Office of the Regional Manager Mineral Rights
JUN 22 1982
WHI
Yukon Territory

Dear Ms. Proudfoot;

As per our correspondence and telephone conversations in recent months, I respectfully submit herewith my report of 1981 mineral exploration on the Lone Star Ridge property as described in the report and for which I had attested to representation work completion during the 1981 exploration season.

Please note that I am submitting two copies of each of the report and the folder containing certain appendices to it.

Sincerely,

Paul S. White P. Eng.

091064

This report has been examined by
the [illegible] and
[illegible] Quartz
[illegible] claims
represents work to the amount
of $ 47,200 .

REPORT ON EXPLORATION
PERFORMED ON LONE STAR GOLD PROPERTY
DAWSON MINING DISTRICT
YUKON TERRITORY
1981

May 31, 1982

INTRODUCTION

Dawson Eldorado Gold Explorations Ltd. acquired nine (nine) Crown granted mineral claims from F. Caley of Dawson City, Y.T. in 1979. The Crown Grants are the core of the Lone Star Mine property, which was mined in the 1912 - 1914 period. The property is located on a ridge between the forks of Eldorado and Upper Bonanza Creeks and was the subject of at least five gold-quartz mining developments over the eighty years since discovery in 1897.

In 1980, line cutting and geophysical surveys were carried out over the Crown Grants, and the geophysical work (resistivity and electromagnetic) was performed to map the old mine workings and indicate possible extensions. The survey met with limited success, indicating shallow drill targets of uncertain reliability, but encouraged the company to proceed with a $250,000+ exploration program in 1981, based on the recommendations of the Company's consultants, (Archer, Cathro & Associates Ltd.).

The company acquired 58 mineral claims by staking, and 61 mineral claims and two crown grants by option in 1981, to assemble an area of approximately 10 square miles, centred at Lat.63°54'N;

Long. 139°14'W, NTS 115-014 covering substantially the area bounded by Eldorado Creek to its headwaters, Victoria Gulch and Upper Bonanza Creek. R.J. Cathro P.ENG. recommended a program of exploration in October 1979 and in June 1981. This report covers the parts of these programs performed between April 1 and October 31, 1981. The work was performed by company personnel and contractors under the direction of R.J. Cathro P.Eng., and under the supervision of P.S. White P.Eng. on a day-to-day basis.

PROPERTY

The Lone Star Ridge property comprises the following claims:

LOT No.	CLAIM NAME	LOT No.	CLAIM NAME
86	Victoria	424	New Bonanza No. 2
106	Esther Edna	533	Swastika
408	New Bonanza	534	Udad
409	Niobe Fraction	535	Cato
410	Lone Star	536	Thistle
411	Zulu Chief		

The Crown Grants can be held indefinitely by paying $100/grant per year in taxes to the Government of the Yukon Territory.

MINERAL CLAIMS	GRANT No.	MINERAL CLAIMS	GRANT No.
DN 1 - 2	YA 32783	DN Fraction	YA 47088
DN 3 - 7	YA 47890-4	1 Fr. - 2Fr.	YA 47090-1
DN 8	YA 47895	ND 1 - 22	YA 49724-45
DN 9	YA 47896	ND Fraction	YA 47089
DN 10	YA 47082	DE 1 - 14	YA 55250-55263
DN 11 - 26	YA 32946-61	AC 1 - 12	YA 64270-64281
DN 27 - 31	YA 47083-7	RJ 1 - 32	YA 64216-64247
DN 32 - 33	YA 47604-5		

All claims are in good standing until December 31, 1985.

In addition to the above, various placer claims and prospecting leases were staked over the property, to protect against nuisance staking in 1981. These placer rights are not considered essential to the company and may be permitted to lapse.

LOCATION AND ACCESS

The Dawson Eldorado property occurs on the Lone Star Ridge between Bonanza and Eldorado Creeks in the Klondike placer gold District. It is situated at 63°54'N Latitude and 139°14'W Longitude, within N.T.S. map area 115-0-14, and is accessible by a 32 Km road from Dawson via Eldorado Creek, and also by a seasonal road from Upper Bonanza Creek.

The topography of the property is dominated by a gently rounded flat-topped ridge ranging in elevation between 860 and 1000 m, trending N55°W and partially dissected by various creek tributaries down to elevations of 450 - 600 m, giving relief of $400^{\pm}$ ($1250' \pm$).

HISTORY

The colorful 80 year history of the property is well described in published reports. The Lone Star mine is the only lode gold occurrence in the Klondike Gold Fields to produce a substantial amount of gold. The following activities are known to have occurred in the property:

1897	Discovery by prospecting placer miners working upslope from the rich placer creeks.
1898 - 1908	Prospecting and pitting staking into claims.
1909 - 1914	Development and Production by Lone Star Ltd., averaging 0.15 - 0.20 oz/ton Au, with small operating profit. Production halted by World War I.

Mining by Eldorado Dome Quartz Mining Co. Ltd. nearby.

1929 - 1936 Exploration by Consolidated Lone Star Limited, localized near old mine but severely restricted in funding.

1946 - 1947 Churn drilling and underground work localized near old mine site by Yukon Consolidated Gold Corporation Ltd. on option. Gold price and discouraging outlook for dredging operations caused option to be dropped.

1960 - 1962 Prospecting, bulldozer trenching and soil panning by Klondike Lode Gold Mines Ltd. Small shallow drill program unsuccessful.

1962 Geological Survey of Canada determines that gold itself is best heavy metal indication for the property.

1979 - 1982 Dawson Eldorado Gold Explorations Ltd. formed to assemble property, and commence long-term technical program to determine gold sources and grades in search for mineable reserves. $350,000 in exploration spent to date.

No comprehensive compilation of data, systematic sampling or mapping program has been taken before 1979.

GEOLOGY & MINERALIZATION

The following geological description of the property is taken from a report dated 15 June 1981 by R.J. Cathro, P.ENG.

"According to the Geological Survey of Canada, the ridge between Eldorado and Bonanza Creeks is mainly underlain by metasedimentary rocks, called Klondike Schist, of Upper Paleozoic age. Principal rock types are white to medium-green quartz-feldspar-sericite schists with micaceous quartite interbeds and some chlorite-and muscovite-rich layers. Quartz lenses and eyes are abundant in the Klondike Schist.

