next outcrop along strike to the south (~30 m up slope) whereas downslope there is abundant mineralized float. A soil line 80 m downslope from the Strebchuk Showing detected a 30 m wide, moderately to very highly anomalous Ag-Pb-Sn-Zn-Mn anomaly and second similar anomaly (with anomalous gold as well) 100 metres east, suggesting additional mineralized zones may occur in the area.

Plate 8: Sample S193113, in float at the north end of North Star soil anomaly. Strongly fractured quartzite with manganese and iron oxides in fractures, weak sericite and silica alteration (459010E/7083965N).

On the north side of North Star Creek, numerous occurrences were found of manganese and iron oxides in veins and on fracture surfaces. A zone of strong fracturing and oxide mineralization was located in float amongst outcrops of massive to phyllitic quartzite on the north slope, coincident with the “North Star” Pb-Ag-Zn soil anomaly. Samples of fractured quartzite from this zone returned up to 8270 ppm Mn but generally low Ag, Pb and Zn (Plate 8).

Other mineralized occurrences on the property such as the Peak Vein and mineralization in the Fortune Creek basin were not mapped in 2018 but are discussed in Jones (2008).

9.0 SOIL GEOCHEMISTRY

A total of 1210 soil samples (including QA/QC samples) were collected as part of the 2018 program as described in Section 6.2. Sample locations are shown in Figures 6a-f (in pocket). The soil sampling program was conducted predominantly in areas that had no previous or recent sampling, testing possible mineralized faults and lineaments outside of the relatively well-known Mt Haldane Vein System. As well, the field work was designed to test the extent of some known geochemical anomalies, such as the Ross Anomaly in the south part of the property. A review of the QA/QC results is included in Appendix E.

The 2018 and 2011 soil results were combined for comparative purposes and statistical analysis as both sample sets were analysed for elements of interest (Ag, Pb, Zn, Sn, Mn, etc.) by the same technique (ICP-MS) for all elements except gold, albeit on a larger sample aliquot for the 2018 samples (25 g vs 5 g). Analytical percentiles and correlations for all soil samples collected from the Haldane property during the 2011 and 2018 soil sampling program are shown in Tables 5 and 6. Certificates of Analysis are included in Appendix C, and Excel files with the field notes can be found in Appendix F.

Table 5: Percentiles for Haldane Soil Geochemistry (2011-2018)

In the following discussion of soil geochemical results, soil samples exceeding the 70th percentile level are considered weakly anomalous, those exceeding the 85th percentile level are considered moderately anomalous, those exceeding the 95th percentile level are considered highly anomalous and those exceeding the 98th percentile are considered very highly anomalous (Table 5).

A correlation matrix measuring the co-variance of elements in soils is shown in Table 6. Within the elements of most interest, there is a very strong correlation between Ag, Pb, and Sn with moderate to strong correlations between these elements and Zn, Cd and Mn. The Mn correlation likely reflects the prevalence of manganese oxide hosted within vein material and the Keno Hill quartzite. Antimony (Sb) shows minor association with Ag and Pb and has been noted as being concentrated in the immediate vicinity of Pb-Zn-Ag veins and associated minerals contained in the veins at Keno Hill (Gleeson and Boyle, 1980; Lynch, 1989). Elevated Sn values (from stannite(?), sphalerite or a related Sn sulphosalt?) have also been found in sphalerite in Pb-Zn-Ag veins of the Keno Hill District and may explain the strong correlation between Ag-Pb-Sn on Haldane (Gleeson and Boyle, 1980). Although, at Haldane, there is not a strong correlation between Zn and Sn, which would be expected if sphalerite were the host for Sn. Cassiterite, which is present in area at the Pro and Fed Showings, is not digested in the analytical method utilized. There is a strong chalcophile element association between Cu, Ni, Bi, as well as, Sb.

Reconnaissance soil sampling has constrained the areas of mineralization fairly well. Highly anomalous soil results are primarily focused around the structures of the MHVS as might be expected. However, sampling identified two new, large Ag-Pb-Sn±Zn±Mn anomalies outside of the MHVS and extended the Ross Anomaly that is situated along strike to the south of the MHVS. Additional areas of weakly to moderately anomalous Pb-Ag results were located that may merit follow-up, albeit on a lower priority basis. A large, diffuse, As-Sb-Zn-Au anomaly, the Firetower Anomaly, was outlined in the northeast part of the property and is most probably related to intrusion-related Au-Sn-W mineralization previously noted in that area (Woodsend, 1979).

The Bighorn Anomaly is a new exploration target based on very highly anomalous 2018 Pb-Ag-Sn soil geochemical results and is located about 2.8 kilometers west of the Mt Haldane Vein System, on the south side of Bighorn Creek. The anomaly lies within the Keno Hill quartzite unit and stretches approximately 750 m north-south by 150-250 m east-west in an area previously unknown for mineralization. The anomaly crosses the main road on the property where quartzite and phyllite occur in outcrop and sub-crop. The anomaly contains up to 1240 ppm Pb in soil, the highest result outside of the immediate Mt Haldane Vein System area, and the lead values are supported by greater than 98th percentile silver and tin results. The north-south trend of the anomaly is consistent with most of the mineralized structures on the Haldane property. Very little mapping or prospecting has been done in the area to date, including 2018. One rock sample was taken on the western margin of the anomaly, where it crosses the road and it returned 582 ppm Pb but only 0.7 ppm Ag (S193103, Plate 9). The sample comes from a small weakly gossanous zone exposed in road cut, with outcrop comprising moderate sericite- and weak silica-altered phyllitic quartzite with fractured filled with goethite and Mn-oxides. It is located about 250 m from the most anomalous soil samples.

The Ross Anomaly is an area of moderately to very highly anomalous Pb-Zn-Ag in soils located just upslope from the main access road south of the ridge between Ross and Bighorn Creeks. The anomaly was originally detected in a couple of soil samples from a reconnaissance survey conducted in 2004 (Stirling, 2004) and confirmed by a couple of detailed sample lines in 2011 (Jones and Branson, 2011). In 2018, the soil anomaly was extended to 600 m in length, doubling the previously known strike length and with anomalous results open to north. The soil results suggest two, possibly three, parallel mineralized zones; the strongest one in the middle with a second of weakly to highly anomalous results lying 100 to 150 m east (Ross East) and a third, suspect zone, with weak to moderate results lying 200 to 250 m west (Ross West). The Ross Anomaly occurs 1.8 km south of the Middlecoff Zone, roughly on strike, and the presence of multiple mineralized structures suggests it could indeed be the extension of the vein system. That would give the Mt Haldane Vein System a strike length of at least 3.5 kilometres.

A lack of outcrop in the Ross Anomaly hindered detailed evaluation of this area on surface. Geological mapping of float and outcrop indicates that it is underlain by Keno Hill quartzite, exposed in a wedge-shaped window between the Ewing Fault to the north and west and the Robert Service thrust to the south. The Ross West soil anomaly is apparently underlain by Hyland Group phyllite and schist that is not a good host for mineralization and that may explain the weaker soil results in that area.

In an attempt to determine the source of the main Ross Anomaly, a single 65 m long, east-west trench (HLT18-01) was dug near the south end of the highest 2011 soil results but failed to reach bedrock at depths of up to 4 m. Nonetheless, soil samples collected at 5 m intervals from the trench returned very highly anomalous results for Pb, Zn and Ag, including >1000 ppm Zn, for the eastern 25 metres (Figure 7). Results for lead range up to 1455 ppm in this eastern section.

