Introduction

The HUN North project is located in west-central Yukon, approximately 61 km northwest of the town of Carmacks and 227 km from the city of Whitehorse (Figure 1). The centre of the property is at approximately 381278 East and 6951107 North (NAD83 Zone 8, NTS Map sheets 115I 11/7/6).

The HUN North property was staked by 536445 Yukon Inc. in February 2018. A 4-day prospecting program was conducted on the HUN North property from late August to early September 2019 with the objective to identify the underlying geology and find mineralized outcrops. This report describes the results of prospecting traverses across the west-central portion of the HUN North property.

Legal Description

The Hun North claim group consists of 102 contiguous quartz claims (HUN 385-486) covering an approximate area of 2,402 hectares in the Whitehorse Mining District. The property is 100% owned by 536445 Yukon Inc. who paid for work completed between September 11th to 14th, 2019. A table summarizing claim data is presented below and full data on each individual claim is available in Appendix I. Claim locations are visible on Figure 2.

Claim Name	Grant No.	No. of Claims	Reg-istered Owner	Recording Date
HUN 385-486	YF72785- YF72886	102	536445 Yukon Inc.- 100%	2018-02-07

Access

The HUN North property is situated 4 km north of the Minto Mine. The Minto Mine is located west of the Yukon River, approximately 20 km WNW of Minto Landing, which is on the east side of the river. The Minto Mine is accessible via the Yukon Highway 2 (North Klondike Highway) to Minto Landing. In summer months, a barge connects the landing with an all-weather gravel road, extending 27 km from the west bank to the mine site. In winter, the crossing is accessible by an ice bridge. Access for the 2019 exploration program was by Capital Helicopter's (1995) Inc.

