SUMMARY

The Mount Profeit Property comprises 150 claims located northeast of Pinguicula Lake in the Mackenzie Mountains, Yukon Territory. Claims were staked to cover lead-zinc showings discovered during follow-up of drainage anomalies generated by the 1974 Yukon Pb-Zn Program.

The property is situated within the northern extremity of the Bonnet Plume carbonate mound. It is underlain by a gently easterly dipping sequence of Upper Hadrynian dolomites interbedded with minor shales and siltstones. Dolomite members thin and shale out to the north of the claim block.

Lead-zinc mineralization occurs in vuggy stromatolitic dolomite units over a continuous strike length of greater than 1,500 feet at the main showing (#1) (Figure 5). Galena and lesser sphalerite occur in (1) veins, breccias, and fractures within a transgressive shear and sheet-jointed zone and (2) as widespread vug fillings. A 21 foot sample across a shear zone (#1) assayed 3.48% Pb, 6.60% Zn and 2.00 oz Ag/ton. The lead to zinc ratio is generally 2:1. A high grade pod directly to the east of the main showing assayed 47.2% Pb, 16.0% Zn, and 17.2 oz Ag/ton over 31 feet.

Geological mapping and prospecting of the property at a scale of 1 inch to 500 feet and sporadic geochemical sampling was accomplished during late July and August of the 1975 field season.

DISCUSSION AND RECOMMENDATIONS

The geology and structure of the Mount Profeit area appear favourable for Mississippi Valley type lead-zinc mineralization. The following features are present on the property: (a) a sandstone-conglomerate sequence above an unconformity and beneath a jointed, locally vuggy, shallow water dolomite, and (b) vertical and lateral facies change from dolomite to a shale-siltstone sequence.

The presence of a possible fluid migration route within the conglomerate and unconformity and the presence of extensive mineralization near the dolomite to shale facies change warrants drill testing. Northwest-trending angled drill holes are recommended to explore the shear zone on claims 26 and 42 (Figure 6) for zones of wider and higher grade mineralization.

Drill holes collared near the northwest flowing creek which passes through the eastern portion of claims 42 and 44 (Figure 6) would test for extensions of the #1 and #2 showings towards the lower contact of Hd^1m and also explore the contact between Hd^1m and the overlying Rapitan shales. An initial five thousand feet of drilling in 8 - 10 holes is sufficient to investigate mineralization extensions and controls.

INTRODUCTION

The Mount Profeit Property is located fifteen miles northeast of Pinguicula Lake in the Bonnet Plume Range of the Mackenzie Mountains, Y.T. (Figure 1). The property comprises a northwest-southeast elongate block of 150 claims covering the top and steep flanks of a rugged northwest trending ridge system (Figure 2). Relief within the claim block is 3,500 feet with the highest peaks reaching 7,400 feet. Arctic willow and stunted alpine fir are found in the lower valley bottoms. The entire property is above tree line. Arctic grasses, moss, and a variety of low leafy plants are found on valley sides up to 5,800 feet. Large masses of snow and ice remained in north facing cirques during the summers of 1974 and 1975.

Access is best afforded by fixed wing aircraft from Mayo, Y.T. to Pinguicula Lake, thence by helicopter to the property.

The Doc 1-150 claims were staked on July 19, 20 and 31, 1974 to cover lead-zinc occurrences located in an Upper Hadrynian dolomite unit. The showings were discovered by prospecting lead silt anomalies located during the 1974 Yukon Pb-Zn Program.

Work carried out in 1974 consisted of preliminary mapping and sampling (see Report by G.M. Leary - April 1975).

A four man field party completed mapping and prospecting the Mount Profeit property in August 1975. Field results were plotted on orthographic air photographs and a topographic map, both at a scale of 1" = 500'. Rock exposure is excellent on the ridge tops and flanks; cirque bottoms, lower valley walls and stream beds are overburden covered.

	Mayo Mining Division	

Enough assessment work was performed to renew 38 claims for one year and 82 claims for two years.

REGIONAL GEOLOGY

The Mount Profeit Property is underlain by lead-zinc occurrences hosted in a Hadrynian dolomite (Unit Hd^1), as shown on Map 106C of Open Files 205 and 206. Unit Hd^1 is part of the Bonnet Plume carbonate mound that developed intermittently from Hadrynian to Lower Cambrian time (Figure 3). The mound is constructed of three carbonate build-ups, a lower Hadrynian unit Hc; a middle Hadrynian unit Hd_1 and a Lower Cambrian unit Ꞓc, each up to 2,000 feet thick. The lower and middle carbonate build-ups are characterized by either domal and columnar or planar stromatolites. Units Hd and Ꞓc are commonly vuggy, pisolitic and/or sandy.