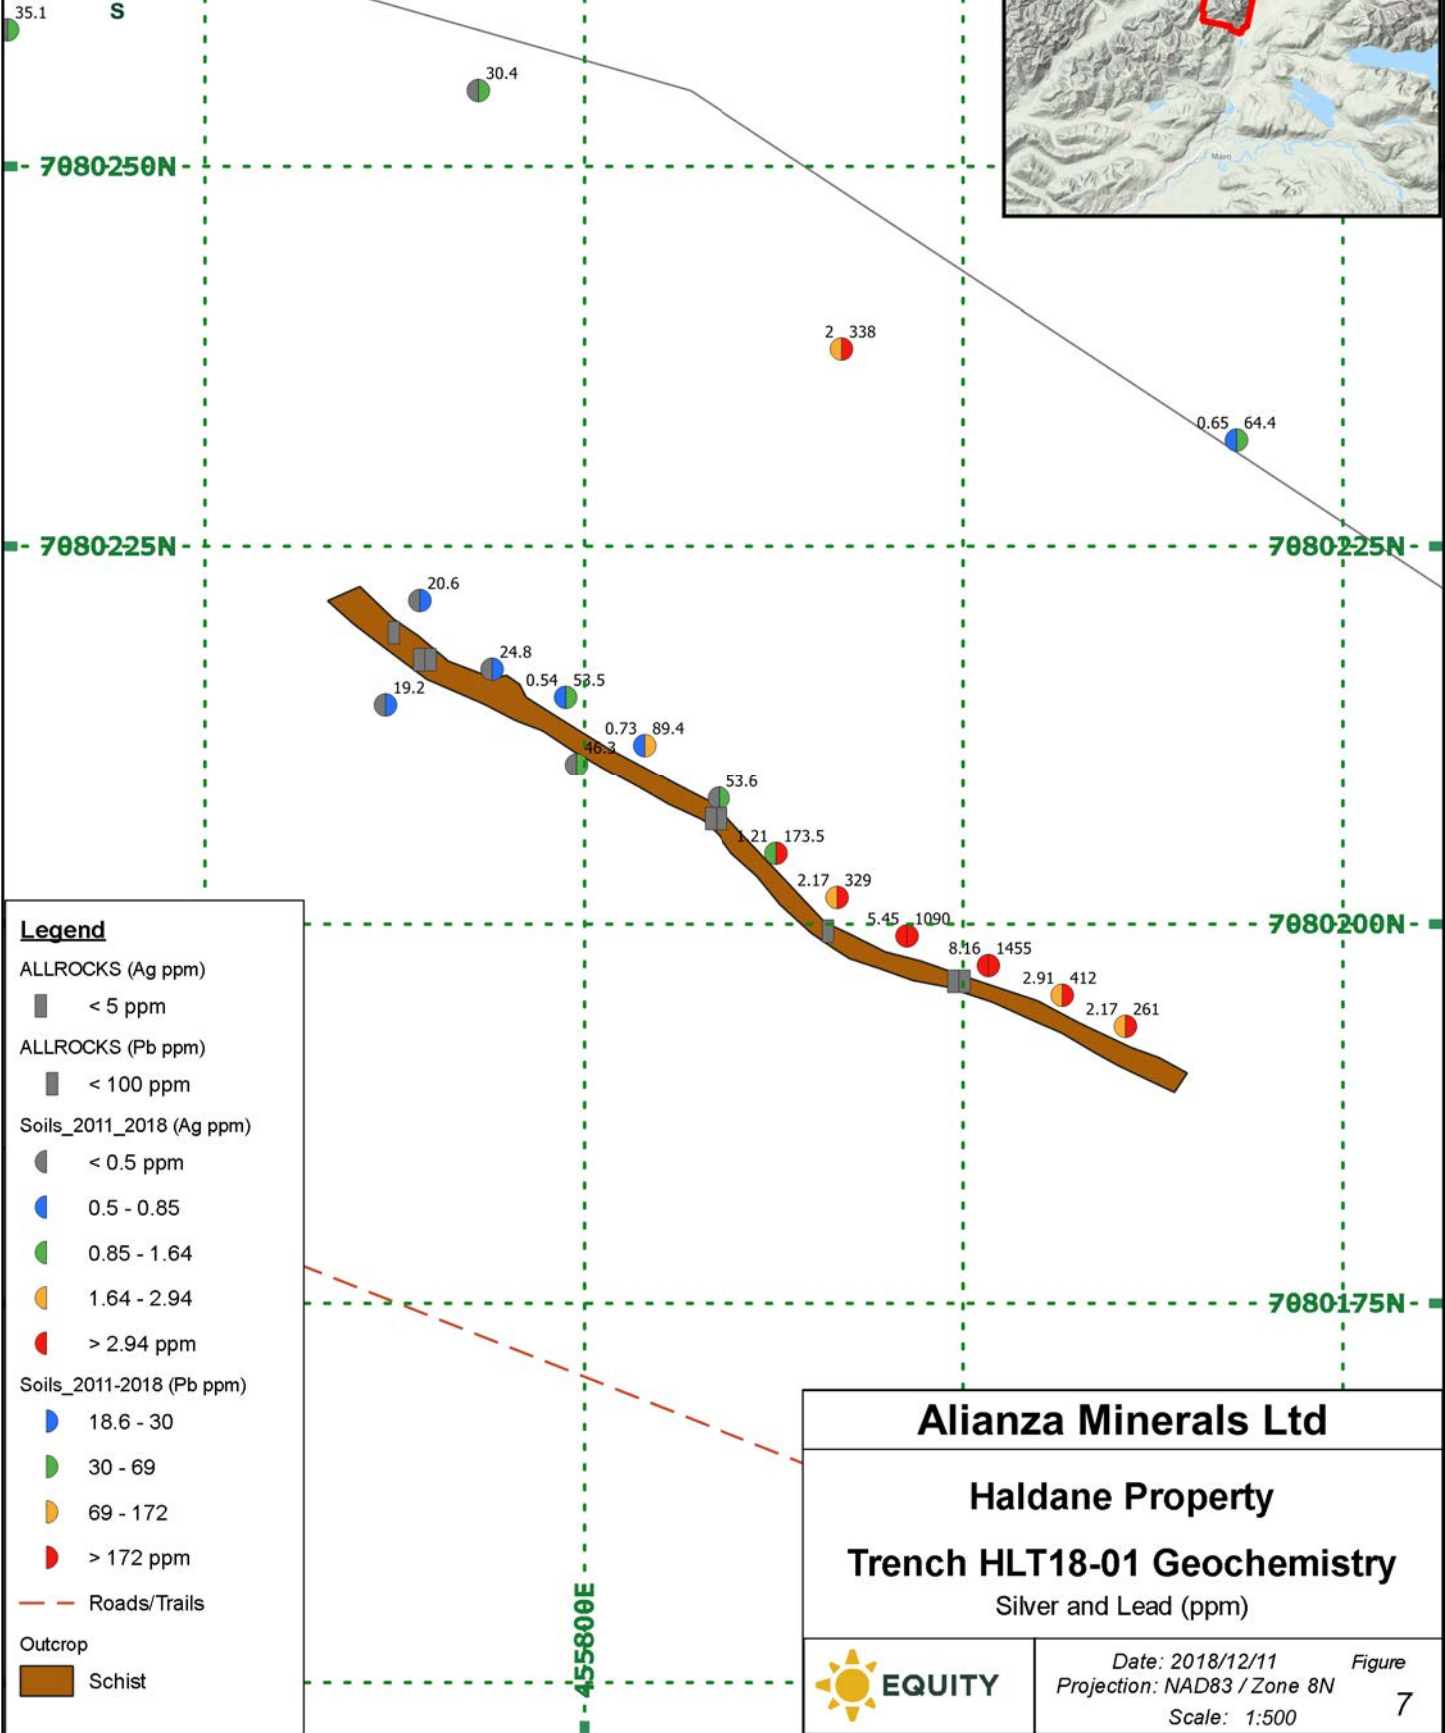

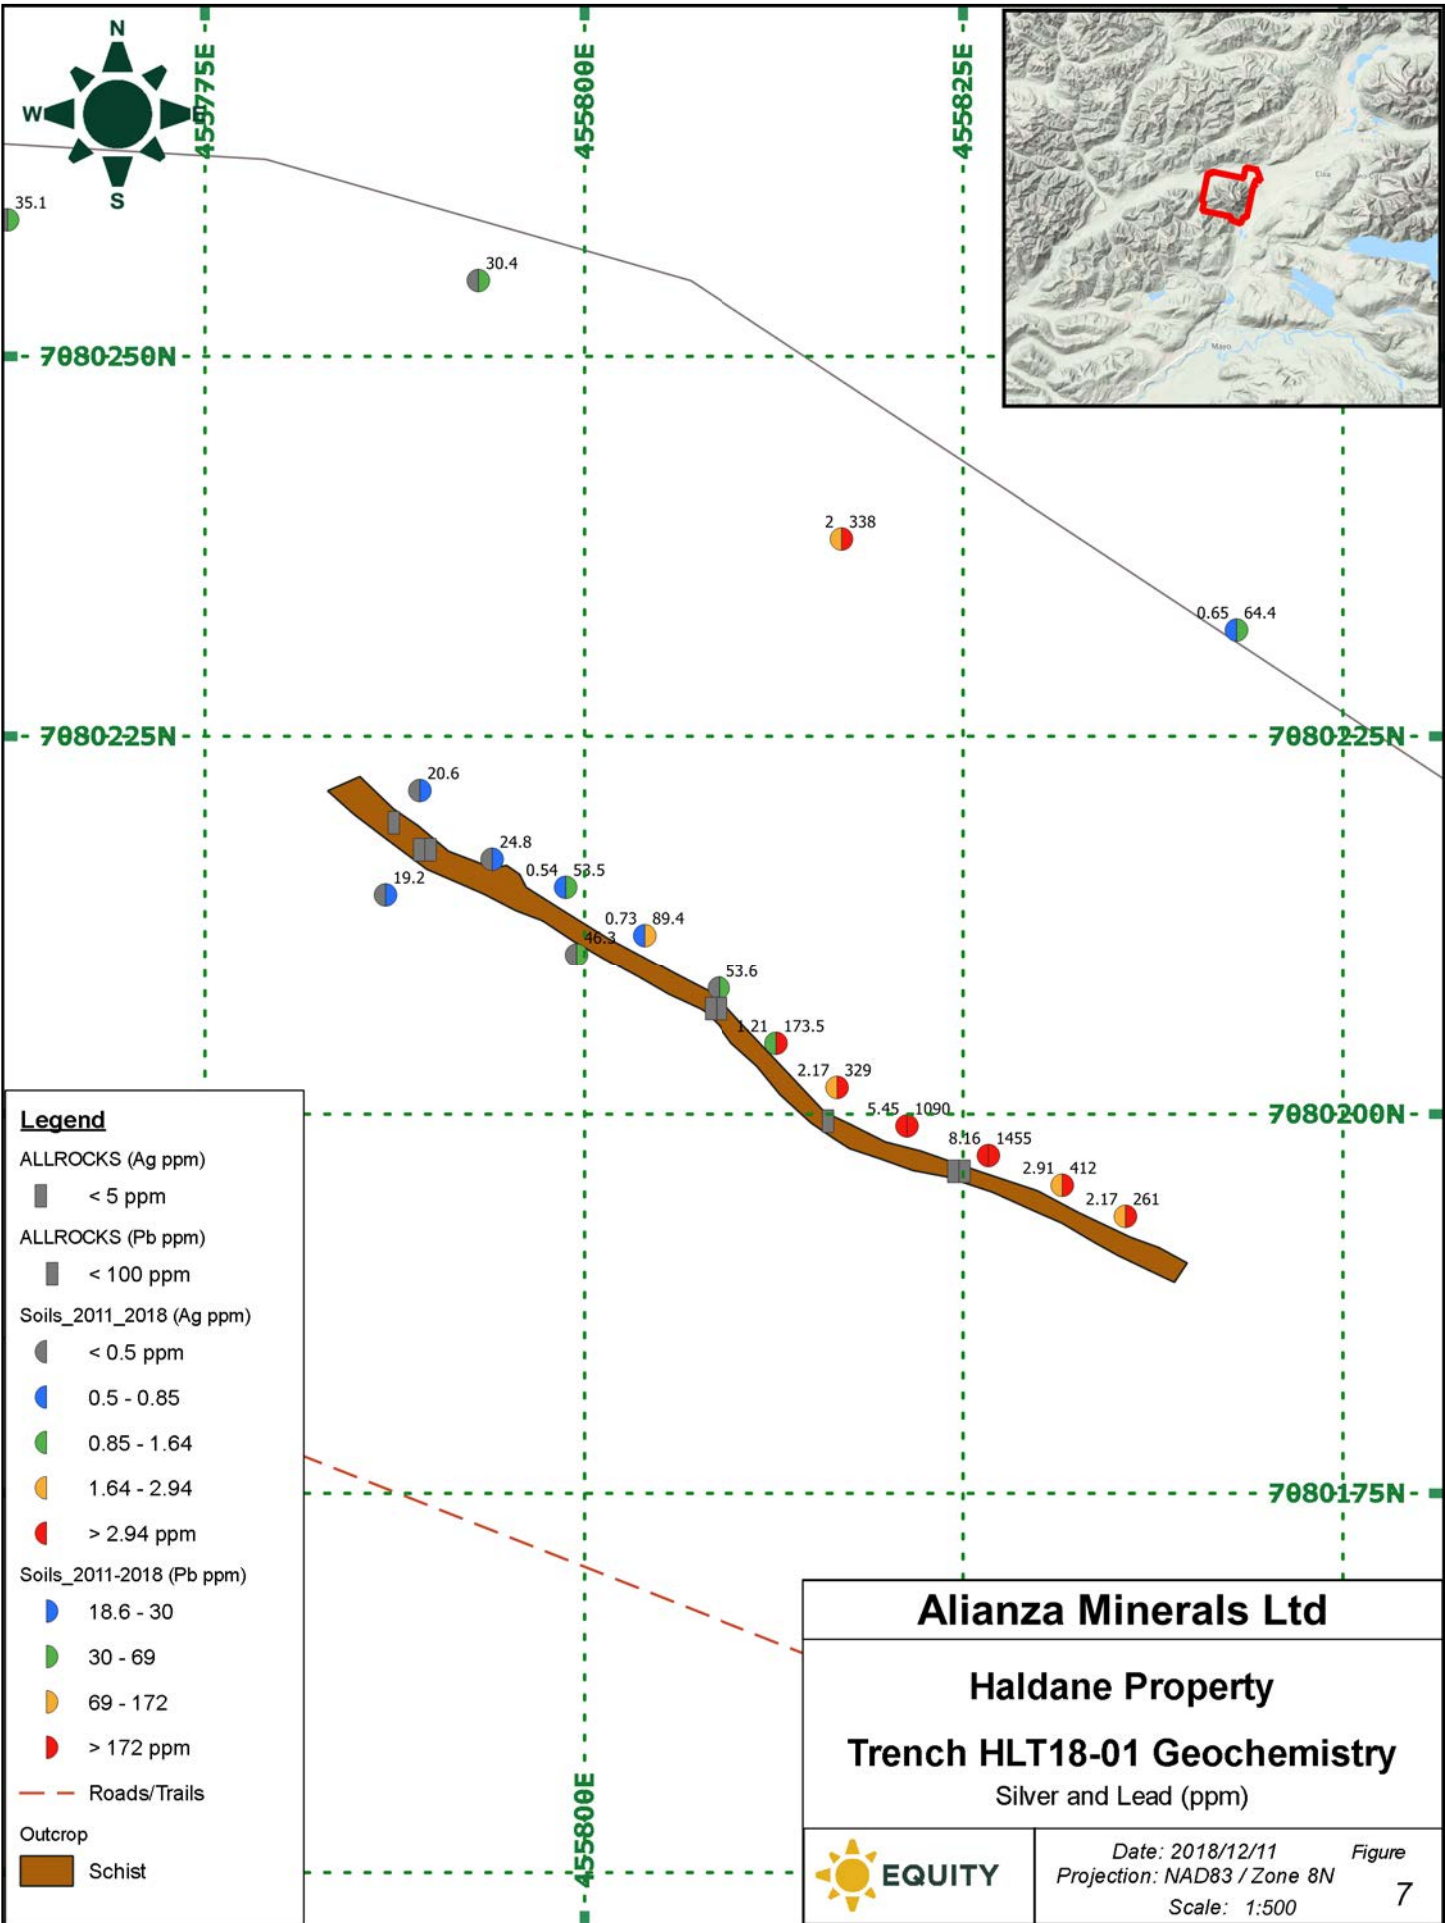

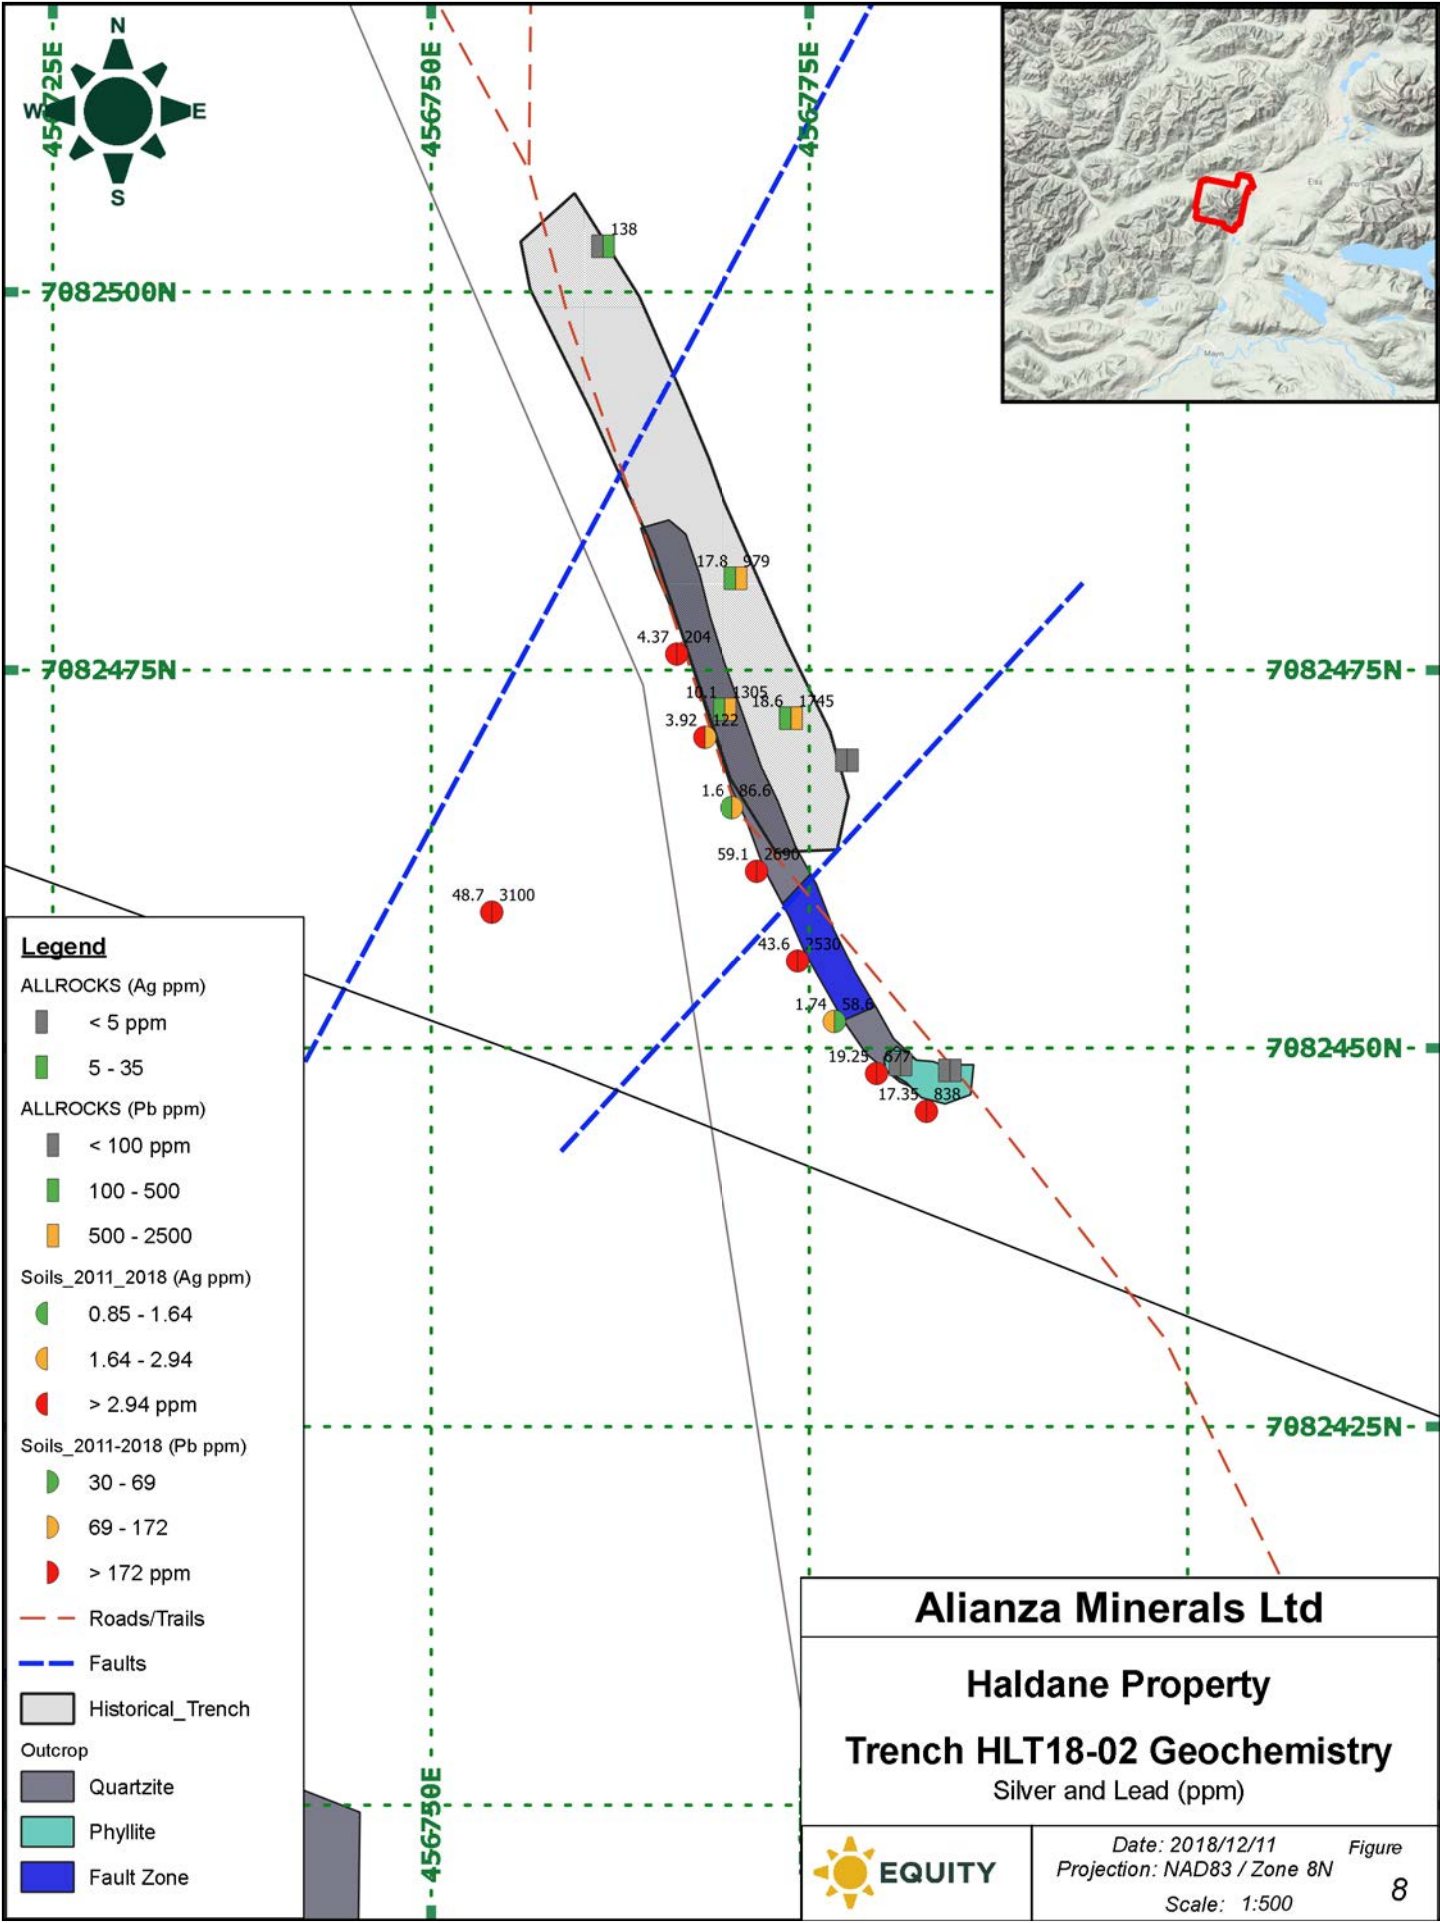

Plate 9: Sample S193103, from altered phyllitic quartzite with abundant iron and manganese oxides in fractures. Sample taken from roadcut near the western margin of the Bighorn Soil Anomaly (454065E/7084252N). No historical work has been recorded in this area.

The northerly trend of mineralized structures within the MHVS is clear and, generally, anomalous soil results follow the known structures. However, the distribution of anomalous soil samples within this corridor also suggests a possible east-west control on mineralization. Just upslope north of the Bighorn Fault, the Ewing West anomaly connects moderately to very highly anomalous Sn-Ag-Pb-Zn results over 450 m along an interpreted east-west lineament located west of the West Fault.

On the north side of the property, the 2018 soil sampling delineated a second new target, called the North Star Anomaly. This narrow, ~1000 m long by 4-75 m wide, weakly to highly anomalous Pb-Ag-Sn-Zn anomaly crosses the ridge on north side of the North Star Creek drainage basin where historical soil sampling in the mid-1960's had detected only scattered anomalous Pb and Zn values (Heard, 1966). The North Star soil anomaly is defined by 200 m spaced lines and is a continuous multi-element anomaly, albeit discontinuous for individual elements. The anomaly is continuous from the north side of the soil grid, striking roughly 200°, to where it disappears under glacial and fluvial material approaching North Star Creek. The anomaly is in an area of large, quartzite-boulder float with minimal outcrop and only minor alteration and mineralization was detected along the anomaly during mapping. However, a mineralized bedrock source would likely be recessive and mineralized rocks may be difficult to find amongst the large boulders. The anomalous trend projects across North Star Creek to the Strebchuk Pb-Ag Showing, 700 metres further south, where galena-siderite mineralization occurs in a fracture zone in quartzite.

East of the MHVS, the Southwest Peak Anomaly is a strong As-Sb-Ag-Hg-Pb anomaly near the east end of a soil sample line on the southwest side of the peak of Mt Haldane. It is primarily an arsenic-antimony anomaly, with up to 2250 ppm As. The chemical signature of this anomaly is very similar to the geochemical character of mineralization in the Peak Vein on the opposite side of the peak. The Peak Vein is a up to 3m thick, massive quartz vein dipping shallowly to the south and a rough structural projection indicates that, if continuous, the vein would daylight in the vicinity of the multi-element soil geochemical anomaly. In fact, mapping in the area of the Southwest Peak soil anomaly located a field of large quartz boulders, possibly representing the down dip extension of the Peak Vein.