In common with other parts of this district, the terrain consists of rounded, gentle hills with few rock outcrops. Bedrock is almost obscured by an extensive frozen blanket of overburden and partially decomposed vegetation. The geology is known mainly from old trenches and workings and, in spite of its long history, previous mapping on the property has been only cursory in nature.

From the abundance of quartz in the overburden and creek gravels, quartz veins are thought to be much more numerous than mapped. Porphyry float also occurs at many widespread places on the property, suggesting that dykes or small stocks of Tertiary quartz-feldspar porphyry are more abundant than previously thought.

Prior to the Pleistocene glacial period, which began about two million years ago, the Klondike climate was somewhat warmer and wetter than the present and the district underwent a period lasting several million years during which erosion proceeded at a slow and steady rate. This resulted in relatively deep leaching by warm surface waters and the accumulation of bleached, clean, chemically mature gravels in wide river valleys. Known as the White Channel Grave, it consists of up to 100 m of white quartz, quartzite and quartz-muscovite-sericite schist with a clay matrix. The upper half is commonly yellowish to reddish. Placer gold concentrations in the White Channel gravels were subsequently reconcentrated by downcutting of the streams into their modern narrow channels within the broader valleys.

The Klondike District lies within the only small portion of Canada that escaped Pleistocene glaciation. In addition to protecting the the placer gold deposits, this also preserved most of the zone of deep surface leaching on the hills.

Placer Gold

Following the Klondike gold discovery on Bonanza Creek in August,

1896, prospectors soon traced the gold upstream to its sources. The most productive gravels were on upper Bonanza Creek and Eldorado Creek, on the north and west sides of Lone Star Ridge. These portions of the creeks were far richer than other parts of the Klondike and were among the richest placer creeks ever discovered in the world.

The best portion was the 5.5 Km stretch of Eldorado Creek from Gay Gulch down to the mouth, which is estimated to have produced over 1.5 million ounces of gold. About 450 ounces per metre of valley length were recovered by hand mining between 1896 and 1903 from the richest claims, located at the mouth of French Gulch, and the creek was subsequently mined at least twice more, with mechanical methods. Gold from Eldorado Creek waw relatively coarse, almost unworn and often angular, with nuggets more plentiful than on other creeks and often crystalline in form. Several were over 20 ounces in weight and one nugget weighing 86 ounces is the largest reported from the Klondike. Gay Gulch was also gold bearing.

On the opposite side of the Lone Star Ridge, the 2.5 Km stretch of Bonanza Creek below Victoria Gulch was the next richest creek in the Klondike. No claims had been mined at a profit above Victoria Gulch by 1903 and dredging was subsequently conducted only below that point. This portion of Bonanza Creek is estimated to have produced about one million ounces, with the richest claims yielding about 150 ounces per metre of creek length by 1903, prior to dredging. Coarse gold was also found in Victoria Gulch, becoming exceedingly rough and angular in the upper part. Coarse, angular nuggets, including one flat oblong 4.5 ounce specimen, were recovered from unworn slide rock at the head of No. 7 pup."

METHODOLOGY OF 1982 PROGRAM

Dawson Eldorado Explorations Ltd. was formed in 1979 to perform the first systematic technical assessment of the lode potential of the probable source area for the 2 - 3 million of ounces of placer gold mined from adjacent portions of Eldorado and Bonanza Creeks.

A small base-line and grid was performed over the core Lone Star crown grants in 1980. Encouraging geophysical survey work was performed thereon.

In 1981 the consultant recommended the following program design, which was carried out essentially to provide a long-term engineering base for exploration, to provide drill targets for a major program.

Sequence of Program

1. Restoration of Lone Star Mine two-story building as base of operations.
2. Construction of tote road from existing ridge trail near Eldorado Dome showing to base of operations, to complete road access.
3. Cutting of survey grid to extend 1980 grid to Bonanza and Eldorado Creeks (122 m line separation with line stations - 50-65 Km).
4. Soil sampling of new grid and analysis of samples on 122 m grid spacing.
5. Staking of open ground in potential lode gold areas, to complete property assembly.
6. Complete property examination and search for old workings, plant, dumps and concentrates.

7. Aerial Photography to Canadian mapping standards.
8. Ground Control survey to provide base for photogrammetric mapping.
9. Production of mosaics and controlled orthophoto photogrammetric maps as an engineering data base.
10. Mapping of all locateable workings, location of old crown grant boundaries, and hand pitting of selected locations to determine bed-rock type, overburden depth and quality, to provide base for future geological mapping.
11. Bulldozer trenching over selected areas, to determine overburden conditions, rock types, and to provide source of bulk samples of rock types.
12. Bulldozer trenching to reopen portions of the 1960-1962 contour trenching performed by Klondike Lode Gold, to expose rock types for future geological mapping.
13. Up-grading of access roads to provide one all weather access trail from Dawson via Eldorado Creek.

Results of Program

Commencing May 1, 1981, approximately 70 kilometers of survey line grid were laid out and cut from the 1980 base line, to extend the grid over an area 4 Kilometers NE/SW X 1.5 Km wide. The main building was restored to habitable, weather proof condition in May 1981, and a prospecting sampling crew was on the ground June 1. R.J. Cathro, P.Eng., P.S. White, P.Eng., and the sampling crew, performed a general surface examination of the property, on foot and by helicopter, on June 1, 1981, and sampling of dumps and the Lone Star mill site tailings area, was performed.

The Eldorado road to the main base was completed and upgraded in early June, and maintained sporadically thereafter with D-8 and D-9 bulldozers. The soil sampling crew took approximately 500 soil samples, which were first analized by Chemex Laboratories of

of Vancouver, B.C., for gold, silver, lead and antimony. Preliminary assay plottings caused cancellation of late antimony assays. As originally suggested in 1962 by the Geological Survey, the gold assays provided the most cohesive plotting of data, and the plotting of the other metals was considered to be superfluous for preliminary purposes. Results were plotted and contoured as shown on accompanying maps and provided strong anomalies of varying sizes. Some anomalies were first considered to result chiefly from known placer gold occurrences at the top of gulches, which are currently being mined. The gold fragments in those locations are sharply angular, the anomalies may indicate underlying bed-rock gold, which has weathered into placer deposits.

