	Log of D.D.H. #18-4	1 inch = 20 feet

SUMMARY

Northlake Mines Limited of 11-425 Howe Street, Vancouver, B.C., acquired from Grassy Lakes Syndicate 560 mineral claims in the Grassy Lakes area of the Watson Lake Mining Division, Yukon Territory. These claims were staked in January 1966. From information gained by compilation of available data plus that obtained by reconnaissance work an additional 264 claims were staked to bring their total number of claims in the area to 824 as of July 25, 1966.

MacDonald Consultants Limited were retained by Northlake Mines Limited to manage a geological, geochemical, geophysical and physical work program under the direction of Dr. P. H. Sevensma, P.Eng.

The exploration program was started by conducting an airborne combined magnetic-electromagnetic survey over the entire claim area. Lockwood Survey Corporation Limited conducted the survey using helicopter-borne equipment, under the supervision of Dr. Sevensma.

The claims were then divided into 19 separate areas of interest (figure 1). Each of these areas contained an airborne geophysical anomaly and/or a mineralized showing that warranted further investigation.

Areas were then selected for gridding and line cutting was carried out on these. The cut grids were surveyed, tied into local topographical features, and then plotted onto a 1000 scale base map that had been prepared by McElhanney Surveying & Engineering Limited.

A geochemical survey was conducted over the grids as it was felt that a preliminary soil sampling program would give an indication to possible vein zones and would define areas for closer follow-up work. In addition to the soil sampling all of the streams draining the area were silt and/or pan sampled.

Geological mapping of the grid areas to 1000 scale plus a preliminary geological reconnaissance of the whole area was conducted. This information was used as an aid in the interpretation of the geochemical results.

Hand trenching was done in one area in conjunction with physical prospecting, and one area containing both an airborne and a ground geophysical anomaly was diamond drilled.

PROPERTY

The properties acquired by Northlake Mines consist of the following claim groups (figure 1):

1. Gee Group. 400 claims. Staking sheets 105-G-6 and 105-G-7

Gee 1-80	Grant Nos. 90172-90250 & No. Y2004
Gee 81-88	Grant Nos. Y2002, Y2003 & Y2005-Y2009
Gee 89-400	Grant Nos. Y2010-Y2321
Gee 401-530	Grant Nos. Y7103-Y7232

2. El Group. 60 claims. Staking sheets 105-G-6 and 105-G-11

El 1-60	Grant Nos. 90012-90071

3. Hoo Group. 123 claims. Staking sheet 105-G-12

Hoo 1-100	Grant Nos. 90072-90171
Hoo 101-123	Grant Nos. Y13368-Y13390

4. P.G. Group. 16 claims. Staking sheet 105-G-6

P.G. 1-16	Grant Nos. Y13352-Y13367

5. P.S. Group. 40 claims. Staking sheet 105-G-7

P.S. 1-40	Grant Nos. Y7854-Y7893

6. Z Group. 2 claims. Staking sheet 105-G-6

Z 1 & Z 2	Grant Nos. Y13085 & Y13086

7. C.W. Group. 23 claims. Staking sheet 105-G-6

C.W. 1-4	Grant Nos. Y13081-Y13084
C.W. 5-23	Grant Nos. Y13333-Y13351

8. Leo Group. 30 claims. Staking sheet 105-G-6

Leo 1-6	Grant Nos. Y13087-Y13092
Leo 7-14	Grant Nos. Y13125-Y13132

LOCATION

All claim groups are located in the Watson Lake Mining District, on N.T.S. 105-G, Finlayson Lake map sheet between 61°20' to 61°32' north, latitude and 130°50' to 131°37' west longitude. The property lies between 10 and 25 miles south of the new Watson Lake-Ross River road and approximately 60 miles east of Ross River.

HISTORY

Nothing is recorded about the early phases of exploration in the area but several old cabins and the remnants of placer workings were discovered. It is probable that the early placer miners passed through and investigated all the creeks and streams in the area for gold around the turn of the century.

The first recorded activity occurred in 1954 shortly after the discovery of the Vangorda Creek lead-zinc deposit. Mr. K. G. Sanders and R. Zielinski initially prospected the Grass Lakes area for Pelly River Explorations Limited, a subsidiary of Pioneer Gold Mines of B.C. Ltd. Nine mineral showings of interest were found in the area now covered by the Gee claims. Some short fibre asbestos was also found in the area now covered by the El group. They also reported minor galena-sphalerite float in limestone and some chalcopyrite in quartz in the vicinity of the Hoo claims. Three showings, the Pit, Rob and Gyp, were staked at that time.

In 1955, the Pit and Rob showings were optioned to Transcontinental Resources of Vancouver, B.C. A ground magnetometer survey was carried out over both showings under the supervision of Andrew Allan, who reported four (4) magnetic anomalies on the Pit and who recommended trenching and stripping. This work was not carried out and the claims were allowed to lapse in 1957.

In 1955, Newmont Mining Corporation prospected the area immediately north and east of the one covered in 1954 by Pelly River Explorations Limited. They reported sulphide float in the vicinity of the Hoo claims. The short fibre asbestos showings now covered by the El claims were staked, but no assessment work was carried out.

Reconnaissance mapping on a scale of 1" = 4 miles was carried out on the Finlayson Lake map sheet in 1958 and 1959 by J. O. Wheeler, L. H. Green and J. A. Roddick of the Geological Survey of Canada. This work was published as map 8 - 1960.

In 1961, the Geological Survey of Canada had an airborne magnetic survey carried out over the Finlayson sheet, the results of which were published in 1963 as map 7006 G on a scale of 1" = 4 miles.

In January 1966, the known showings in the Grassy Lakes area were staked by Grassy Lakes Syndicate of Vancouver, B.C. under the direction of the original prospectors Sanders and Zielinski. These claims were subsequently acquired by Northlake Mines Limited.

There has since been other staking activity and exploration programs were conducted by Riviera Mines Limited, Kerr Addison Mines Ltd, and Atlas Exploration Ltd. in the same general area.

GENERAL GEOLOGY

The general geology of the area has been described by J.O. Wheeler, 1958, 1959; L. H. Green and J. A. Roddick, 1959, map sheet 8 - 1960.

The predominate rocks in the Grassy Lakes area are quartz biotite, quartz-chlorite schist, micaceous quartzite, hornfels, minor phyllite, dolomite, micaceous quartzose gneiss, granitordal gneiss and minor quartz biotite schist.

I GEOLOGICAL SURVEY

A. Detailed Geology

The area is for the most part drift covered and in many instances mapping was done from observation of slide rock or felsenmeer. There is approximately 30% outcrop in the area although fairly good geological sections can be obtained from the scarp faces and on the higher mountains.

The area under consideration forms part of the Anvil Range - Finlayson Lake belt of quartz micaschist and slate rocks as described on G.S.C. Map 30 - 1963. This Finlayson Lake belt contains a greater abundance of serpentinized dunite than the Anvil Range to the northwest and an increase in quartzite and grits and a decrease in mica schist and graphite schist from north to south. In addition there is granitic gneiss present in the Finlayson Lake Belt. There are also numerous small granodiorite masses. In general, a progressive lithological change is indicated from north to south.

B. Structure

The dominant structural configuration is the Tintina Fault. This fault is not visible on the surface but shear faults were encountered in diamond drilling which are assumed to be associated. The fault valley trends northwest-southeast and in this vicinity parallels the Hoole River. There has been considerable folding, faulting and weathering of the beds. The true structure of the area is unknown as the dedrital cover (Pleistocine) obscures most rock. There were no extrusive rocks found in the area.

C. Mineralization

Prospecting and geological mapping found several mineralized locations. These have been plotted on the accompanying maps. Following is a brief description of each area and of any mineralization found therein:

Area #1: minor pyrite in quartz vein material and some pyrrhotite specks in float.

Area #2: 3 showings were located here and were designated as 2, 2a and 2b.

No. 2 - this is a strong gossan zone, approximately 100 x 200 feet in area on the east slope of the mountain near a granite gneiss - limonitic schist contact. Granite and schist bedrock in place. Heavy float of nearby massive pyrrhotite with small blebs and specks of chalcopyrite were found in 3 separate locations within this area. An attempt was made to trench where the float was picked up but due to excessive overburden and permafrost, bedrock could not be reached. Samples of float were assayed but results were negative.

No. 2a - this is a three foot wide dissemenated quartz vein with minor amounts of arsenopyrite and pyrrhotite in the hanging wall.

No. 2b - this showing consists of disseminated and blebs of pyrrhotite and chalcopyrite in a dark green host rock resembling amphibolite. The gossan zone (100 feet x 50 feet) can be spotted from the air. Samples takenhere gave negative results when assayed, ie trace nickel and copper.

Area #3: a silicified mineralization zone was located here but very little of it was exposed from under snow which remained all season. Float containing replacement type mineralization, galena, sphalerite, pyrrhotite, pyrite, and small blebs of chalcopyrite, was picked up. Assays of float material were negative.

Area #4: a small lens of replacement mineralization (galena, sphalerite and chalcopyrite) was located in the schist near the contact with granite gneiss but was of no consequence. A few pieces of pyrrhotite float picked up in the creek below this showing were assayed with negative results.

Area #5: several small quartz veins carrying galena were found cutting the schist in this area.

Area #6: the showing in this area is located at approximately 6000 feet. It is a small showing containing arsenopyrite and very minor chalcopyrite mineralization. Assays were negative.

Area #7: a large gossan zone caused by widespread mineralization of pyrite and pyrrhotite in the granatoid gneiss was observed here. Several quartz veins carrying minor arsenopyrite were located. Some pyrrhotite, chalcopyrite and bornite was observed in place. Float carrying sphalerite, a little galena, arsenopyrite, and chalcopyrite was picked up above the small lake in the centre of the area. Gangue quartz caused by faulting in the area and dolomite were the hosts for this replacement mineralization. Assays were low grade.

Area #8 and #9: a few pieces of quartz float having minute specks of chalcopyrite was found in this area. These were of no consequence. No assays run.

Area #10: arsenopyrite and chalcopyrite float were found in the northern portion of this area. However,the geological examination and mapping did not detect the source for the float, but it probably came from the crest of the mountain near area #6.

Area #11, 12, 13, 14, 15 and 16: there was no mineralization detected in any of these areas.

Area #17: Asbestos float was found in this area at 3 locations and asbestos in place at one. The asbestos examined is spicky and short fibred and would not be commercial. A gossan zone was spotted just outside the claim group to the southeast. This appears to be the source rock for a very good copper anomaly picked up in the creek by geochemistry. Ah additional 30 claims were staked over this area in January of this year.

Area #18: no economic mineralization was found here either by prospecting or in any of the 4 diamond drill holes that were drilled to test an airborne, and supporting ground geophysical anomaly. Some pyrite, arsenopyrite, mareposite and a little chalcopyrite were discovered but assays of the core gave insignificant results.

Area #19: there was no mineralization found in this area.

II GEOCHEMICAL SURVEY

A. Grid Detail:

Grids were cut over 12 of the 19 areas of interest for a total of 127.3 line miles.

Area #2: 4.2 miles. Baseline and 400' spaced cross lines.

Area #5: 23.4 miles. Baseline, cross lines at 400' intervals and tie lines both north and south.

Area #8 and 9: 2.3 miles. Baseline with cross lines at 400' intervals.

Area #10: 37.6 miles. Baseline, cross lines at 400' intervals and tie lines on both the east and west sides.

Area #11: 12.5 miles. Baseline with cross lines at 400' intervals.

Area #12: 8.2 miles. Baseline and tie line with cross lines running between at 400' intervals.

Area #13: 7.5 miles. Baseline and tie line with cross lines running between at 400' intervals.

Area #14: 4.0 miles. Baseline and tie line with cross lines running between at 400' intervals.

Area #15: 2.5 miles. Baseline with cross lines at 800' intervals. No tie lines.

Area #16: 3.0 miles. Baseline with cross lines at 400' intervals.

Area #18: 14.0 miles. Baseline and tie lines both north and south with cross lines at 400' intervals.

Area #19: 8.1 miles. Baseline and tie line, with cross lines running between at 800' intervals.

B. Sampling:

A total of 4615 soil samples were taken from 11 grid areas. Size of the grid plus the terrain over which it was laid governed the sample spacing. In conjunction with the soil sampling all streams making up the drainage of the area were sampled and/or panned at approximately 800 foot spacings. 653 pan/silt samples were taken. All samples were tagged and bagged in polyethylene bags. They were then shipped to Bio Metals Corporation Limited (N.P.L.) in North Vancouver, B.C. to be analysed for lead, zinc and copper.

Samples were taken from areas as follows:

Area #2:	129 soil samples	
Area #5:	1600 soil samples	
Area #8 & 9:	123 soil samples	
Area #10:	1082 soil samples	
Area #11:	364 soil samples	
Area #12:	189 soil samples	
Area #13:	165 soil samples	
Area #14:	202 soil samples	
Area #15:	204 soil samples	
Area #16:	128 soil samples	and 8 silt samples within grid.
Area #17:	192 silt samples	were taken encircling the whole area
Area #18:	22 silt samples	were taken. No soil samples
Area #19:	25 silt samples	and 421 soil samples were taken.

Drainage samples: 653 including those taken from areas 17, 18 and 19 listed above.

C. Method of Analysis:

All samples were analysed at the Bio Metals Corporation Limited (N.P.L.) laboratory located at 204 - 1515 Pemberton Avenue, North Vancouver, B.C. Samples were shipped periodically from Whitehorse via C.P.A. air freight.

When the samples were received by the laboratory, each was dried and then screened to - 80 mesh. A 0.5 gram sample was weighed out and digested in hot aqua regia. They were then diluted, clarified for 20 hours and then tested for copper, lead and zinc content on an atomic absorption spectrophotometer. The "AA" unit used was an 'Evans' manufactured by Evans Co.of Essex, England. Accuracy of this instrument ideally is 1.5 ppm, 0.05 ppm & 0.15 ppm/% absorption for lead, zinc and copper respectively. Individual cathode lamps were used for each element and results were reported in parts per million (ppm).

