S05911 105, 30, <1, 16
S05912 86, 50, 1, 24

SAMPLE NUMBERS: Soil: S 05910 - S05912 PAN 9008-A-5A, 9008-A-5B, 9008-A-27A, 9008-A-27B

PANNING CONCENTRATE DESCRIPTION:

- See adjoining page.

Panning Concentrate Description

PS9008A-27A	Sample taken from approximately 1.3m above the trench floor -? m the grey → black felted soil horizon (CL) @ 27m; subrounded grains of decomposed granodiorite / fine-grained quartz monzonite. mostly Qz; minor feldspar, mica, magnetite; light orange-brown colour; average particle size = 10 µm., minor yellow fluorescent grains
PS9008A-5B	Sample taken from the upper med-grey soil/clay layer, @ 5m @ 2.5m from the bottom of the trench; minor MG; tan coloured; Remnant granodiorite that has broken down: mostly Qz, mafics (HB>BI); very minor magnetite; some remnant Pyrite.
PS9008A-27B	Sample taken from the upper soil/clay layer @ 27m, tan coloured; minor magnetite; remant granodiorite: mostly quartz, muscovite, pyrite, mafcs (BI > HB); minor feldspar; Ave. partical size: 15-20µm.
PS9008A-5a	Sample taken from the upper soil/clay layer @ 5m; Orange-tan coloured; decomposed granodiorite: mostly quartz, some feldspar., remnant Pyrite; HB > BI. Ave. partical size = 20 µm.

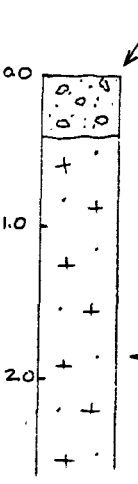
- blocky habit

40-45.6 - banded rust-weathering; colluvium matrix supported w clasts of granodiorite and QMFX; clast size ranges from 2-7cm (QMFX to 1.5m)
- matrix is a mixture of clay and sand-silt sized particles.

SCALE: 1:500

* taken @ 50m

SOIL PROFILE



0.0-0.4m
- Fine grained colluvium and broken, weathered rock.
- Brownish green and light yellow
- trace organics; very poorly sorted → 50% silt-sand → 50% heavily weathered, weak, angular rock fragments.

0.4-2.3m
- strongly weathered/altered very friable rock (granodiorite); well-jointed, Limonite staining on fractures.

Scale: 1:50

REPORT ON
PRELIMINARY SURFICIAL GEOTECHNICAL INVESTIGATIONS
(REF. NO. 1831/1)

VOLUME I OF II
REPORT

EXECUTIVE SUMMARY

Preliminary surficial geotechnical investigations were carried out at the Casino Project by Knight Piesold Ltd. during the period June 4 to October 1, 1993. The investigations were carried out as part of the Placer Lease Assessment Program to provide a preliminary overview of the surficial materials and foundation conditions for the various potential minesite components, including the Open Pit, Plantsite, Heap Leach Pad, Waste Rock Storage and Tailings Impoundment sites. The results of these investigations will provide information for conceptual studies and selections of each of the components and requirements for further, more detailed, geotechnical and hydrogeological investigations.

The investigation program included the excavation of geotechnical trenches for visual description and characterization of surficial materials, and for the collection of representative samples for laboratory testwork. The laboratory testwork was carried out on-site by Knight Piesold Ltd. and included particle-size analyses, natural moisture contents, Atterberg limits, compaction tests and laboratory permeability tests.

1831/1,
March 18, 1994

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

Results of the investigations generally indicate favourable surficial materials and foundation conditions for each of the potential minesite components. Surficial materials comprise alluvial cobbly sands and gravels, well-graded colluvium and in-situ heavily weathered residual gravelly sands. Bedrock lies at shallow depths of from 1 to 4 metres over most of the project area and comprises blocky, hard, fresh to moderately weathered granodiorite. These materials will provide excellent borrow for tailings embankment, leach pad or other minesite earthworks construction. The distribution of surficial materials and foundation conditions in the project area are characterized by four (4) distinct soil profiles which are identified by specific vegetation types, as follows:

(i) A thick blanket of residual sands overlies bedrock along well-drained, non-frozen south-facing slopes and ridges adjacent to Casino and tributary creek valleys. These areas are identified by groves of aspen and poplar and provide excellent foundation conditions and borrow sources of dense, strong compacted fill for embankment or leach pad construction.