The accompanying Geochem Map shows 9 distinct gold anomalies centered on the following locations and of the following sizes:

NAME	STATION (100 FEET)	APPROXIMATE SURFACE CLOSURE	(CLOSURE) p.p.b. Au VALUE
Gay 1	68S - 16W	Open Ended to West	25
Gay 2	68S - 4W	800' X 400'	25
Robin E	28S - 0W	800' X 600'	25
Eldorado Dome	23S - 32E	1200' X 1200' $\pm$ (Open to East)	25
Lone Star	6S - 10E	2000' X 2400' (Irregular)	25
O'Neal S	00 - 16W	800' X 800' (Open to West)	25
O'Neal N	20N - 8W	1000' X 600'	25
Leamon 7	20N - 8E	700' X 600' (Old placer site)	25
7 Pup	32N - 20E	1200' X 400' (Old placer site)	25

Of these anomalies, all demand pitting and trenching, and at least four are now considered to be favourable drill targets. Further bulldozer trenching to aid in datailed geological mapping is required before the final drilling program of phase 2 of R.J. Cathro's 1981 recommendations is performed.

The significance of the strong and widely distributed gold anomalies, can only be tested by trenching and drilling, but has provided great encouragement to continue the systematic, technical approach. The final geochem results were available only at the end of the 1981 season, and thus were not a main subject of follow up work on the property during the summer season.

The property was photographed from two altitudes in June 15, 1981, by a recognized Canadian photogrammetric survey Company, and follow up ground control survey was done thereafter. The contractor supplied 9"X9" prints of the original photography, as well as mosaics and enlargements. The property was then mapped topographically to provide orthophotographic base maps, copies of which accompany this report. The maps are drawn at a scale of 1:5000 (metric) and with vertical contour intervals of 5 metres. The photographs and maps showed all ground features, workings and grid lines in a satisfactory, measureable manner, and were extensively used for the first compilation of ground features.

The sampling crew located and tied in the grid all locateable workings and significant topographic features, and the data was trasferred to the base map, which accompanies this report.

Ten bulldozer trenches of various depths and widths in excess of 4 metres wide, were dug at various locations on the property. Five trenches were so numbered (1 - 5) on the higher ground, and 3 lower trenches were deepenings of the lower contour trenches on the Bonanza Creek slope, of the 1960-1962 Klondike Lode Gold programs. All trenches were sampled, bagged and specimens stored at Whitehorse for future geological analysis and reference. The bulldozer work was performed over the August - October, 1981 period by leased D-8 and D-9 bulldozrs equipped with rippers.

Fuel was trucked to the property via Eldorado Creek and stored for use as required. All samples were examined for rock type and found to be favourable for gold content as per Lone Star specimens of gold bearing wall rock and Boulder Lode zone material. Some pinhead sized free gold was observed in specimens taken from a trench in the area of the Eldorado Dome workings, but no attempt was made to determine grade. The second phase of the program to be conducted in 1982 - 1983 consists of detailed geological mapping, and the trenches were left open to wash naturally until they could be properly dealt with by the consultant in 1982.

During the summer months, 58 quartz claims, 3 placer prospecting leases and 22 placer claims were located for exploration purposes on the Lone Star Ridge property.

The field program concluded with boarding up of facilities and removal of samples in September - October, 1981. Copies of cost invoicing accompanies this report. Exploration expenditures totalled approximately $250,000 in 1981.

CONCLUSIONS & SUMMARY

A program recommended by R.J. Cathro, P.Eng. was undertaken and substantially completed as to phase I of his June 15, 1981 report. The program was directed by Mr, Cathro, performed by Company personnel, and supervised on the ground by P.S. White, P.Eng., the Company President, in conjunction with visits by the Company consultant.

The program was designed to provide the first systematic, comprehensive approach to analyzing the known gold occurrences of the Lone Star property for genesis and distribution, with the

object of locating sufficient ore reserves to justify open pit or underground mine development.

The 1981 program saw the following accomplished:

1) The assembling of the property by options and staking to 9 - 10 square mile assemblage of old workings and known gold occurrences.
2) The provision of ground survey grid and survey control as an engineering base for future detailed mapping and drilling.
3) The provision of aerial photographs and orthophoto maps to assist in 2).
4) The discovery of ten strong geochemical anomalies of various sizes, which at least four provide primary drill targets with large volume potential.
5) The production of base maps with all known workings depicted to aid in comprehending the previously unrelated gold occurrences.
6) The geological sampling of outcrops, trenches and mine dumps as a step to develop a model for the proposed Lone Star drilling program.
7) The development of an indicated model of near surface mineralization underlying the geochemical anomalies and old production zones, with potential for open pit mining subject to bulk sampling and/or core drill testing.
8) The development of an indicated model of deeper gold mining potential for underground mining by comparison of the rock samples and geological alteration of some to recently developed gold mines, such as the Carlin, Nevada, deposit.
9) The performance of ten bulldozer trenches of various dimensions which produced the following salient facts:

   a) Confirmation of shallow overburden (1 - 10') in the Lone

Star ridge area, of bedrock suitable for stripping and mapping with bulldozer exposure.

b) Rock types favourable for gold occurrences and free gold in some bedrock samples.

c) Exposure of significant areas of bedrock and near bedrock over the property for 1982 detailed mapping program.

10) Confirmation from geology that the Lone Star Mine operated on leached zone material, and while near surface economic mining reserves may exist on the property, there is reason to test deeper zones in the light of the development of similar deposits elsewhere.

The verification by assay of concentrator tailings of low recovery of the original Lone Star mine-mill, which raises the potential of the near surface gold deposits from 0.15 oz/ton to 0.25 oz/ton, in economic mining volumes.

In final summary, the first historic attempt to analyze the colorful Lone Star property was performed and completed with results that further enhanced the property's known potential and provided the proper sound technical base for major exploration and potential development

The question which can only be answered by drilling and determination of gold-silver fineness ratios remains: Is the Lone Star Ridge deposit at the root of the Pre-White Channel quartz gravel gold concentration, or is there enough vertical gold mineralization remaining in place to mine?

Respectfully,

Paul S. White, B.Eng.

