SUMMARY

During the 1987 field season, the area from Upper Hunker Creek, over the Hunker Summit, across Upper Dominion Creek and south to Dominion Mountain was prospected by soil geochemistry on 10 separate grids. A total of 4,443 soil samples were taken on 100 m x 25 m intervals and were assayed for Au plus 32 other elements for a total of 130,680 determinations. Many Au anomalies were obtained.

Geological mapping was unsuccessful due to less than one percent outcrop in the area. To facilitate geological mapping on the Hunker Dome grid, a TD25C bulldozer with ripper was contracted to cut 18 trenches over anomalous Au soil geochemical targets. Mapping and sampling of these trenches identified an en echelon vein zone of white quartz veins carrying trace pyrite and galena and occasional free gold and tellurides. Ore grade assays were obtained from channel samples in these trenches.

Several of the other grids, notably King Solomon's Dome, Green Gulch and Mackay had very widespread soil geochemical anomalies in Au, some in excess of 1.5 km x 400 m in area, and from 10 ppb to 600 ppb Au in value. No follow-up work was possible during the 1987 program due to lack of time so most of the grids will require follow-up prospecting, geological mapping, *et cetera* at some future date to determine the source of the soil anomalies.

INTRODUCTION

A five-man crew prospected the Hunker Dome-Dominion Mountain area during the 1987 field season. Since outcrop was less than one percent, it was decided that soil geochemistry would be employed. However, since virtually all the valley floors in the area have been subjected to soil profile contamination by placer mining and most of them are also blanketed by deep, frozen muck, it was assumed that soil geochemistry would be useless on the valley floors. Consequently, the 10 grids were established on ridge tops in the area, where the soil profile was uncontaminated by mining, shallow in depth to bedrock, mostly thawed in summer, and not subject to the confusion of the geochemistry results caused by mass wasting downslope, which is a problem on the lower slopes in the Klondike.

Results indicated widespread gold anomalies in the soil on most of the grids. Time and budget constraints allowed follow-up cat trenching on only one grid. The Hunker Dome grid was selected as it had a large number of anomalies, and several old prospect shafts and one 2,600 foot adit from the early 1900s which were reputed to carry visible gold.

Eighteen trenches were completed over Au soil anomalies and a series of north-south striking near vertical white quartz veins were exposed. These veins are coincident with the soil geochemistry anomalies and carry traces of disseminated pyrite and galena and free gold and sylvanite (AuAg)Te2. A total of 243 channel samples were taken from these trenches and results were encouraging.

Follow-up prospecting and geological mapping is recommended on all grids to determine the source of the other soil anomalies.