D. Treatment of Data:

The results of geochemical tests were returned airmail to the field as soon as they were available. The values in ppm were plotted onto field maps and contoured to see whether any areas required follow-up sampling.

In contouring results a background was determined from the % frequency of occurrence of results in ppm. This information was used as a control for detailed mapping and prospecting.

E. Interpretation of Results

All samples taken were analysed for lead, zinc and copper. It was found that copper values (anomalous) were slightly erratic but a definite pattern developed as it was found that they seemed to reflect areas of ultrabasics. There were several good anomalies of copper found though. Silt samples from area #17 gave results up to 7562 ppm. Soil samples taken from area #11 gave copper readings to 409 ppm and seem quite significant due to the lack of ultrabasic intrusives in the area. There were several isolated copper highs in area #19 but more work is required here to define them.

Lead indicated several veins in the vicinity of area #5 which were proven to exist by visual prospecting. These do not appear to be significant at this time but further work should be done in this area.

F. Conclusions and Recommendations

Conclusions and recommendations are made in Dr. Sevensma's report which follows the physical work section of this report.

III GEOPHYSICAL SURVEY

A. Airborne Geophysics:

The airborne geophysical survey was conducted by Lockwood Survey Corporation Limited under the supervision of Dr. P. H. Sevensma, Ph.D. P.Eng. The actual field work was broken into three separate programs by claim groups. These were the Hoo, El, and the Gee groups of claims.

Following are three separate reports written by Dr. Sevensma covering each of these programs. Also on the Gee group of claims nine small showings were checked using the Gee Cal helicopter-borne electromagnetic method. Details of this survey are included in Dr. P. H. Sevensma's report "Airborne Geophysical Methods" - Gee Group of Claims.

B. Ground Geophysics:

1. Summary

Huntec Limited of Toronto were contracted to carry out ground electromagnetic surveys on Northlake Mines ground in the Grassy Lakes area. Huntec completed surveys on these grids as follows:

Area # 5: Horizontal loop E.M. survey using the Ronka Mark III unit.
Area #10: Turam Inductive Loop E.M. survey.
Area #18: Turam Inductive Loop E.M. survey.

The methods of conducting these surveys is explained in a separate report contained herein as written by Norman R. Patterson, Ph.D., P.Eng.of Huntec Limited.

Huntec's operator for the Ronka Mark III Horizontal Loop E.M. unit left their employ on July 29. The operator, Mr. Meryl Currie, had trained one of Northlake Mines employees to operate this unit. It was felt by MacDonald Consultants Ltd. that this man was competent enough to operate this E.M. unit and surveys were conducted on the following grid areas: No. 10, No.11, No. 14, No. 15 and No. 19. Maps of these five surveys are included in this report.

United Geophysical were contracted and a small gravity survey was run over the soil anomaly on area #11 but results were inconclusive. A larger more detailed survey will have to be conducted before a true interpretation could be made.

2. Conclusions and Recommendations:

See Dr. Sevensma's report of Conclusions and Recommendations following the physical work section.

IV PHYSICAL WORK

A. Trenching

Trenching employing the use of a drill and explosives was carried out on showing No. 2 in area #2 on Mineral claim numbers Gee 173 and 174.

A total of 95 cubic yards of rock and frozen material was excavated in 9 trenches. Bedrock was not reached in any of the trenches due to the permafrost and the depth of the slide rock covering the area.

One sample of nearly massive pyrrhotite from one of the trenches was assayed spectrographically.. Results were negative.

B. Diamond Drilling

Four fiamond drill holes were drilled on the Hoo claim group for a total of 1596 feet of AQ wire line. The contractor was A. Arsenault Diamond Drilling of Whitehorse.

There was 565 feet of AX casing, 186 feet of BX casing, 86 feet of NX casing, as well as 8 cement jobs and 4 dip tests run.

All diamond drill holes have been surveyed and plotted on topographical map.

CONCLUSIONS AND RECOMMENDATIONS

See Dr. P. H. Sevensma's report which is attached hereto.

APPENDIX

APPENDIX

Summary of 1966 Assessment Work and Costs

In order that a better understanding may be had of the following breakdown of costs a few notes of explanation will be made here:

Note #1: Costs are broken into two sections; directly chargeable and not chargeable to a specific project.

Note #2: Section 1 is broken down into three separate claim areas - (1) El claims; (2) Hoo claims and (3) Gee claims, which includes the P.G., C.W., Z, Leo, and P.S. claims which are contiguous.

Note #3: Section 2 is distributed to the three claim groups by the percent claims in each group, i.e.,

EL	60/824	or 7.3%
Hoo	124/824	or 14.9%
Gee	641/824	or 77.8%

Note #4: Complete cost breakdowns follow in the included job cost account journal. This journal has been audited to December 31, 1966. Accounts payable from January 1st to the present have not been included in the assessment costs.

SECTION A (directly chargeable)

El Group	$ 7,736.96
Hoo Group	58,746.70
Gee Group	84,958.41
TOTAL	$151,442.07

SECTION B (not directly chargeable to any specific project)

El (7.3%)	$ 5,775.52
Hoo(14.9%)	11,788.39
Gee(77.8%)	61,552.78
TOTAL	$ 79,116.69

TOTAL MONIES APPLICABLE AS ASSESSMENT WORK:

$230,558.76

El	$ 16,830.79
Hoo	34,353.26
Gee	179,374.71

AFFIDAVIT OF COSTS

I, R. T. HEARD, of 11 - 425 Howe Street, Vancouver 1, Province of British Columbia, HEREBY MAKE OATH AND SAY:

That the cost statement on page 11 of the Geological, Geochemical, Geophysical and Physical Work Report on the El, Hoo, Gee, Leo, P.S., P.G., C.W. and Z Claim Groups, to the best of my knowledge and belief, is the true amount of monies spent on the 1966 exploration program of the said Claims.

SWORN before me at the City of Vancouver, Province of British Columbia, this 7th day of February, A. D. 1967.

A Commissioner for Oaths for the Yukon Territory.

Dear Sir:

Re: Northlake Mines Ltd. (N.P.L.)

At the request of MacDonald Consultants Ltd. we have summarized on the attached sheet the expenditures for the period from May 18, 1966 to December 31, 1966 made by MacDonald Consultants Ltd. on behalf of Northlake Mines Ltd. (N.P.L.) from the records maintained by MacDonald Consultants Ltd.

Yours very truly,

H. M. C.

Watson Lake M.D., Y.T.

REPORT ON AIRBORNE GEOPHYSICAL SURVEY

MAY 8 - 23, 1966

1. INTRODUCTION

In early 1966, Northlake Mines acquired several large claim blocks located in the general Grass Lake area, in a belt stretching from the Hoole River in the Tintina Trench in a Southeasterly direction towards the Grass Lakes. (Figure 1)

An exploration program on these claims was initiated by flying a combined magnetic-electromagnetic survey using the helicopter-borne Lockwood Survey Corporation method.

The present report deals with the results of this survey on the El Group, where a total of 82 line-miles were flown.

2. PROPERTY

The property consists of the following claims:

El 1 - 60	Grant Nos. 90012 - 90071
El 61 - 90	Grant Nos. Y17292 - Y17321

The El Group is located about four miles East of the Tintina Trench, and centered on some 6500' high serpentine mountains at approximately 61°28'N, and 131°21'W.

The claims lie between elevations of 4200' and 6500', about 15 airmiles South of the Watson Lake to Ross River road and about 2 miles South of some lakes accessible by fixed wing.

The airborne survey was carried out from a camp on Grass Lakes, but due to poor weather conditions, Ross River had to be used as a secondary base.

3. HISTORY

There is no record of the early phase of exploration in the area. Old cabins and remnants of placer workings were found near the mouth of the Creek draining the SW slopes of the El claims, and in all probability many creeks in the area have been investigated by the early placer miners for gold around the turn of the century.

Following the discovery of the Vangorda Creek lead-zinc deposits, the area of the present claims was examined in 1954 by Messrs. K.G. Sanders and R. Zielinski for Pelly River Explorations Limited, who noted the presence of short-fibre asbestos. No action was taken as a result of that discovery at that time.

The El claims were staked in January 1966 by the same prospectors and subsequently, these claims were acquired by Northlake Mines Limited.

4. REGIONAL GEOLOGY

During the last ten years, the Geological Survey of Canada has been very active in reconnaissance mapping on a scale of 1" = 4 miles of large areas in the Yukon. In addition, large areas have been flown aeromagnetically.

As a result of the correlation of the 1" = 4 mile mapping, new concepts on the age of various rock belts have emerged. The newer concepts have been published in 1964 on a map of the Yukon and the N.W.T. on a scale of 1: 3,000,000, map 30-1963, which has served the writer as a base for figure 1.

The area under consideration forms part of the Anvil Range - Finlayson Lake belt, a belt of metamorphic rocks characterized by extensive mica schist formations and varying amounts of ultrabasic bodies. In the Finlayson Lake area there are also a number of masses of gneiss of unknown origin.

Broadly speaking, the schistose formations, probably of Mississippian age, form a definite belt, although the relationships between the more intensively metamorphosed gneissic rocks and the much lesser metamorphosed schists is not clear. In addition, the degree of metamorphism decreases very gradually from South to North throughout the area pictured on figure 1.

A persistent characteristic of the belt is the presence of the ultrabasics, and 1966 fieldwork has indicated to the writer that these rocks are often associated with very low-grade meta-chlorite schists, slates and even argillites, frequently accompanied by significant amounts of graphitic schists, which occasionally form zones of true graphite slates.

As the change from the more highly metamorphic schist-gneiss assemblages to the less metamorphic slates and argillites is often very sudden but hidden by overburden, it is probable that significant tectonic features have so far remained undetected.

In addition, in the general area of the Northlake holdings, there appears to exist a significant change in tectonic style between the very flat lying schist-gneiss areas and the more steeply dipping slate-ultrabasic assemblages.

Notwithstanding these perhaps very significant differences, the overall characteristics of the schist-ultrabsic association is similar throughout large areas of the central Yukon.

The tudy and correlation of these belts has led to the concept that the Anvil Range - Finlayson belt is nothing else but the offset by the Tintina Fault of the Klondike schists with a right-lateral movement of about 250 miles (G.S.C. paper 65-2, page 57).

There is therefore a good reason to consider these schists an economically very productive unit, as the Klondike has produced some 250 million dollars of gold, and in the Anvil Range, massive sulphide bodies outlined sofar total at least something of the order of 60 million tons containing better than 10% zinc and lead combined with a gross total value of some 1.5 to 2 billion dollars in base metals and silver.

Significant ore-deposits are usually associated with major structural disturbances, and in the area under consideration the regional geology (figure 1) suggests a large regional E-W striking fold within the normal NW-SE trend of the formations.

Also, geologically and topographically, the area has the characteristics of a recently uplifted dome, and the trend of the valleys suggests pronounced fracturing and faulting along N-S and NE-SW cross-trends; both these features are present in many ore-bearing districts. And as a number of small showings are known in the Fire Lake-Northlake-Grass Lake area, some of them of the strata-bound type, this district is considered an excellent target area for exploration for massive sulphide deposits with base metal values.

These various factors have led to the choice of a combined magnetic-electromagnetic airborne survey as a method well suited to an area with extensive but relatively thin overburden covering structures and lithologies favorable for the occurrence of massive sulphide bodies.

5. LOCKWOOD AIRBORNE METHOD

This method will detect formations that are electrically conductive, and subsequent work can then be concentrated over and near these zones, by using geochemical and geophysical reconnaissance methods.

This method of initial reconnaissance is particularly suited to areas without a well defined drainage pattern along which streamsilt sampling could provide complete initial reconnaissance. It is also the best tool for areas with relatively extensive overburden and few outcrops.

The Lockwood method uses a single frequency of 4000 cps to generate a primary electromagnetic field. The transmitter loop is carried in a fibreglass bird and is oriented with the loop axis parallel to the direction of flight. A receiving loop is located 30' away in the other end of the bird; the loops are coaxial.

The bird is suspended at the end of a 70' cable and is towed by a helicopter at an elevation of 100' above the ground.

A magnetometer of the Gulf Mark III type, also located in the bird, measures the total intensity of the magnetic field.

Recorders and a positioning camera are carried on the helicopter and are handled by an operator who indicates to the pilot the planned course plotted on 1" = 1320' airphotographs and who marks fiducial points on the recorder's strips.

In general, the flight lines are laid out at right angles to the strike of the formations and at distances varying from 600' to 1500' apart.

If a conductive body in the ground is crossed by the helicopter carrying this equipment, the primary electromagnetic field creates eddy currents in this conductor which cause the generation of a secondary electromagnetic field. This secondary field is generally of the same frequency as the primary field but out-of-phase with it; it is detected by the receiver loop in the bird.

As a variation in the distance between the transmitter and the receiver coils will create a strong in-phase response, both coils are in a fixed position in the relatively rigid bird. This will eliminate false responses. Increasing out-of-phase responses will be obtained over bodies of low to medium conductivity; as the conductivity increases beyond the medium range, this out-of-phase response falls off again.

In-phase responses are increasingly stronger as the conductivity rises from poor to very high.

The strength of the response is measured in parts per million. For the above-cited reasons, the ratio of the in-phase to the out-of-phase responses is less than one for bodies of poor to medium conductivity and increases rapidly as the conductivity varies from medium to high.

The response is also a function of the size of the conducting body and of the distance from the bird to it.

The maximum distance at which a highly conductive body of large size will give a response is still somewhat unknown, but appears to be about 300' between the bird and the top of the conducting body.

Various geological bodies are electrical conductors and geological conductors are manifold and of greatly varying size, shape and conductivity, the latter often being a function of the internal texture of the conductor.

Some examples of conducting bodies are:

Massive pyrrhotite
Massive pyrite
Disseminated pyrrhotite and/or pyrite
Graphitic schists
Talc schists, especially when wet
Chlorite (serpentine) schists
Wet overburden in swamp
Lake-bottom deposits
Wet shears

Due to their schistose nature, graphitic schists may be excellent conductors if the individual graphite flakes form a conductive layer.