The mound is northwesterly elongate in plan and measures 30 by 50 miles. To the west and southeast of the mound, facies changes indicate a deeper water shale environment. Shallow water clastics including red, purple, brown and green siltstones and shales, ripple marked silty and shaly dolomites and quartzites are interbedded with the mound carbonates and are generally the dominant facies to the northeast. Facies relationships within the mound are illustrated in Figure 4.

Regional Laramide deformation has produced northwest trending open folds cut by numerous parallel reverse, normal, and thrust faults.

Lead-zinc mineralization is regionally associated with each of the three main carbonate units of the Bonnet Plume mound. Lead-zinc occurrences within the Hd and Ꞓc carbonate units are characterized by breccia, vug, fracture and vein fillings in vuggy sucrose dolomite, whereas, those within the Hc carbonate unit are associated with shear-related fracture and vein stockworks in massive and platy dolomite.

PROPERTY GEOLOGY

Property geology at a scale of 1" to 500 feet is illustrated on Figure 5. A stratigraphic column for the property is shown on Figure 4.

The Mount Profeit property occupies part of the northern extremity of the Bonnet Plume mound where Upper Hadrynian dolomite (Unit Hd^1) changes facies northwesterly into dominantly basinal clastics of the Rapitan Group (Hr). Rock units strike north-northwest and dip 20^0- 35^0E on the property. The Hadrynian dolomite and shale unconformably overlie older Hadrynian thin bedded dolomite, siltstones and shale (Unit Hsc).

Several faults with small displacement occur in units Hsc and Hd^1, Northeasterly trending sheet jointing and local shearing occur in the area of the main showing. Small folds are locally present beneath an unconformity in unit Hsc.

The property stratigraphy includes twenty-eight mappable units as shown in Figure 4. They are discussed below in ascending order.

Hc^2 consists of light to medium grey weathering massive fine grained thick bedded dolomite, with minor limestone beds. Locally the dolomite is sucrose and vuggy.

Unit Hc^2 is exposed adjacent to the northwest corner of the claim block where it is in fault contact with Hsc.

FIG. 4

Hsq consists of brown shale, siltstone and minor conglomerate and orange weathering platy dolomite exposed in the southwest portion of the property where they are in fault contact with Hsc. Mud cracks and graded bedding are prominent throughout the shale-siltstone portion of this unit.

Hsc comprises a sequence of interbedded brown-black slates and gritty limestone grading upward into tan to rusty weathering platy dolomites, crystalline grey-black limestone, brown to black shales and siltstones and rusty to clean quartzites which can be divided into ten mappable members, Hsc_{1-10}. For a more detailed discussion of these members see Appendix IV.

Since contact relations between some of the members are not always visible, erosional contacts may exist. The contact between Hsc and the overlying conglomerate (Hcgl) is an angular unconformity with considerable erosional relief.

Hcgl is a tan to rusty brown, locally maroon weathering, very coarse to fine grained, basal clastic assemblage up to 600 feet thick. Generally this unit fines upward from a coarse unsorted conglomerate $Hcgl_1$ at the base to the bedded coarse sandstones $Hcgl_2$ and maroon siltstones $Hcgl_3$. A more detailed description is given in Appendix IV.

$Hcgl_1$ unconformably overlies quartzites and dolomites of unit Hsc. Where Hcgl overlies Hsc_{10} the entire Hcgl unit thins and the coarse conglomerate component vanishes, indicating that the resistant quartzite of Hsc_{10} formed paleohills during Hcgl deposition. Hcgl forms an undulating lens that tails out on the property. Twelve miles south of the claim group another similar lens of Hcgl is present (G.S.C. Open File 206). This unit may be a fanglomerate or a coarse channel deposit which would account for its limited lateral

extent and rapid changes in thickness.

Mineralization within $Hcgl_1$ is scattered and minor. Pyrite concretions are scattered vertically and horizontally throughout the matrix of Hcgl. Rare quartzite boulders contain fine disseminated chalcopyrite and possibly tetrahedrite (up to 8000 ppm Cu). Trace lead and zinc are present in Hcgl on claim 10 where a prominent mineralized fracture zone crosses the conglomerate and overlying dolomite.