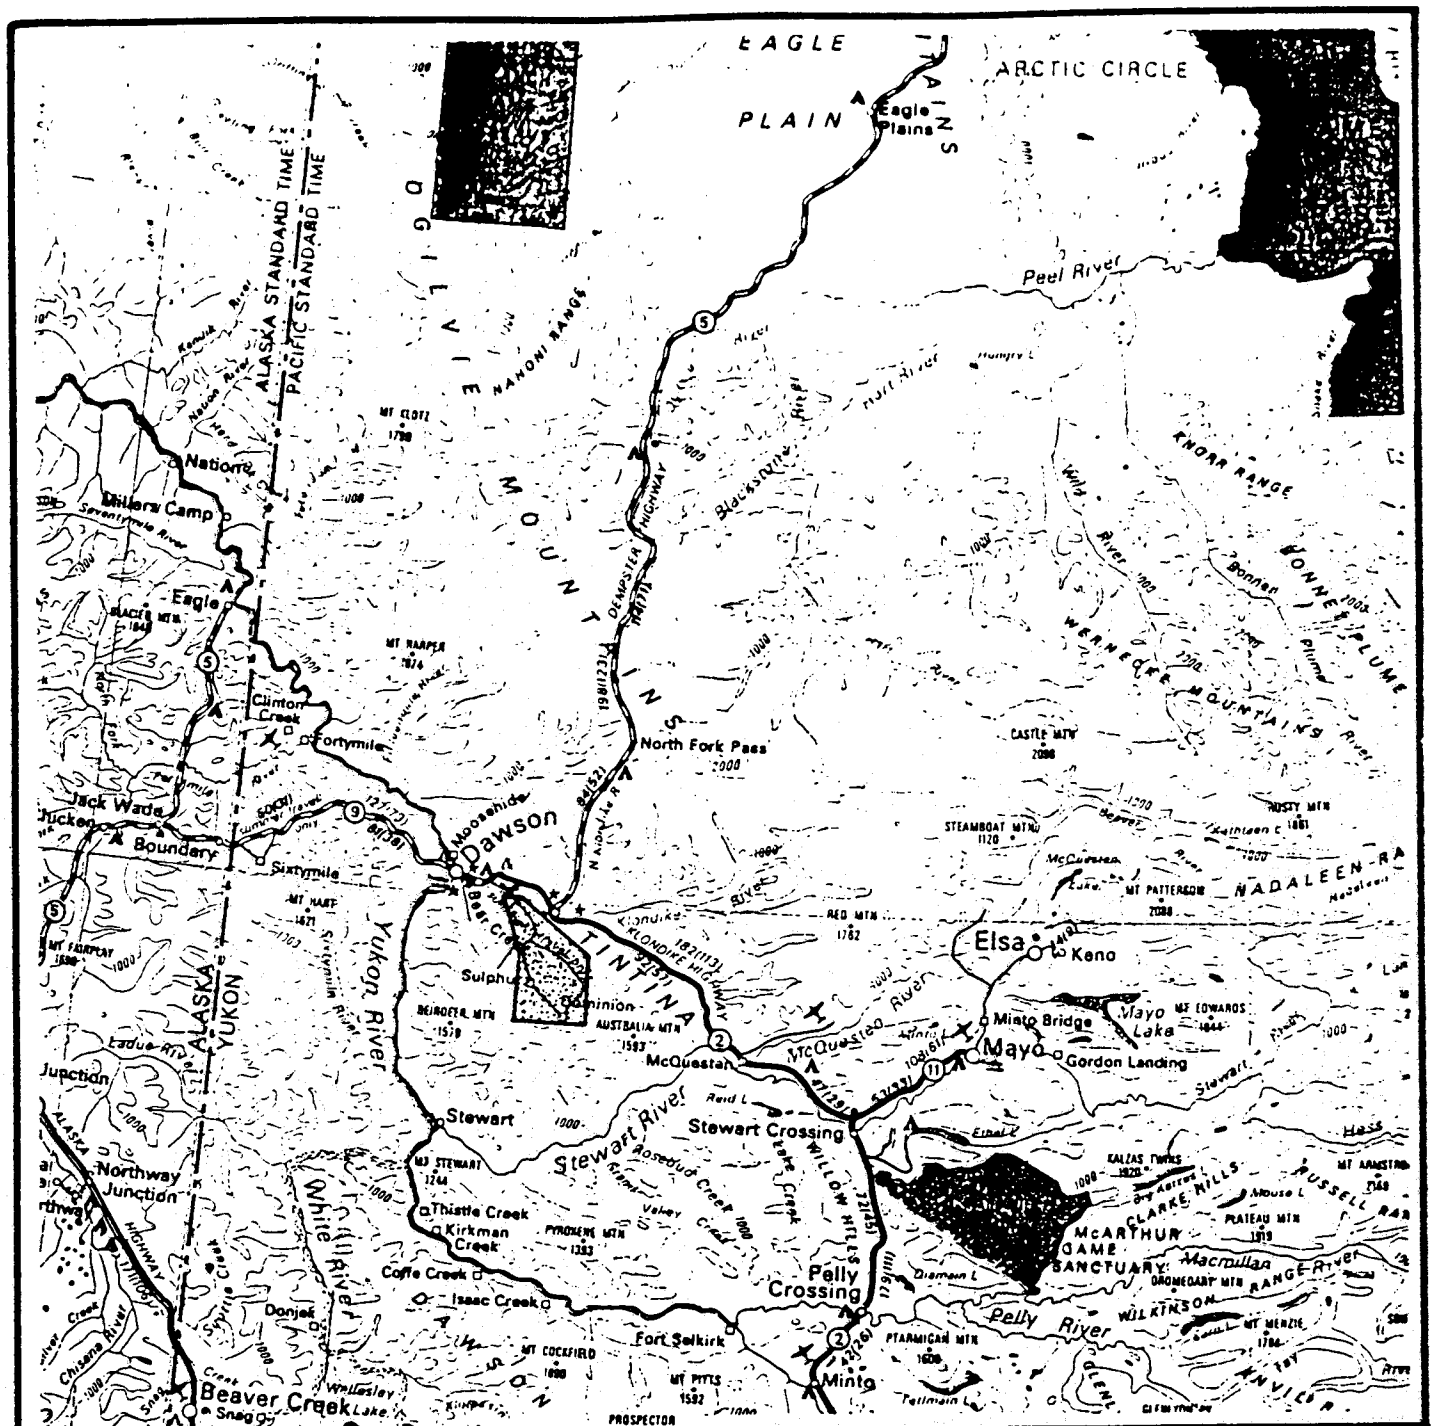

PROPERTY

The 10 grids are covered by the KIN 1-82 (YA89442-YA89517) and KIN 83-172 (YB04083-YB04142) and (YB04185-YB04244) claims staked under the *Yukon Quartz Mining Act* in 1987.