Massive sulphide bodies with 10 - 20% interstitial quartz may be excellent conductors if the main sulphide is pyrrhotite and if the individual grains of sulphide have large contact areas.

Their conductivity drops off rapidly if the main sulphide is pyrite and if the individual iron sulphide grains are isolated by interstitial non-conductors like silica or sphalerite.

For these reasons, a combined magnetic - electromagnetic airborne survey is essentially a geological mapping tool, especially so as the amount of magnetite in rock is even more of a geological variable than conductivity.

The reliability of the method is principally a function of the elevation above ground that can be maintained. Correlation of responses on adjacent lines flown at different elevations, due to weather or topographical conditions, may not be satisfactory. This happens if the survey if flown with too light a helicopter.

Providing the bird is flown at a steady elevation above the ground, interpretation of airborne data is largely a function of the geological conditions.

Different geological environments will lead to different appraisals of quantitatively very similar airborne geophysical responses.

In general, experience has shown that long conductors (several thousand feet or several miles) with relatively low ratios of 1 or less are likely to be of a formational nature, like graphitic schists. Smaller conductors of better than 1, or preferably 2, ratios may represent near-surface sulphide occurrences.

In certain areas, coincidence of magnetic and electromagnetic highs is critical because of an association of sulphides and magnetite. Most magnetic highs are however a reflection of increased magnetite content of the underlying rock formations, and high magnetic readings may have no more than a very indirect relationship to unusual sulphide concentrations in any given area.

Other geological factors complicating a qualitative interpretation are, for example, the frequent association of graphite and sulphide bodies or the presence of sulphide deposits the mass of which is buried beyond the range of the electromagnetic field but that do have a small near-surface expression.

An airborne geophysical survey should therefore be considered as a mapping tool enabling the exploration effort to be directed towards limited portions of the area flown and further ground work in restricted areas should use methods like geological mapping, geochemical reconnaissance, ground EM and gravity to assess conductors or magnetic highs detected by airborne methods.

6. SURVEY OF THE EL GROUP

Due to the strong relief and the poor weather conditions while the survey was being flown, very few lines could be flown across the property. As, however, the higher elevations are mostly talus and bare rock, this was not considered critical.

In addition, the available geological mapping by the G.S.C. (figure 2) and the aeromagnetic maps published by the G.S.C. (figure 4) indicated quite clearly the probable extent of the ultrabasics and it had therefore been decided to fly the areas covering the indicated broad contact zone of these intrusives with the surrounding schists East and North of the property, using a 1320' line spacing.

In view of the significance of the magnetics in the area, a complete data reduction was requested from Lockwood Survey Corporation (figures 5 and 6).

On the basis of previously obtained results in the area of the Gee, Leo and CW claims, it was felt that the contact zone presented potentially the most interesting target area.

While weather conditions precluded flying all lines as laid out on the mosaics, interesting conductors of limited extent and with field strengths and ratios of a type that are often associated with sulphide bodies buried at shallow depth, were located. Subsequent field investigations have indicated that several of these conductors warrant detailed follow-up work.

For comparative purposes and for future reference, a set of maps have been prepared on a scale of 1" = 1 mile, showing the topography, the G.S.C. high level aeromagnetics and the Lockwood Survey magnetics and electromagnetics, attached to this report as figures 3, 4, 5 and 6.

For reference purposes, the El area is identified as Area 17 in the overall exploration program of Northlake Mines.

7. PERSONNEL AND COSTS OF LOCKWOOD SURVEY

The Lockwood Survey was flown under supervision of P.H. Sevensma Consultants Ltd. out of a camp on Grassy Lake, between May 8th and 23rd, 1966.

Due to meltwater on the ice starting May 12th, 1966 and poor weather conditions, Ross River had to be used as a secondary base, and additional helicopter support was required.

A. Personnel on Lockwood Survey

Helicopters were supplied by Klondike Helicopters Ltd.

Geophysical Helicopter:	Bell 47G-3, CF-NJW
Supporting Helicopters:	Hiller UH-12E, CF-MLL
	Bell 43G-3, CF-UAJ
Pilots:	G.F. Kerr
	R. Peters
	J. Dirkie
Engineer:	R. Smegalski
Geophysical Operator:	H. Sandau of Lockwood Survey Corp., Toronto
Field Supervisor:	P.H. Sevensma, P. Eng., Vancouver, B.C.
Auxiliary Personnel:	M. Cloutier, Richmond, B.C.
	J.L. Stout, Mayo, Y.T.
	N. Menegos, Whitehorse, Y.T.
	S. Lothrop, Vancouver, B.C.
	M. Shorty, Ross River, Y.T.

B. Costs of Lockwood Survey

Costs were as follows:

Group	Line Miles	Instrument Rental	Field Expenses	Data Reduction	Total
Gee	462.5	$7,956.34	$9,745.32	$ -	$17,701.66
Hoo	106	1,823.50	2,233.51	1,607.99	5,664.50
El	82	1,410.64	1,727.81	1,243.53	4,381.98
TOTAL	650.5	11,190.48	13,706.64	2,851.02	27.748.14
Cost per line mile		$17.203	$21.071	($15.00)	$42.657

Field costs include labour, fixed wing aircraft, helicopter, sundry expenses and consulting fees.

A cost breakdown is attached as Appendix A.

8. SUMMARY AND RECOMMENDATIONS

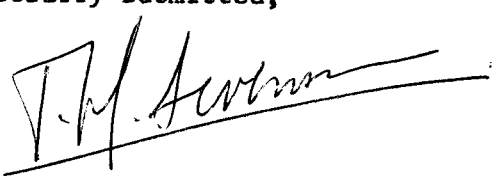
The airborne magnetic-electromagnetic survey of the El group of claims, flown at a cost of $4,381.98, has indicated the presence of promising conducting zones in the schist formations surrounding the ultra-basic plug.

Detailed recommendations for work on this property form part of a separate report being prepared by the writer, and are to a great extent based on geochemical reconnaissance follow-up work carried out in the area during the summer of 1966, as well as on general geological considerations.

These recommendations may be summarized as follows, without any commitment as to their detailed sequence or timing, as they should be viewed within the framework of the overall program. Their priority is rated as 1.

Tote road: 25 miles @ $800		$ 20,000
Linecutting: 20 miles @ $100		2,000
Geological mapping: 4 man-months @ $1,500		6,000
Soil Sampling: 1000 samples @ $3.00		3,000
Electromagnetic surveying: 15 line miles @ $100		1,500
Gravity survey: 10 line miles @ $150		1,500
Transportation: Bombardier, truck		6,000
	Total	$ 40,000
Contingent core drilling: 3000' @ $20		60,000
	Total	$100,000
Engineering, overhead, contingencies; 20%		20,000
Total appropriation		$120,000

Respectfully submitted,



P.H. Sevensma, Ph. D., P. Eng.

CERTIFICATE

I, PETER H. SEVENSMA, of Vancouver, B.C., do hereby certify that:

1. I am a graduate of the University of Geneva, Switzerland (Physics and Chemistry, 1937) (Geology and Mineralogy, 1937) where I obtained my Ph.D. in Geological and Mineralogical Sciences in 1941.

2. I am a Consulting Geological Engineer and a registered member in good standing of the Association of Professional Engineers of British Columbia and of the Association of Professional Engineers of Yukon Territory.

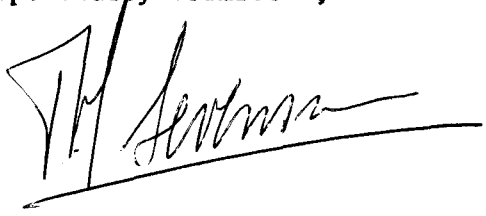
3. From February 1948 until December 1965 I have been engaged continuously in mining and exploration geology in the employ of Cominco Limited. As a Senior Exploration Geologist, I have worked extensively both in Eastern and Western Canada.

4. I have personally examined on several occasions the claims which are the subject of this report and have acted as a consulting geologist since early 1966 on the exploration program conducted by Northlake Mines Limited on these claims.

5. I have personally supervised in the field the airborne geophysical survey conducted by Lockwood Survey Corporation between May 8th and 23rd, 1966 for Northlake Mines Limited.

6. I have not received, nor do I expect to receive or acquire, directly or indirectly, any interest in any of the properties or securities of Northlake Mines Limited.

Respectfully submitted,



P.H. Sevensma, Ph.D., P. Eng.

Report on

AIRBORNE GEOPHYSICAL SURVEY

May 8 - 23, 1966

by

P.H. Sevensma, Ph.D., P. Eng.

TABLE OF CONTENTS

ILLUSTRATIONS

1. INTRODUCTION

In early 1966, Northlake Mines acquired several large claim blocks located in the general Grass Lake area, in a belt stretching from the Hoole River in the Tintina Trench, in a Southeasterly direction towards the Grass Lakes (figure 1).

An exploration program on these claims was started by flying a combined magnetic-electromagnetic survey using the helicopter-borne Lockwood Survey Corporation method.

The present report deals with the results of this survey on the Hoo Group, where a total of 106 line miles were flown.

2. PROPERTY

The property consists of the following claims:

Hoo 1 - 100 Grant Nos. 90072 - 90171
Hoo 101 - 123 Grant Nos. Y13368 - Y13390

The group is located on the Hoole River in the Tintina Trench and on the gently rising NE slope of this valley, approximately centered on 61°32'N and 131°33'W, on claim sheet 105-G-12.

The claims lie between elevations of 3700' in the valley and 4900' on the NE hillside, (figures 1, 2 and 3) about 10 airmiles South of the Watson Lake - Ross River road.

The nearest lake suitable for fixed wing lies about 6 airmiles to the East.

The airborne survey was conducted out of a camp on Grass Lakes, but due to poor weather conditions the aircraft had to use Ross River as a secondary base.

3. HISTORY

Nothing is recorded about the early phases of exploration in the area. Old cabins and remnants of early placer workings have been found further East and in all probability, the Hoole River and its tributaries were investigated by the early placer miners around the turn of the century.

The first recorded activity in the Hoole River area known to the writer occurred in 1954, shortly after the discovery of the Vangorda Creek lead-zinc deposit by A. Kulan and associates.

Messrs. K.G. Sanders and R. Zielinski prospected the area of the present Hoo claims for Pelly River Explorations Limited, a Pioneer Gold Mines of B.C. subsidiary, in the summer of 1954 and reported minor galena=sphalerite float in a limestone host in the creek crossing claims Hoo 44, 46 and 63.

They also reported chalcopyrite in quartz in the creek crossing Hoo 76 and 88.

None of thisfloat could be traced to a source.

They staked the area in January 1966, as part of several groups of claims subsequently acquired by Northlake Mines Limited.

4. REGIONAL GEOLOGY

During the last ten years, the Geological Survey of Canada has been very active in reconnaissance mapping on a scale of 1" = 4 miles of large areas in the Yukon. In addition, large areas have been flown aeromagnetically.

As a result of the correlation of the 1" = 4 mile mapping, new concepts on the age of various rock belts have emerged. The newer concepts have been published in 1964 on a map of the Yukon and the N.W.T. on a scale of 1: 3,000,000, map 30-1963, which has served the writer as a base for figure 1.

The area under consideration forms part of the Anvil Range - Finlayson Lake belt, a belt of metamorphic rocks characterized by extensive mica schist formations and varying amounts of ultrabasic bodies. In the Finlayson Lake area there are also a number of masses of gneiss of unknown origin.

Broadly speaking, the schistose formations, probably of Mississippian age, form a definite belt, although the relationships between the more intensively metamorphosed gneissic rocks and the much lesser metamorphosed schists is not clear. In addition, the degree of metamorphism decreases very gradually from South to North throughout the area pictured on figure 1.

A persistent characteristic of the belt is the presence of the ultrabasics, and 1966 fieldwork has indicated to the writer that these rocks are often associated with very low-grade meta-chlorite schists, slates and even argillites, frequently accompanied by significant amounts of graphitic schists, which occasionally form zones of true graphite slates.

As the change from the more highly metamorphic schist-gneiss assemblages to the less metamorphic slates and argillites is often very sudden but hidden by overburden, it is probable that significant tectonic features have so far remained undetected.

In addition, in the general area of the Northlake holdings, there appears to exist a significant change in tectonic style between the very flat lying schist-gneiss areas and the more steeply dipping slate-ultrabasic assemblages.

Notwithstanding these perhaps very significant differences, the overall characteristics of the schist-ultrabsic association is similar throughout large areas of the central Yukon.

The study and correlation of these belts has led to the concept that the Anvil Range - Finlayson belt is nothing else but the offset by the Tintina Fault of the Klondike schists with a right-lateral movement of about 250 miles (G.S.C. paper 65-2, page 57).

There is therefore a good reason to consider these schists an economically very productive unit, as the Klondike has produced some 250 million dollars of gold, and in the Anvil Range, massive sulphide bodies outlined sofar total at least something of the order of 60 million tons containing better than 10% zinc and lead combined with a gross total value of some 1.5 to 2 billion dollars in base metals and silver.

Significant ore-deposits are usually associated with major structural disturbances, and in the area under consideration the regional geology (figure 1) suggests a large regional E-W striking fold within the normal NW-SE trend of the formations.

Also, geologically and topographically, the area has the characteristics of a recently uplifted dome, and the trend of the valleys suggests pronounced fracturing and faulting along N-S and NE-SW cross-trends; both these features are present in many ore-bearing districts. And as a number of small showings are known in the Fire Lake-Northlake-Grass Lake area, some of them of the strata-bound type, this district is considered an excellent target area for exploration for massive sulphide deposits with base metal values.

These various factors have led to the choice of a combined magnetic-electromagnetic airborne survey as a method well suited to an area with extensive but relatively thin overburden covering structures and lithologies favorable for the occurrence of massive sulphide bodies.

5. LOCKWOOD AIRBORNE METHOD

This method will detect formations that are electrically conductive, and subsequent work can then be concentrated over and near these zones, by using geochemical and geophysical reconnaissance methods.

This method of initial reconnaissance is particularly suited to areas without a well defined drainage pattern along which streamsilt sampling could provide complete initial reconnaissance. It is also the best tool for areas with relatively extensive overburden and few outcrops.