$\underline{Hd^1}$ consists of a variety of dolomites readily divisible into three members. These include a lower member (Hd^1_l) of light grey weathering, mottled, vuggy, stromatolitic dolomite; a middle member (Hd^1_m) of light yellow weathering, featureless, dolomite and an upper member (Hd^1_u) of massive dark grey to orange weathering stromatolitic dolomite.

$\underline{Hd^1_l}$ dolomite varies considerably along strike. At the north end of the central ridge (claims 25 - 31) the base of the unit is predominantly a dark grey, medium grained dolomite host with a light cream to tan, sucrose, dolomite mottles up to one inch across. Higher up in the section, the mottles increase in size, are recessive weathering and occasionally contain small cores of galena and sphalerite.

Further south, near the centre of the ridge, the mottled dolomite grades into a light to medium grey, sucrose dolomite in which domal stromatolite horizons are still recognizable. Patches of vuggy, sucrose dolomite contain galena as vug fillings (i.e. showing #4).

Near the bottom of the cliff on claims 2 and 146 concentrically laminated spheres of probably algal origin from 1/8 to 24 inches in diameter form the base of Hd^1_l.

The dolomite containing these spheres changes southward into medium bedded, grey micritic dolomite, characterized by abundant fenestrate textures, intercalated with pisolite and intraclast beds. Generally the micritic beds contain numerous open irregular vugs, elongated parallel to the bedding plane and lined with light grey to blue fine grained silica. Crystalline dolomite occasionally fills the vugs; sphalerite is rarely present.

Textures indicate that Hd^1_l changed from a supratidal-intertidal environment in the south to a slightly deeper water environment dominated by domal stromatolites. The development of sucrose dolomite in the northern portion of the ridge has destroyed most of the primary textures.

The contact between Hd^1_l and the overlying yellow, tan weathering, dolomite of Hd^1_m appears to be gradational although scattered outcrops of a three foot thick pisolitic bed locally mark the contact.

Hd^1_m consists of a light yellow tan weathering, fine grained, generally featureless light grey dolomite. Thickness varies up to about 800 feet on claim 144 and gradually decreases towards the shale out on claims 90 - 92. Finely sucrose, vuggy sections that weather a pink-tan colour occur in the upper portion of the unit.

As the contact with the overlying Hd^1_u dolomite is approached Hd^1_m becomes sandy and slightly pyritic. The contact is marked by a shaly quartz pebble conglomerate with minor light grey dolomite fragments. The clasts of quartz are generally well rounded. Where present the conglomerate is up to three feet thick.

Hd^1_u consists of a dark grey to light orange weathering, fine grained, massive stromatolitic dolomite with faint bedding plane markings. Scattered vugs in the lower portion are commonly up to inch across. Thickness varies from greater than 200 feet in the south but gradually decreases in thickness to the north where it shales out into the Rapitan Group (Hr).

Hr (Rapitan Group) consists of a sequence of shales, quartzite, and carbonate rocks which are readily divisible into seven mappable members. These rocks have a total thickness of greater than 3000 feet. A carbonate conglomerate, within the shales, is thought to be a debris flow from the Hd^1 carbonate mound.

Hd^2 is a yellow-tan, weathering light grey, fine grained, dolomite occasionally thin bedded. A narrow black shale band Hd^2_s is restricted to one exposure on claim 16. Although contacts with over and underlying rocks are not exposed they appear to be conformable and sharp.

$H\epsilon_{sc}$ (Sheepbed Formation) consists of a lower light to dark grey weathering, dark grey laminated, thin bedded, micritic limestone with interbedded dark grey, shaly limestone and an overlying section of dark grey to black recessive shales and minor siltstones. Locally, up to 5% pyrite is present as nodules and disseminations within the limestone.

The Figure 7 sketch illustrates facies changes and contact relations on the property.

The angular unconformity beneath the Hcgl conglomerate may change to a disconformity off of the property. Coarse conglomerate of limited areal extent fills small basins within the less resistant lithologies of Hsc. A channel deposit or fanglomerate best explains observed textures within the conglomerate.