Staking was contracted out to Coureur des Bois Ltée Mineral Exploration of Whitehorse for United Keno Hill Mines Limited.

These claims cover a nearly contiguous block from the right fork of Upper Hunker Creek to Dominion Mountain, plus a separate block at the head of Gold Run Creek. These claims total 226 full or fractional claims.

LOCATION AND ACCESS

The Hunker Summit target area is located from King Solomon Dome and the Hunker Dome south to Dominion Mountain, a distance of 13 km, and covering an area approximately 5 km wide. This area is the headwaters of several famous placer creeks in the Klondike region, including Hunker, Dominion, Gold Run, and Sulphur.

This area is located 32 km southeast of Dawson City, Yukon, and approximately 500 km northwest of Whitehorse, Yukon at latitude 63°53' longitude 138°52'.

It is accessible by the all-weather Klondike Highway from Whitehorse to the Hunker Road junction at the mouth of Hunker Creek. From there, access is by summer-only gravel road up Hunker Creek approximately 22 km to the Hunker Summit. From here, the gravel road junctions with the Dominion, Bonanza, Sulphur and Gold Run roads which access the remainder of the target area.

UKHM established a campsite on the north end of the Hunker Dome grid, approximately 500 m southeast of the Bonanza/Sulphur road and 1.8 km northeast of King Solomon Dome, between the head of Upper Dominion Creek and Lombard Pup. This is an excellent campsite, except for lack of drinking water, which must be trucked from Dawson City.

HISTORY

The Klondike is a world famous placer camp discovered in the 1890s which has yielded some ten million ounces of gold. The Klondike gold fields were worked primarily by individual placer miners in the early days and, from 1930 to 1966, by the Yukon Consolidated Gold Corporation (YCGC), the only large corporation to work in the area. YCGC operated several electric and/or steam powered bucket line dredges on Sulphur, Hunker, Bonanza, Quartz, Dominion, and Eldorado Creeks. The last dredge ceased operation in the mid-1960s but activity picked up dramatically in the early 1970s with the increase in the price of gold. At that time, a number of small hydraulic and bulldozer operations went into production and many of these are still working today. Teck Corporation is the largest company now operating in the Klondike.

In 1878, G. M. Dawson reported a mineral occurrence in the northern Canadian Cordillera and, together with R. G. McConnell and William Ogilvie, led the Yukon Expedition of 1887-88. McConnell and Ogilvie passed Deer Flats, which became the site of Dawson City in 1897. McConnell revisited the area in 1903 and completed the first bedrock geology map. In 1906, McConnell evaluated the gold bearing high level gravels and Cairnes, in 1911, visited the area briefly to examine lode gold prospects. He noticed that the most promising properties were the Lone Star group, near the head of Victoria Gulch, a tributary of Bonanza Creek; the Violet group, situated along the divide between Eldorado and Ophir Creeks; the Mitchell group, on the divide between the heads of Hunker and Gold Bottom Creeks; the Lloyd group and neighbouring claims, situated along the divide between the heads of Green Gulch and Caribou Gulch, tributaries of Sulphur and Dominion Creeks; and several groups of claims on Bear Creek joined by nearby Lindow Creek. The Lone Star has been the only producer of lode gold in the Klondike. Milling grades indicated a hand sorted mine grade of 0.18 ounces per ton Au in 1912.

Most of the lode gold occurrences in the Klondike have not been explored thoroughly because of their erratic distribution and the heavy overburden cover. No activity of any significance has taken place recently.

The Hunker Summit area was historically an excellent producer of placer gold since 1898 on Upper Dominion, the Right Fork of Upper Hunker, and Sulphur Creek below Green Gulch as well as Green Gulch itself. Most of these creeks are still being actively mined today. Lode sources for this placer gold have never been satisfactorily located to date.

Ten lode showings were located in this area in the early 1900s. Most are white quartz veins with trace pyrite and galena

and occasionally free gold. Several were prospected by open cuts, hand trenches and small, shallow prospect shafts prior to 1910. One, the Hunker Dome (or Dome Lode) was also opened up by a 2,600 foot crosscut adit that intersected several of the quartz veins in the area, approximately 450 feet below surface. None of these showings has reached production status.

Several companies, including Yukon Consolidated Gold Company in the 1950s, Orekon and Cominco in the 1960s, Lindex Exploration Ltd. and Dawson Eldorado Ltd. in the 1970s and 1980s, staked and prospected this region and carried out geological mapping, geochemistry, geophysics and bulldozer trenching. All these claims were subsequently abandoned.