The Lockwood method uses a single frequency of 4000 cps to generate a primary electromagnetic field. The transmitter loop is carried in a fibreglass bird and is oriented with the loop axis parallel to the direction of flight. A receiving loop is located 30' away in the other end of the bird; the loops are coaxial.

The bird is suspended at the end of a 70' cable and is towed by a helicopter at an elevation of 100' above the ground.

A magnetometer of the Gulf Mark III type, also located in the bird, measures the total intensity of the magnetic field.

Recorders and a positioning camera are carried on the helicopter and are handled by an operator who indicates to the pilot the planned course plotted on 1" = 1320' airphotographs and who marks fiducial points on the recorder's strips.

In general, the flight lines are laid out at right angles to the strike of the formations and at distances varying from 600' to 1500' apart.

If a conductive body in the ground is crossed by the helicopter carrying this equipment, the primary electromagnetic field creates eddy currents in this conductor which cause the generation of a secondary electromagnetic field. This secondary field is generally of the same frequency as the primary field but out-of-phase with it; it is detected by the receiver loop in the bird.

As a variation in the distance between the transmitter and the receiver coils will create a strong in-phase response, both coils are in a fixed position in the relatively rigid bird. This will eliminate false responses. Increasing out-of-phase responses will be obtained over bodies of low to medium conductivity; as the conductivity increases beyond the medium range, this out-of-phase response falls off again.

In-phase responses are increasingly stronger as the conductivity rises from poor to very high.

The strength of the response is measured in parts per million. For the above-cited reasons, the ratio of the in-phase to the out-of-phase responses is less than one for bodies of poor to medium conductivity and increases rapidly as the conductivity varies from medium to high.

The response is also a function of the size of the conducting body and of the distance from the bird to it.

The maximum distance at which a highly conductive body of large size will give a response is still somewhat unknown, but appears to be about 300' between the bird and the top of the conducting body.

Various geological bodies are electrical conductors and geological conductors are manifold and of greatly varying size, shape and conductivity, the latter often being a function of the internal texture of the conductor.

Some examples of conducting bodies are:

Massive pyrrhotite
Massive pyrite
Disseminated pyrrhotite and/or pyrite
Graphitic schists
Talc schists, especially when wet
Chlorite (serpentine) schists
Wet overburden in swamp
Lake-bottom deposits
Wet shears

Due to their schistose nature, graphitic schists may be excellent conductors if the individual graphite flakes form a conductive layer.

Massive sulphide bodies with 10 - 20% interstitial quartz may be excellent conductors if the main sulphide is pyrrhotite and if the individual grains of sulphide have large contact areas.

Their conductivity drops off rapidly if the main sulphide is pyrite and if the individual iron sulphide grains are isolated by interstitial non-conductors like silica or sphalerite.

For these reasons, a combined magnetic - electromagnetic airborne survey is essentially a geological mapping tool, especially so as the amount of magnetite in rock is even more of a geological variable than conductivity.

The reliability of the method is principally a function of the elevation above ground that can be maintained. Correlation of responses on adjacent lines flown at different elevations, due to weather or topographical conditions, may not be satisfactory. This happens if the survey if flown with too light a helicopter.

Providing the bird is flown at a steady elevation above the ground, interpretation of airborne data is largely a function of the geological conditions.

Different geological environments will lead to different appraisals of quantitatively very similar airborne geophysical responses.

In general, experience has shown that long conductors (several thousand feet or several miles) with relatively low ratios of 1 or less are likely to be of a formational nature, like graphitic schists. Smaller conductors of better than 1, or preferably 2, ratios may represent near-surface sulphide occurrences.

In certain areas, coincidence of magnetic and electromagnetic highs is critical because of an association of sulphides and magnetite. Most magnetic highs are however a reflection of increased magnetite content of the underlying rock formations, and high magnetic readings may have no more than a very indirect relationship to unusual sulphide concentrations in any given area.

Other geological factors complicating a qualitative interpretation are, for example, the frequent association of graphite and sulphide bodies or the presence of sulphide deposits the mass of which is buried beyond the range of the electromagnetic field but that do have a small near-surface expression.

An airborne geophysical survey should therefore be considered as a mapping tool enabling the exploration effort to be directed towards limited portions of the area flown and further ground work in restricted areas should use methods like geological mapping, geochemical reconnaissance, ground EM and gravity to assess conductors or magnetic highs detected by airborne methods.

6. SURVEY OF THE HOO GROUP

Outside of relative poor weather conditions with low cloud and snow, the Hoo survey did not encounter any serious obstacles.

As it had not been possible to delimit accurately and at a reasonable cost the exact property boundaries previous to the survey, care was taken to extend the lines well beyond the estimated property boundary and beyond the distance required for a good turn around.

Subsequently, the SE boundary of the property was found to lie 3000' beyond the limits of the survey, leaving unsurveyed about 8 claims overlying the ultrabasic. Flight line spacing on the Hoo Group averaged 660'.

In view of the significance of the magnetics in the area as established by the G.S.C. aeromagnetic survey, a complete data reduction was requested from Lockwood Survey Corporation (figures 5 and 6).

Four interesting conductive zones were found (figure 6). Two of these lie beyond the claim boundaries, in the NE part of the area. Subsequent field investigations did not provide any interesting features and no further follow-up work was recommended.

In the most Westerly claims, a restricted conductive zone of medium strength (50 ppm) and ratios of 1.5/0.5, 5.5/1.5 and 3.3/0.8 was located. This conductor was located on the ground using a Turam instrument, as the overburden was estimated to be of the order of 100'. The zone was subsequently drilled, but no economic mineralization was encountered. This area is identified as Area 18 in the overall Northlake Mines program.

In the field, two separate conductive areas were identified and drilling was completed on the most Northerly one. Overburden was found to be only about 30'.

Both graphitic schists and a significant talc zone were intersected in the drilling in Area 18. The best part of the conductivity appears related to the talc zone rather than to the graphitic schists, as an outcrop of the latter was found outside the conducting zone.

In the Southeasterly portion of the claims, a rather extensive conductive zone is located on the NE flank of the aeromagnetic anomaly. This zone, known as Area 19 in the overall program, has been investigated by a Ronka horizontal loop electromagnetic ground survey and by soil sampling. Both investigations were conducted along picket-lines spaced at 800'. Further follow-up work is recommended.

In the general geological context of the area, the 1966 program has demonstrated that the best target zones occur in the schist areas within about one to two miles from the ultrabasics. Both area 18 and 19 justify therefore further investigation.

7. PERSONNEL AND COSTS OF LOCKWOOD SURVEY

The Lockwood Survey was flown under supervision of P.H. Sevensma Consultants Ltd. out of a camp on Grassy Lake, between May 8th and 23rd, 1966.

Due to meltwater on the ice starting May 12th, 1966 and poor weather conditions, Ross River had to be used as a secondary base, and additional helicopter support was required.

A. Personnel on Lockwood Survey

Helicopters were supplied by Klondike Helicopters Ltd.

Geophysical Helicopter:	Bell 47G-3, CF-NJW
Supporting Helicopters:	Hiller UH-12E, CF-MLL
	Bell 43G-3, CF-UAJ
Pilots:	G.F. Kerr
	R. Peters
	J. Dirkie
Engineer:	R. Smegalski
Geophysical Operator:	H. Sandau of Lockwood Survey Corp., Toronto
Field Supervisor:	P.H. Sevensma, P. Eng., Vancouver, B.C.
Auxiliary Personnel:	M. Cloutier, Richmond, B.C.
	J.L. Stout, Mayo, Y.T.
	N. Menegos, Whitehorse, Y.T.
	S. Lothrop, Vancouver, B.C.
	M. Shorty, Ross River, Y.T.

B. Costs of Lockwood Survey

Costs were as follows:

Group	Line Miles	Instrument Rental	Field Expenses	Data Reduction	Total
Gee	462.5	$7,956.34	$9,745.32	$ -	$17,701.66
Hoo	106	1,823.50	2,233.51	1,607.99	5,664.50
El	82	1,410.64	1,727.81	1,243.53	4,381.98
TOTAL	650.5	11,190.48	13,706.64	2,851.02	27.748.14
Cost per line mile		$17.203	$21.071	($15.00)	$42.657

Field costs include labour, fixed wing aircraft, helicopter, sundry expenses and consulting fees.

A cost breakdown is attached as Appendix A.

8. SUMMARY AND RECOMMENDATIONS

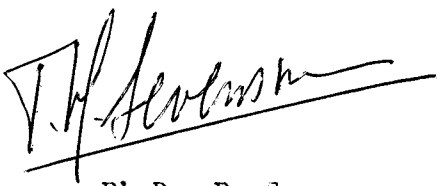
An airborne magnetic-electromagnetic survey of the Hoo Group, flown at a total cost of $5,664.50, has revealed the presence of several interesting conducting zones, two of which are quite extensive and located in the schists close to their contact with the ultrabasics.

Initial drilling on one of these has not encountered economic mineralization, but several targets of interest remain and justify further investigation.

The summary of recommendations which follows must be considered within the framework of the overall program of Northlake Mines; it's priority is rated as 3. These recommendations do not take into account the sequence and timing within the broader program.

Geological mapping: 2 man months @ $1,500		$ 3,000
Soil Sampling: 350 samples @ $3.00		1,000
Transportation, helicopter, 15 hours		2,000
Camp preparation		1,000
	Total	$ 7,000
Contingent linecutting, geophysics, 15 line miles @ $200		3,000
Contingent drilling, 1600' @ $25		40,000
	Total	$50,000
Engineering, overhead, contingencies, 15%		7,500
	Total	$57,500

Respectfully submitted,



P.H. Sevensma, Ph.D., P. Eng.

CERTIFICATE

I, PETER H. SEVENSMA, of Vancouver, B.C., do hereby certify that:

1. I am a graduate of the University of Geneva, Switzerland (Physics and Chemistry, 1937) (Geology and Mineralogy, 1937) where I obtained my Ph.D. in Geological and Mineralogical Sciences in 1941.

2. I am a Consulting Geological Engineer and a registered member in good standing of the Association of Professional Engineers of British Columbia and of the Association of Professional Engineers of Yukon Territory.

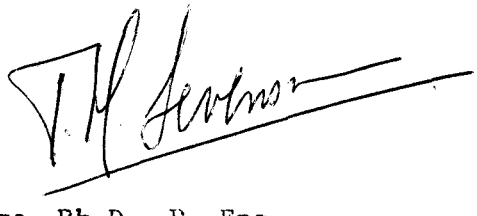
3. From February 1948 until December 1965 I have been engaged continuously in mining and exploration geology in the employ of Cominco Limited. As a Senior Exploration Geologist, I have worked extensively both in Eastern and Western Canada.

4. I have personally examined on several occasions the claims which are the subject of this report and have acted as a consulting geologist since early 1966 on the exploration program conducted by Northlake Mines Limited on these claims.

5. I have personally supervised in the field the airborne geophysical survey conducted by Lockwood Survey Corporation between May 8th and 23rd, 1966 for Northlake Mines Limited.

6. I have not received, nor do I expect to receive or acquire, directly or indirectly, any interest in any of the properties or securities of Northlake Mines Limited.

Respectfully submitted,



P.H. Sevensma, Ph.D., P. Eng.

Report on
AIRBORNE GEOPHYSICAL SURVEYS
April 4-12 & May 8-23,1966

1. INTRODUCTION

In early 1966, Northlake Mines acquired several large claim blocks located in the general Grass Lake area, in a belt stretching from the Hoole River in the Tintina Trench in a Southeasterly direction towards the Grass Lakes (figure 1).

On the Gee Group of claims, 9 small showings were known on the high-lying ridges. In view of the rugged topography of the area, it was decided to use the Geo Cal helicopter-borne electromagnetic prospecting method near some of the showing areas at high altitude, and to conduct a helicopter-borne magnetic-electromagnetic survey by the Lockwood method along the main valleys.

Targets located by these methods early in the 1966 season have subsequently been investigated by geophysical, geochemical and geological methods during the summer of 1966.

The present report deals with the results of the airborne surveys on the Gee Group area. Line-miles flown by the Lockwood method totalled 462.5 miles in this area.

2. PROPERTY

The property consists of the following claims:

	Grant Nos.	Date of record
Gee 1 - 80	90172 - 90250 & Y2004	January 31, 1966
Gee 81 - 88	Y2002, 3 and 5 - 9	January 31, 1966
Gee 89 - 400	Y2010 - Y2321	January 31, 1966
Gee 401 - 530	Y7103 - Y7232	April 20, 1966
FS 1 - 40	Y7854 - 7893	May 9, 1966
Z 1 and 2	Y13085 & Y13086	June 14, 1966
Leo 1 - 6	Y13087 - Y13092	June 14, 1966
Leo 7 - 14	Y13125 - Y13132	July 4, 1966
Leo 15 - 30	Y13093 - Y13108	June 14, 1966
CW 1 - 4	Y13081 - Y13084	June 14, 1966
CW 5 - 23	Y13333 - Y13351	July 25, 1966
PG 1 - 16	Y13352 - Y13367	July 25, 1966

These claims form a contiguous group centered on the high mountains between Grass Lakes and Riviera Lake at approximately 61°27'N and 131°00'W.

The claims lie between elevations of 4300' and 7000' about 20 airmiles South of the Watson Lake - Ross River road (figures 1 and 2). The best access by fixed wing is on the Westerly Grass Lake, which served as a base for the airborne surveys. This lake, at 4300' elevation, lies in a bad weather belt, and during the Lockwood Survey, conducted at the start of break-up, Ross River had to be used as a secondary base due to poor weather conditions, which increased the cost of the survey by about 15%. Starting May 12, 1966, fixed wing aircraft where precluded from landing on the lake by flooding of the ice.

3. HISTORY

There is evidence in the area of activity by the early placer miners, probably around the turn of the century.

The area was initially prospected in 1954 by K.G. Sanders and R. Zielinski for Pelly River Explorations Limited and the Rob, Pit and Gyp claims were staked. The two former groups were optioned by Trans-continental Resources, who carried out a ground magnetometer survey, but allowed the claims to lapse.