FIG. 7

Above the Hsc and Hcgl units a thick assemblage of Hd^1 dolomite grades laterally into deeper water shale and siltstone of the Rapitan Formation. The wide variation in textures within the dolomite suggest that both reef and bark reef environments existed during the development of the Hd^1 carbonate mound. At the north end of the central ridge (claims 27 to 32) dolomitization destroyed original textures and produced a vuggy sucrose dolomite. Local erosion and addition of clastic material took place prior to development of the stromatolitic unit Hd^1_u.

Within the recessive weathering shales and siltstones of the Rapitan Formation a chaotic carbonate conglomerate up to 200 feet thick forms light grey weathering cliffs. Deposition by a debris flow from disintegration of the reef is suggested as an origin for this unit.

The reef dolomite and deeper water shales are overlain by a clean quartzite and micritic dolomite of uniform thickness.

MINERALIZATION

Thirty-four lead-zinc occurrences were located within the claim block in 1975 and are summarized in the following table. Location of the occurrences and assay data are given on Figure 5 and Figure 6 respectively. Only the first eight showings listed in the table are considered significant.

Sulphides occur as massive pods (showing #2), breccia and fracture fillings in shear and sheet jointed zones (#1 and #3), irregular replacement patches (#5 and #7), vug fillings or linings (#4) and stratabound bedding plane and fracture fillings (#8). All of the occurrences, except #8 and #26 are hosted in Hd^1 dolomites, generally within 1,000 feet of the Hd^1_l - Hd^1_m contact. Although a large part of the sulphides

occur in fractures, shears and breccia zones and thus appear to be structurally related, the clustering of occurrences near the Hd^1_l - Hd^1_m contact demonstrates stratigraphic control.

G.N. Leary, P.Eng.

TABLE OF MINERAL OCCURRENCES

NO.	LOCATION	MINERALIZATION	HOST ROCK	DESCRIPTION
1	DOC 26	Galena sphalerite pyrite marcasite (smithsonite hydrozincite)	Hd^1_l	Hosted in vuggy upper portion of Hd^1_l on east facing dip slope; dominantly galena with lesser amounts of pale green and red sphalerite that is commonly leached and altered to smithsonite in varying degrees. Mode: breccia and fracture fillings along narrow (are 14' wide) shear zones. Assays (>1700' in length) of 2.24% Pb, 0.91% Zn, 0.62 oz/T Ag.
2	DOC 42	Galena sphalerite tetrahedrite (hydrozincite malachite)	Hd^1_l	Massive (31'x27') pod of galena and red-green sphalerite with minor tetrahedrite. Assays yielded: 31' @ 16.8% Zn, 47.2% Pb, 17.2 oz/T Ag; 27' @ 9.6% Zn, 52.0% Pb, 20.8 oz/T Ag.
3	DOC 26	Galena pyrite marcasite	Hd^1_l	Coarse grained galena with minor sphalerite, tetrahedrite and marcasite in a dolomite breccia that is exposed in an area 4'x30'. Breccia contacts with massive dolomite vary from sharp to crackled. Breccia grades 30% Pb and 4 oz/T Ag over 15'.
4	DOC 25	Galena	Hd^1_l	Galena and minor tetrahedrite fill vugs in a vuggy, sucrose Hd^1_l dolomite over an area 15'x10' by <10' thick, est. <5% Pb.
5	DOC 23	Sphalerite (galena)	Hd^1_l	Green ZnS, PbS and quartz occur as pods along an E-W fracture zone. Splotches and disseminations of red sphalerite replace grey, fine grained to stromatolitic dolomite over strike length of 15' and up to 3' wide. A grab sample of replacement sphalerite graded 24% Zn.
6	South of DOC 19/ 20	Sphalerite (galena)	Hd^1m	Red and green coarsely, crystalline sphalerite, galena, pyrite and minor tetrahedrite with crystalline dolomite fill fractures in a finely sucrose, dense dolomite. Mineralization over an area 2'x25' ZnS>>PbS.
7	DOC 18	Galena sphalerite	Hd^1m	Red sphalerite and galena, as splotches and disseminations have replaced yellowish, Hd^1m dolomite. Mode of occurrence is very similar to that of #5. ZnS>PbS.