In 1984, UKHM staked the surrounding areas to cover the headwaters of known placer creeks such as Gold Bottom, Upper Hunker, Dominion, Gold Run and Sulphur. In 1987, the intervening ground was staked to cover the target area and the 10 soil geochemistry grids and the bulldozer trenching on Hunker Dome grid were completed.

PHYSIOGRAPHY

The Klondike region is characterized by drainage divides of about 3,300 feet locally rising to 4,500 feet. These are crooked ridges separated by dendritic valleys which are drained by master streams from 1,000 to 1,500 feet above sea level. A few summits, locally called domes, are rounded and attain elevations of 5,000 feet.

The Klondike is part of the Yukon Plateau, a thoroughly dissected upland. Many of the small creeks and streams run parallel to each other in a northwesterly direction. They parallel the Tintina Trench, a major structural feature in the Territory, suggesting that the streams themselves may be following related structural features. The valleys are flat and wide in the lower reaches but gradually narrow towards their heads into steep-sided, narrow gulches which end abruptly in broad cols.

The rolling upland surface of the Klondike owes its existence to a general uplift in mid-Tertiary time. The area was probably faulted, eroded, and warped in later Tertiary time. Tropical weathering conditions subjected the area to deep supergene alteration conditions followed by periglacial modification and permafrost development during Quaternary time.

The target area comprises some of the highest points of land in the Klondike. King Solomon Dome, at 4,048 feet above sea level, is the height of land in the region. The remaining ridge tops are a series of long branching, interconnected ridges radiating out from King Solomon Dome. This is a good example of a thoroughly dissected upland.

The ridges are approximately 1,500 feet above the valley floors, and are well-rounded in nature with 10° to 20° slopes. This is evidence of long-term erosion without glaciation.

The valleys are wide and flat in the lower reaches but gradually narrow towards their headwaters, in the target area becoming narrow, steep-walled gulches which end in steep rounded amphitheatres. Numerous small tributaries or "pups" enter both sides of the main drainages all along their courses.

GEOLOGICAL SUMMARY

The Klondike District is in the Yukon Crystalline Terrain which has developed as the result of Triassic regional metamorphism southwest of the Tintina Trench. This trench is the topographic expression of a Mesozoic right lateral fault of some 450 miles displacement. Shear zones parallel to the Tintina Fault occur in the Klondike and major lineaments and faults with similar trends occur in and to the southwest. The faults consist of a series of thrust sheets separated by thrust faults. Mylonites and altered ultramafic rocks occur along these thrust surfaces.

The rocks in the Klondike may be divided into four categories: ultramafics, Nasina series, Klondike schists, and the Pelly gneiss. The ultramafics consist of peridotite serpentinized to various degrees. The Nasina is a group of low grade matamorphic rocks of predominantly sedimentary origin. These are principally graphitic phyllite, black quartzite, black carbonate phyllite, marble and banded quartzite. The Klondike schists vary from quartz-feldspar-muscovite schists to quartz-feldspar-biotite gneisses. Chlorite is an important constituent of some of the schists. This group is interpreted to be a highly metamorphosed volcanic pile. The Pelly Gneiss is a coarse grained massive to schistose quartzo-feldspathic rock which may be a metamorphosed intrusive body.

The bulk distribution of the metamorphic rocks proved too impractical in the field and a more detailed lithological breakdown was developed, based on J. K. Mortensen's 1984 report for United Keno Hill Mines Limited. In this scheme, the metamorphic rocks are divided into nine mapable units and their respective sub-units. Most of the Company's claims are underlain by units 6, 7, and 8, with several units being locally present only.

TABLE 1
LITHOLOGIC UNITS IN THE KLONDIKE DISTRICT

1. FELSIC INTRUSIVES
   (a) massive quartz-diorite
   (b) blocky grey-brown weathering gneiss
   (c) slabby quartz-muscovite schist ± quartz eyes ± chlorite

2. INTERMEDIATE INTRUSIVES
   (a) meta-diorite, weakly to moderately gneissic

3. MAFIC INTRUSIVES
   (a) coarse grained intrusive, locally altered to amphibolite and chlorite

4. ULTRAMAFICS

5. MORTENSEN'S FELSIC SCHIST
   (a) tan to rusty weathering quartz-muscovite schist

6. ANDESITE PORPHYRY
   (a) massive, weakly foliated porphyry with quartz and/or feldspar phenocrysts
   (b) sheared and recrystallized porphyry - "quartz eye schist"; quartz-muscovite schist ± blue to white quartz eyes ± minor chlorite
   (c) banded and blocky quartz and/or feldspar porphyry; green fine grained groundmass
   (d) banded and blocky pink and green gneiss; quartz-feldspar-muscovite-chlorite gneiss