CERTIFICATE OF EXPENDITURES

1981 LONE STAR PROGRAM

I, Paul S. White, Professional Mining Engineer, of Whitehorse, Yukon and Calgary, Alberta, do herewith solemnly declare that I did cause work to be done on the mineral property on the Lone Star Ridge as described in a report signed by me and dated 31 May, 1982, and did cause Dawson Eldorado Gold Explorations Ltd. to pay for said work in my capacity as President of the Company. The cost of said work was in excess of $200,000, as supported by the attached invoice copies for said work, and as per applications for certificates of work supplied in 1981 to the Mining Recorder at Dawson, Y.T.

Solemnly declared and certified
at Calgary, Alberta, this
31st day of May, 1982.

June 15, 1981

SUMMARY

Dawson Eldorado Gold Explorations Ltd. controls, through staking and option, 70 mineral and 4 placer claims that cover all of the known mineralization and favourable ground on Lone Star Ridge. Lone Star Ridge is situated between the most productive portions of Eldorado Creek and upper Bonanza Creek, the richest in the Klondike Gold Field and among the most productive placer creeks in the world. These two rich sections are estimated to have yielded over 2.5 million ounces of gold and are still being mined.

Although the records of the eighty year history of previous work on the property are incomplete, it is known that five gold quartz showings were explored at various times and that limited and partially successful production was achieved from the Lone Star showing. Some 7655 tonnes milled between 1912 and 1914 averaged at least 0.2 oz/ton Au and the old records suggest that some of the gold was contained in the schist wall rocks, porphyry dykes and quartz stockworks. Early attempts to correlate conventional chip sampling with mill production were unsuccessful and the source of the gold recovered by the mill and the gold in the placer creeks was never adequately explained.

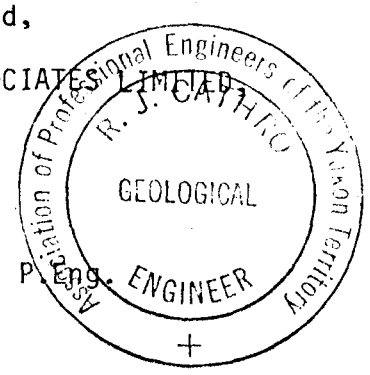

Conventional prospecting has been repeatedly frustrated by a combination of frozen overburden, extensive vegetation cover and deep weathering, while previous attempts to evaluate the potential of the showings have been restricted by inadequate equipment and financing. The recent development of sensitive gold analytical techniques has made it possible to perform a systematic survey to determine the distribution of the lode gold and the grade of the deposit.

The current high gold price makes such a search for large and possibly low-grade gold deposits worthwhile.

A $450,000 program of geochemical sampling, mapping, trenching and drilling is recommended to determine the lode gold potential of the property.

INTRODUCTION

This report has been written at the request of Paul S. White, President of Dawson Eldorado Gold Explorations Ltd. It incorporates portions of a more detailed description of the original nine-claim Lone Star property prepared by the writer on October 15, 1979, which was reproduced in the company Prospectus dated July 2, 1980.

Subsequent to that report, the company has acquired title by option to an additional 61 mineral claims covering favourable ground along strike. In addition, the company obtained all of the available exploration data on the new claims. The writer examined the property on June 1, 1981.

Since the price of gold is still quoted on world markets in troy ounces, that unit is retained in this report. However, all other English units of measurement from old reports have been converted to metric equivalents.

CLAIMS

The enlarged property currently consists of 70 mineral (quartz or lode) claims, aggregating about 1300 hectares, and 4 placer claims. All the claims are recorded at the Dawson Mining Records office. Eleven of the mineral claims that date from early in the century have been surveyed and Crown-Granted. These claims can be held indefinitely by payment of annual taxes of $100 per claim. The other mineral claims and the placer claims can be maintained in good standing by the performance

of work valued at $100 per claim per year or payment-in-lieu of work.

The writer has not personally inspected all of the claims but during his visit he examined some of the claim location lines and posts and found them to be well staked. The expiry dates have been verified with the Mining Recorder. Those claims with current expiry dates can be renewed by filing work that is underway.

The Lone Star Ridge property comprises the following claims:

LOCATION AND ACCESS

The Dawson Eldorado property occurs on Lone Star Ridge, between Bonanza and Eldorado Creeks, in the Klondike placer gold district. It is situated at 63°54'N latitude and 139°14'W longitude, within NTS map-area 1150/14, and is accessible by a 32 km road from Dawson, of which the last 5 km are quite steep (see Figure 1).

The topography of the property is dominated by a gently rounded, flat-topped ridge ranging in elevation between 860 and 1000 m (2900 to 3400 feet). The ridge, which trends approximately N55°W, has been partially dissected by tributaries of the two major creeks down to elevations of about 450 and 600 m (1500 to 2000 feet).

HISTORY

In addition to a colourful 80-year history, the Dawson Eldorado property has the honour of being the only lode gold occurrence in the Klondike Gold Field to produce more than a few ounces of gold. Although the early records are far from complete, a fairly reliable picture of the scope and location of previous work has been compiled from unpublished reports provided by Dawson Eldorado and from government reports, which are listed at the end of this report. A brief historical summary of that work follows.

The Lone Star showing was discovered in 1897 and was explored with a short shaft and adit prior to 1904. Approximately $100,000 was expended on development and mining during the years 1909-1914, 1929-1931 and 1946-1947 by Lone Star, Limited; its successor Consolidated Lone Star, Limited; and Yukon Consolidated Gold Corp. Development work completed at that time included an opencut 105 m long and up to 10 m wide, 480 m of drifting, 60 m of raises and shafts, 6 churn holes and 6 bulldozer trenches. Some 7655 tonnes that were treated in a stamp mill between 1912 and 1914 yielded gold and silver with a recoverable value of about $25,000. Although a small operating profit was being realized, the outbreak of World War I, the increasing stripping ratio

and caving problems, and a serious shortage of working capital led to the closure of the mine. Subsequent attempts to reopen the mine after the war were impeded by the closure of the Klondike Mines Railway and a shortage of labour.

Initial exploration of the Eldorado Dome, Victoria and Robin showings also occurred prior to World War I, although an exhaustive search has failed to turn up more than a few scraps of history. The Eldorado Dome and Robin showings were part of a 31 claim property adjoining the Lone Star property that was owned in 1912 by the Eldorado Dome Quartz Mining Co. Ltd. The overgrown nature of the old workings both here and at the Victoria showing indicate they have been idle for at least 50 or 60 years.