EQUITY

Date: 2018/12/11
Projection: NAD83 / Zone 8N
Scale: 1:500

Figure 8

The Firetower Anomaly covers a large area in the northeastern part of the property. This anomaly consists primarily of moderately to highly anomalous As-Sb-Zn-Au, with local Sn, but lacks strong silver enrichment. It may be indicative of intrusion-related Au mineralization that occurs in this part of the property.

10.0 DISCUSSION AND CONCLUSIONS

The Keno Hill area of central Yukon is one of the premier silver-producing districts in North America. The mining camp appears to be part of a large mineralized system that may include a range of deposits from relatively high-temperature (proximal) plutonic-associated tin-tungsten deposits to intrusion-related gold-arsenic deposits to distal Ag-Pb-Zn deposits. Mineralization on the Haldane property has characteristics of proximal and distal deposits but is primarily equivalent to vein-fault silver deposits in the Keno Hill camp that feature manganiferous siderite gangue and moderate silver to lead ratios (Lynch, 1986). These deposits make up a large percentage of past production in the camp.

In summary, the Haldane property shares several geological characteristics with the Keno Hill mining camp:

- mineralization is primarily hosted by a thick section of Keno Hill quartzite that crosses the property from east to west, lying on the south limb of the McQuesten Anticlinorium and immediately below the Robert Service Thrust.
- structurally controlled, vein and breccia mineralization in northerly trending, complex fault systems
- silver (g/t) to lead (%) ratios ranging from 20:1 to 1100:1, similar to the 100:1 to 1000:1 ratios in the Keno Hill camp
- sulphide mineralization consists of galena, sphalerite, tetrahedrite and pyrargyrite (or proustite)
- quartz and manganiferous carbonate gangue are prevalent
- better grades are found in proximity to northwest cross-faults, exemplified by the significant showings adjacent to the Bighorn fault

Past exploration has identified silver mineralization related to the Mt Haldane Vein System (MHVS) over more than 3500 m of strike length from the Main Zone in the north to the Ross Anomaly, and perhaps, stretching as far as the Sundown Showing, in the south. Most previous work spans about 1400 m of this strike length, from the Main Zone to the Middlecoff Zone. Drill programs in 2011 and 2013 identified additional mineralized structures within the MHVS, such as the West Fault. Potentially mineralized structures within the favourable Keno Hill quartzite outside of the MHVS corridor were known but exploration in these areas prior to 2018 was preliminary at