7. MAFIC META-VOLCANICS
   (a) amphibolite; massive fine grained
   (b) quartz-chlorite gneiss ± minor muscovite and abundant pyrite
   (c) no rock type
   (d) chlorite schist ± minor muscovite ± talc alteration ± actinolite ± disseminated pyrite ± quartz sweats
   (e) muscovite schist ± minor chlorite ± quartz sweats
   (f) siliceous schist; fine grained, white to rusty muscovite-feldspar-quartz schist ± pyrite
   (g) highly altered equivalent of 7(b) and 7(d); incompetent, yellow-orange weathering saprolite

8. CARBONACEOUS META-SEDIMENTS
   (a) graphite-phyllite schist
   (b) massive to moderately gneissic quartzite; black to blue-grey sucrosic quartz ± minor sericite ± graphite

9. FELSIC META-VOLCANICS
   (a) quartz-feldspar porphyry rhyolite
   (b) rusty weathering rhyolite

LOCAL GEOLOGY

Geologic mapping was attempted on the Hunker Dome grid, but was not very successful due to less than one percent outcrop. The remaining nine grids in the target area were not mapped due to a similar lack of outcrop. Once bulldozer trenching was completed on the Hunker Dome grid, the geology in this area was exposed.

Two main rock types were exposed in the trenches, one being a tan to rusty weathering quartz-muscovite felsic schist and the second being a medium to dark green chlorite schist with minor muscovite plus talc alteration and quartz sweats. This is a possible mafic metavolcanic.

These units are deeply weathered at surface and details of schistosity, *et cetera*, were not visible.

Both units are cut by north-south striking near vertical narrow white quartz veins. The average width of these veins is 1.0 m. The quartz is massive and moderately fractured with occasional limonite stains on the fractures.

Mineralization consists of trace disseminated blebs of pyrite and occasional galena. Bleb diameter seldom exceeds 2 mm. Very occasional traces of free gold and sylvanite telluride were also observed, particularly in the vicinity of shaft number one. The gold occurs as very fine disseminated crystals in vugs with lattice-like limonite which is undoubtedly decomposed pyrite cubes. Gold was also observed as tiny individual blebs in white quartz. The sylvanite also occurred as tiny disseminated blebs in white quartz.

Of the 243 channel samples cut from the trenches, only seven were of economic interest. The remainder were background in value (<0.01 ounces Au/ton).

Five of the seven high assays were obtained in trenches TR87-3, TR87-4 and TR87-5, adjacent to shaft number one. The vein found in shaft number one appears to junction with an east-west striking fault in TR87-3. Sampling of this junction gave assays of 1.37 ounces Au/ton/2 m on the east side of the junction and 0.51 ounces Au/ton/2 m on the west side for an average of 0.94 ounces Au/ton/4 m. A composite of quartz vein material from this trench assayed 1.54 ounces Au/ton. In TR87-4, 16 m north of TR87-3 and on the same vein, an assay of 0.29 ounces Au/ton/0.5 m was obtained.

Fourteen metres to the west of the vein in TR87-4, another quartz vein intersected in TR87-5 assayed 1.35 ounces Au/ton/0.1 m.

Four hundred metres west of shaft number one, another quartz vein had been exposed by shaft number four. Trench TR87-10 cut this vein adjacent to the shaft and stripped it for 18 m along strike south of the shaft. At the shaft, the vein assayed 0.001 ounces Au/ton/0.5 m. At the south end of the stripped area, it assayed 0.11 ounces Au/ton/0.5 m.

Sixty-seven metres northwest of shaft number four, shaft number two had exposed another quartz vein. This vein was further exposed by trenches TR87-13, TR87-14 and TR87-15. An assay of 0.24 ounces Au/ton/0.5 m was obtained in TR87-13, eight metres south of the shaft.

The remainder of the assays were very low value, indicating the mineralization is highly erratic and "spotty."

The trenching exposed an en echelon system of quartz veins over the entire grid, a width of 450 m and a strike length of 1,100 m. The veins seldom exceed 1.0 m in width and approximately 25 parallel veins are exposed. The veins appear to be quite persistent over long distances, but are very inconsistent over short distances due to cross faulting and pinching out. The best mineralization may be controlled partly by the junction of cross faults with the quartz veins.

Alteration haloes of 0.1 to 1.0 m into the wall rocks were observed next to some of the veins. The alteration appears to be primarily pyritization, with 10-15 percent very fine grained disseminated pyrite flooding the wall rock next to the veins. Subsequent oxidization of this pyrite gives the schists a distinctive brown-buff colour.