The first modern attempt at exploration occurred in 1960-1962 when Gordon Hilchey interested Klondike Lode Gold Mines Ltd. in acquiring all of the land presently held by Dawson Eldorado and searching for the source of the gold. The exploration technique used consisted of overburden sampling below the frozen vegetation layer with bulldozer trenches, followed by churn and diamond drilling. Gold content of the overburden was measured as "colours" (flakes) of gold recovered in a sluice box and gold pan. This rudimentary attempt at geochemical sampling was successful in outlining anomalies near Victoria Gulch and Gay Gulch and led to the discovery of the Hilchey showing. However, the program was restricted by inadequate equipment and financing and was terminated prematurely when the initial drill holes were unsuccessful.

In 1962, C.F. Gleeson of the Geological Survey of Canada conducted an extensive sampling program of creek gravels and overburden around Lone Star Ridge to determine if heavy minerals could be used to locate gold deposits. He concluded that gold was the best indicator.

In 1979, Dawson Eldorado Gold Explorations Ltd. was formed to acquire the original nine Crown-Granted mineral claims covering the Lone Star showing. During 1980, the company performed a small resistivity survey and test electromagnetic survey near the old workings. That survey met with limited success in detecting the mineralized zone.

During 1979 and 1980, Klondike Ken Ventures Inc. restaked part of the former Klondike Lode Gold Mines property surrounding the Lone Star property and performed a small program of test pitting, bulldozer trenching and road building. These claims were acquired by Dawson Eldorado early in 1981.

In spite of this extensive work history covering a period of over eighty years, no comprehensive compilation of the data has ever been made and no systematic sampling and mapping program has been conducted.

GEOLOGY

According to the Geological Survey of Canada, the ridge between Eldorado and Bonanza Creeks is mainly underlain by metasedimentary rocks, called the Klondike Schist, of Upper Paleozoic age. Principal rock types are white to medium-green quartz-feldspar-sericite schists with micaceous quartzite interbeds and some chlorite-and muscovite-rich layers. Quartz lenses and eyes are abundant in the Klondike Schist.

In common with other parts of this district, the terrain consists of rounded, gentle hills with few rock outcrops. Bedrock is almost totally obscured by an extensive frozen blanket of overburden and partially decomposed vegetation. The geology is known mainly from old trenches and workings and, in spite of its long history, previous mapping on the property has been only cursory in nature.

From the abundance of quartz in the overburden and creek gravels, quartz veins are thought to be much more numerous than mapped. Porphyry float also occurs at many widespread places on the property, suggesting that dykes or small stocks of Tertiary quartz-feldspar porphyry are more abundant than previously thought.

Prior to the Pleistocene glacial period, which began about two million years ago, the Klondike climate was somewhat warmer and wetter than at present and the district underwent a period lasting several million years during which erosion proceeded at a slow and steady rate. This resulted in relatively deep leaching by warm surface waters and the accumulation of bleached, clean, chemically mature gravels in wide river valleys. Known as the White Channel Gravel, it consists of up to 100 m of white quartz, quartzite and quartz-muscovite-sericite schist with a clay matrix. The upper half is commonly yellowish to reddish. Placer gold concentrations in the White Channel gravels were subsequently reconcentrated by downcutting of the streams into their modern narrow channels within the broader valleys.

The Klondike district lies within the only small portion of Canada that escaped Pleistocene glaciation. In addition to protecting the placer gold deposits, this also preserved most of the zone of deep surface leaching on the hills.

MINERALIZATION

Placer Gold

Following the Klondike gold discovery on Bonanza Creek in August, 1896, prospectors soon traced the gold upstream to its sources. The most productive gravels were on upper Bonanza Creek and Eldorado Creek, on the north and west sides of Lone Star Ridge. These portions of the creeks were far richer than other parts of the Klondike and were among the richest placer creeks ever discovered in the world.

The best portion was the 5.5 km stretch of Eldorado Creek from Gay Gulch down to the mouth, which is estimated to have produced over 1.5 million ounces of gold. About 450 ounces per metre of valley length were recovered by hand mining between 1896 and 1903 from the richest claims, located at the mouth of French Gulch, and the creek was subsequently mined at least twice more, with mechanical methods. Gold from Eldorado Creek was relatively coarse, almost unworn and often angular, with nuggets more plentiful than on other creeks and often crystalline in form. Several were over 20 ounces in weight and one nugget weighing 86 ounces is the largest reported from the Klondike. Gay Gulch was also gold-bearing.

On the opposite side of the Lone Star Ridge, the 2.5 km stretch of Bonanza Creek below Victoria Gulch was the next richest creek in the Klondike. No claims had been mined at a profit above Victoria Gulch by 1903 and dredging was subsequently conducted only below that point. This portion of Bonanza Creek is estimated to have produced about one million ounces, with the richest claims yielding about 150 ounces per metre of creek length by 1903, prior

to dredging. Coarse gold was also found in Victoria Gulch, becoming exceedingly rough and angular in the upper part. Coarse angular nuggets, including one flat oblong 4.5 ounce specimen, were recovered from unworn slide rock at the head of No. 7 Pup.

Lode Gold

Placer miners, recognizing that the creeks draining Lone Star Ridge were exceptionally rich, turned their attention to the search for a source and discovered the Lone Star showing in 1897. Four other showings were subsequently found within the boundaries of the Dawson Eldorado Gold Explorations Ltd. property. The Lone Star is the best documented and was the only lode property in the Klondike that ever produced more than a few ounces of gold.

The Lone Star showing consists of an irregular network of quartz veins, lenses and irregular masses named the Boulder Lode. The history of this property and the previous development work have been described in more detail in an earlier report by the writer for Dawson Eldorado Gold Explorations Ltd. According to previous geological reports, three types of quartz are present: (a) quartz pegmatite veins, (b) quartz-pyrite stringer zones, and (c) gold-quartz veins.

Quartz pegmatite veins, known to prospectors as "bull quartz" veins, are the most prominent and consist of white, milky quartz with occasional feldspar and hornblende crystals. These contain only traces of gold but were the object of most of the early prospecting in the Klondike district since they are abundant, continuous and easily traced.