best. The 2018 exploration program was designed to test for silver-lead-zinc mineralization within the preferred quartzite host rocks outside the established areas of mineralization and to follow up lesser known and weaker signs of mineralization identified by earlier exploration efforts. The 2018 soil sampling was successful in that the work has discovered a previously undocumented mineralized zone, the Bighorn Anomaly, and confirmed the presence of other mineralized structures outside of the MHVS, such as the North Star Anomaly.

The Bighorn soil anomaly is a new discovery located on the west side of the Haldane property. The anomaly is very significant in that it contains higher lead values in soil than any previous results on the property other than from samples situated directly on mineralized structures within the MHVS. The anomaly trends cross-slope (i.e. not caused by downslope transport), roughly north-northeast, and follows a gully, suggesting that the zone is likely controlled by a vein-fault system similar to the other mineralized zones on the property. The Bighorn Anomaly opens the possibility of more structures to the west where the Keno Hill quartzite wraps around to the west boundary of the property. These slopes have not been previously mapped and could have additional significant structures. Also, there are several other weaker anomalies on the lower slopes south of Bighorn Creek east of the Bighorn Anomaly, heading south towards the MHVS.

The 2018 program has further delineated soil anomalies associated with the MHVS, including doubling the strike length of the Ross Anomaly from 300 to 600 m. The Ross Anomaly is situated 1.8 km south, roughly on strike from the Middlecoff Zone and the apparent presence of multiple mineralized structures suggests it could indeed be the extension of the MHVS, which should project below the ridge that lies between the Middlecoff Zone and the Ross Anomaly. That would give the Mt Haldane Vein System a strike length of at least 3.5 kilometres.

The north-south trend of mineralized structures within the MHVS is clear and, generally, anomalous soil results follow the known structures. However, the distribution of anomalous soil samples within the structural corridor suggests a possible east-west control on mineralization locally e.g. the Ewing West anomaly. Conversely, anomalous soil results taper off quickly north of the Main Zone and this may be related to interpreted east-west lineaments that cuts through the area (one at roughly 7083050N), possibly cutting off or offsetting the vein-faults. Small scale east-west structures occur within the Main Zone and some of these are mineralized. These interpreted structures could be analogous to the longitudinal faults in the Keno Hill district.