SOIL GEOCHEMISTRY

Ten separate grids, using 100 m x 25 m sample spacing, were samples for soil geochemistry. On the Mackay grid 456 samples were taken, on Dominion grid 415 samples, on Hunker Dome grid 483 samples, on King Solomon Dome grid 702 samples, on Lombard grid 400 samples, on Lloyd grid 468 samples, on Lloyd II grid 418 samples, on Lloyd III grid 400 samples, on Green Gulch grid 391 samples and on Dominion Mountain grid 310 samples, for a total of 4,443 samples. These were sent to Chemex Labs in North Vancouver, British columbia, and were assayed for gold plus 32 elements on MAC, DOM, KSD and Hunker Dome and Lloyd grids. Due to budget cuts, the remaining grids' samples were only assayed for gold. This means 2,524 samples were assayed for 33 elements and the remaining 1,919 were single element assays, totalling 85,211 analyses.

Samples were taken using a mattock to dig down to 'B' horizon soil. Samples were placed in kraft paper envelopes for shipment. Analysis for gold was done by fire assay with atomic absorption finish and one assay ton. The crushed sample was also screened for visible gold. The remaining 32 elements were analyzed using Inductively Coupled Plasma (ICP) analysis. Minor problems were encountered from permafrost and swamp areas on the grids. No samples were taken when these conditions were encountered.

Results were plotted on 1:5,000, 1:7,500 or 1:2,500 scale and contoured. Only elements with significantly anomalous values were plotted. Elements scarcely above background are not plotted.

In the Hunker Summit area only gold was anomalous over significant areas. The other 32 elements were very weak and erratic or background only. This confirms observed geology as the gold occurs as free gold with very little additional mineralization. Traces of pyrite and galena occur occasionally in the gold bearing veins but in such small amounts as to be useless in producing geochemical anomalies. Due to budget restraints, several grids were assayed only for gold and not for additional elements. As a result, only gold was plotted and contoured for all grids.

Gold anomalies are found on all 10 grids and are discussed on a grid-by-grid basis.

Mackay grid showed widespread gold anomalies trending north-south over contiguous areas up to 1,100 m x 200 m. The values are generally in the 10-50 ppb Au range with a few samples in excess of 100 ppb Au. This may be a continuation of the anomalies on Hunker Dome grid.

Dominion grid adjoins the Mackay grid to the east. Gold values are small and erratic, indicating an overall weakening of gold content from the Mackay grid eastward. Anomalous values are again generally in the 10-50 ppb range with a high value of 73 ppb Au. Possible north-west trends are interpreted.

Lombard grid adjoins the east side of the Dominion grid. Gold anomalies are very scattered, small and weak, and there are very few of them. This area is not well mineralized in gold.

Hunker Dome grid is strongly anomalous in gold, with values as high as 377 ppb Au. Interpretation appears to show linear, north-south and east-west trending anomalies. Subsequent bulldozer trenching confirmed these anomalies are expressing the presence of an en echelon quartz vein system striking north-south and carrying free gold. It is imperative to note that some of the highest assays obtained from bedrock samples (in excess of 1.5 ounces Au/ton) came from an area with only a 16 ppb Au soil geochemistry anomaly. This implies that any gold anomaly of greater than 10 ppb may be expressing a bedrock gold structure of much higher value. There are literally hundreds of such values on the 10 geochemistry grids.

King Solomon Dome grid is anomalous in gold over most of its 3,400 m length and 400 m width. In the south end, the anomalies are moderate in size, up to 300 m x 100 m, but in the north end of the grid the anomaly is contiguous over a 1,100 m x 400 m area. Most anomalous values range from 10-50 ppb Au with occasional spot highs to 270 ppb Au.

Lloyd grid shows several narrow northwest trending gold anomalies indicative of an en echelon vein system of narrow structures. These anomalies are 800 m southeast of and on strike with the known goldbearing veins on the DOC claims adjacent to the Lloyd grid and may represent a continuation of this vein system. The anomalous values are in the 10-50 ppb range with occasional spot anomalies up to 103 ppb Au.

LLoyd II grid is adjacent to and south of the Lloyd grid. Its baseline starts at Lloyd grid station (900,-200). Its results show another northwest trending en echelon system of narrow gold anomalies 500 m south of the Lloyd grid to 2,000 m south of the Lloyd grid. This zone also strikes towards known gold veins on the DOC claims 1,300 m to the northwest and may represent a continuation of these veins. The strongest anomalies on Lloyd II grid are located on the known Lloyd showing--an en echelon quartz vein system striking northwest and carrying visible gold. Anomalous values are in the 10-50 ppb Au range and the maximum assay returned was 272 ppb Au. Many of the samples from this grid were lost due to contamination. This resulted from budget cuts necessitating the storage of the samples for

several months before they were assayed. Moisture in the samples rotted the paper sample bags and the bags spilt their samples, mixing them together thus resulting in contamination.