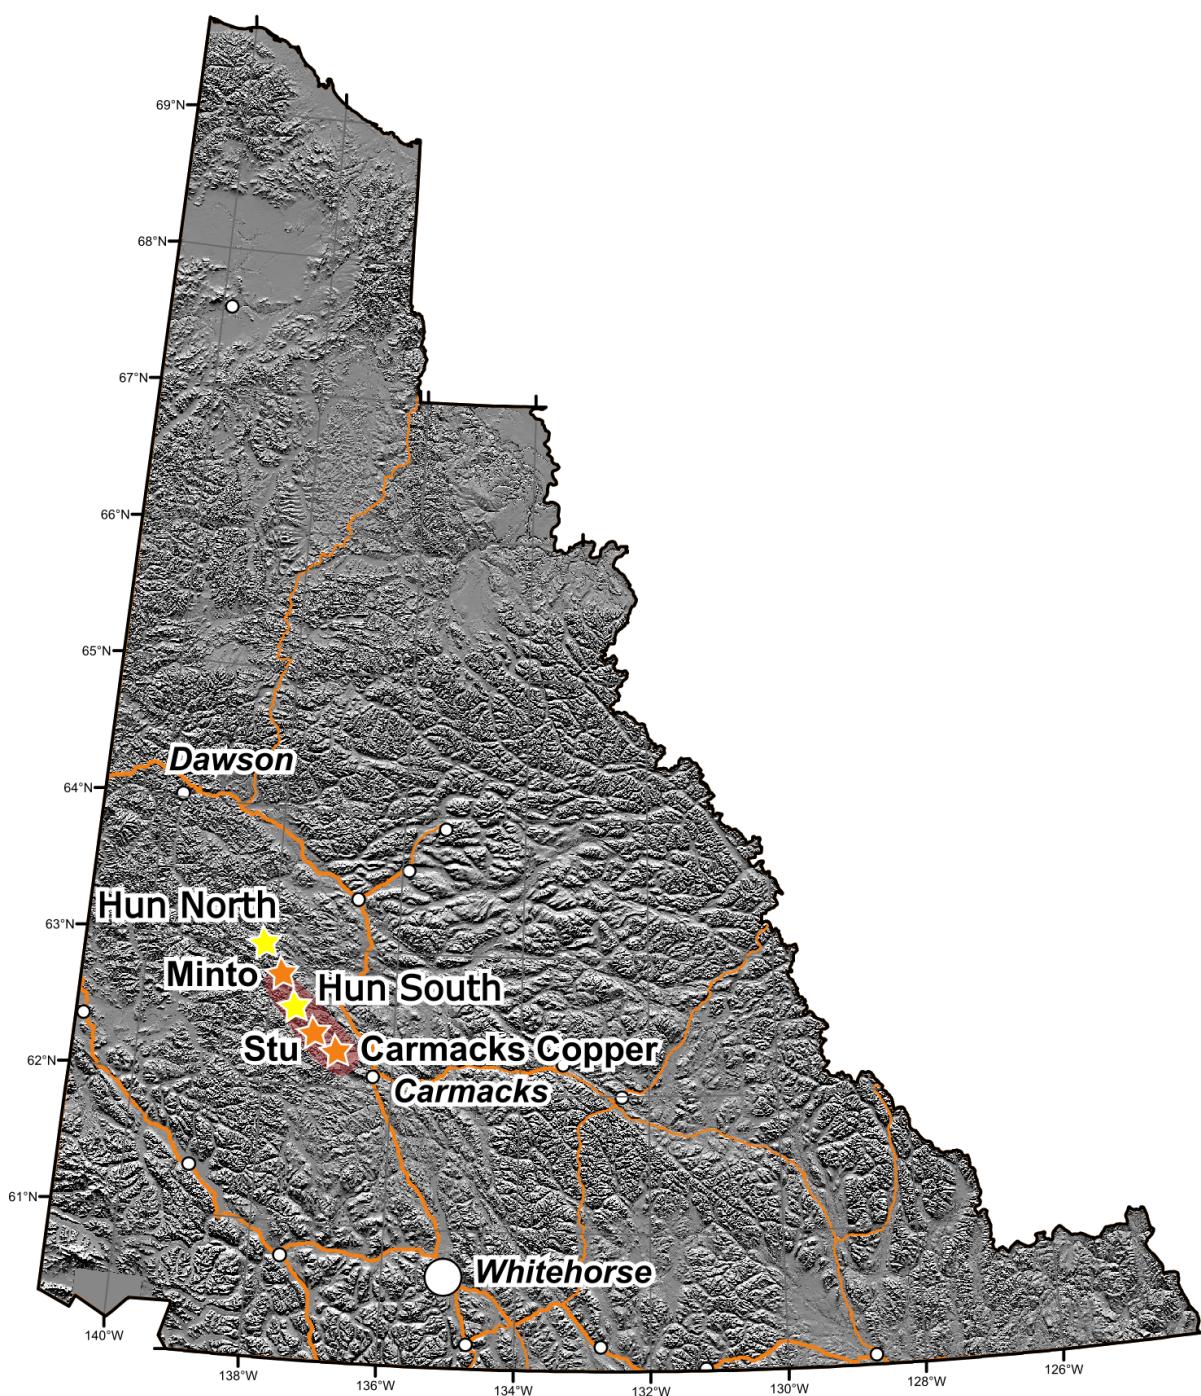

Figure 1. Location of the HUN North property.