From 1955 until the early 1960's, various other mineral discoveries were made to the NW and SE of the present Gee Group. During the same period, the area was mapped on a scale of 1" = 4 miles by J.O. Wheeler, L.H. Green and J.A. Roddick of the G.S.C. and an airborne magnetic survey was flown by Aero Surveys for the same organization.

In January 1966, Messrs. Sanders and Zielinski staked 560 claims in the area, including the Gee 1 - 400. All 560 claims were acquired by Northlake Mines.

The description by the stakers of the 9 showing areas covered by the Gee claims is recorded in the writer's report on the area dated March 18, 1966.

Subsequent to the airborne surveys carried out by Northlake Mines in April and May of 1966, A. MacDonald Consultants Limited of Vancouver conducted an extensive ground exploration program during the summer of 1966 for Northlake Mines Ltd.

The writer has acted as a consulting geologist for both the airborne and ground follow-up programs since mid-February 1966.

4. REGIONAL GEOLOGY

During the last ten years, the Geological Survey of Canada has been very active in reconnaissance mapping on a scale of 1" = 4 miles of large areas in the Yukon. In addition, large areas have been flown aeromagnetically.

As a result of the correlation of the 1" = 4 mile mapping, new concepts on the age of various rock belts have emerged. The newer concepts have been published in 1964 on a map of the Yukon and the N.W.T. on a scale of 1: 3,000,000, map 30-1963, which has served the writer as a base for figure 1.

The area under consideration forms part of the Anvil Range - Finlayson Lake belt, a belt of metamorphic rocks characterized by extensive mica schist formations and varying amounts of ultrabasic bodies. In the Finlayson Lake area there are also a number of masses of gneiss of unknown origin.

Broadly speaking, the schistose formations, probably of Mississippian age, form a definite belt, although the relationships between the more intensively metamorphosed gneissic rocks and the much lesser metamorphosed schists is not clear. In addition, the degree of metamorphism decreases very gradually from South to North throughout the area pictured on figure 1.

A persistent characteristic of the belt is the presence of the ultrabasics, and 1966 fieldwork has indicated to the writer that these rocks are often associated with very low-grade meta-chlorite schists, slates and even argillites, frequently accompanied by significant amounts of graphitic schists, which occasionally form zones of true graphite slates.

As the change from the more highly metamorphic schist-gneiss assemblages to the less metamorphic slates and argillites is often very sudden but hidden by overburden, it is probable that significant tectonic features have so far remained undetected.

In addition, in the general area of the Northlake holdings, there appears to exist a significant change in tectonic style between the very flat lying schist-gneiss areas and the more steeply dipping slate-ultrabasic assemblages.

Notwithstanding these perhaps very significant differences, the overall characteristics of the schist-ultrabsic association is similar throughout large areas of the central Yukon.

The study and correlation of these belts has led to the concept that the Anvil Range - Finlayson belt is nothing else but the offset by the Tintina Fault of the Klondike schists with a right-lateral movement of about 250 miles (G.S.C. paper 65-2, page 57).

There is therefore a good reason to consider these schists an economically very productive unit, as the Klondike has produced some 250 million dollars of gold, and in the Anvil Range, massive sulphide bodies outlined sofar total at least something of the order of 60 million tons containing better than 10% zinc and lead combined with a gross total value of some 1.5 to 2 billion dollars in base metals and silver.

Significant ore-deposits are usually associated with major structural disturbances, and in the area under consideration the regional geology (figure 1) suggests a large regional E-W striking fold within the normal NW-SE trend of the formations.

Also, geologically and topographically, the area has the characteristics of a recently uplifted dome, and the trend of the valleys suggests pronounced fracturing and faulting along N-S and NE-SW cross-trends; both these features are present in many ore-bearing districts. And as a number of small showings are known in the Fire Lake-Northlake-Grass Lake area, some of them of the strata-bound type, this district is considered an excellent target area for exploration for massive sulphide deposits with base metal values.

These various factors have led to the choice of a combined magnetic-electromagnetic airborne survey as a method well suited to an area with extensive but relatively thin overburden covering structures and lithologies favorable for the occurrence of massive sulphide bodies.

5. LOCKWOOD AIRBORNE METHOD

This method will detect formations that are electrically conductive, and subsequent work can then be concentrated over and near these zones, by using geochemical and geophysical reconnaissance methods.

This method of initial reconnaissance is particularly suited to areas without a well defined drainage pattern along which streamsilt sampling could provide complete initial reconnaissance. It is also the best tool for areas with relatively extensive overburden and few outcrops.

The Lockwood method uses a single frequency of 4000 cps to generate a primary electromagnetic field. The transmitter loop is carried in a fibreglass bird and is oriented with the loop axis parallel to the direction of flight. A receiving loop is located 30' away in the other end of the bird; the loops are coaxial.

The bird is suspended at the end of a 70' cable and is towed by a helicopter at an elevation of 100' above the ground.

A magnetometer of the Gulf Mark III type, also located in the bird, measures the total intensity of the magnetic field.

Recorders and a positioning camera are carried on the helicopter and are handled by an operator who indicates to the pilot the planned course plotted on 1" = 1320' airphotographs and who marks fiducial points on the recorder's strips.

In general, the flight lines are laid out at right angles to the strike of the formations and at distances varying from 600' to 1500' apart.

If a conductive body in the ground is crossed by the helicopter carrying this equipment, the primary electromagnetic field creates eddy currents in this conductor which cause the generation of a secondary electromagnetic field. This secondary field is generally of the same frequency as the primary field but out-of-phase with it; it is detected by the receiver loop in the bird.

As a variation in the distance between the transmitter and the receiver coils will create a strong in-phase response, both coils are in a fixed position in the relatively rigid bird. This will eliminate false responses. Increasing out-of-phase responses will be obtained over bodies of low to medium conductivity; as the conductivity increases beyond the medium range, this out-of-phase response falls off again.

In-phase responses are increasingly stronger as the conductivity rises from poor to very high.

The strength of the response is measured in parts per million. For the above-cited reasons, the ratio of the in-phase to the out-of-phase responses is less than one for bodies of poor to medium conductivity and increases rapidly as the conductivity varies from medium to high.

The response is also a function of the size of the conducting body and of the distance from the bird to it.

The maximum distance at which a highly conductive body of large size will give a response is still somewhat unknown, but appears to be about 300' between the bird and the top of the conducting body.

Various geological bodies are electrical conductors and geological conductors are manifold and of greatly varying size, shape and conductivity, the latter often being a function of the internal texture of the conductor.

Some examples of conducting bodies are:

Massive pyrrhotite
Massive pyrite
Disseminated pyrrhotite and/or pyrite
Graphitic schists
Talc schists, especially when wet
Chlorite (serpentine) schists
Wet overburden in swamp
Lake-bottom deposits
Wet shears

Due to their schistose nature, graphitic schists may be excellent conductors if the individual graphite flakes form a conductive layer.

Massive sulphide bodies with 10 - 20% interstitial quartz may be excellent conductors if the main sulphide is pyrrhotite and if the individual grains of sulphide have large contact areas.

Their conductivity drops off rapidly if the main sulphide is pyrite and if the individual iron sulphide grains are isolated by interstitial non-conductors like silica or sphalerite.

For these reasons, a combined magnetic - electromagnetic airborne survey is essentially a geological mapping tool, especially so as the amount of magnetite in rock is even more of a geological variable than conductivity.

The reliability of the method is principally a function of the elevation above ground that can be maintained. Correlation of responses on adjacent lines flown at different elevations, due to weather or topographical conditions, may not be satisfactory. This happens if the survey if flown with too light a helicopter.

Providing the bird is flown at a steady elevation above the ground, interpretation of airborne data is largely a function of the geological conditions.

Different geological environments will lead to different appraisals of quantitatively very similar airborne geophysical responses.

In general, experience has shown that long conductors (several thousand feet or several miles) with relatively low ratios of 1 or less are likely to be of a formational nature, like graphitic schists. Smaller conductors of better than 1, or preferably 2, ratios may represent near-surface sulphide occurrences.

In certain areas, coincidence of magnetic and electromagnetic highs is critical because of an association of sulphides and magnetite. Most magnetic highs are however a reflection of increased magnetite content of the underlying rock formations, and high magnetic readings may have no more than a very indirect relationship to unusual sulphide concentrations in any given area.

Other geological factors complicating a qualitative interpretation are, for example, the frequent association of graphite and sulphide bodies or the presence of sulphide deposits the mass of which is buried beyond the range of the electromagnetic field but that do have a small near-surface expression.

An airborne geophysical survey should therefore be considered as a mapping tool enabling the exploration effort to be directed towards limited portions of the area flown and further ground work in restricted areas should use methods like geological mapping, geochemical reconnaissance, ground EM and gravity to assess conductors or magnetic highs detected by airborne methods.

6. SURVEY OF THE GEE GROUP

In view of the general high elevations in the area and the limited carrying capacity of the Bell 47G-3 helicopter at these altitudes, flying was purposely confined to the main valleys (figure 4). Flight-line spacing was 660'.

As the formations on the Gee Group have in general relatively flat dips, care was taken to fly several of the valleys adjoining the claims, so as not to miss possible significant extensions of nearby showings into adjacent valleys.

Tapes were examined in the field. As few conductive zones were found and as the magnetic profiles in general were flat and the flight-elevations irregular, it was decided not to obtain a detailed data reduction. A preliminary data reduction of those areas that evidenced significant electromagnetic profiles was carried out by personnel of Exploration Geophysics (Yukon) Limited at Whitehorse (see attached maps).

Very highly conductive zones were located on the Leo claims (Area 11). Medium conductors were located in area 10 near the Lake on the NW portion of the Gee claims, and weak but localized conductors were found on the area of the PG claims at the SW corner of the Gee Group (Area 16), in the valley bottom 1½ miles NE of Grass Lake (Area 14) and in areas 10, 12 and 13. The latter two are covered by the CW claims.

No conductors were found either in the lower part of Area 5 on the slopes to the NW of Grass Lake which is upslope from the galena float at that point, or in Area 15, covering the long conducting zone located by the Geo Cal method.

In both areas, topography and crosswinds combined to force the helicopter to fly at a higher terrain clearance than normal.

In Area 5, where overburden cover increases rapidly when proceeding down the valley, a horizontal loop-frame survey failed to pick up any significant conductors, and the same condition prevailed in Area 15.

Streamsilt and soil sampling failed to locate any significant and continuous anomalies in Area 15, but Area 5 was found to be generally high in lead.

In Area 15, the negative verdict of the Lockwood Survey and of geochemical and ground electromagnetic surveys led to interpret the Geo Cal conductor as reflecting the presence of conductive schists lying under overburden beyond the range of the horizontal loop method.

Area 5 could only be partially flown, and it is felt that the airborne survey did not materially contribute to the assessment of this area, mainly due to its rugged topography.

The subsequent geochemical reconnaissance of all the valleys of the area flown has in general confirmed the results of the Lockwood Survey and the combination of these two methods has resulted in providing a few definite target areas and in eliminating, with good confidence, large areas.

An element of doubt subsists in the centre of the valleys where depth of overburden may preclude the detection of any large base metal occurrence by either or both geochemical reconnaissance and airborne geophysics.

It is believed however, that this may not apply to any more than perhaps 20% of the valley bottoms, and any discovery under those physical handicaps would have to be very substantial to have an economic potential.

When the results of the Lockwood surveys conducted by Northlake Mines Limited over its three main groups, the Gee, El and Hoo, are considered together, it is felt that the survey has focussed the attention on those situations where subsequent geochemical follow-up has proven very worthwhile targets and has significantly contributed to eliminate, with confidence, large sections of ground without any near-surface potential.

The Gee Group area as flown was, in general, at or somewhat beyond the limit of the capacity of the Bell 47G-3 and the quality of the survey in areas with this type of topography would be improved by using a much heavier machine capable of maintaining the proper terrain clearance under all conditions.

7. PERSONNEL AND COSTS OF LOCKWOOD SURVEY

The Lockwood Survey was flown under supervision of P.H. Sevensma Consultants Ltd. out of a camp on Grassy Lake, between May 8th and 23rd, 1966.

Due to meltwater on the ice starting May 12th, 1966 and poor weather conditions, Ross River had to be used as a secondary base, and additional helicopter support was required.

A. Personnel on Lockwood Survey

Helicopters were supplied by Klondike Helicopters Ltd.

Geophysical Helicopter:	Bell 47G-3, CF-NJW
Supporting Helicopters:	Hiller UH-12E, CF-MLL
	Bell 43G-3, CF-UAJ
Pilots:	G.F. Kerr
	R. Peters
	J. Dirkie
Engineer:	R. Śmegalski
Geophysical Operator:	H. Sandau of Lockwood Survey Corp., Toronto
Field Supervisor:	P.H. Sevensma, P. Eng., Vancouver, B.C.
Auxiliary Personnel:	M. Cloutier, Richmond, B.C.
	J.L. Stout, Mayo, Y.T.
	N. Menegos, Whitehorse, Y.T.
	S. Lothrop, Vancouver, B.C.
	M. Shorty, Ross River, Y.T.

B. Costs of Lockwood Survey

Costs were as follows:

Group	Line Miles	Instrument Rental	Field Expenses	Data Reduction	Total
Gee	462.5	$7,956.34	$9,745.32	$ -	$17,701.66
Hoo	106	1,823.50	2,233.51	1,607.99	5,664.50
El	82	1,410.64	1,727.81	1,243.53	4,381.98
TOTAL	650.5	11,190.48	13,706.64	2,851.02	27.748.14
Cost per line mile		$17.203	$21.071	($15.00)	$42.657

Field costs include labour, fixed wing aircraft, helicopter, sundry expenses and consulting fees.

A cost breakdown is attached as Appendix A.

8. GEO CAL AIRBORNE METHOD

The Geo Cal method is based on the observation that a helicopter equipped with metal rotor blades generates a primary electromagnetic field of approximately 900 c.p.s. with an effective radius of some 150' when the blades are rotating at their normal speed of 320 R.P.M.