8	DOC 82	Sphalerite (hydrozincite) ± pyrite	Hsc_3	Consists of a sphalerite bearing strata-bound zone in a shaly dolomite bed overlain by shale within the upper part of Hsc. Sphalerite occurs along cross fractures and bedding planes, closely associated with thin interbeds of dolomite-arenite. A 3' channel sample across the zone assayed 4.00% Zn strike length >12'; dip length unknown.
9	DOC 80	Sphalerite, galena, minor tetrahedrite (malachite)	Hd^1_1	Sphalerite pods with scattered galena blebs in a coarse white crystalline dolospar within the upper portion of Hd^1_1.
10	DOC 82/ 91	Marcasite galena minor sphalerite (smithsonite hydrozincite)	Hd^1_1	Irregular ribbons of marcasite enveloped by thin rinds of galena with minor sphalerite within a coarse white crystalline dolospar of the lower portion of Hd^1_1.
11	DOC 46	Galena sphalerite (hydrozincite)	Hd^1m	Widespread vug fillings of galena and sphalerite in upper portion of Hdm.
12	DOC 46	Sphalerite (hydrozincite)	Hd^1m	Fracture and vug fillings of pale green sphalerite in upper portion of Hd^1m.
13	DOC 42	Galena sphalerite	Hd^1m	Similar occurrence as #11 and #12.
14	DOC 33	Galena (PbO)	Hd^1m	Scattered blebs and fracture fillings in massive sandy dolomite within the lower portion of Hd^1u.
15	DOC 33	Tetrahedrite	Hd^1m	Similar occurrence as #14.
16	DOC 150	Sphalerite (smithsonite hydrozincite)	Hd^1m	Fracture fillings in Unit Hd^1u believed to be a shear zone similar to occurrence #1.
17	DOC 150	Tetrahedrite (malachite)	Hd^1m	Similar to occurrence #16.
18	DOC 150	Sphalerite (hydrozincite)	Hd^1m	Similar to occurrence #16 & 17 and all (16,17,18) are believed to be the same or parallel shear zone.
19	DOC 18	Galena	Hd^1m	Minor galena and marcasite occur in a small fault zone.
20	DOC 18	Sphalerite	Hd^1m	Float occurrence of green sphalerite filling vugs.

21	DOC 18	Sphalerite	Hd^1m	Yellow-green sphalerite with quartz and red dolomite fill vugs.
22	DOC 17	Hydrozincite	Hd^1_1	Hydrozincite occurs along fractures near the upper contact of Hd^1_1.
23	DOC 23	Sphalerite	Hd^1_1	Sphalerite and minor galena fill fractures, small crackle breccias and vugs over a strike distance of 30' near top of cliffs.
24	DOC 23	Sphalerite	Hd^1_1	Green sphalerite with calcite and dolomite fill scattered vugs, fractures and pods up to 8" wide over a vertical distance of 60'.
25	DOC 27	Sphalerite (Hydrozincite)	Hd^1_1	Pale red and green sphalerite and trace galena in widespread vug and fracture fillings in Hd^1_1.
26	DOC 10	Sphalerite (hydrozincite)	$Hcgl_2$	Minor red sphalerite in voids between clasts in sand-pebble conglomerate.
27	DOC 10	Sphalerite trace galena	Hd^1_1	Float occurrence believed to be related to occurrence #4 or #24. Vug fillings in Hd^1_1.
28	DOC 147	Sphalerite Tetrahedrite (hydrozincite malachite)	Hd^1u	Red to brown sphalerite along laminations in upper sandy dolomite. Tetrahedrite smears on fractures and portion of Hd^1u.
29	DOC 137	Sphalerite	Hd^1_1	Green sphalerite partially fills 2" vugs in boulders of fenestrate textured dolomite.
30	DOC 141	Galena tetrahedrite sphalerite (malachite)	Hd^1_1	Scattered vug fillings and fracture smears in a gossanous outcrop of massive vuggy dolomite in Hd^1_1 (much quartz present).
31	DOC 35	Galena	Hd^1m	Galena with minor marcasite and tetrahedrite occur in quartz veins and coat fractures in a pisolitic grey dolomite. Mineralization exposed over 12'x15'.
32	DOC 26	Galena	Hd^1m	Small galena filled fractures. Probably an extension of showing #3.
33	DOC 33	Sphalerite tetrahedrite	Hd^1m	Minor red and green sphalerite and tetrahedrite occurs in a small fracture zone with quartz and dolomite.
34	DOC 33	Sphalerite tetrahedrite	Hd^1m	Green sphalerite and tetrahedrite fill vugs in a narrow ravine. Mineralized vugs in float are present for 200' above showing.