Quartz-pyrite stringer zones consist of numerous gash veins or lenses of quartz found over considerable widths in the schist formation. Individual veinlets are generally conformable with foliation and crumpled and broken, but are not continuous, either along the strike or down the dip of the schists. Euhedral, fine-grained pyrite crystals are usually associated with the quartz stringers, occurring both in the quartz and in the enclosing schists. The quartz stringers are rarely over 15 cm in width, usually ranging from 1 to 5 cm. The gold content of both the pyrite and the quartz stringers was reportedly low and it was concluded that the stringer zones, along with the pegmatite veins, have contributed most of the quartz pebbles in the White Channel gravel deposits but only a small portion of gold.

The gold-bearing quartz veins are more restricted in distribution and more difficult to trace. Those seen in the Lone Star Mine are small, ranging from 2 to 10 cm in thickness. They cross-cut the foliation of the schists in most places and tend to be uncrumpled and lenticular, which suggests they are the youngest type. This type of vein strikes from N20°W to N30°W and usually dips 25° or less to the east. Occasional patches or grains of galena with lesser amounts of chalcopyrite, tetrahedrite, sphalerite and arsenopyrite are present but are very erratically distributed. Gold can occur either as discrete grains of free gold in quartz or in the sulphides.

In the Lone Star workings, which penetrated below the leached zone, the younger quartz veins were interpreted as the source of most of the gold. However, the mill records show that gold was more widespread in the vicinity of the Boulder Lode and occurred in the pyritic schists as well.

The production records from the opencut for 1912, 1913 and 1914 show that 7655 tonnes were milled with a recoverable grade of 0.148 oz/ton Au. Smelter returns indicate that the bullion had an average gold to silver ratio of about 4:1. Since mill recovery by the amalgamation method was probably no higher than 75 per cent and the gold contained in the sulphide mineralization could not be recovered at all, the ore grade from the mine was more than 0.2 oz/ton Au. Two samples of pyritic mill tailings collected by the writer in 1981 assayed 1.06 and 0.20 oz/ton Au and 1.02 and 0.20 oz/ton Ag, respectively.

The most thorough examination of the Lone Star Mine was made in 1912 by T.A. MacLean of the Canadian Mines Branch. He reported that the initial 902 tonnes milled that year was quartz-rich mineralization that was carefully sorted at the mine. It represented about one third of the rock mined during this period. The records show that the recoverable value was $4.30 per tonne (gold valued at $20.00 per ounce and silver at 60 cents per ounce) for the 902 tonnes. As a test, the balance of the 1912 mine production, 1362 tonnes, was milled without sorting and it was found that recoverable value only dropped to $4.10 per tonne. This indicates a high probability that much of the gold was contained in the schists themselves and not in the quartz.

Only a few assays are available of the sulphide mineralization. A hand picked sample of sulphides weighing 844 kg that was shipped to the Selby Smelting Works, San Francisco, in 1913, returned $2,009 in gold, a grade of about 107.4 oz/ton. Ten sacks of waste from the adit dump shipped to the Trail, B.C. smelter in 1930 averaged 0.062 oz/ton Au, with a recovery of 97%. Two picked sulphide specimens collected in 1925 from a shaft below

the floor of the opencut returned assays of 312 and 324 oz/ton Au and 76 and 88 oz/ton Ag. It is unfortunate that few sulphide specimens from the Lone Star property were assayed for silver since tetrahedrite-rich specimens collected elsewhere in the Klondike district have assayed as high as 1000 to 1500 oz/ton.

Although the large bulk sample milled from the Lone Star showing proved that gold content averages at least 0.2 oz/ton, the gold was found to be very difficult to measure with conventional chip, channel or muck sampling. Various geologists who sampled this property over the years all obtained assays that averaged less than mill grade, and each concluded that surface chip sampling did not adequately account for the presence of occasional high-grade veinlets or sulphide patches. For example, chip samples of the 1929 adit average less than 0.01 oz/ton Au but muck sampling of 24 drift rounds (about 32 m of drift) in 1930 gave average assays of 0.19 oz/ton. The following year, 38 rounds averaged 0.13 oz/ton Au, which is substantially higher than any chip sample assays obtained from the Lone Star property.

In contrast to the abundant information available on the Lone Star showing, the other four showings are either undocumented or inadequately explored. They are discussed individually below.

When visited by MacLean in 1912, the Eldorado Dome workings consisted only of a single 16 m shaft. A sample of pyritic quartz collected by him from the dump assayed 0.04 oz/ton Au and 0.06 oz/ton Ag. An extensive adit dump representing at least 100 m of drifting is now present about 200 m downhill from the shaft but no history has been found for this work. Both the shaft

and adit were apparently driven on quartz veins associated with a quartz-feldspar porphyry dyke, which is bleached and altered and contains disseminated pyrite. A sample of quartz from the adit dump taken by the writer assayed 0.27 oz/ton Au and 0.37 oz/ton Ag, whereas samples of representative porphyry and schist from the dump all assayed less than 0.01 oz/ton in both Au and Ag.

On the Robin claim, MacLean sampled an opencut about 6 m by 5 m in area. A quartz lens or vein exposed in the opencut contained " a number of good specimens with free gold of crystalline character, in the quartz, while very fine gold was disseminated through the associated schists, which are of green chlorite and sericite much crushed and decomposed. A small proportion of pyrite was noticed." Four samples collected by MacLean, including one containing free gold all gave low assays - two were 0.04 oz/ton Au and no silver and the other two were trace gold. This was an excellent example of the unreliable assaying obtained by early workers.

Very little is known of the Victoria showing on the Victoria Crown-Grant, at the head of No. 7 Pup. Old workings were found on the claim in 1981 but they were not seen by the writer and no history is known. Klondike Lode Gold Mines Ltd. recovered substantial amounts of gold by sluicing and panning large overburden samples from bulldozer trenches in this vicinity in 1960. Colours of gold were noted in all samples collected on the south side of No. 7 Pup. According to pioneer placer miner Harry Leaman, who was interviewed in 1960 by G.R. Hilchey and A.E. Aho, 7 Pup was the only tributary of Victoria Gulch that was mined. Much of the placer gold was so ragged that it had to be mortared by hand to separate the gold from quartz. A

15 m shaft on the Victoria claim reportedly intersected a red-weathering porphyry dyke containing finely disseminated free gold and a little quartz. No assays are available. A churn hole drilled by Klondike Lode Gold in 1961 (hole VC 11) was described as gold-bearing, although no assays were given.