(ii) Frozen, organic and ice-rich colluvium overlies residual soils in the deposit area along slopes north of Patton Hill and along the upper reaches of Casino and Canadian Creek valleys. These areas are identified by permafrost features, very thick moss cover, and alpine tundra-like shrub vegetation. Open pit development in these areas will likely require sediment control, shallow slope angles and staged development to control thawing ice-rich overburden.

(iii) Extensive permafrost exists along valley bottoms, north-facing slopes and in shaded draws, as indicated by the presence of sparse, stunted black spruce trees and very thick moss cover. Surficial materials along valley bottoms comprise a veneer of organic and ice-rich fine-grained alluvial silty sediments overlying thick deposits of stratified, coarse-grained alluvial sands and cobbly sands and gravels. Non-frozen areas adjacent to creeks comprise coarse-grained alluvial (fluvial) cobbly sands and gravels near

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

surface. These materials will provide excellent sources of structural fill for embankment or leach pad construction. Permafrost areas along north-facing slopes and draws comprise ice-rich colluvium overlying residual sands and bedrock. The depth to bedrock in the valleys is not known and requires further investigation.

(iv) Surficial colluvium overlies residual sand and/or broken bedrock along east, west and south-facing slopes south of Patton Hill along Casino and tributary creek valleys. These areas are indicated by stands of tall spruce with mixed birch and aspen. These materials provide good foundation conditions for waste rock storage, plantsite facilities or heap leach pad construction. Much of the colluvium in these areas is suitable or may be mixed with underlying residual soils and broken rock to provide potential borrow sources of random fill for earthworks construction.

Association des Ingénieurs-Conseils du Canada

SECTION 1.0 - INTRODUCTION AND SCOPE OF WORK

1.1 PROJECT DESCRIPTION

The Casino project is a venture by Pacific Sentinel Gold Corp. to develop a large open pit, gold-copper-molybdenum mine in the Yukon Territory. Overall preliminary geological reserves for the deposit are estimated to be greater than 600 million tonnes. The project will likely comprise an Open Pit, Plantsite, Heap Leach Facility, Waste Rock Storage, Tailings or Effluent Impoundment and other miscellaneous facilities to support mining operations. The project is situated in the Dawson Range of the Klondike Plateau approximately 300 km northwest of Whitehorse, Yukon Territory. The location of the project is shown on Figure 1.1.

This report contains results of preliminary surficial geotechnical investigations carried out in the summer of 1993 and includes preliminary implications for design of the various minesite components and recommendations for further work.

1.2 SCOPE OF WORK

A preliminary surficial geotechnical investigation program was carried out at the Casino project site by Knight Piésold Ltd. during the period June 4 to October 1, 1993. The work was carried out as part of the placer lease assessment program and included the excavation of test trenches and surficial mapping to evaluate the surficial materials and the foundation conditions at the potential development areas. The program also included the collection of representative soil samples for on-site laboratory testwork.

This report is intended to provide an overview of the surficial materials and foundation conditions over the entire project area. The results of these investigations will provide the basis for site selection and requirements for more detailed investigations. Details of the geotechnical investigation program are discussed in Section 2.0. Results of laboratory testwork are included in

SECTION 2.0 - GEOTECHNICAL INVESTIGATION DETAILS

A geotechnical test trench program was carried out to investigate the surficial materials and foundation conditions at the various potential development areas for the Casino project. In addition, surficial mapping, air-photo interpretation and terrain analysis were performed to provide additional information. Specifics of the work included the following:

- Construction of roads and access trails with Cat D6 and D7 dozers.
- Stripping trench sites with Cat D6 and D7 dozers.
- Excavation of test trenches with a Hitachi UH09LC backhoe.
- Detailed geotechnical logging of test trench excavations.
- Representative sampling of the various overburden materials for visual description and laboratory testwork.
- On-site laboratory index, compaction and permeability testwork.