When a helicopter with metal blades flies at an elevation of 50' to 100' above a conducting body of some size, a secondary electromagnetic field is induced, and the resultant field shows a significant distortion.

This resultant field can be analyzed with a search coil with a vertical axis held by an operator in the helicopter.

The audio amplifier attached to the search coil is tuned to a signal of 900 c.p.s. and has a gain switch and a feed back squelcher switch.

The former is regulated to produce a barely audible signal when the coil is held with its axis vertical, and the latter is adjusted so that only the 900 c.p.s. signal goes through the amplifier. When the aircraft flies close to the terrain in the absence of a conducting zone, the field signal will have minimum amplitude. If, under these conditions, a conducting zone is traversed, the signal strength will markedly increase in amplitude. Under favorable conditions, the orientation of the resultant field can be analyzed by having the helicopter hover over the conducting zone.

By landing, the conducting zone so discovered can be traversed on the ground with the same receiver coil, using a power-pack transmitter. A Sharp SE 250 unit was used in the present case.

Since the survey was flown, recordings of signals have been made on magnetic tape. Also, a fixed horizontal coil can be carried under the belly of the helicopter. This is fed direct current by the helicopters electrical system to create a non-pulsating strong magnetic field.

In this field, the alternating EM field created by the rotor will be much stronger than in the natural magnetic field, providing increased depth penetration.

The method is a low cost prospecting tool. As it is sensitive to all types of conductors to the same extent as more sophisticated devices, but less discriminating, it could lead to higher ground follow-up costs in the presence of conductive overburden.

9. RESULTS OF THE GEO CAL SURVEY

The survey was restricted to the rugged areas at high elevations (5000 - 6500') where small showings had previously been found by conventional prospecting methods.

Conductors were located on the following claim areas: (figure 4)

Area	Airborne Anom. on claim #	Ground survey with Sharp SE 250 Cross over	Maximum Amplitude	Rating
1	111, 146	Weak	2L, 2R	Insignificant
2	100, 174, 176	no landing possible		unknown
	173-175-186	Good	6L, 8R	Good
	187	Nil	0, 10R	Poor
3	209-210-211	Nil	0, 4R	Insignificant
5	2, 4, 6, 236	no landing possible		unknown
	237, 238	no landing possible		unknown
	240-242	Fair	6L, 10R	Good
6	337	None	0, 8R	Poor
7	322-324	None	0, 2R	Insignificant
8, 9	376-378	Fair	8L, 4R	Fair
15	91, 93	no landing possible		unknown
	151,153,155	no landing possible		Strong HEM only

It is felt that in rugged terrain, the absence of a definite crossover and a weak amplitude suggests topographical effects, or a weak conductor at the limit of depth penetration. The generally schistose rocks of the area may also contribute to weak crossovers.

The maximum depth of penetration of the Sharp SE 250 is probably of the order of 150'.

It is also believed that the depth penetration of the airborne device may be somewhat greater than assumed, and may be beyond the depth range of any of the usual horizontal loop instruments, like a Ronka, which at 200' coil spacing, does not exceed 70' - 80'.

All conductors have subsequently been followed up in the field, all by visual inspection, some by a Ronka survey and most by either stream silt sampling and/or soil sampling. These results may be tabulated as follows:

Area	Visual examination	Geochem	Ronka survey	Total assessment
1	pyrite	streams: spotty Cu, Pb	not required	not significant
2	pyrrh. showings up to 4' wide	spotty Cu	not required	due to pyrrh. showings
3	no visual explanation	nil	not required	not significant
5	quartz & galena veins only	high Pb soils	nil	high Pb requires further evaluation
6	faulting	nil	not required	not significant
7	faulting & various minor showings	streams: weak	not required	not significant
8, 9	considerable faulting	Soils: + BG. Cu, Lead	not required	nothing of economic interest observed
15	deep overburden	streams: spotty Soils: low	nil	N-S fault or N.S. striking schists beyond Ronka range

In summary, areas 1, 3, 6, 7 and 8 + 9 did not reveal anything of economic potential, and the conductors are most likely related to faults or slightly conductive schists.

Area 2 covers showings of massive pyrrhotite with very minor chalcopyrite which would give conductivity readings as observed. The showings do not show economic promise.

Area 5 shows geochemical and visual evidence of the presence of probably numerous quartz veins with galena. Ground follow-up with a Ronka horizontal loop indicated one weak conductor, but in the Southeast portion of the area, the overburden thickness increases rapidly, probably well beyond the range of the Ronka.

The galena-bearing quartz veins could be part of a halo of a larger galena-bearing body related to the granodiorite-schist contact and additional investigations to check this working hypothesis will be recommended.

In area 15, there is no satisfactory explanation for the conductive zone, which may be due to a N-S fault or a conductive schist formation. As there is no geochemical support other than some spotty highs, further work is not recommended in this area.

The Lockwood survey failed to confirm the presence of this conductor, but crosswinds forced the helicopter to fly higher than required for a thorough exploration, whereas the Geo Cal survey was flown no more than 50' above ground level. This may account for the non-confirmation.

It is concluded that the Geo Cal survey did not miss any major near-surface occurrences of possible economic interest in the areas flown.

10. PERSONNEL AND COSTS OF THE GEO CAL SURVEY

The Geo Cal survey was flown out of a temporary staking camp located at Grass Lake, and part of the cost is based upon a split between staking and surveying. Camp costs have been absorbed by the staking account,

A. Personnel on Geo Cal Survey

Helicopters supplied by Klondike Helicopters Ltd.

Geophysical Helicopter	CF-UAA	Bell 43-G-3 B1
Supporting Helicopter	CF-KEL	Bell 47-G-2

Pilots: P. Langlois
E. Burgess

Engineer: McKay

Geophysical contractor: Geo Cal Ltd., 2658 Nelson Avenue, West Vancouver

Geophysical operator: Ian Poyntz, Geo Cal Ltd.

Consulting Geologist: P.H. Sevensma, Ph. D., P. Eng.

Field personnel: M. Cloutier, Richmond, B.C.

B. Costs of Geo Cal survey

Geo Cal, contractor	$ 1,673.10
Helicopter costs	1,362.00
Helicopter gas	222.75
Fixed wing	200.00
Consulting fees	500.00
* Consulting expenses	739.45
**Camp costs	none charged
Total	$ 4,697.30

* Charged all expenses to Geo Cal survey
** Charged all expenses to Staking

A cost breakdown is attached as page 2 of Appendix A.

11. SUMMARY AND RECOMMENDATIONS

An airborne Geo Cal electromagnetic survey was flown at a cost of $4,697.30 over 8 selected rugged areas of the Gee claims, followed by an airborne Lockwood magnetic-electromagnetic survey, flown mainly along the valleys, at a cost of $17,701.66 in the Gee Area.

Total cost of the two surveys was $22,398.96.

In conjunction with information obtained by the Lockwood Survey on other Northlake Mines Limited ground (El and Hoo Groups), it is felt that the airborne surveys, combined with geochemical follow-up, have:

1. Conclusively indicated a potential copper-belt related to chlorite-sericite-graphite schists intruded by ultrabasics, towards the N and NW.

2. Eliminated large areas without conductors and geochemical highs in the more highly metamorphic schist-gneiss assemblage underlying the Gee claims.

3. Proven the value of the existence of 1" = 4 miles reconnaissance geological maps and both 1" = 4 miles and 1" = 1 mile aeromagnetic maps, the combination of which has permitted to formulate exploration guide lines at an early date.

As a result of these surveys on all Northlake's holdings and their ground follow-up, recommendations are being prepared in a separate report by the writer.

These recommendations, as they pertain to the Gee claim area, may be summarized as follows without any commitment as to their sequence and timing, as they should be viewed with the framework of the overall program.

Abandonment of the following areas is recommended:

Detail areas 1, 3, 4, 6, 7, 8, 9 and 15
NW central area

Retention of the following areas is recommended:

Detail areas 2, 5, 10, 11, 12, 13, 14 and 16

In the overall program, the areas recommended for retention in the Gee area are rated as follows:

Priority 2 - Areas 11, 12 and 13, i.e. the Leo Group and its extension to the West (CW). Strong EM anomaly supported by geochemical copper (lead-zinc) highs near the contact of the conductive and the non-conductive formations.

Priority 4 - Area 5. Shallow Ronka ground EM failed to pinpoint conductors located by airborne methods in an area of quartz veins with galena and a high lead background.

Priority 5 - Areas 10, 14 and 16. Airborne work and ground follow-up have indicated various weak targets requiring additional assessment.

Priority 6 - Area 2. Pyrrhotite showings with minor copper values have been located. A review of this situation may be indicated if other discoveries are made in the area.

A summary of recommended expenditures follows. All proposed geological mapping is of a detailed nature, on a scale of 1" = 400', to produce a map of outcrops, float and overburden as related to topography and soil sampling along 400' or 200' picket-lines.

It is assumed that existing camp-gear is about adequate for these programs.

Priority 2

Tote road: 10 miles @ $1,000		$10,000
Geological mapping, 2 man-months @ $1,500		3,000
Linecutting, 10 miles @ $150		1,500
Soil Sampling, 350 samples @ $4.00		1,500
EM surveying, 10 line miles @ $100		1,000
Gravity surveying, 15 line miles @ $200		3,000
Transportation; Bombardier, truck		4,000
Bulldozer trenching, 100 hours @ $35		3,500
Aircraft		2,500
	Total	$30,000
Contingent core drilling: 2000' @ $25		50,000
	Total	$80,000
Engineering, overhead, contingencies @ 20%		16,000
Total appropriation		$96,000

Priority 4

Geological mapping, 1 man-month @ $1,500		$ 1,500
Deep EM or IP survey, 15 line miles @ $300		4,500
Aircraft transportation		1,500
	Total	$ 7,500
Contingent core drilling: 1500' @ $25		37,500
	Total	$45,000
Engineering, overhead, contingencies: 20%		9,000
Total appropriation		$54,000

Priority 5

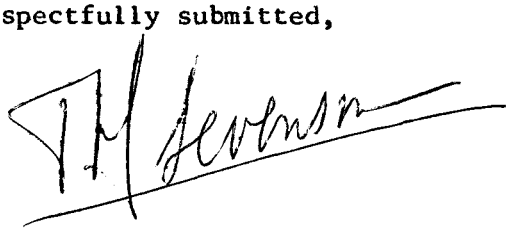
Detailed geological mapping, additional soil sampling, prospecting	$15,000
EM surveying, as indicated	5,000
Engineering, overhead, claim maintenance; 20%	4,000
Total appropriation	$24,000

Priority 6 Nil

Summary

	Fixed cost	Contingent drilling	Engineering, etc.	Total
Priority 2	$30,000	$50,000	$16,000	$96,000
Priority 4	7,500	37,500	9,000	54,000
Priority 5	20,000	-	4,000	24,000
Priority 6	-	-	-	-
Total	$57,500	$87,500	$29,000	$174,000

Respectfully submitted,



P.H. Sevensma, Ph.D., P. Eng.

CERTIFICATE

I, PETER H. SEVENSMA, of Vancouver, B.C., do hereby certify that:

1. I am a graduate of the University of Geneva, Switzerland (Physics and Chemistry, 1937) (Geology and Mineralogy, 1937) where I obtained my Ph.D. in Geological and Mineralogical Sciences in 1941.

2. I am a Consulting Geological Engineer and a registered member in good standing of the Association of Professional Engineers of British Columbia and of the Association of Professional Engineers of Yukon Territory.

3. From February 1948 until December 1965 I have been engaged continuously in mining and exploration geology in the employ of Cominco Limited. As a Senior Exploration Geologist, I have worked extensively both in Eastern and Western Canada.

4. I have personally examined on several occasions the claims which are the subject of this report and have acted as a consulting geologist since early 1966 on the exploration program conducted by Northlake Mines Limited on these claims.

5. I have personally supervised in the field the airborne geophysical survey conducted by Lockwood Survey Corporation between May 8th and 23rd, 1966 for Northlake Mines Limited, as well as the Geo Cal Survey.

6. I have not received, nor do I expect to receive or acquire, directly or indirectly, any interest in any of the properties or securities of Northlake Mines Limited.

Respectfully submitted,

P.H. Sevensma, Ph.D., P. Eng.

IN THE MATTER OF NORTHLAKE MINES LIMITED
AND IN THE MATTER OF AIRBORNE GEOPHYSICAL
SURVEY REPORT AND HOO, EL, AND GEE CLAIMS

AFFIDAVIT

I, PETER SEVENSMA, of 715-850 West Hastings Street, Vancouver, Province of British Columbia, HEREBY MAKE OATH AND SAY AS FOLLOWS:-

That attached hereto to this my Affidavit, is a report and an Appendix A, providing a list of firms and individuals having been engaged in work for the above, as well as a cost-breakdown and a cost-distribution for 1966 work, which I certify to be true and accurate to the best of my knowledge and belief.

SWORN before me at the City of Vancouver, Province of British Columbia, this 30 day of January, A.D. 1967

A Commissioner for taking Affidavits in and for the Yukon Territory.

Peter Sevensma

REPORT ON

GROUND GEOPHYSICAL SURVEYS

ROSS RIVER, YUKON TERRITORY

FOR

NORTHLAKE MINES LTD.

BY

HUNTEC LIMITED

TORONTO, ONTARIO

JANUARY, 1967

TABLE OF CONTENTS

INTRODUCTION

Between July 9th and September 11th, 1966, ground electromagnetic surveys were carried out by Huntec Limited for Northlake Mines Limited in an area near Grass Lake, approximately 50 miles south of Ross River, Yukon Territory.

The party chief for the survey was Mr. A. Dyck, supervision being provided in the field by Mr. P.E. Lane and from Toronto by Messrs. A.R. Dodds and N.R. Paterson. Final drafting of results, interpretation and report writing were done in the Toronto office of Huntec Limited.

The survey was divided into three separate grids as follows:

Area 5 Horizontal Loop E.M. survey using ABEM Mini-Gun and Ronka Mark III unit.

Area 10 Turam Inductive Loop E.M. survey.

Area 18 Turam Inductive Loop E.M. survey.