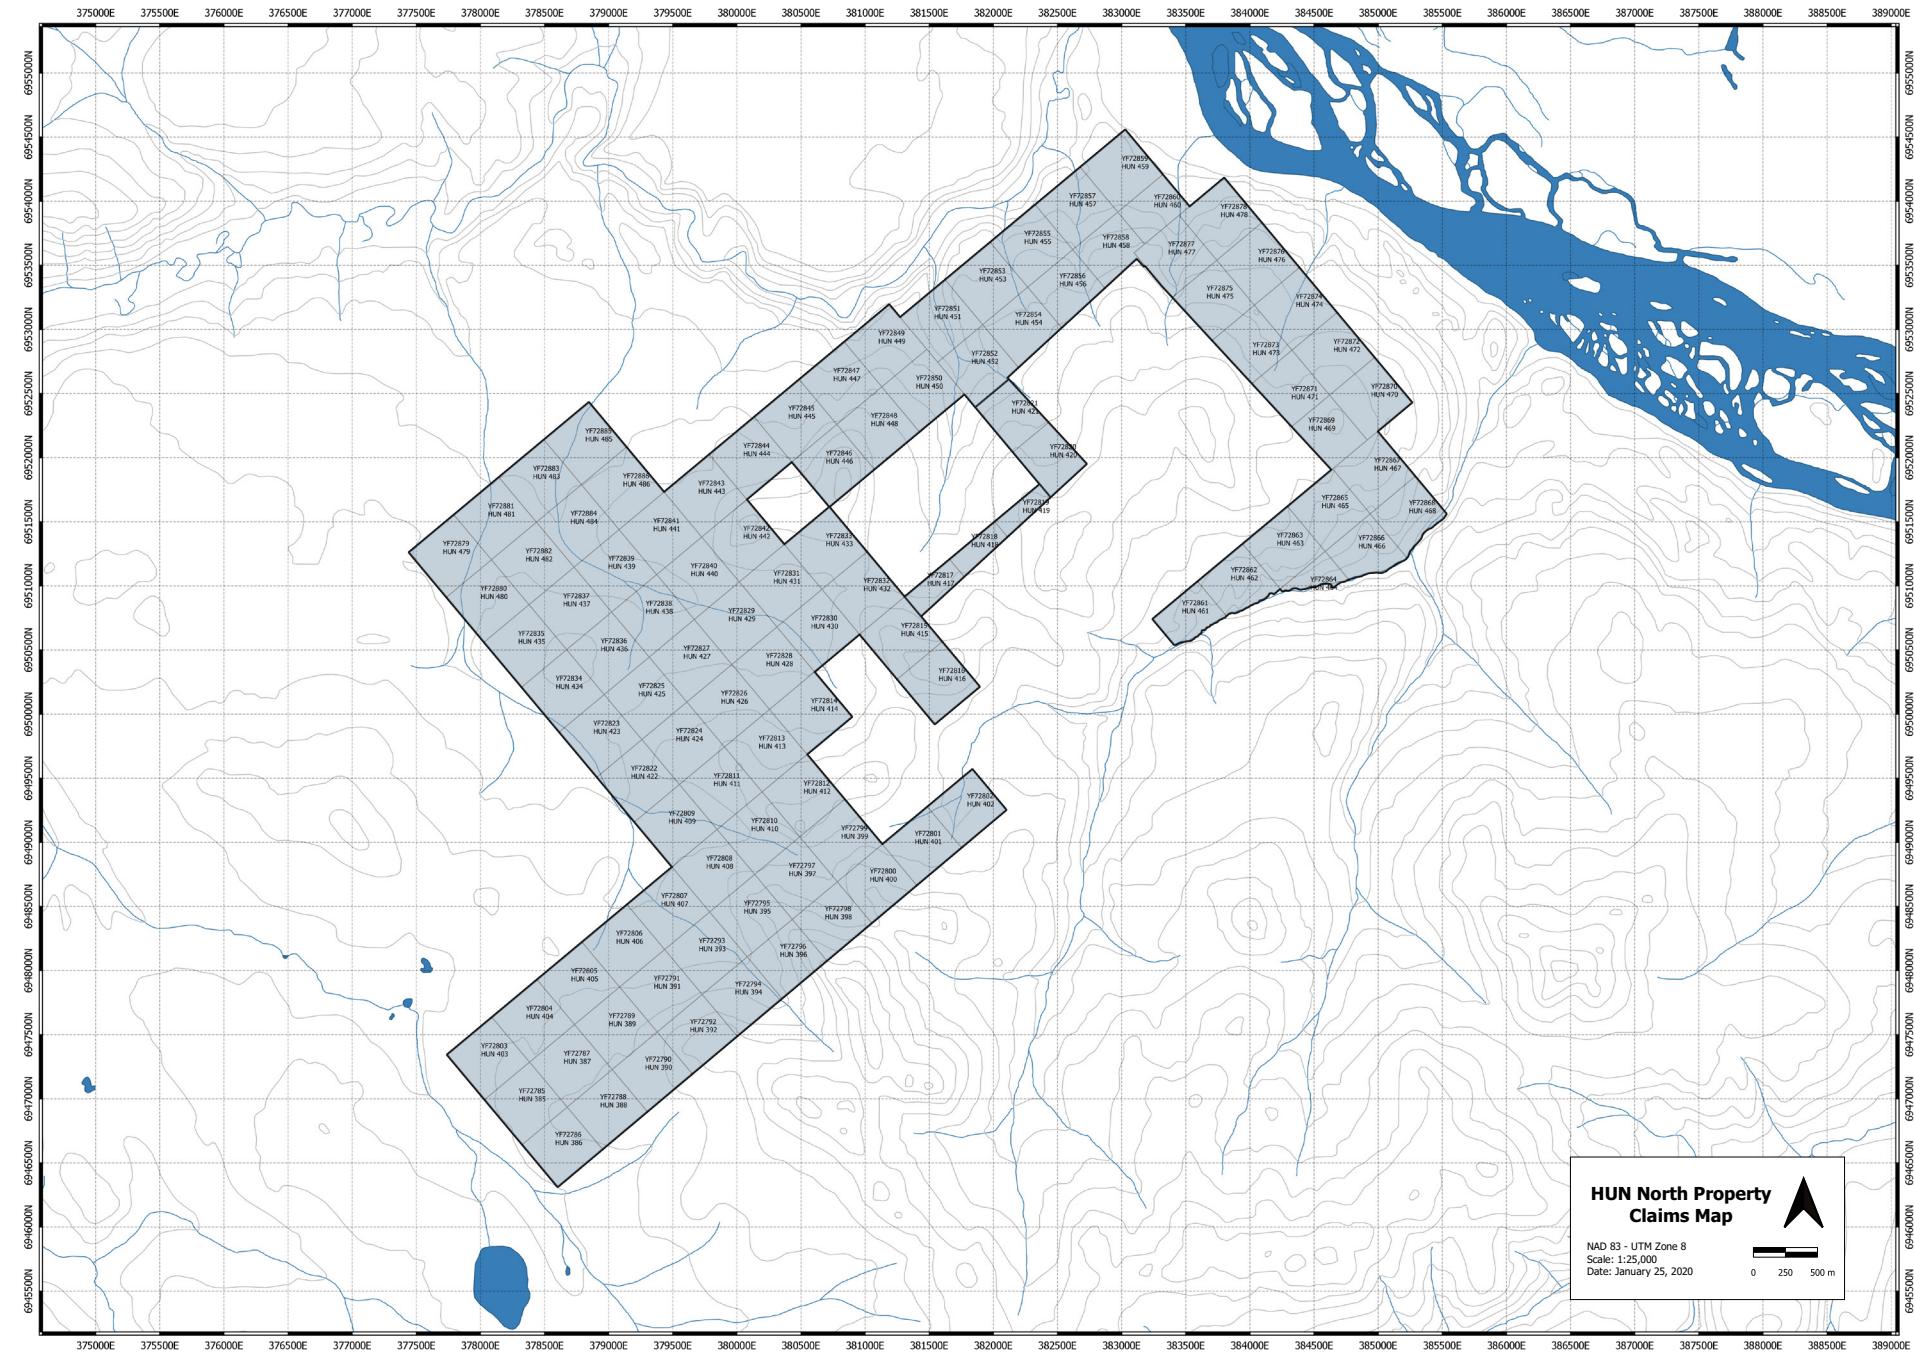

Figure 2. Location of the HUN North quartz mineral claims.

helicopter from the Minto Mine's airstrip, which is 6 km southeast from the HUN North property. Part of the HUN North project is accessible by a maintained trail located north of the Minto North pit.

Property History

The HUN North property (HUN claims 385-486) was staked in its current configuration on February 4, 2018. Portions of the current claim block have been previously staked as various properties including the Wain, Ori, Navajo, Spear, Mel, and Apex. Two major periods of work occurred in the area between 1972 – 1974, following the initial staking rush in the Minto Copper Belt, and later between 2006-2010. The current configuration of HUN North claims enclose the active MEL and APEX claims held by Minto Explorations Ltd. and BCGold Corp., respectively.