APPENDIX II

STATEMENT OF QUALIFICATIONS

A.C. Hitchins

BASc. Geological Engineering, Univeristy of Toronto, 1970, M.Sc. Geology, University of Toronto, 1973
Experience includes; geological assistant with AMAX Minerals Exploration 1968-1969, geologist with AMAX Minerals Exploration 1970 to present.

J.B. Alsen

B.Sc. Honour Geology, University of British Columbia, 1975
Experience includes; student summer employment with Texas Gulf Sulfur Co. 1968, Canex Placer Ltd. 1969-1970, Junior for Archer, Cathro & Associates, 1971, Senior for Amoco Canada Petroleum Co. Ltd. 1972, senior for Imperial Oil Ltd. 1973-1974
Currently geologist with AMAX Minerals Exploration.

L.V. Penco

BASc. Geological Engineering, University of British Columbia, expected 1976.
Experience includes; geologist assistant for Pechiney Development Co. 1970, prospecting for Newmont Company of Canada Ltd. 1971, assayer for Granduc Operating Co. 1972, junior for AMAX Minerals Exploration 1974-1975.
Currently enrolled at U.B.C. for final year.

J.K. Mortensen

BASc. Geological Engineering, University of British Columbia, expected 1977.
Experience includes; student employment with Conwest Exploration in 1972, warehouseman with Climax Molybdenum (B.C.) Ltd. in 1973, drillers helper for Connors Drilling 1973, geological assistant for AMAX Minerals Exploration 1974-1975.
Currently enrolled at U.B.C.

APPENDIX IV

DETAILED ROCK DESCRIPTIONS

Hsc_1 consists of interbedded brown-black slate and gritty limestone with minor dolomite grading downward into black, medium-coarse grained, thinly to thickly bedded, crystalline limestone.

Hsc_2 consists of finely laminated rusty black slate with minor limy mudstone that often exhibit soft sediment deformation.

Hsc_3 is a light orange to tan weathering, medium bedded dolomite with shale interbeds.

Hsc_4 consists of tan-grey weathering, massive dolomite with local interbeds of black to dark grey, fine grained, calcareous sandstone up to 40 feet thick. Scattered calcite filled vugs are surrounded by a stockwork of calcite and minor quartz stringers. Minor iron sulphides are associated with the dolomite beds. The lower portion is characterized by "zebra" textured dolomite and barite and minor planar stromatolites in contrast to the upper portion which contains abundant domal stromatolites.

Hsc_5 consists of coarse crystalline mottled massive thick bedded dark grey to black weathering, cliff forming dolomite with minor limestone.

Hsc_6 is a stromatolitic, bright orange to red weathering, grey, dolomite with beds up to two feet thick interbedded with black shale beds up to ten feet thick. The shale also forms partings between individual stromatolitic laminae. Domal and columar stromatolites are common throughout the dolomite; minor planar stromatolities occur in the lower portion.

Hsc_7 is a finely laminated, grey weathering dolomite in beds up to four feet thick that often contain rip-up clasts and load casts. Black lenticular and irregular pods of chert up to six inches thick and six feet long and occasionally sinuous in outline are indicative of the unit. Dark grey shale locally forms parting planes within dolomite.

Hsc_8 consists of light orange to tan weathering, medium to dark grey, finely laminated, medium bedded dolomite. Ripple marked shaly partings separate the dolomite beds. Occasional vugs are filled with quartz and calcite.

Where the dolomite is directly overlain by conglomerate of Unit Hcg_1 vertical cracks and irregular cavities within the dolomite are often filled with pebbles similar in composition to pebbles in the conglomerate, indicating that incipient karstification of the dolomite took place before deposition of the conglomerate.

Hsc_9 consists of a rusty brown to black weathering dark grey quartzite beds less than two feet thick separated by narrow dark grey shale beds. Although Unit Hsc_9 appears to generally underlie the clean quartzites of Hsc_{10}, it may grade laterally and/or vertically into Hsc_{10}.

Hsc_{10} consists of a massive, thick, bedded, resistant, light grey, light brown to purplish weathering, medium to coarse grained, light coloured orthoquartzite. Cross beds and laminations are rare. Hematite staining is concentrated in outcrops close to the unconformity with the overlying Hcgl. In a large outcrop on the northern portion of claim 137 the upper contact of the quartzite is hummocky and the hollows are filled with angular to subrounded quartzite boulders that grade rapidly upwards into more typical Hcgl. Fractures, extending down into the quartzite from the erosion surface often contain angular to rounded quartzite fragments.