The soil results in the north part of the North Star Creek basin indicate that the Strebchuk Showing aligns with a structure that extends some 1700 m north to the north boundary of the Keno Hill quartzite. The extensive quartzite-boulder cover in the area may have negatively impacted the intensity and continuity of the results. The anomaly does highlight that there is potential yet to be evaluated in areas with less historical work.

11.0 RECOMMENDATIONS

The Bighorn Anomaly should be followed up with detailed mapping, prospecting and soil sampling. There is abundant float and possibly outcrop within the extent of the anomaly that should provide clues to the style of mineralization. The anomaly is easily accessible and field work should be able to identify areas for excavator trenching and, possibly, later diamond drilling. As well, soil sampling and prospecting should be extended to the west slopes area below the main access road and south above Bighorn Creek, following the trend of the Keno Hill quartzite through the area. A detailed soil grid around the Strebchuk Showing is merited given there is only one soil line in that area currently.

Further detailed geological mapping, with an emphasis on structural interpretation, should be continued to help gain a better understanding of the control on ore shoots within the mineralized vein-faults. Outcrops within the MHVS should be investigated in more detail to determine the potential for longitudinal faults and to extract additional information on potential controls of mineralized shoots along the vein-faults. The slopes above the Ross Anomaly have not been mapped and they should be examined for vein-faults and the trace of the Ewing or other related faults.

Excavator trenching would be a cost-effective, early-stage alternative to diamond drilling and provide a near-surface investigation of vein zones indicated by mapping and by geochemical anomalies. Several targets would be amenable to trenching, including:

- -the Bighorn Anomaly, above and below the road
- - the Strebchuk Showing, testing downslope side and also the soil anomaly to the east
- -the North Star Anomaly, several trenches across the anomaly to try and expose the bedrock source which may be buried under large quartzite talus
- -the east-west trending soil anomaly (lineament related?) west of the West Fault,
- -testing and re-opening existing trenches at Johnson and South Johnson,

This work could require as much as 1000 linear metres of trenching. Most of this trench work would require construction of new access trails and significant upgrading of roads, such as west of the West Fault and, in the case of the Strebchuk Showing and North Star Anomaly areas, upgrading the trail from the north end of the MHVS down into the North Star Creek drainage.

The mineralized structures at the Middlecoff Zone should be continuous south through the ridge between Bighorn and Ross Creeks. The structures would lie below the Ewing Fault and Robert Service Thrust and emerge in the area of the Ross Anomaly. Testing the structures under the ridge is a logistical problem but, as a start, they can be drilled on either side of the ridge. Additional trenching may be possible at the Ross Anomaly but the depth of overburden suggests that it may make sense to go directly to diamond drilling. A fence of two or three drill holes, roughly along the access road, would likely suffice to identify the number and significance of mineralized vein-faults that are contributing to the soil anomaly. A total of 800 metres drilling would be required to test the breadth of the Ross Anomaly in proximity to the road.

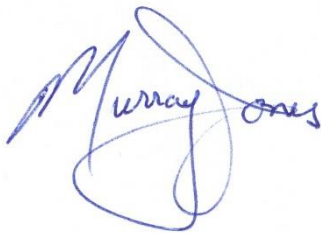

Initial drilling at the Middlecoff Zone should focus on testing for continuation of the high-grade shoots sampled by previous workers in the 1918-1920 timeframe and in the mid-1960's (Cockfield, 1919; Aho, 1964; McClintock, 1988). A fan drilling program, 4 holes for a total of 700 metres, should give an idea of the extent and, hopefully, plunge of the mineralization around the underground workings.

No significant geophysical surveys have been reported on the property. Historically, ground electromagnetic and gravity surveys had limited success in identifying vein-faults within the Keno Hill quartzite in the Keno Hill area due to a combination of graphitic schist (phyllite?) horizons, conductive clays and pyrite hosted within fault zones, and the high density of structural features within the survey areas. Exceptions include ground VLF EM-16 and horizontal loop EM-17 surveys combined with airborne DIGHEM III data, which met with more success in locating vein-faults (Watson, 1986). An airborne magnetic and electromagnetic survey flown on northwest-southeast lines would be a cost-effective survey method to cover the entire property and delineate structures for follow-up mapping and ground geophysics. Alternatively, ground VLF-EM and magnetics surveys over smaller target areas could be conducted.

Following additional exploration work as recommended above, further drilling should be done on the Main, West Fault, Johnson zones of the MHVS and, depending on trench results, the Bighorn Anomaly. Potential remains to expand the strike length of known mineralization and discover significant, high-grade, bodies of mineralization similar to those found in the rest of the Keno Hill district. Particular emphasis should be given to using structural geology to project high grade shoots within the MHVS. Testing of these targets would require an additional 500 m drilling.

Significant problems have been encountered in previous drill programs on the Haldane project, primarily rapid wearing of drill bits in the hard quartzite units and poor recovery from the friable mineralization of the vein-faults that may have adversely affected assay results. The efforts to date to enhance core recovery using larger diameter core barrels and bits and specifically designed muds have only marginally improved the situation (Jones, 2013). It may be time to explore alternative drilling techniques, such as reverse circulation, rotary percussion or rotary air blast (RAB) drilling when planning future programs to determine the usefulness of such methods, particularly towards recovery of the mineralized zones.

Respectfully submitted,

Murray Jones, M.Sc., P.Geol.

Appendix B: Statement of Expenditures

STATEMENT OF EXPENDITURES

Haldane Project
June 26 to July 31, 2018

PROFESSIONAL FEES AND WAGES:

Marie-Pier Boivin, Senior Sampler, fieldwork			
	22.00 days @ \$350/day	7,700.00	
Tyler Glubrecht, Geologist, fieldwork		-	
	28.50 days @ \$600/day	17,100.00	
Murray Jones, Project Geologist, report, preparation		-	
	53.50 days @ \$750/day	40,125.00	
Keith Milne, Assistant Geologist, fieldwork		-	
	24.00 days @ \$450/day	10,800.00	
Scott Parker, GIS/Logistics, report preparation		-	
	35.00 hours @ \$75/hour	2,625.00	
Chris Sokalofsky, Senior Sampler, fieldwork		-	
	28.50 days @ \$350/day	9,975.00	
Clerical, report, First Nation		-	
	3.73 hours @ \$75/hour	279.75	\$88,604.75

EQUIPMENT RENTALS:

Field Camp Rental (mandays)			
	115.00 days @ \$40/person-day	\$ 4,600.00	
Chainsaw, as used			
	12.00 days @ \$30/day	360.00	
Field Computers, office, field			
	63.00 days @ \$40/day	2,520.00	
Generator (2 x 1kVA)			
	49.00 days @ \$20/day	980.00	
Micromine Software, vein fault modelling			
	17.00 hours @ \$50/hour	850.00	9,310.00

EXPENSES:

Chemical Analyses, ALS Labs, Whitehorse, 1210 soils, 13 silts, 52 rocks	\$ 30,797.92	
Field Consumables	579.15	
Materials and Supplies	4,182.87	
Plot Charges	869.98	
Printing and Reproductions-Scan Conversions	1,280.00	
Camp Food, Mayo Bigway	4,920.03	
Meals	748.59	
Accommodation-Yukon Inn, North Star, Gold and Galena, Bedrock	1,813.85	
Taxis and Airporters	160.22	
ATV Rental-Yukon Wide Adventures Inc.	6,000.00	
Truck Rental-K&K Truck Rentals	4,426.39	
Automotive Fuel-AFD Petroleum	1,253.07	
Helicopter Charters-Fireweed Helicopters	13,397.00	
Airfare - Air North Whitehorse to Mayo	705.00	
Freight, Small's Expediting, Haldane Services	6,085.00	
Satellite Phone Rental (Non-Equity)	1,023.40	
Radio Rental (Non-Equity)	703.44	
Other Equipment Rental (Non-Equity)	425.00	
Excavator-TNT Enterprises and Snow Removal	6,900.00	
Community Consultation	3,283.33	
Expediting-Small's Expediting, Haldane Services	2,818.84	
Report, estimate	500.00	92,873.08
Project Supervision		24,427.58

TOTAL:

\$215,215.41

Appendix C: Rock Sample Descriptions

MINERALS AND ALTERATION TYPES

AC	Actinolite	FP	feldspar	PF	plagioclase
AL	alunite	GA	garnet	PH	phlogopite
AM	amphibole	GE	goethite	PL	pyrolusite
AS	arsenopyrite	GL	galena	PO	pyrrhotite
AU	augite	GR	graphite	PY	pyrite
AZ	azurite	HB	hornblende	QZ	quartz veining
BA	barite	HE	haematite	RE	realgar
BI	biotite	HS	specularite	RN	rhodonite
BO	bornite	HZ	hydrozincite	SB	stibnite
BT	pyrobitumen	IL	illite	SD	siderite
CA	calcite	JA	jarosite	SI	silicification
CB	Fe-carbonate	KF	potassium feldspar	SK	skarn
CC	chalcocite	MC	malachite	SM	smithsonite
CD	chalcedony	MG	magnetite	SP	sphalerite
CL	chlorite	MI	mica	SR	scorodite
CP	chalcopyrite	MN	Mn-oxides	SS	sulphosalts
CU	native copper	MO	molybdenite	ST	smectite
CV	covellite	MR	mariposite/fuchsite	TP	topaz
CY	clay	MS	sericite	TT	tetrahedrite
DC	dickite	MT	marcasite	VG	gold
DS	diaspore	MU	muscovite	ZE	Zeolite
DU	dumortierite	NA	natroalunite	ZN	zunyite
EP	epidote	NE	neotocite		
FL	fluorite	PA	pyrargyrite		

ALTERATION INTENSITY

w	weak	s	strong
m	moderate	i	intense

CERTIFICATE WH18166433

Project: ANZ18-01
P.O. No.: ANZ18-01001
This report is for 144 Soil samples submitted to our lab in Whitehorse, YT, Canada on 11-JUL-2018.