The following is a timeline summary of work programs which either completely or partially overlap the current HUN North property:

1972 – Soil sampling is performed over the Wain 1-64 claims owned by Wainoco Oil Ltd. which overlap with the southwest edge of the HUN North group (Archer 1972). A total of 1,012 samples were taken along an 800 x 200 ft grid and analyzed for copper, molybdenum, and silver. All samples returned silver values < 0.5 ppm and molybdenum < 1 ppm. A northwest-trending 3000 feet long by 400 feet wide linear zone of anomalous Cu values ranging from 40 to 100 ppm was identified in the northwest corner of the claim block. No further work was performed.

1972 – Soil sampling and geologic mapping were done on the Ori 1-64 claims owned by NRD Mining Ltd. which overlap with the central area of the HUN North claims (Archer 1972). Soil samples were analyzed for copper, molybdenum, and silver; however, no anomalous copper values were detected. All silver and molybdenum values were below detection limit.

1973 – Soil sampling was preformed on the Navajo Claim group. At the time of this program the Navajo claim group western half was owned by Black Giant Mines Ltd. and the eastern half was owned Tay River Mines Ltd. The Navajo group overlaps the central HUN North claims. Between the two halves of what would become the single Navajo claim group in 1974, 1,800 soil samples were taken and analyzed for copper. Several northeast oriented linear trends of anomalous copper values ranging from 40 to 1,440 ppm were identified in the south portion of the group (Nusbaum, 1974).

1974 – The Navajo claim group was fully owned by Black Giant Mines Ltd. during this time. A ground magnetometer survey was completed and followed by mechanical trenching and 818 m diamond drilling. Drilling and trenching was planned to follow up on coincident soil and magnetometer anomalies. Most work from the 1974 season occurred south of the current HUN North property boundary to the southeast of HUN North claims. Minor geologic mapping, prospecting and the upper boundary of the magnetometer survey overlapped with the current HUN North property. A total of 5 diamond drill holes ranging in depth from 140 to 200 m were completed aiming to intercept a zone of malachite and azurite mineralized biotite gneiss. The biotite gneiss was intersected in several holes; however, all grades were low with the best intersections being 0.26 Cu % over 0.3 m and 0.10 Cu % over 3.048 m (Nusbaum, 1974).

2006 – MMI and ICP geochemical soil sampling were conducted on the SPEAR 1-4 claims owned by S. Ryan which are currently contained within the northwest corner of the HUN North property. The goal of this program was to identify which soil geochemical method would best identify anomalous copper values. A total of 5 ICP and 5 MMI soil samples were taken at identical points for comparison; however, due to a lack of data the work was inconclusive. (Ryan, 2007).

2007 – A program of MMI soil sampling and prospecting was completed on the APEX 1-39 claims owned by S. Ryan and optioned to BCGold Corp. A total of four rock samples were collected on the APEX 28-39 claims, which are now covered by the Hun North claim group. All samples returned assays of < 0.03 g/t gold and < 0.01 % copper (Doherty, 2007).

2008 – A program of MMI soil sampling and prospecting was conducted on the APEX 1-39 claims. A total of 100 MMI soil samples were collected on the western block of the claims (APEX 28-39). A linear trend oriented to the northwest was identified in the southern portion of the APEX claims including one highly anomalous sample of 3200 ppb Cu (Newton, 2008).

2008 – A ground IP survey was conducted on the SPEAR 1-12 claims. Three moderately chargeable anomalies were identified, none of which correlated to previous soil sampling (Newton, 2008).

2008 – The majority of the land covered by the present HUN North property was staked as the MEL claims by Northern Tiger Resources Inc. who performed a program of soil and silt geochemical surveys and geologic mapping. As a result of a claim dispute between S. Ryan and Northern Tiger Resources Inc., Northern Tiger Resources was not able to claim the full area. A total of 2 rock, 102 soil, and 16 silt samples were collected across the property, none of which returned anomalous results (Schulze, 2008).

2009 – An airborne radiometric and magnetic survey was flown across the entire MEL block (encompassing both the MEL East and MEL West claim blocks and roughly matching the current HUN North property boundary). A ground IP geophysical survey was performed with soil sampling along the IP line in the NE corner of the MEL East claim block. No anomalous results were noted from any survey method, and east-west radiometric and magnetic trends were interpreted to be the result of regional geology.

2010 - A program including a ground IP geophysical survey and soil, rock, and silt geochemistry was conducted over the MEL East and MEL west claim blocks. A zone of anomalous soils samples was then revisited with a ground IP geophysical survey within the MEL East claim. In addition, 3 rocks, 55 soils, and 1 silt sample were also takenThe IP survey returned no anomalous features. (Ouellette and Pollries, 2011). A total of 5 soils and 1 silt samples were collected on the MEL West claim block, none of which returned anomalous values (Ouellette and Pollries, 2011).

Regional Geology

The HUN North property is located near the most northern apical junction of the Stikine and Yukon Tanana terranes within the Minto pluton (Figure 3). The Minto pluton encompasses a total area of 172 km² and comprises intrusive rocks of the Late Triassic to Early Jurassic Minto suite (ca. 204-195 Ma) (Colpron et al., 2015). The Minto suite contains inliers of deformed and metamorphosed rocks that host Cu-Au-Ag mineralization at the Minto mine, Carmacks Copper deposit, Stu prospect, and the VERLENE occurrence (MINFILE 115I 014). The occurrences form a 42 km-long, northwest-trending continuous belt that's referred to as the Minto Copper Belt (Figure 4) (Kovacs, 2018). Correlative, Mesozoic calc-alkaline to alkaline plutons of Stikinia and Quesnellia are known to host prolific porphyry Cu-Au ± Ag ± Mo deposits in British Columbia (Nelson et al., 2013; Logan and Mihalynuk, 2014).