Lloyd III grid ties onto the south end of Lloyd II grid. Results are in the 10-50 ppb range with spot highs to 407 ppb. These anomalies appear to be a continuation of the anomalous zone trending northwest on Lloyd II grid. The anomalies are narrow and irregular.

Dominion Mountain grid ties onto the south end of Lloyd III grid. The en echelon system of northwest trending anomalies appears to end at the north end of the DMM grid. A 1,000 meter gap ensues with only two weak spot anomalies. On the southern 500 m of the grid, a continuous northwest trending anomaly 500 m x 25 to 50 m is found running up to the peak of Dominion Mountain. This anomaly is 10-50 ppb au in value with a spot high of 603 ppb Au. The remainder of this end of the grid is barren.

Green Gulch grid adjoins the Lloyd II grid to the west. Its baseline starts at Lloyd II station (1600,-200). The eastern end of the Green Gulch grid shows only a few weak discontinuous gold anomalies which are narrow and northwest trending and may be continuations of the en echelon vein system interpreted on Lloyd II and Lloyd III grids. Values are low, in the 10-20 ppb Au range. The western end of the grid is very anomalous for gold with large widespread anomalies trending north-south and possibly northwest-southeast over a 900 m x 400 m area. This is interpreted as large auriferous shear zones. Values are in the 10-50 ppb Au range with spot highs to 185 ppb Au.

Overall, it appears that all 10 grids are anomalous in gold to some extent. Most of the anomalies are narrow and linear, which could be interpreted as vein structures. This interpretation is confirmed on Hunker Dome and Lloyd II grids where known auriferous veins are coincident with gold geochemical anomalies. The widespread anomalies on KSD, Mackay and Green Gulch grids are more likely to be auriferous stratigraphic units or large auriferous shear zones.

Although the values of the anomalous samples are low, this does not appear to be a direct indication of low gold values in the underlying bedrock. As evidenced in the trenching on Hunker Dome and in old prospect shafts on Hunker Dome and Lloyd II, high grade goldbearing quartz veins are often expressed by gold soil geochemistry values as low as 16 ppb Au. Therefore, the soil geochemistry results should be used more in a qualitative than quantitative interpretation.

CONCLUSIONS

It can be concluded that soil geochemistry is effective in outlining zones of bedrock gold mineralization in this area. It must be noted, however, that the results should be interpreted in a qualitative rather than an quantitative manner as high grade auriferous veins have been found to produce very low gold geochemistry soil anomalies. Furthermore, gold is the only useful element to assay for in this area. None of the other 32 elements assayed for give useful interpretable results for locating auriferous structures.

Results are weakly anomalous for gold on all 10 grids sampled. Several of the grids can be interpreted as outlining large en echelon auriferous quartz vein systems trending north-south or northwest-southeast. Some of these interpreted vein systems are hundreds of metres wide.

Three grids show very widespread, contiguous gold anomalies over large areas, which may represent auriferous stratigraphic units or large shear zones.

Trenching of soil geochemistry gold anomalies on Hunker Dome grid confirmed a north-south trending en echelon quartz vein system 400 m wide and 1,100 m along strike and open in all directions. The veins are auriferous with visible gold and also carry traces of finely disseminated pyrite, galena and tellurides. Ore grade assays were obtained from several veins showing the gold mineralization to be very erratic and "nuggety."

RECOMMENDATIONS

All large gold geochemical anomalies should be further explored by bulldozer trenching to expose the bedrock sources of the anomalies. Particular attention should be paid to the large anomalies on Mackay, King Solomon Dome and Green Gulch grid and to following up ore grade veins on Hunker Dome grid.

CERTIFICATE OF QUALIFICATIONS

I, Jim McFaull, with business address of:

United Keno Hill Mines Limited
409 Black Street
Whitehorse, Yukon
Y1A 2N2

and residential address:

5-100 Lewes Boulevard
Whitehorse, Yukon
Y1A 3W1
Telephone: (403) 667-7935

do hereby certify that:

1. I am a practicing geologist.

2. I hold a Bachelor of Science Degree (1976) in Exploration Geology from the University of British Columbia.

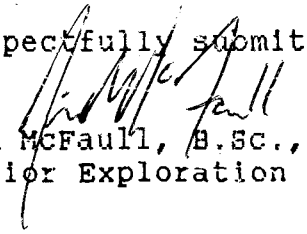

3. I am a Fellow of the Geological Association of Canada.

4. I have been practicing my profession since 1972, for several companies in British Columbia, and with United Keno Hill Mines Limited since 1975. I am currently employed as Senior Exploration Geologist in UKHM's Whitehorse Exploration Department.