The surveys were conducted on lines approximately 400 feet apart, with station intervals of 100 feet. The Ronka survey employed a coil separation of 200 feet and a frequency of 876 cps; the Turam survey used a 100 foot separation between receiving coils and a basic frequency of 660 cps. Some detailing was also done at a frequency of 220 cps.

The data are presented in the form of profiles of in-phase and out-of-phase secondary field components (for the horizontal loop survey) and reduced amplitude ratio and phase differences (for the Turam surveys).

E.M. SURVEY METHODS

The basic principle of all E.M. methods is that when an electrical conductor is subjected to a primary alternating field, a secondary current is induced in the conductor. This in turn produces a secondary alternating field which, together with the primary field, causes a resultant field whose amplitude and phase is different from that of the primary field. Distortions of the primary field are related therefore to the present subsurface conductors.

In the horizontal loop method, the primary field at the receiving coil is compensated for electronically, and the two secondary field components (in-phase and out-of-phase) are recorded as percentages of the primary field at the receiver coil.

With the Turam method, the primary field is set up by closed inductive loops laid out on the ground. Two receiving coils or staffs, with vertical axes, connected by a lightweight shielded cable to a compensating amplifier are used to measure the resultant electromagnetic field. The quantities recorded are:

a. The ratio of the field strength at the two coils.

b. The phase difference between the fields at the two coils.

Lines are surveyed perpendicular to the long side of a rectangular primary loop, readings commencing 200 feet from the side of the loop. Several primary loop setups were required for the surveys of Area 10 and Area 18.

INTERPRETATION

Area 5

In relatively hilly terrain such as prevails in most of the Yukon Territory, the out-of-phase component is by far the most reliable indicator of subsurface conductors. The in-phase component is affected positively by cable shortening and negatively by coil misorientations (non-parallelism), both of these effects originating from topographic variations. On this particular survey, variations of the in-phase component were kept generally below ± 4%, indicating close attention to both of the above mentioned effects.

The out-of-phase component responds most strongly to the weaker conductors, such as clay beds and water saturated zones in overburden and bedrock. The in-phase component responds more strongly to the massive, metallic conductors, ratios of 1 or more (in-phase to out-of-phase) generally indicating massive sulphides or graphitic zones.

On Area 5, the only out-of-phase anomalies exceeding 3% are in the positive direction and most probably represent very shallow layers of clay or water-saturated overburden. Examples of these can be seen on Lines 0, 4, 28 and 32. With the exception of the last two, coincident in-phase response is lacking. The weak anomalies on Lines 28 and 32 may possibly indicate a subsurface condition consisting of a shallow, weak conductor plus a deeper and more massive conductor. However,

they are also typical of a combination of topographic effects, such as a valley or creek bed. This possibility should be determined before any further investigation of the anomaly is done.

Area 10

The Turam survey of Area 10 revealed six weak to medium strength conductors.

Conductor 1 is the strongest, exhibiting phase/ratio and frequency characteristics common to the more weakly conducting metallic conductors and the more highly conducting electrolytic conductors. The zone is approximately 1500 feet long, maximum conductivity occurs at a depth of approximately 130 feet, and the zone has a steep dip to the east.

The survey by the Ronka horizontal loop method on Lines 32 to 40N, give only very minor out-of-phase response, confirming the low conductivity of the zone. Normally, on the basis of this evidence, a low priority would be assigned for further investigation. On the other hand, the conductor is definitely associated with some bedrock structure, and certainly contains conducting material. Supporting geological evidence might justify further work.

Conductors 2, 3 and 5 are of still weaker conductivity, as evidenced by the phase/ratio characteristics. Conductor 2 exhibits

locally better conductivity as it crosses the projection of the strike of Conductor 1. The three conductors are fairly continuous along strike, varying in length from 1400 feet to approximately 3200 feet. Depth to maximum conductivity is generally in excess of 200 feet. The conductors are believed to represent water-filled faults or shears, though the lack of any geologic or magnetic data in the area renders such an interpretation somewhat speculative.

Conductors 4 and 6 are represented by one-line anomalies whose phase/ratio characteristics suggest local conductivity of medium strength. Conductor 4 is poorly defined as it coincides with the edge of a primary loop where the data overlap and are unreliable. These conductors should be considered significant only if encouragement is provided by further investigation of Conductor 1.

Area 18

At least eight conductors have been located in this area. They vary in strength from weak to strong and in strike length from a few hundred feet to more than 2000 feet.

Conductor 1, lying at the west end of the area, is of low conductivity and typical of a water-filled fault or shear zone. Depth to the main conductor axis is probably of the order of 150 to 200 feet, though the conductor probably widens and becomes weaker at depth.

Conductor 2 is likewise of weak strength and may be an extension of Conductor 1. The axes of these and the following conductors is inferred on the basis of assumed strike continuity and general similarity from line to line. Since the lines are 400 feet apart, the axes can therefore be considered tentative only.

Conductors 3, 4, 5 and 6 occur in a generally conductive area between Lines 32 and 44W. Conductor axes are highly speculative. Conductivity varies from weak in the case of portions of Conductors 3 and 6, to strong in the case of Conductors 4 and 5, and part of Conductor 3. The anomalies caused by these conductors merge with one another making quantitative interpretation impossible. Depth to main conductor axes appear to vary from 100 to 200 feet. Dips are probably nearly vertical.

Conductors 4 and 5 are definitely considered worthy of drilling. Recommendations for drill locations were made in August and it is understood that considerable diamond drilling followed. Any detailed interpretation made without the benefit of these data would serve no useful purpose.

Conductor 7 is based on a one-line anomaly and, although sharp and strong on the phase component, shows very weak conductivity. It is not considered worthy of further investigation.

Conductor 8 has the greatest strike length on the grid, exhibiting continuity of over 2000 feet. The conductor is still open east of Line 0. Conductivity is strong from Line 0 to Line 8W, medium thereafter. The conductor may be banded, the second zone occurring at least 100 feet north of the main zone. Quantitative interpretation is complicated by this factor. Depth to the main conductor axis seems to vary from 150 to about 200 feet. Drilling has been recommended on Line 8W and it is understood that the conductor was explained.

SUMMARY AND CONCLUSIONS

The horizontal loop survey of Area 5 revealed only one conductor whose characteristics are such that no further investigation can be recommended on the basis of geophysics.

Several weak to medium strength conductors were located by Turam in Area 10, one of which was confirmed by the horizontal loop survey. Conductor 1 is recommended for careful consideration as it exhibits the sort of conductivity that is common to some poorly connected sulphide bodies in similar geological environments. The decision should be based on geological and any other geophysical information available.

A number of strong and quite favourable conductors were found in Area 18 and have been recommended at the time of the survey for drilling. It is understood that subsequent diamond drilling has confirmed these conductors, though the results have not been provided to the interpreters.

SUMMARY REPORT AND RECOMMENDATIONS
JANUARY 31, 1967

1. INTRODUCTION

During 1966 Northlake Mines Limited conducted an extensive exploration program in the area lying in general WNW of the Grassy Lakes, Finlayson Map Sheet 105-G in the Yukon Territory. (Figure 1). Details of the program have been reported elsewhere by MacDonald Consultants Limited, property managers, and by the writer, Consulting Geologist.

This report is intended to set out a brief summary and the recommendations for follow-up work.

For details, the reader should refer to the above mentioned reports.

2. PROPERTY

	Initial claims, March 30, 1966	560
Plus	Staked March 30, 1966 - January 30, 1967	294
	Total claims, January 30, 1967	854
Minus	Recommended for abandonment	574
	Recommended for retention	280

3. REGIONAL GEOLOGY

The basic concepts underlying Northlake Mines program are as follows:

a. The belt of variously-metamorphic rocks originally known as the Yukon schists has been, at least in part, subdivided and correlated by the G.S.C. (map 30 - 1963).

b. Part of this belt is believed to be of Mississippian age and consists of biotite-chlorite-sericite schists with limey and quartzitic members characterized by ultrabasic intrusives.

c. This type of formation has produced in excess of $250 million of gold in the Klondike. More recently, in excess of 60 million tons of massive sulphide bodies averaging about 10% lead and zinc combined with minor copper and close to 1½ oz/t of silver have been outlined in these schists in the Vangorda Creek area. The gross value of these sulphide bodies, which are of long term commercial grade and for a large part minable by open pit, is of the order of $1.5 billion.

d. These schists may be called the productive schists and merit extensive exploration, especially in areas where there is evidence of strata-bound sulphide deposition and of favorable structure.

e. Minor-size copper-zinc-(lead) bearing deposits of this type are known in the Fire Lake - North Lake - Grass Lakes area.

f. This area is characterized by a pronounced East-West trend across the normal NW-SE structural grain. There is also evidence of pronounced NE and N trending faulting, and of recent domal uplift accompanied by Tertiary basalts.

g. The area, especially in the lower lying parts, is covered by extensive overburden which does not appear to reach the great thicknesses of several hundred feet more common much further south.

h. This set of favorable conditions warrants an exploration program by airborne magnetic and electromagnetic methods with a ground follow-up program consisting of electromagnetic and geochemical prospecting.

4. PROGRAM SUMMARY

The program was initiated in early April 1966 by flying the vicinity of nine minor showings lying at high altitude with a reconnaissance-type electromagnetic helicopter-borne device, the Geo Cal method.

In May, the program continued with a helicopter borne magnetic-electromagnetic survey over the less rugged parts of the claims by Lockwood Survey Corporation.

The airborne programs located a total of 19 areas of interest.

In June, linecutting and ground surveys started. A summary of the overall program in table form is attached. In general, the details of the program were adjusted to conditions. Considerable emphasis was placed

on streamsilt and soil sampling, the former along streams draining the surveyed areas, the latter confined to the vicinity of electrically conducting zones, usually after grids had been cut and the zones located by a ground survey.

One anomaly located by airborne methods on the Hoo Group was pinpointed by Turam and drilled without geochemical work as the depth of overburden was estimated to be in the vicinity of 100'. However, overburden was found to be in the vicinity of 30'; the drilling intersected graphitic schists, chloritic-sericitic schists, and a talc-schist zone and encountered only traces of copper in disseminated pyrrhotite.

After completion of the field program in October, assay returns of the geochemical reconnaissance continued to come in until well into December and assessment of the complete results was not completed until about mid-January 1967.

As a result of this assessment, it has been recommended to abandon 574 claims and to continue work on the remaining 280 claims, representing 11 of the original 19 areas. These have been divided into 6 priorities, defined from 1 to 6 in order of decreasing interest.

5. PROGRAM RESULTS

a. The airborne geophysical surveys did not reveal any outstanding conductors near any of the known showings, ruling out the presence of near-surface large sulphide bodies in their vicinity.

b. The Lockwood Survey located a number of interesting electromagnetic anomalies in the vicinity of ultrabasic intrusives, specifically in areas 11, 17, 18 and 19.

c. Streamsilt sampling revealed a definite pattern of increased coppers and occasionally lead and zinc, in the vicinity of the ultrabasics. One outstanding anomaly was found to originate in an area of rust and near a conducting zone of characteristics that may reflect the presence of massive sulphides in area 17.

Zinc anomalies did not show a very significant pattern.

Lead, and to a lesser degree copper, show a definite increase in areas draining the granodiorite intrusives, especially around the intrusive at Grass Lake.

Remarkable are the absence of lead and the relatively low zinc in the high copper anomaly in the streams draining the South part of the El Group. In the main streambed, the copper in silts shows a constant increase over a length of about 2½ miles from 240 ppm to 7562 ppm.

d. Soil sampling, conducted over 11 of the 19 areas on grids with both 800' and 400' line spacing, with a 200' or 100' sample spacing, showed in general spotty results. Over area 11 however, a significant copper anomaly was found with peak values of 409 ppm Cu, 100 ppm Pb and 660 ppm Zn. This anomaly occurs on a well drained slope and originates in a strongly conducting zone, apparently from a contact between chlorite schists and graphite schists of very low metamorphic grade and known to contain strata-bound fine grained massive pyrite-pyrrhotite on a nearby property. Both folding and faulting are indicated nearby.

e. Linecutting, picketing and line surveying was done respectively over 10, 15 and 6 areas, as conditions suggested.

f. Reconnaissance geological mapping on a scale of 1" = 1000' was carried out over all the significant claim areas and surroundings, with emphasis on the showing areas, using a 1" = 1000' base map prepared by McElhanney Surveying and Engineering.

g. Ground EM surveys were conducted with a moving source Ronka instrument over 5 areas, and with a constant source Turam instrument over two areas (see table).

These surveys pinpointed several conductors detected by airborne methods.

h. Ground magnetics were not used, as the government aeromagnetic maps and the results of the Lockwood surveys showed high magnetics over ultrabasics and very uniform low magnetics over the more highly metamorphic schists of the Gee area.

Some magnetic surveying is indicated in further proposed work.

i. Gravity. One small gravity survey was run in area 11 near the source of the geochemical anomaly. Results were inconclusive and suggested that a much larger survey should be carried out.

j. Trenching in area 2, where massive pyrrhotite showings with minor chalcopyrite occur, was not successful and failed to find significant extensions to the showings.

k. Core drilling, totalling 1,596' in 4 holes in area 10 on an airborne EM anomaly confirmed by Turam, failed to encounter commercial mineralization.

l. Summary

(i) Two significant discoveries were made. In area 17, as a result of a combination of airborne surveying and reconnaissance geological work, which led to the decision to sample the streamsilts, an outstanding copper anomaly was discovered.

In area 11, as a result of airborne surveying followed by soil sampling in the area of a promising HEM anomaly pinpointed by a Ronka survey, a significant Cu - Pb - Zn anomaly was discovered.

(ii) The combination of airborne surveying and streamsilt and soil sampling has permitted the elimination, with a high degree of confidence, of about 2/3 of the staked areas.

(iii) Seven other areas have provided enough encouragement to justify some further investigation. Streamsilt and soil sampling results have been important factors in several of these areas.

6. INDIVIDUAL TARGET AREAS

The remaining target areas have been divided into 6 priorities, which will be discussed separately.