The various plutons and batholiths of the Minto suite are generally located along the contact between mid-Paleozoic rocks of the Yukon-Tanana terrane to the west and Late Triassic rocks of the Stikinia terrane to the east. West of the Minto pluton, the Yukon-Tanana terrane is represented mainly by orthogneiss of the Mississippian Simpson Range plutonic suite (Mortensen, 1992). East of the Minto pluton, Stikinia is composed of volcanic and sedimentary rocks and local subvolcanic intrusions of the Upper Triassic Povoas Formation of the Lewes River Group (Figure 4) (Hart, 1997). The Povoas Formation in southern Yukon is characterized by variably deformed, green-schist to amphibolite facies augite porphyritic basalt, volcaniclastic rocks, and hornblende gabbro (Hart and Radloff, 1990). Near the HUN North property, the Minto suite is in faulted contact with both Stikinia and Yukon-Tanana terrane rocks. All units are overlain by younger conglomerates and intermediate to mafic volcanic rocks of the Late Cretaceous Carmacks Group and basalt flows of the Quaternary Selkirk Group.

Property Geology

The most common rock-type on the HUN North property is a K-feldspar megacrystic granodiorite that is interpreted to be part of the Minto suite (Figure 5). Preliminary observations in 2019 and previous reporting on the property suggest that the mappable sub-units underlying the HUN North property are similar to those noted elsewhere in the Minto pluton (specifically near the Minto Mine) and include: 1. equigranular, medium to coarse grained, biotite hornblende diorite, 2. K-feldspar megacrystic granodiorite, 3. centimetre to metre scale, variably oriented pegmatite dykes with lesser aplite. These intrusives units are overlain by massive to columnar jointed basalt flows of the Quaternary Selkirk Group along the north-northwest boundary of the HUN North property.

The 2019 mapping program on the project located several metre-scale outcrops of mafic schist, which may be xenoliths of the Upper Triassic Povoas Formation similar to those seen elsewhere in the Minto Copper Belt (Kovacs, 2018) (Figure 4).