5. This report, entitled "Geological and Geochemical Exploration of the Mackay, Dominion, King Solomon Dome, Hunker Dome, Lombard, Lloyd, Lloyd II, Lloyd III, Green Gulch and Dominion Mountain Grids - Hunker Summit Area," is based on work supervised by me as an employee of United Keno Hill Mines Limited.

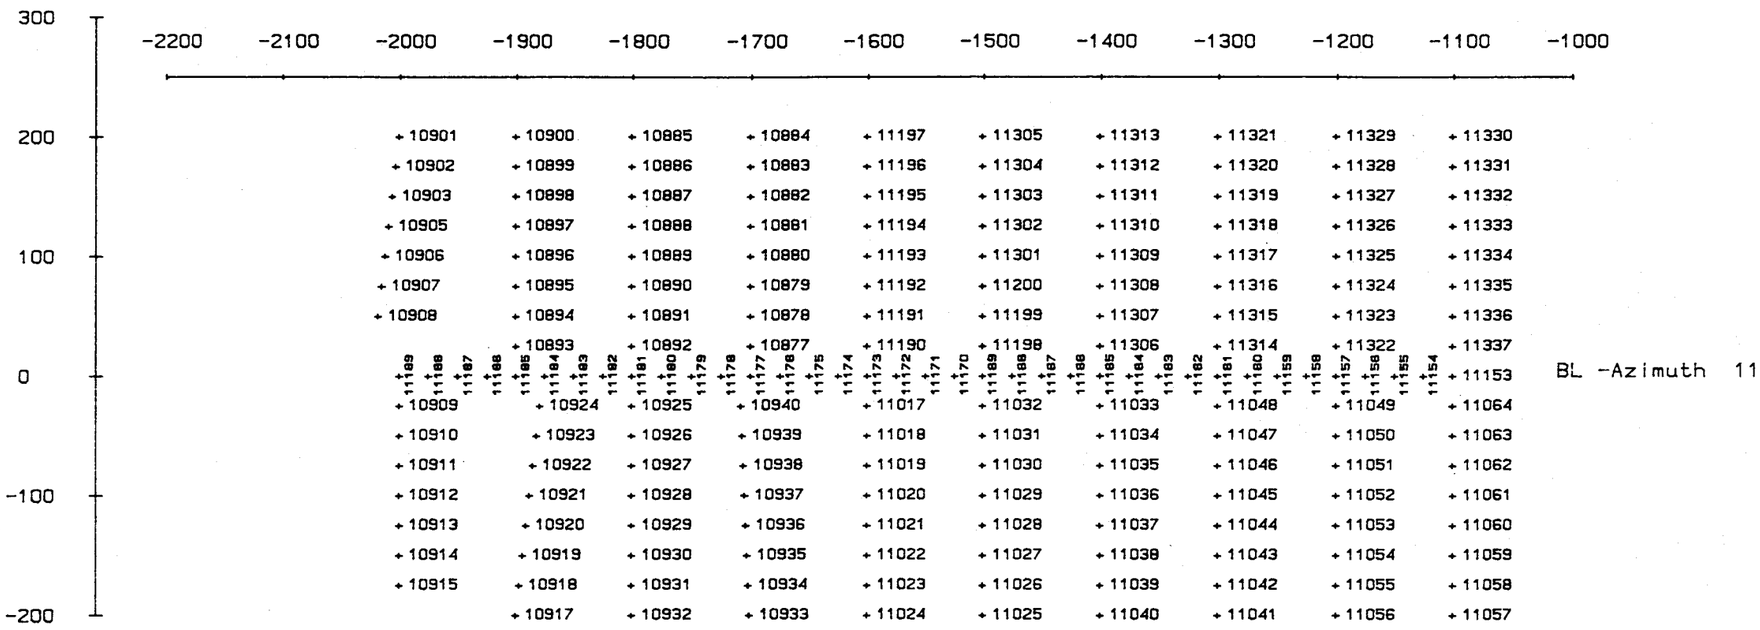

6. I have not received, nor do I expect to receive, any interest, either directly or indirectly, in the properties concerned in this report or in United Keno Hill Mines Limited.

Respectfully submitted,

Jim McFaull, B.Sc., F.G.A.C.
Senior Exploration Geologist