The following have access to data associated with this certificate:

MURRAY JONES

ALIANZA MINERALS

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION
AuME-TL43	25g Trace Au + Multi Element PKG

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE WH18166438

Project: ANZ18-01
P.O. No.: ANZ18-01001
This report is for 166 Soil samples submitted to our lab in Whitehorse, YT, Canada on 11-JUL-2018.

The following have access to data associated with this certificate:

MURRAY JONES

ALIANZA MINERALS

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION
AuME-TL43	25g Trace Au + Multi Element PKG

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE WH18175182

Project: ANZ18-01
 P.O. No.: ANZ18-01002
 This report is for 32 Rock samples submitted to our lab in Whitehorse, YT, Canada on 20-JUL-2018.
 The following have access to data associated with this certificate:

MURRAY JONES	ALIANZA MINERALS
--------------	------------------

SAMPLE PREPARATION	
ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES		
ALS CODE	DESCRIPTION	
Aq-OG46	Ore Grade Ag - Aqua Regia	
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES
Zn-OG46	Ore Grade Zn - Aqua Regia	
Au-AA23	Au 30g FA-AA finish	AAS
ME-ICP41	35 Element Aqua Regia ICP-AES	ICP-AES

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE WH18175197

Project: ANZ18-01
P.O. No.: ANZ18-01002
This report is for 229 Soil samples submitted to our lab in Whitehorse, YT, Canada on 20-JUL-2018.

The following have access to data associated with this certificate:

MURRAY JONES

ALIANZA MINERALS

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION
AuME-TL43	25g Trace Au + Multi Element PKG

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE WH18175204

Project: ANZ18-01
P.O. No.: ANZ18-01002
This report is for 230 Soil samples submitted to our lab in Whitehorse, YT, Canada on 20-JUL-2018.

The following have access to data associated with this certificate:

MURRAY JONES

ALIANZA MINERALS

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION
AuME-TL43	25g Trace Au + Multi Element PKG

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE WH18175212

Project: ANZ18-01
P.O. No.: ANZ18-01002
This report is for 203 Soil samples submitted to our lab in Whitehorse, YT, Canada on 20-JUL-2018.

The following have access to data associated with this certificate:

MURRAY JONES

ALIANZA MINERALS

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION
AuME-TL43	25g Trace Au + Multi Element PKG

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE WH18178450

Project: ANZ18-01
P.O. No.: ANZ18-01003
This report is for 20 Rock samples submitted to our lab in Whitehorse, YT, Canada on 24-JUL-2018.

The following have access to data associated with this certificate:

MURRAY JONES

ALIANZA MINERALS

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA23	Au 30g FA-AA finish	AAS
ME-ICP41	35 Element Aqua Regia ICP-AES	ICP-AES

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE WH18178476

Project: ANZ18-01
P.O. No.: ANZ18-01003
This report is for 252 Soil samples submitted to our lab in Whitehorse, YT, Canada on 24-JUL-2018.

The following have access to data associated with this certificate:

MURRAY JONES

ALIANZA MINERALS

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-21	Sample logging - ClientBarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION
AuME-TL43	25g Trace Au + Multi Element PKG

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE OF ANALYSIS WH18178476

CERTIFICATE COMMENTS

ANALYTICAL COMMENTS

Applies to Method: NSS is non-sufficient sample.
ALL METHODS

LABORATORY ADDRESSES

Applies to Method: Processed at ALS Whitehorse located at 78 Mt. Sima Rd, Whitehorse, YT, Canada.
LOG-21 SCR-41 WEI-21

Applies to Method: Processed at ALS Vancouver located at 2103 Dollarton Hwy, North Vancouver, BC, Canada.
AuME-TL43

Appendix E: Quality Assurance/Quality Control

QUALITY ASSURANCE / QUALITY CONTROL

I Chain of Custody

All samples were packed in rice sacks and sealed with uniquely-numbered non-resealable security straps. Rice sacks were delivered via Haldane Services to the ALS Minerals Labs Ltd. preparation facility in Whitehorse, an ISO 9001 registered laboratory. ALS Minerals reported that all bags were received in good condition, with all security straps intact, and with no evidence of tampering.

II Blanks

A total of 30 blanks consisting of silica sand were submitted for analysis with the soil samples, a rate of approximately 1 in 40 samples. In general, the blanks returned values at or below detection for all elements of interest and, in fact, for all elements analysed. There are a few samples where the returned values were more than one standard deviation from the average for all blanks. However, these higher values were still insignificant and well below background values for the element for all samples in the survey.

III Field Duplicate Analysis

Field duplicates represent the collection and analysis of two separate samples from the same field location, each of which were submitted as separate samples creating the duplicate-pair. These field duplicates are used to measure the reproducibility or precision of sampling, which includes both laboratory variation and sample variation. The duplicate-pairs will contain all the cumulative error associated with the sampling and analytical process and may also allow the determination of true, or effective, detection limits (where the cumulative uncertainty of sampling and analytical techniques, or precision, equals 100%). A total of 27 field duplicate-pairs were inserted into the sample sequence (approximately every 40th sample) and submitted for analysis.

Inspection of duplicate samples shows very good correlation between two samples taken from the same site. Looking at the differences between the parent and duplicate samples, there is an average difference of less than 5% for all elements of interest where the average abundance is significantly greater than the lower detection limit of the analytical technique for the element in question. As well, the weighted difference (the difference between the sum of all parents and the sum of all daughters for the element in question) between the parent and daughter samples was less than 5% for all elements of interest, except gold, which was still acceptable at 22%. The correlation coefficient (r^2) between the parent and daughter samples was greater than 0.90 for all elements with a significant number of results greater than the lower detection limit.

IV Standards

Standard reference materials (SRM) are inserted into the sample stream to gauge the accuracy of the lab's analyses. Given the reconnaissance nature of the sampling program, no samples were inserted into the soil sample stream.

V Conclusions

- There is no evidence of tampering with the samples between collection and the laboratory.
- Near lower detection limit values for metals of interest in blank samples indicate that there was no contamination of samples in the field or in the lab.
- Field duplicates indicate acceptable reproducibility at low concentrations. There is variability apparent in samples with higher values i.e. greater than 90th percentile. This is not common and exchanging the results would not change the classification of the samples as anomalous.
- The final results discussed within the report are considered valid and robust.

Appendix G: Geologist's Certificate

GEOLOGIST'S CERTIFICATE

I, Murray I. Jones, of 8606 144A St., City of Surrey, in the Province of British Columbia, DO HEREBY CERTIFY:

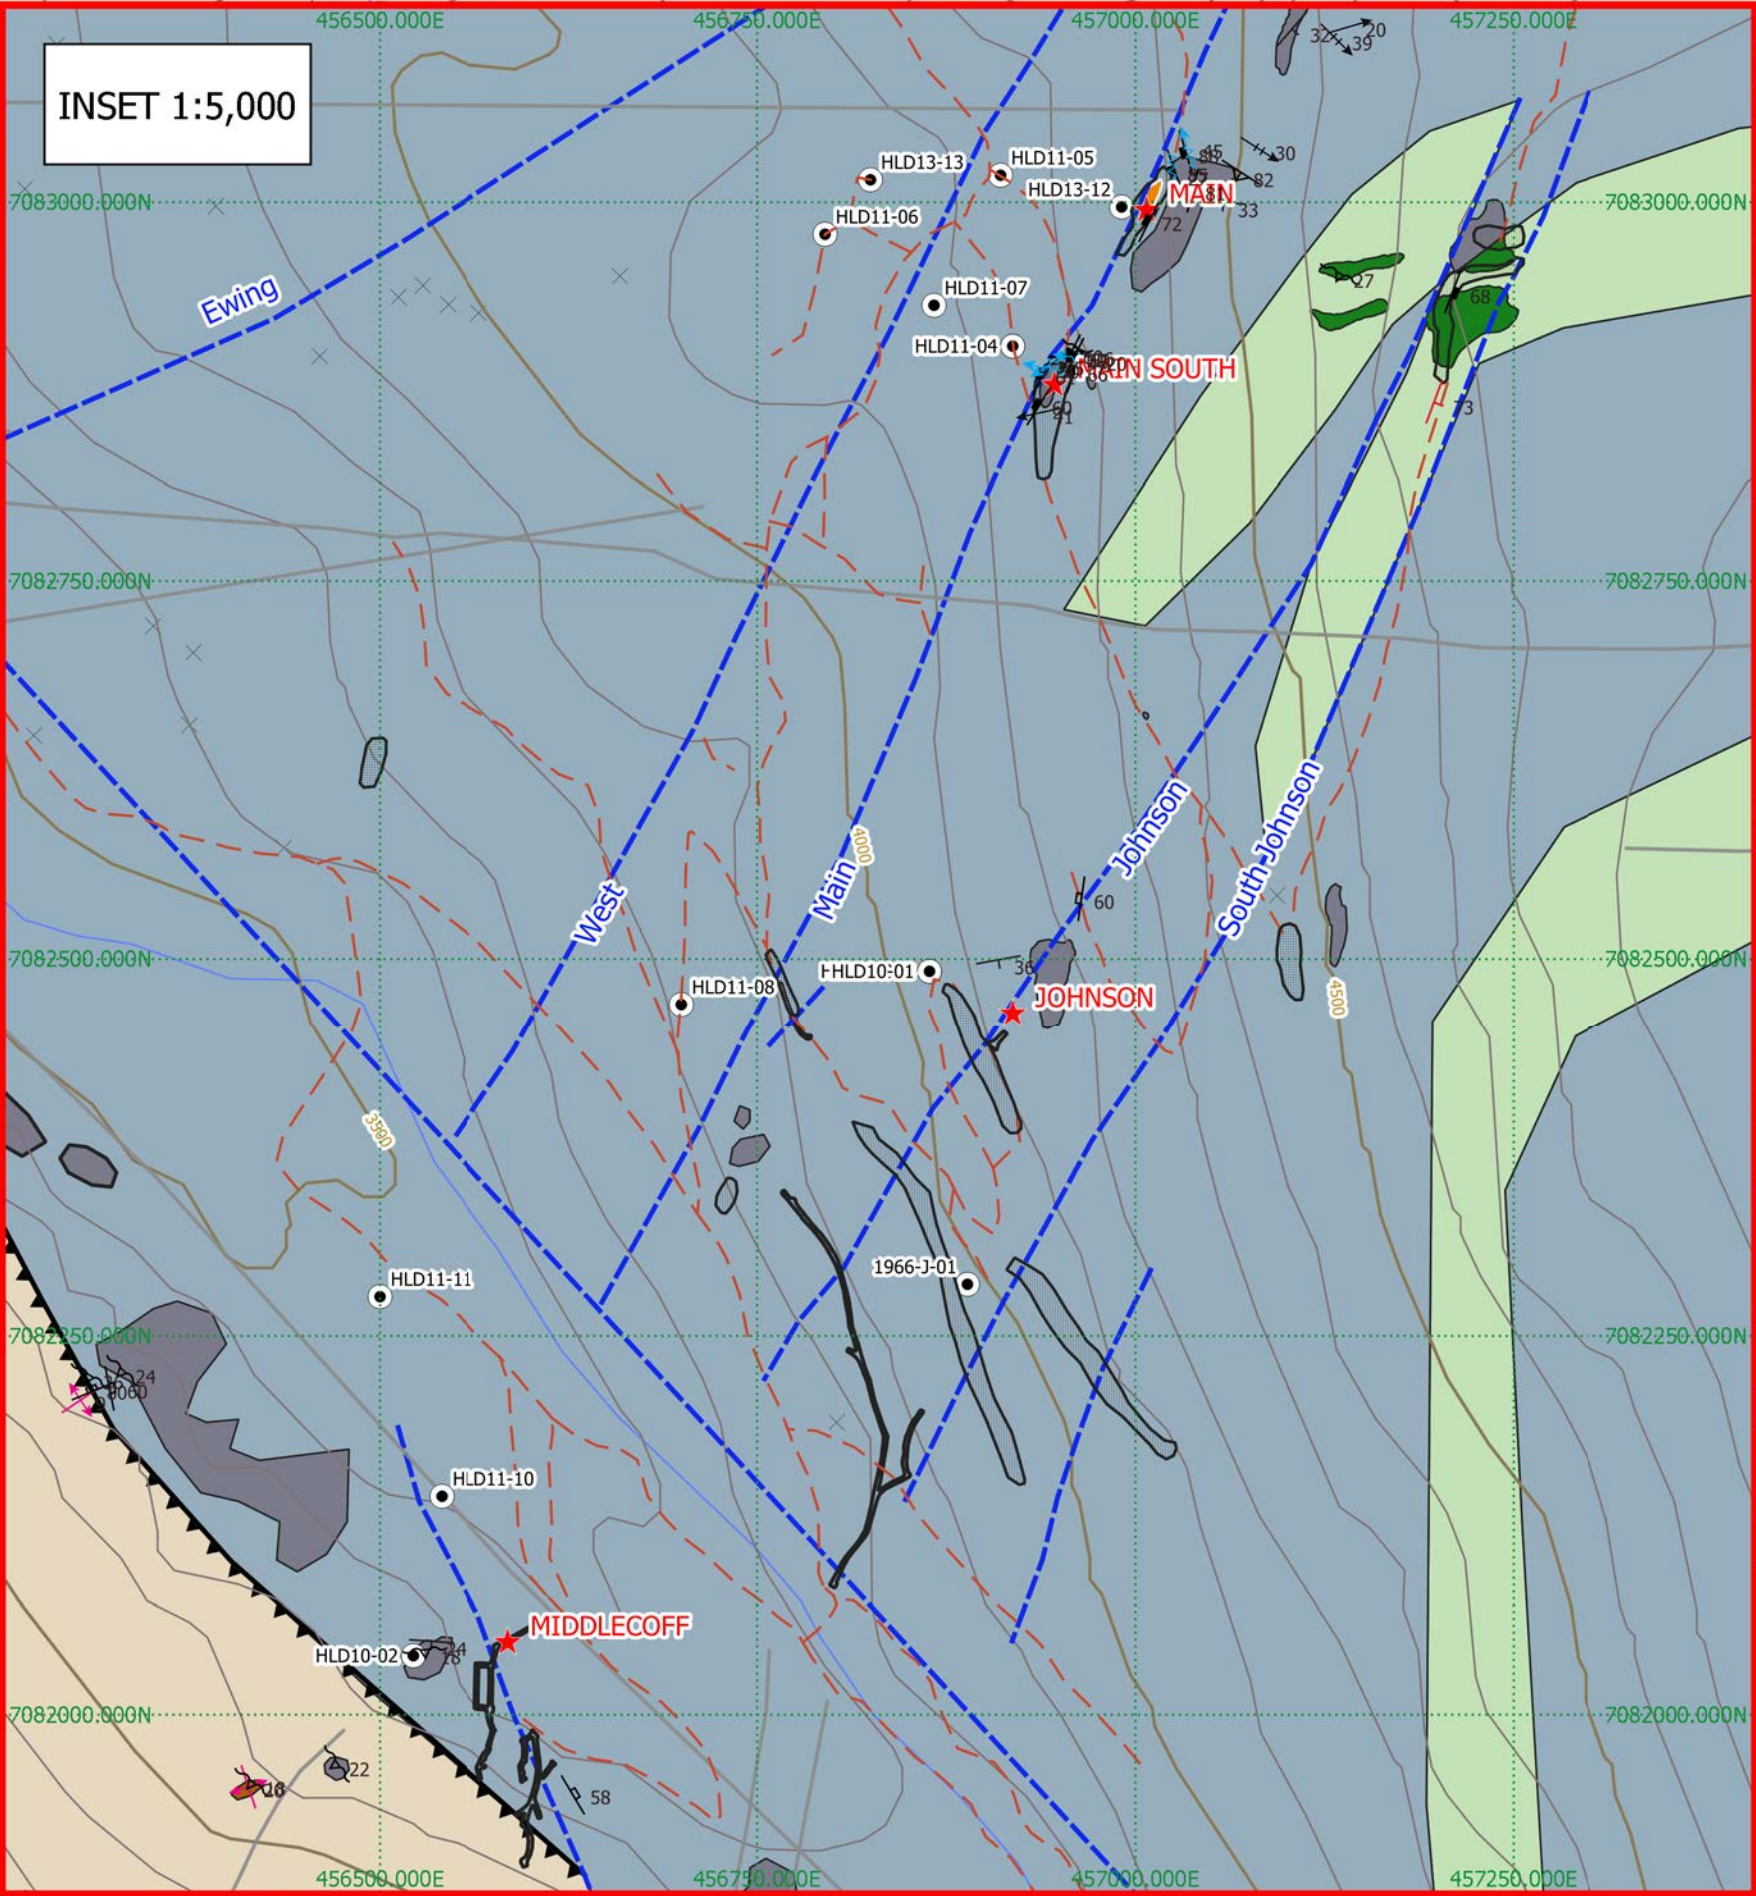

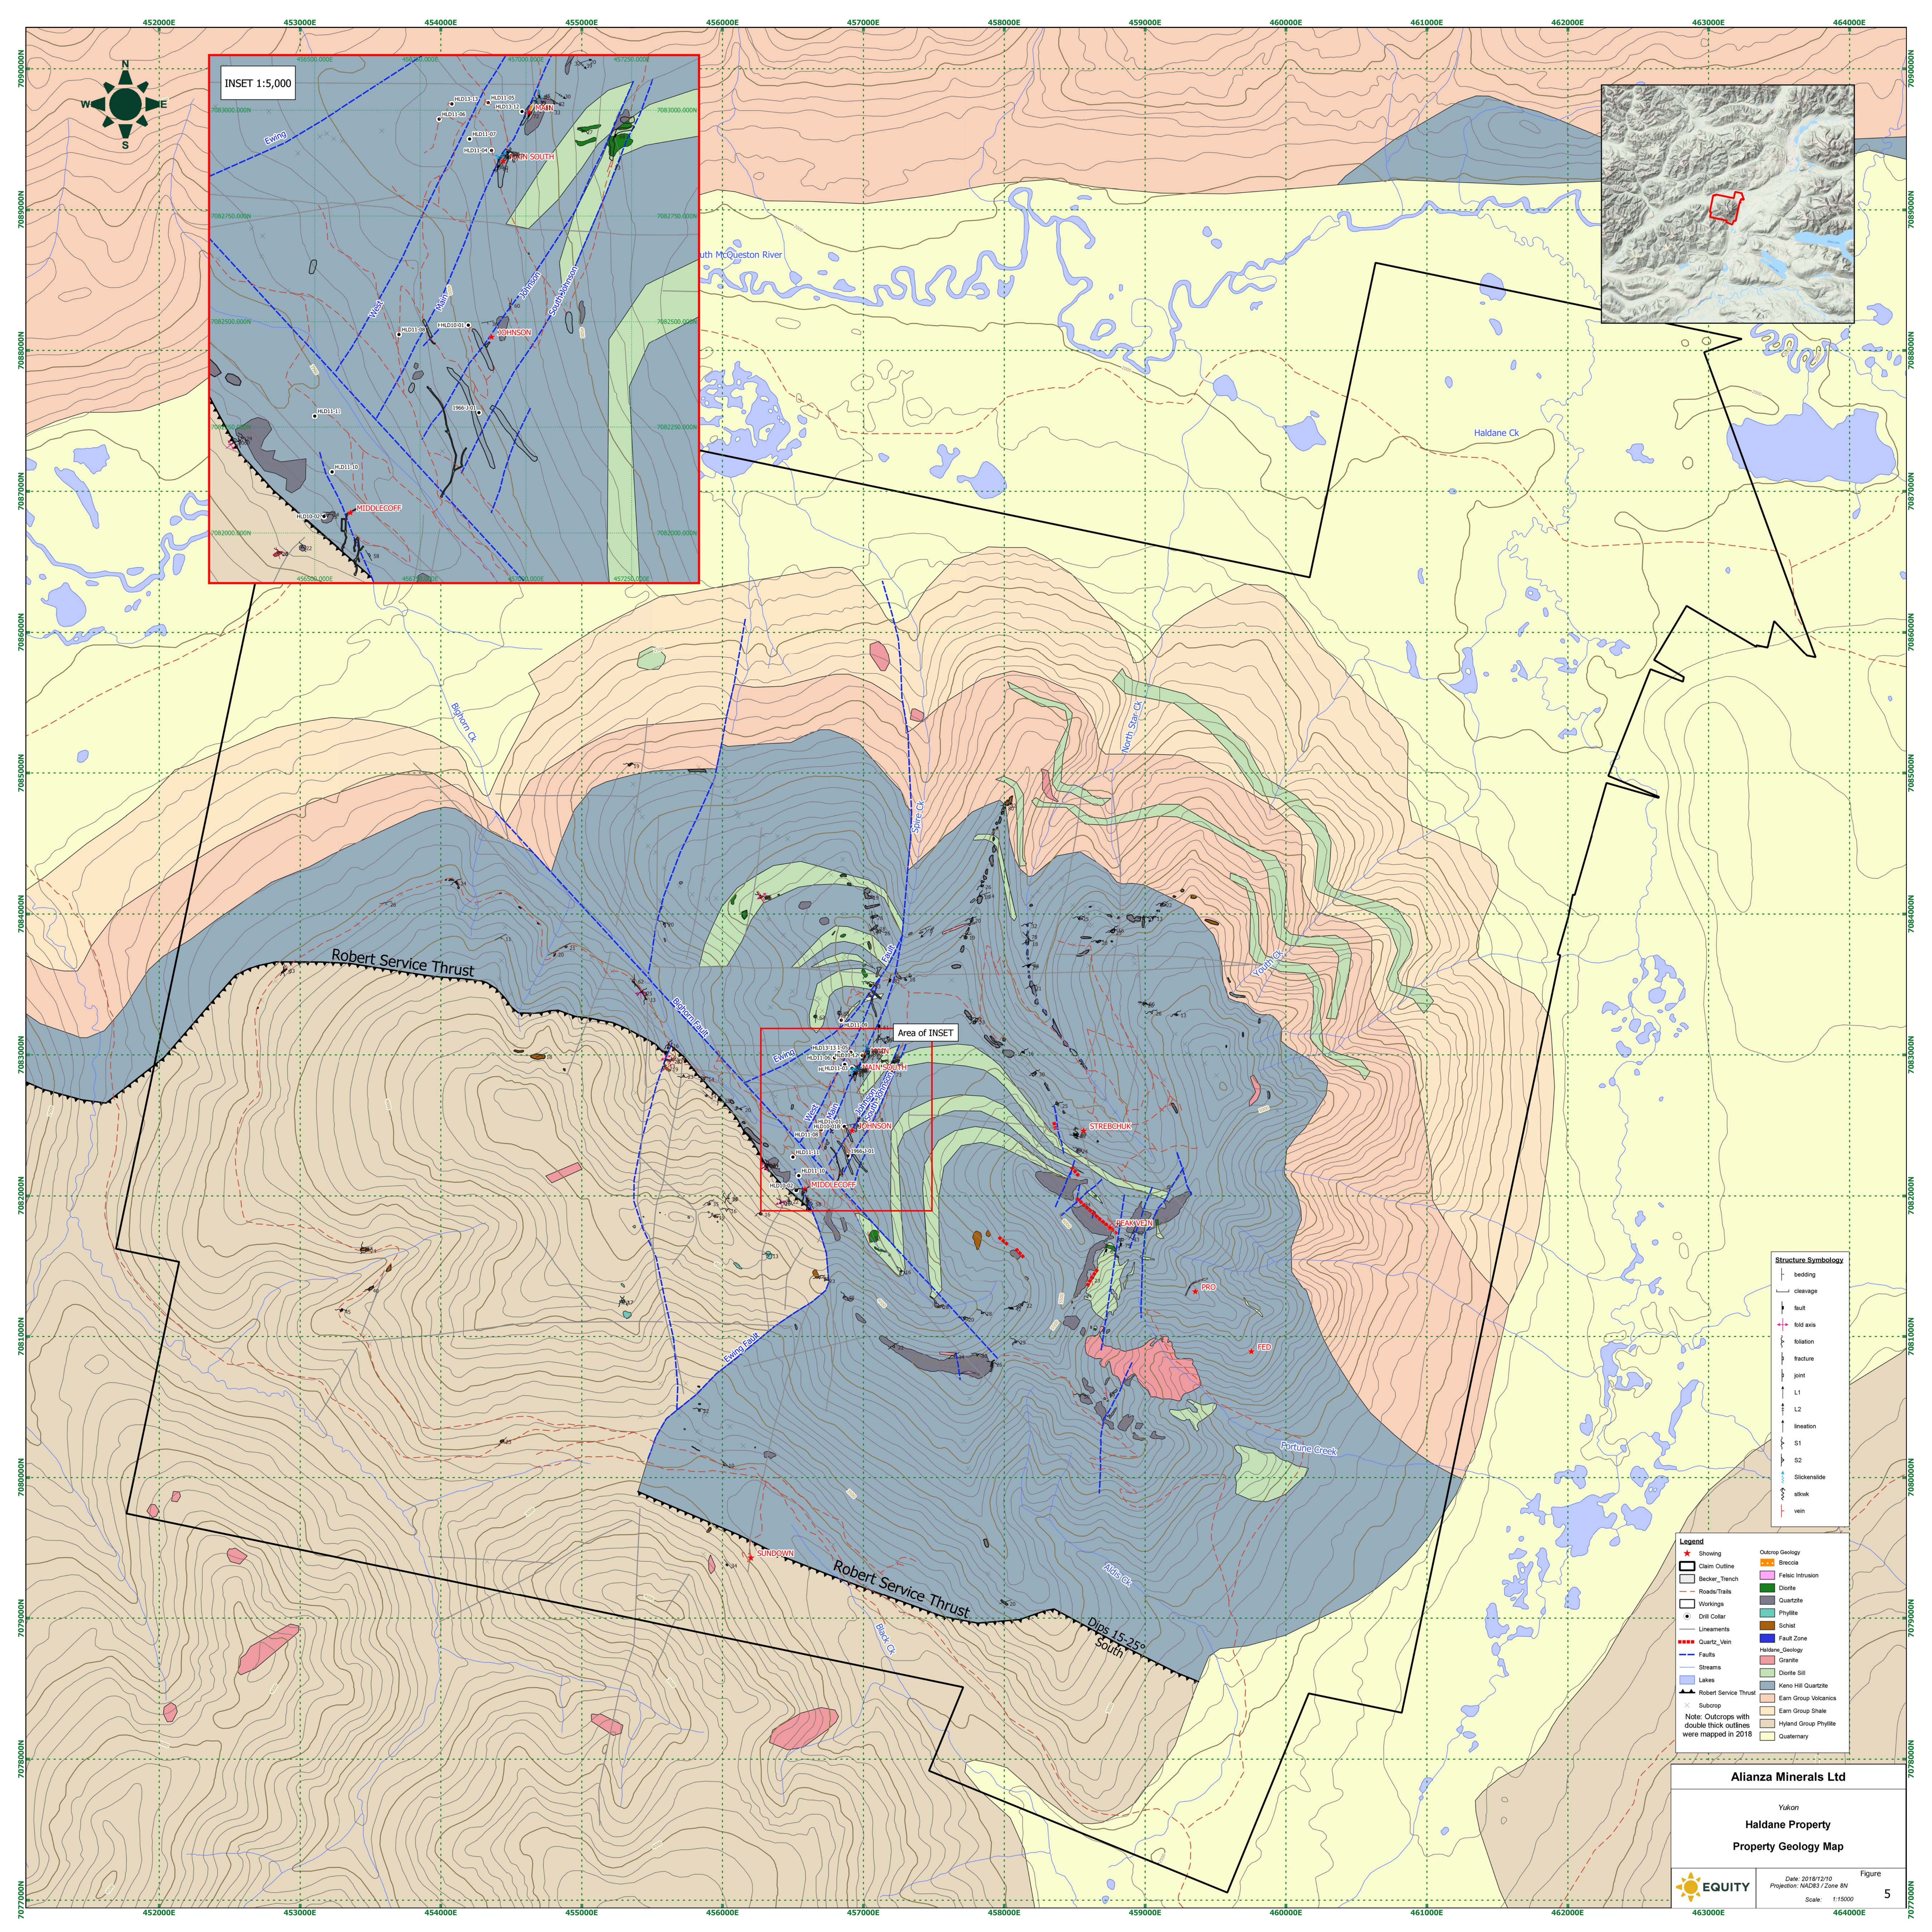

1. THAT I am a Consulting Geologist with offices at Suite 200, 900 West Hastings Street, Vancouver, British Columbia.
2. THAT I am a graduate of the University of British Columbia with a Bachelor of Science degree in Geology in 1982, and a graduate of the University of Ottawa with a Master of Science degree in Geology in 1992.
3. THAT I am a Professional Geoscientist registered in good standing with the Association of Professional Engineers and Geoscientists of the Province of British Columbia (#20063).
4. THAT this report is based on a field program carried out under my direct supervision in the period between June 29 and July 23, 2018 and on publicly available and company reports

DATED at Vancouver, British Columbia, this 14th day of December, 2018.

The image shows a handwritten signature in blue ink that reads "Murray I. Jones". The signature is written over a circular professional seal. The seal has a decorative border and contains the text: "PROFESSIONAL PROVINCE OF M. I. JONES BRITISH COLUMBIA GEOSCIENTIST".

Murray I. Jones, M.Sc., P.Geo.