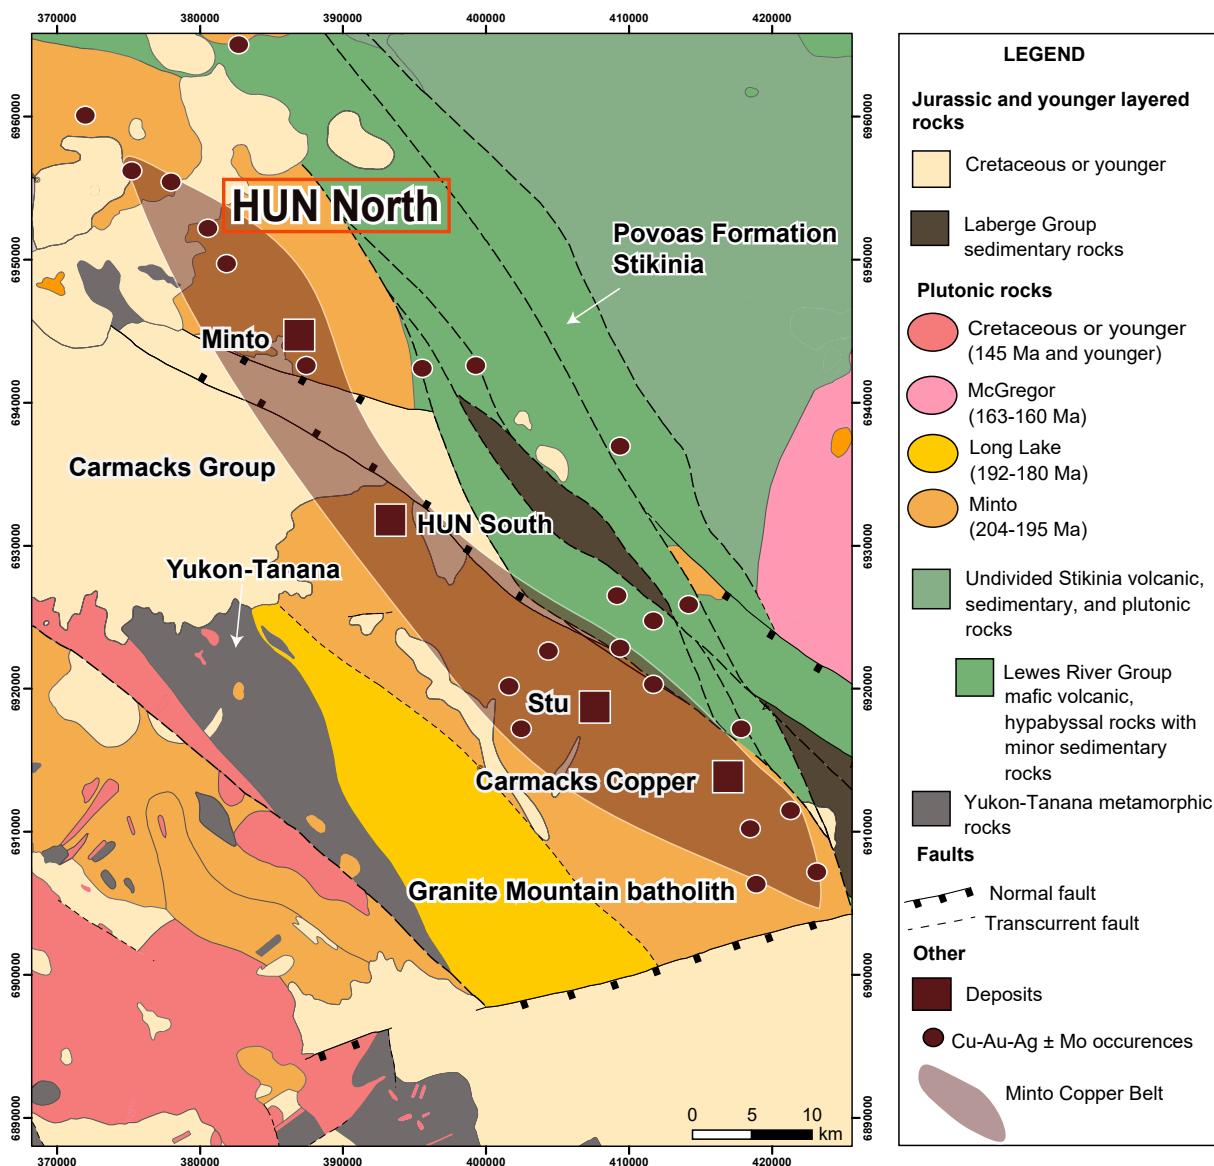

Figure 4. Regional geology map of the Minto Copper Belt.

Prospecting

Prospecting Overview

A total of 4 man-days – including 4 individual traverses measuring a total 5.5 km in length – were completed between September 11th to 14th, 2019 on the HUN North property focusing on ridges in the west-central property area.

Prospecting Procedure

Field prospecting was performed by trained geological technicians. Prospecting set outs were made by helicopter daily from the Minto Mine airstrip. Traverses focused on ridges due to the known scarcity of outcrop in the field area, and wherever possible were planned to intersect target areas and areas of previous work. Outcrops were collected as point data from Garmin brand portable GPS units in NAD 83 / UTM Zone 8. At each outcrop, data on lithology, time/date, and additional observations were recorded in a field notebook and later digitized. Original point data is available in Appendix II. Traverse lines and outcrops were later drawn from prospecting point data (Figure 6) and available ESRI imagery in QGIS 3.2.10 software.

Prospecting Results and Interpretation

Scarcity of outcrop and thick vegetation cover presented difficulties to the prospecting program. Prospecting confirmed the main regional unit in the HUN North area is the Late Triassic to Early Jurassic Minto suite. Locally, metre-scale outcrops of strongly foliated, quartz-plagioclase-biotite schist were observed in multiple locations on the HUN North property (Figure 6). These outcrops may potentially represent inliers of the Late Triassic Povoas Formation, which is the original host rock to the Minto-style copper-gold mineralization within the Minto Copper Belt (Kovacs, 2018); however, further investigation is required to confirm the origin of these foliated outcrops.

Future Recommendations

Exploration on the HUN North property remains challenging due to thick vegetation, scarcity of outcrop, and the variable cover of Quaternary Selkirk Group basalt flows. Furthermore, the temporal, spatial, and organizational discontinuity of various work programs also limit the interpretation of exploration results. Although, prospecting in the area did not encounter mineralized lithologies, the presence of the Late Triassic to Early Jurassic Minto suite proves to be a good indicator for finding mineralized rafts. As such, the HUN North property represents a highly geologically prospective area for Minto-style copper-gold mineralization which would benefit from a comprehensive review and compilation of previous work prior to targeted exploration. Recent developments in the understanding of copper-gold mineralization within the Minto Copper Belt (Kovacs, 2018) may allow for new inferences to be made from previous geophysical, geochemical, and geologic studies.