The Hilchey showing, on the north side of Gay Gulch, was discovered by Klondike Lode Gold Mines Ltd. in 1960. According to pioneer placer miners Harry Leaman and Tom Hebert, the lower six placer claims (500 m) on Gay Gulch were rich and the upper part was relatively lean. Bulldozer trenching in this vicinity exposed a number of quartz veins associated with small faults cutting quartz-chlorite-sericite-feldspar schists. Free gold occurs in small specks or nuggets in quartz, in and near pyrite grains or wall rock inclusions, or at edges of the veins. The gold-bearing veins also contain traces of scattered galena and chalcopyrite. They are up to one metre wide, lenticular and seldom more than 10 m or so long. Assays varied from trace up to 2.8 oz/ton Au. A.E. Aho, who examined the showing in 1960, concluded that the values were so erratic that bulk sampling would be necessary to determine the average grade, and that schists adjoining the veins were unmineralized.

In addition to these five mineral occurrences where gold has been found in bedrock, indications of mineralization have been found in overburden in several places. For example, a large area of hydrothermally-altered rock reportedly 300 m across, was found by Klondike Lode Gold Mines near Oro Grande Gulch, downhill from the Robin showing. Considerable quartz and some gold was found in the overburden but insufficient work was done to locate the source.

CONCLUSIONS AND RECOMMENDATIONS

For over eighty years, prospectors have been intrigued by the search for a source for the Klondike placer gold. The search has naturally focused on Lone Star Ridge, which is situated between Eldorado and upper Bonanza Creeks, the richest in the Klondike Gold Field and among the most productive in the world.

Although five small lode gold showings have been found on the ridge, and limited, partially successful production was achieved from one of these, the Lone Star Mine, prior to World War I, no satisfactory explanation has been found for the abundance of placer gold in the creek gravels. Prospecting efforts have been repeatedly frustrated by a combination of frozen overburden and partially decomposed vegetation that effectively obscures the bedrock geology and mineralization; by deep weathering, particularly on the higher parts of the ridge, that has probably leached away most of the sulphide minerals in the altered, permeable zones that are most favourable for mineralization; and by the lack of sensitive analytical techniques and heavy equipment capable of trenching to bedrock.

Although many theories have been advanced for the source of the gold, failure to find a substantial lode deposit led to general acceptance of the hypothesis that most of the placer gold has been derived from disseminated flakes in small quartz lenses and veins, which were too low in grade to constitute an economic lode target. While this idea may be true, it does

not account for the spectacular richness of the creek gravels draining Lone Star Ridge, and it has not been substantiated by the results of previous work on the Ridge.

The work on Lone Star Ridge has shown that visible gold occurs in the quartz in several places and that coarse gold can be followed as it weathers out of bedrock and migrates through the overburden into the creek gravels. Moreover, evidence exists that very fine gold is also present in the schists around the Boulder Lode at the Lone Star showing, and in porphyry at the Victoria showing.

The degree to which fine gold leaches in the weathering zone and is transported in solution to precipitate in the placer gravels is still quite controversial but is believed by many geologists to be the source of much of the fine gold. Until quite recently, analytical techniques for gold were not sufficiently sensitive to accurately measure the grade of individual rock units and overburden in these low ranges, and the price of gold was too low to justify the effort.

Current gold prices have significantly enhanced the potential of the Dawson Eldorado property. The potential exists for a substantial tonnage of low-grade gold ore in more than one zone, related either to porphyry dykes, quartz-vein stockworks and/or shear zones. The evidence from previous work indicates that the gold may occur in one or more of several forms: disseminated as both fine and coarse grains in quartz veins and with sulphide patches in the quartz; disseminated in sericite schist , chlorite schist and porphyry dykes; and possibly associated with skarn alteration of limy bands in the schists.

The recommended exploration method consists of systematic sampling and mapping to determine how the gold is distributed, and trenching and/or drilling to determine the grade. More specific details are as follows:

First Phase

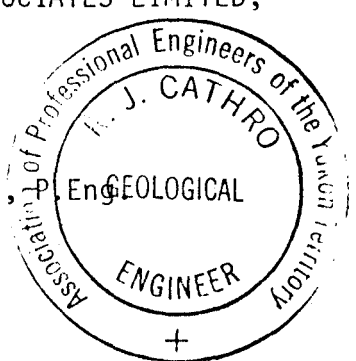

Grid linecutting, targeting and preliminary field surveys to locate all previous work	$20,000.00
Aerial photography and orthophoto basemap preparation; compilation of survey data	20,000.00
Grid soil sampling of entire property; more detailed sampling of old workings and anomalous areas	40,000.00
Geological mapping of old workings, trenches, and roads; logging of rock chips collected from soil sample pits	10,000.00
Engineering and supervision	10,000.00
Total - First Phase	$100,000.00

Second Phase

Repair roads, clean out old trenches, trench or pit anomalous areas, and move drill using a large bulldozer or excavator (assume 900 hours at $180 incl. fuel, operator, transportation)	$162,000.00
Diamond drilling - 5000 feet @ $30.00 (incl. room and board, mobilization)	150,000.00
Engineering and supervision (including mapping, core logging, report preparation and assays)	38,000.00
Total - Second Phase	350,000.00
Grand Total	$450,000.00

RE: Assessment Report by Dawson Eldorado Gold Exploration on "Lone Star" property, 115-0-14.

This report is approved for $47,200.00. However, please explain to P. White that the statement of costs is not satisfactory. It is almost impossible to sort out the 50-odd pages of receipts without a summary breakdown of costs into categories such as geochem, trenching etc. ~~In this case, only, the report will be approved~~. Some invoices appear to cover both allowable (ie line-cutting) and non-allowable (ie claim staking) expenses, which are not separated.

In this case, only, the report will be approved, but in future an adequate statement of costs will be required. This would certainly expediate the handling of assessment reports by this office

Thanks Bonnie

Pat

SUBJECT
OBJET

Assessment report by Dawson Eldorado on the DN, ND, AC, RJ, DE claims.