Priority 1 E1 Group, area 17 (figure 4)

This group consists of 60 claims. Figure 4 shows the relation of the copper streamsilt anomaly to the geology and the airborne EM anomalies.

The lead content of the streamsilts is nil or trace; the zinc content varies between 0 and 117 only, which is normal background.

Viewed in the regional streamsilt pattern, the absence of lead and the normal zinc background in this high copper anomaly may be very significant. Both to the West (Hoo Group) and to the East, minor lead appears about 8 miles away from the E1 Group and at the same time, zinc starts to pick up. This suggests that the E1 Group is the copper-bearing centre of a base metal area where lead and zinc are concentrically arranged away from this centre.

To the East, however, the geological environment is different, and the regional sampling to the North and South is insufficient to non-existent. Additional sampling could well show that the geological environment

has a greater bearing on the base metal distribution. Also, this distribution may not be roughly circular, but could have some oblong shape following some as yet unknown structural trend.

Whatever base metal distribution is ultimately found to exist, there is at least a strong regional suggestion that the El Group lies at the core of the regional copper distribution.

Examining the anomaly in detail, it shows a near-textbook distribution with two sources, a weak one in the Creek West of the group, and a strong one in the Creek on the East part of the group, with a weak "halo" effect upstreams in both cases.

As the sample nearest the source in the Easterly creek assays 7562 ppm, which is equal to 0.756%, it is obvious that the best part of this 1½ mile long copper-bearing zone should lie close to this high anomalous reading.

It is of considerable interest that a line drawn between the two sources is about parallel to the geological structure, which is well defined by the aeromagnetics. The high magnetics reflect the presence of the serpentinized ultrabasic, and one must assume that the surrounding schist formations are more or less parallel to the contact of the ultrabasics, as is usually the case around this type of intrusive.

The conclusion that the odds favor a stratabound high-copper zone very low in zinc and lead is therefore well nigh inescapable. The map shows clearly that this zone produces a marked effect in the streamsilts in locations about 1½ miles apart,

The airborne electromagnetic pattern is also of considerable interest, as it shows, near the high copper anomaly, a well defined conductor of characteristics that may typically reflect the presence of a sulphide body.

When it is remembered that attention was drawn to the area by the existence of a very rusty pinnacle-like hill during reconnaissance-type geological mapping located in the general area of the HEM anomaly, and that this led to the decision to take streamsilt samples in the nearby creek as this pinnacle was not easily accessible, the conclusion is peremptory that a mineralized copper-bearing body lies somewhere in this vicinity.

It is very seldom indeed that so many strong and favorable features point to a target area of as large a size and so well defined as the present one.

The writer has therefore no hesitation in defining the odds of discovering a large-size copper-bearing body in this location as unusually high.

The following program is recommended for an early start in March 1967. A winter road as near as possible to an all-weather location is recommended rather than helicopter-transportation, as it is practically certain that drilling will be justified, and that this can be demonstrated by line-cutting and trenching with a bulldozer while the snow is still on the ground. It is very likely that outcrops with substantial copper will be found in this area.

Snow fell early in October 1966 and in nearby areas there is little frost in the ground. A ripper-equipped bulldozer will permit the taking of soil samples as line-cutting in the area proceeds.

Tote road: 25 miles @ $800		$ 20,000
Linecutting: 20 miles @ $100		2,000
Geological mapping: 4 man-months @ $1,500		6,000
Soil Sampling: 1000 samples @ $3.00		3,000
Electromagnetic surveying: 15 line miles @ $100		1,500
Gravity survey: 10 line miles @ $150		1,500
Transportation: Bombardier, truck		6,000
	Total	$ 40,000
Contingent core drilling: 3000' @ $20		60,000
	Total	$100,000
Engineering, overhead, contingencies: 20%		20,000
Total appropriation		$120,000

Drilling on this property can hardly be considered as contingent, and as the drill should be moved in before break-up, i.e. before May 1st, the full appropriation of $120,000 is recommended for this project.

Priority 2 Leo Group, area 11 (figure 5)

A strong HEM was located in this area. After linecutting, a Ronka survey pinpointed this anomaly and subsequent soil sampling showed a significant copper-lead-zinc anomaly with peaks of 409 ppm Cu, 100 ppm Pb and 660 ppm Zn in an environment similar to the one prevailing on the El Group. Drilling of one hole on nearby ground is known to have located fine-grained massive pyrite-pyrrhotite in a narrow argillite bed very near the contact of thin-bedded and laminated chloritic argillites with graphite slates.

The source of the copper-lead-zinc anomaly in the soil, which has its peak on a well drained slope with little vegetation at an elevation of about 4800', is located near what appears to be the same contact, at the edge of a strongly conducting zone, and, as on the El Group, only a short distance away from an ultrabasic.

It is thought that the base-metal anomaly may not reflect an outcrop of commercial grade copper, but rather indicates the presence of a formation with unusually high copper and probably lead and zinc. As massive sulphide of typical stratabound texture is present nearby and as an apparently similar zone on the El does carry high copper, it is postulated that a specific assemblage may occur throughout the area, i.e. that a favorable "horizon" with massive sulphide deposits occurs.

The Leo Group warrants therefore a high rating, and further exploration as early in the season as possible.

If this general working hypothesis is confirmed by success, or even partial success, on either or both the El and Leo Group, the key to further successful exploration in the area may well have been found.

The following program is therefore recommended for an early start, preferably with a gravity survey in March 1967. It is anticipated that a winter road can be built quite easily, if this appears desirable, from the El road. This road could follow the lower part of talus slopes with Southerly exposures for a good portion of the way, thus preparing the building of an all-weather road.

In the area of the geochemical anomaly, there does not appear to be significant perma frost and bulldozer trenching is therefore strongly recommended.

A small initial gravity survey in 1966 has indicated that the gravity profile rises with the hillside and that a significant gravity anomaly could be present.

Tote road: 10 miles @ $1,000	$10,000
Geological mapping: 2 man-months @ $1,500	3,000
Linecutting: 10 miles @ $150	1,500
Soil Sampling: 350 samples @ $4.00	1,500
EM surveying: 10 line miles @ $100	1,000
Gravity surveying: 15 line miles @ $200	3,000
Transportation: Bombardier, truck	4,000
Bulldozer trenching: 100 hours @ $35	3,500
Aircraft	2,500
Total	$30,000

continued ...

Contingent core drilling: 2000' @ $25		50,000
	Total	$80,000
Engineering, overhead, contingencies @ 20%		16,000
Total appropriation		$96,000

Priority 3 Hoo Group, areas 18 and 19 (figure 6)

These target areas are in an environment similar to the El and Leo groups, i.e. in the general contact area of schistose rocks with the ultrabasics.

One conductor remains to be tested in area 18; good conductors with low soil sampling results and indicated faults are present in area 19.

The possible potential of these areas would be enhanced by economic discoveries on either the El or Leo Groups, and they would become much more accessible.

Only a minor program is therefore proposed for either 1967 or 1968, the timing depending upon the progress of the El and Leo programs.

The importance of detailed mapping taking into account the topography, and soil sampling in judiciously selected locations in area 18, should be stressed.

The recommended expenditure is as follows:

Geological mapping: 2 man-months @ $1,500		$ 3,000
Soil Sampling: 350 samples @ $3.00		1,000
Transportation: helicopter, 15 hours		2,000
Camp preparation		1,000
	Total	$ 7,000
Contingent linecutting, geophysics, 15 line miles @ $200		3,000
Contingent drilling: 1600' @ $25		40,000
	Total	$50,000
Engineering, overhead, contingencies: 15%		7,500
Total appropriation		$57,500

Priority 4 Gee Group, area 5

Soil sampling at 100' spacing on lines 400' apart gave generally spotty trends of high lead and zinc and some spotty high copper values over the West third of the grid. Peak values are:

Pb 840 ppm Zn 500 ppm Cu 210 ppm

A number of galena bearing quartz veins occur in the area.

Further study is required, particularly to determine whether the high lead is due to minute galena particles or is really adsorbed geochemical secondary lead.

This block of ground appears to lie between two contacts. The Ronka survey found only one weak in-phase reaction near the creek; this could be due to short-cable effect but is located near a galena showing and the peak copper value in the soils.

The property requires detailed mapping and exact assessment of topographical conditions near the high lead areas.

The quartz veins and high lead soils could represent a halo around a much larger galena-bearing body buried beyond a depth of 100' and the proposed detailed geological investigation should determine whether a deep-penetration EM like Turam, or an IP survey is justified.

The proposed expenditure is as follows:

Geological mapping: 1 man-month @ $1,500		$ 1,500
Deep EM or IP survey: 15 line miles @ $300		4,500
Aircraft transportation		1,500
	Total	$ 7,500
Contingent core drilling: 1500' @ $25		37,500
	Total	$45,000
Engineering, overhead, contingencies; 20%		9,000
Total appropriation		$54,000

Priority 5 Gee Group, areas 10, 14 and 16

In each case, further assessment is warranted, but the suggestion is not to spend any funds until the El and Leo areas have been more closely assessed.

In each areas, favorable indications are conducting zones, which in 10 and 16 are supported by spotty geochemical highs; in 14, the zone occurs under apparently deep (100' or plus) overburden.

Further investigation involves detailed mapping in area 10, prospecting near area 16 and possible Turam surveying over area 14.

Turam surveying could be done any time an instrument is used on any of the other projects.

Recommended expenditures are as follows:

Detailed geological mapping, additional soil sampling, prospecting	$ 15,000
EM surveying, as indicated	5,000
Engineering, overhead, claim maintenance: 20%	4,000
Total appropriation	$ 24,000

Priority 6 Gee Group, area 2

No expenditures recommended at present.

Prospecting

An appropriation should be available to continue areal streamsilt sampling and follow-up soil sampling, as various localized areas appear of interest even now. Success on the El and/or Leo would (i) enhance the attractiveness of certain situations, (ii) provide good geological guide lines for further areal exploration and (iii) create a staking rush.

It would be desirable for Northlake Mines to be in a position to capitalize immediately on any success obtained on the present holdings.

Using the bulldozer for soil sampling while putting in a winter road and lines would be advantageous and fulfill the requirements of further areal exploration at very little additional cost.

It is recommended that $30,000 be set aside for aerial reconnaissance and property acquisition, covering the following:

Helicopter, one month	$10,000
3000 soil samples	10,000
Property acquisition	10,000
Total	$30,000

7. SUMMARY AND RECOMMENDATIONS

The 1966 Northlake Mines Limited exploration program in the Grass Lakes area has resulted in the discovery of several very attractive exploration targets.

On the El Group, streamsilt sampling, airborne EM and favorable geological environment suggest the presence of a copper-bearing zone of significant size and possibly of major importance.

On the Leo Group, a very good target is reflected by high Cu - Pb - Zn soil samples near a contact zone between chloritic argillites and

graphitic slates known to contain bedded iron-sulphides nearby. Geological conditions are comparable to those on the El Group.

On the Hoo Group, conductive zones in a geological environment similar to the one on the El and Leo are worthwhile targets requiring further assessment.

In area 5 on the Gee Group, a high lead environment suggests the possibility of a significant buried galena deposit.

Several other targets require further work for a final assessment, but are less promising than the first group.

Large areas with an estimated very low potential are recommended for abandonment.

Recommended expenditures may be summarized as follows:

Group	Area	Priority	Firm	Contingent	Engineering	Total
El	17	1	$40,000	$60,000	$20,000	$120,000
Leo	11	2	30,000	50,000	16,000	96,000
Hoo	18, 19	3	7,000	43,000	7,500	57,000
Gee	5	4	7,500	37,500	9,000	54,000
Gee	10, 14, 16	5	20,000	-	4,000	24,000
Gee	2	6	-	-	-	-
Areal Prospecting			30,000			30,000
TOTAL			$134,500	$190,500	$56,500	$381,500

Out of this amount, the following appropriation is recommended for an early start of the program in 1967.

Firm		
El, Area 17	$120,000	Includes drilling
Leo, Area 11	36,000	Drilling is contingent
Priorities 3, 4, 5	24,000	50% of initial work
Areal Prospecting	30,000	Spend at a rate related to success on El, Leo
Cost of 1967 Program	$210,000	Firm commitment
Probable 1967-1968	$171,500	Contingent expenditures
Total Program	$381,500	

CERTIFICATE

I, PETER H. SEVENSMA, of Vancouver, B.C., do hereby certify that:

1. I am a graduate of the University of Geneva, Switzerland (Physics and Chemistry, 1937) (Geology and Mineralogy, 1937) where I obtained my Ph.D. in Geological and Mineralogical Sciences in 1941.

2. I am a Consulting Geological Engineer and a registered member in good standing of the Association of Professional Engineers of British Columbia and of the Association of Professional Engineers of Yukon Territory.

3. From February 1948 until December 1965 I have been engaged continuously in mining and exploration geology in the employ of Cominco Limited. As a Senior Exploration Geologist, I have worked extensively both in Eastern and Western Canada.

4. I have personally examined on several occasions the claims which are the subject of this report and have acted as a consulting geologist since early 1966 on the exploration program conducted by Northlake Mines Limited on these claims.

5. I have personally supervised in the field the airborne geophysical survey conducted by Lockwood Survey Corporation between May 8th and 23rd, 1966 for Northlake Mines Limited.

6. I have not received, nor do I expect to receive or acquire, directly or indirectly, any interest in any of the properties or securities of Northlake Mines Limited.

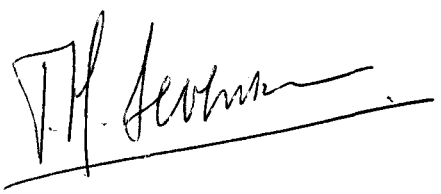
Respectfully submitted,

P.H. Sevensma, Ph.D., P. Eng.

January 30, 1967

If a situation with a definite economic promise is encountered on the El or Leo, an extensive road-building and drilling program would follow involving perhaps anywhere from 10,000' to 20,000' of drilling. It's cost would lie between $300,000 and $500,000.

Respectfully submitted,



E.H. Sevensma, Ph. D., P. Eng.

Personnel and costs are being reported separately by A. MacDonald Consultants Ltd.