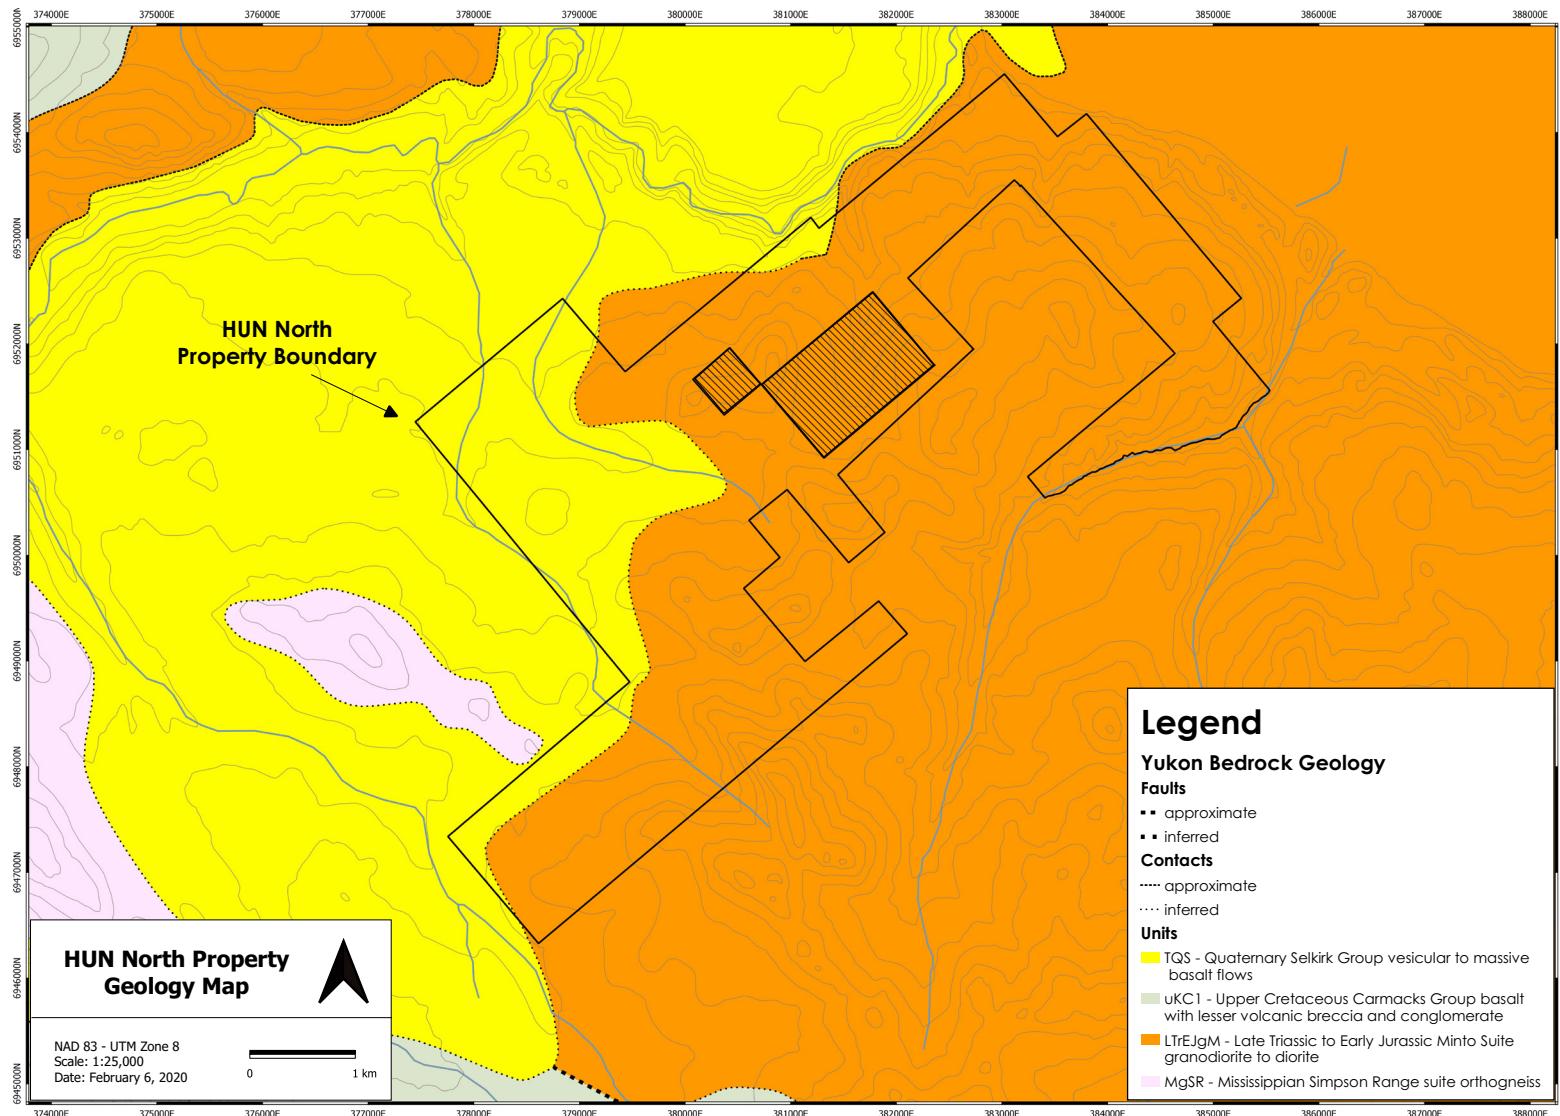

Figure 5. Bedrock geology map of the HUN North area showing the claim boundary (Yukon Geological Survey, 2020).