$Hcgl_1$ is a brown weathering, cliff forming polymictic conglomerate. Clasts within the conglomerate vary from 1 - 48 inches across but average 8 - 10 inches and are usually subrounded to well rounded. At least 85 per cent of the clasts are identical to the quartzite of Unit Hsc_{10}, even where $Hcgl_1$ directly overlies dolomite. The remaining fragments consist of varying proportions of rusty sandstone-orange dolomite, and grey dolomite from the underlying Hsc units.

$Hcgl_2$ consists of buff to yellow weathering pebble conglomerate, sandstone, grit and siltstone overlying the more resistant $Hcgl_1$. Individual beds, often exhibiting graded bedding and ripple marks, vary in thickness from several inches to over five feet. Generally the upper part of $Hcgl_2$ is a quartz pebble conglomerate with a dolomite matrix in which the dolomite clast content increases as the upper contact is approached. Although only locally exposed, the contact between the clastic dolomite and overlying massive dolomite appears conformable.

$Hcgl_3$ consists of lenses of well bedded maroon siltstone and shale up to 20 feet thick near the upper contact $Hcgl_2$.

Hr_1 is a rusty, medium to fine grained quartzite with up to 5 - 10% disseminated pyrite. This lithology is prominent in the northeast corner of the property but pinches and shales out into Hr_2 to the south. Thickness reaches a maximum of 400 feet.

Hr_2 consists of brown, black and grey-blue shale and forms the dominant rock type in the lower portion of the Hr Group. This shale is the facies equivalent of Hd^1_m and Hd^1_u.

Hr_3 is a thinly bedded, black to grey, coarse grained limestone which grades into Hr_2 towards the south. Small lenses of Hr_3 occur within Hr_2.

Hr_4 is a cliff forming chaotic carbonate conglomerate containing clasts of limestone and dolomite which vary in shape from very angular through tabular to sub-rounded and range in size from 1/8 inch pisolites to blocks ten feet across. The majority of pebbles and boulders are limestone but dolomite boulders identical to the three dolomite members of Hd^1 are conspicuous within the conglomerate. At many exposures the fragments are grain supported with only minor amounts of dark grey micritic to coarsely crystalline limestone matrix which has a fetid odour on fresh surface.

Scattered through the conglomerate are commonly contorted lenses of a black, slightly calcareous recessive weathering shale. At the base of the conglomerate and included in map unit Hr_4 is a thin bedded dark grey limestone.

Within the property the conglomerate occupies a stratigraphic position equivalent to the upper dolomite of Hd^1. The presence of fragments of dolomite units lower in the section implies considerable relief either original or erosional on the reef forming dolomite nearby. Although the conglomerate is not in contact with the reef dolomites, the wide range in clast shape and size and lack of sorting indicates possible origin by debris flows from the reef.

Hr_5 is a finely laminated, dark brown to black shale with minor silty interbeds. Hr_5 appears to grade into Hr_6 to the south.

Hr_6 is a thin bedded, dark brown, green or purple assemblage of siltstone and silty shales with minor fine grained quartz rich sandstone. Locally the beds are calcareous and/or dolomitic. Towards the northern property boundary this unit thickens to greater than 1,200 feet.

Hr_7 consists of white to light grey, often rusty weathering coarse grained quartzite and quartz pebble conglomerate. Greater than 90% of the clasts are subangular to well rounded quartzite or white vein quartz fragments. Near the fault zone on claim 62 the quartzite is stained a bright red from oxidizing pyrite. Along strike to the north, Hr_7 becomes darker and the content of black shale, chert and feldspar clasts increases.

DATE REPORTS MAILED

ANALYST

BONNET PLUME MOUND CARBONATE UNITS

LOWER CAMBRIAN

€s — *Brown and orange weathering dolomite, limestone and shale.*

€c — *2. Buff yellow weathering porous dolomite.*
1. Grey weathering pisolitic dolomite.

UPPER HADRYNIAN

Hd — *2. Porous light grey weathering dolomite.*
1. Grey weathering dolomite; Hcgl basal conglomerate.

Hc — *2. Grey weathering massive dolomite and limestone.*
1. Orange weathering banded dolomite and limestone.

SYMBOLS

Limit of mapping and/or outcrop.

Geological contact.

Fault.

Synclinal fold axis.

Outline of claims held by AMAX.