Bonnie,
Please inform Dawson Eldorado of the following:

"A statement of costs for work on these claims was submitted to the Dawson Mining Recorder on October 19, 1981 and forwarded to the Supervising Mining Recorder in Whitehorse. Since this was just a statement of costs and did not include a complete report as required, it was put aside pending receipt of two copies of that report. However, since that time, no report has been received and"

(add your own blurb of what should be done by whom to keep in good standing etc.)

Feel free to reword this as you see appropriate and also include a copy of the schedule with section 6 clearly marked and noted.

I assume that this is why Ruth put this on hold, though I don't know why she didn't follow through. - Because I didn't get it until Nov. 1, & I felt it would take 6-8 wks before the report came - by which time I was gone!

In your letter please give them a good indication of what is expected in a report by referring them to the schedule.

Thanks Bonnie. I hope that this clears this one up.

It is agreed that the goods described herein are accepted in apparent good order and condition (except as noted) for carriage SUBJECT TO THE CONDITIONS OF CONTRACT ON THE REVERSE HEREOF. THE SHIPPER'S ATTENTION IS DRAWN TO THE NOTICE CONCERNING CARRIER'S LIMITATION OF LIABILITY. Shipper may increase such limitation of liability by declaring a higher value for carriage and paying a supplemental charge if required.

Shipper certifies that the particulars on the face hereof are correct and that insofar as any part of the consignment contains restricted articles, such part is properly described by name and is in proper condition for carriage by air according to the International Air Transport Association's Restricted Articles Regulations.

CERTIFICATE

I, Robert J. Cathro, with business addresses in Whitehorse, Yukon Territory, and Vancouver, British Columbia, and residential address in West Vancouver, British Columbia, do hereby declare that:

1. I am a 1959 graduate of the University of British Columbia in geological engineering.

2. I am registered as a professional engineer in both British Columbia and Yukon Territory.

3. I have been engaged in mineral exploration and evaluation in northern Canada since 1959. Since January, 1966, I have been a partner in Archer, Cathro & Associates Limited.

4. I have had full access to previous data on the Lone Star property.

5. I have not received, nor do I expect to receive, any direct or indirect interest in the properties, securities, or companies referred to in this report.

Respectfully submitted,

R.J. Cathro, B.A.Sc., P.Eng.

PLAN 3 R.M.K./sa/Apr. 1982

Legend

MESOZOIC-TERTIARY?

- Q.V. — Quartz vein
- gQM$_2$ — Greisenized quartz-monzonite

PROTEROZOIC-PALEOZOIC?

Yukon Series Metasedimentary Rocks

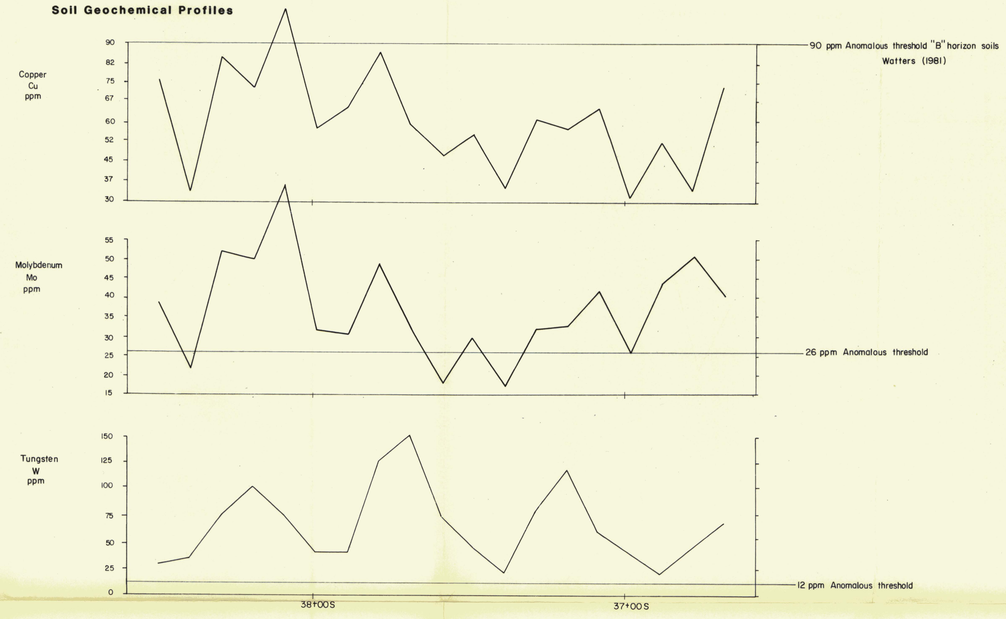

- csh — calc-silicate hornfels
- sk — skarn; variable proportions of gar, Q, am, di, mt, py, po
- sq — quartzitic biotite schist
- q — quartzite
- qm — micaceous quartzite

Symbols

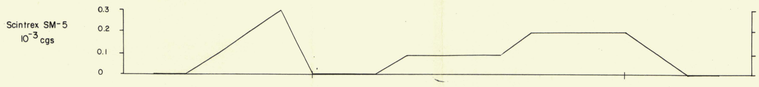

gar	garnet		geologic contact; defined, approximate
chl	chlorite		bedrock exposure
am	amphibole	(82-YP)9012R	rock sample location
Q	quartz		chip sample interval
py	pyrite	1,2	skarn zones discussed in text
po	pyrrhotite		
mt	magnetite		
cp	chalcopyrite		
sch	scheelite		
mo	molybdenite		

True North
30°32'
Magnetic North

PLAN 4 **R.M.K./sa/Apr. 1982**

LEGEND

- Hydrography
- Chained and picketed grid
- A — Limit of magnetic unit
- C9 — Approximate outline of magnetic skarn and identification
- F1 — Interpreted shear zone with identification V = VLF-EM support
- Fault
- V2 — Axis of VLF-EM conductor: poor, mediocre, fair
- 82-T-1 — 1982 Trench
- Quart - Feldspar Porphyry
- Muscovite - Quartz Monzonite(?)
- Skarn
- Carbonate rocks
- Fractures; inclined, vertical
- x po,py — py = pyrite, po = pyrrhotite, Mo = molybdenite, Sch = scheelite mag = magnetite, (f) = float