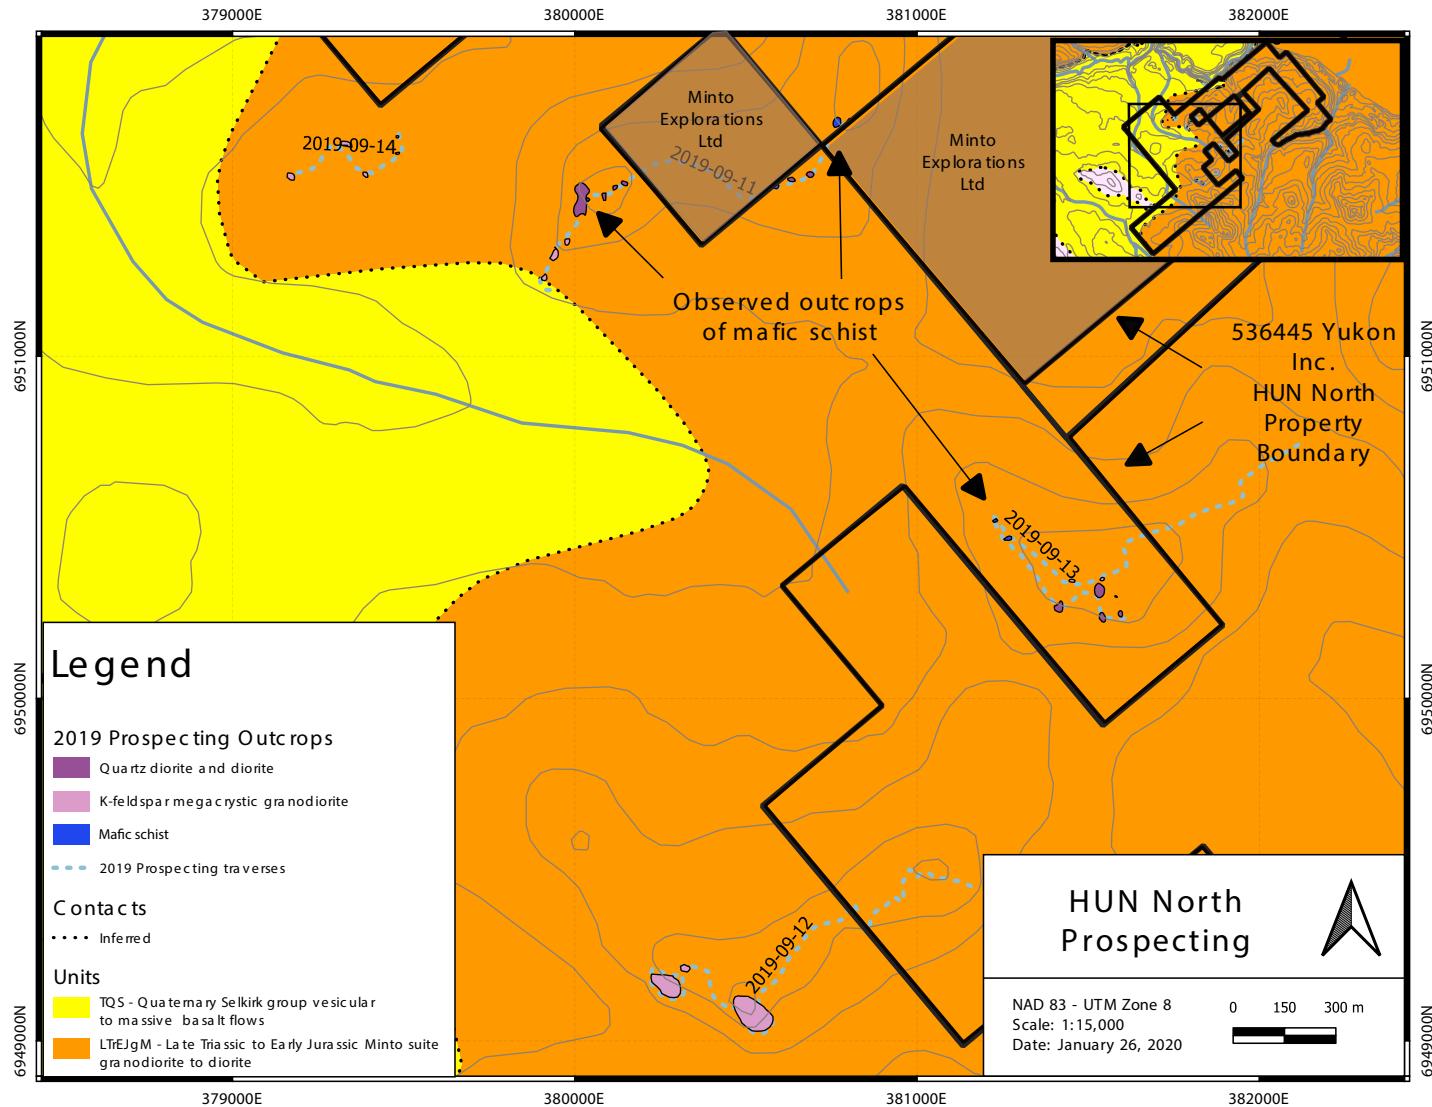

Figure 6. Geological bedrock map showing the prospected areas and outcrops during the 2019 exploration field season in the HUN North area (Yukon Geological Survey, 2020).

Future programs should focus on the follow-up and proper identification of known outcrops, particularly those of mafic schist in the northwest and centre of the property. Given the scarcity of outcrop exposure, geophysical and geochemical techniques including a UAV-MAGTM survey and MMI soil sampling should be considered. In particular, the area previously covered by the APEX 28 – 39 claims showed anomalous copper MMI results which would benefit from tighter MMI sample spacing and a high-resolution UAV-MAGTM survey to identify correlative anomalies.

Acknowledgments

The author would like to thank Stephen Bartlett, (BSc Hons, GIT) for the review of this assessment report.

Statement of Qualifications

I, Nikolett Kovacs, do hereby certify that:

I am a geologist, graduated from Memorial University of Newfoundland, Canada, in 2015 with a BSc Honours degree in Earth Sciences.

I acquired a MSc degree from the University of British Columbia in 2018 in Geological Sciences.

I am a Geologist In Training under the Professional Engineers and Geoscientists of Newfoundland & Labrador, registration G3862.

I am the director of 536445 Yukon Inc.

I am employed by Minto Explorations Ltd. as the Exploration Manager of the Minto Mine.

I have worked in mineral exploration and mining since 2011 and have related work experience in Canada, USA, China, Turkey, Georgia, and Eastern Europe.

I have been involved in the HUN exploration project from the beginning, supervising staking, data collection, interpretations, and the preparation of this assessment report.