The locations of the geotechnical trenches are shown on Drawing No. 1831.101, along with the proposed locations for the various potential minesite components. A summary of material descriptions and conditions for each trench are summarized on Table 2.1. Detailed trench logs are included in Appendix A. The results and implications of the geotechnical investigations are presented in Sections 4.0 and 5.0, respectively.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

SECTION 3.0 - LABORATORY TESTWORK AND RESULTS

3.1 GENERAL

Laboratory index testwork was carried out on selected representative soil samples obtained from the test trenches to determine the physical characteristics of the surficial materials. Compaction and permeability tests were also carried out to evaluate the suitability of the materials for construction purposes. The laboratory testwork was carried out on-site by Knight Piésold Ltd. personnel and included the following:

- Particle-size analyses
- Natural moisture contents
- Atterberg limits
- Compaction (modified proctor) tests
- Laboratory Air Entry Permeameter (AEP) permeability tests

Results of the laboratory testwork are included in Tables 3.1 and 3.2. The characteristics for each material type are summarized in the following sections.

3.2 ALLUVIUM

- Particle-size analyses generally indicate that the alluvium is a poorly-graded gravelly sand with trace silt. Sand and gravel contents range considerably from 39 to 95 percent and 2 to 51 percent, respectively, due to the stratified nature of the material. Silt contents range from 1 to 20 percent.

- Natural moisture contents of the sandy alluvium range from 5 to 17 percent, with an average value of 10 percent. These values indicate a well-drained material with natural moisture contents less than the optimum moisture content, as determined from compaction tests.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

- Atterberg limits tests could not be carried out on the alluvium due to the coarse-grained nature of the material. However, by visual inspection, it is clear that the material is granular and non-plastic.

- One compaction test carried out on the alluvium indicated a moderately high, maximum dry density value of 1.925 g/cm^3 at an optimum moisture content of 11.5 percent. A low natural moisture content of 6.4 percent indicates that the material is dry of optimum and may require some moisture conditioning during construction.

- One permeability test performed on a sample of alluvial sand compacted at natural moisture content indicated a relatively high permeability value of 3 x 10^{-5} cm/s. The alluvial materials may be suitable for filter zone or structural fill in embankment construction.

3.3 COLLUVIUM

- Particle-size analyses indicate that the colluvium is very well graded and comprises silty sand and gravel with some coarse gravel to small cobble-size rock fragments and trace clay. Sand and gravel contents range considerably from 23 to 55 percent and 14 to 55 percent, respectively. Fines (silt and clay) contents range from 12 to 46 percent. The wide range in values results from local compositional variations associated with varying degrees of down-slope transport and deposition of surficial materials. Average percentages of sand, gravel and fines contents are 42, 34 and 24 percent, respectively.

- Natural moisture contents range from 9 to 20 percent with a mean value of 14 percent for non-frozen samples, indicating a moist to very moist material. Samples collected along well-drained slopes or containing high fractions of sand and gravel generally have lower moisture contents than those along the base of slopes, near permafrost, or with high fines contents.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

Natural moisture contents are typically 3 to 5 percent greater than optimum values. Tests on frozen ice-rich samples of silty colluvial matrix indicate total moisture contents ranging from 24 to 84 percent. This material is typically medium to highly saturated and becomes unstable when thawed.

- Atterberg limits tests indicate a low plasticity material with plasticity indices ranging from 4 to 10 percent with an average value of 6 percent. The fines fraction of the colluvium may be classified as a ML-CL (low plasticity silt-clay) material. Natural moisture contents are lower than the plastic limits.

- No compaction tests were carried out on the colluvium due to high fractions of coarse material. High in-situ moisture contents and field observations suggest that much of this material may be too wet to be utilized as embankment fill. Dry zones along well-drained and non-frozen slopes, however, may be utilized or mixed with residual soils to provide random fill for embankment construction.

- Three (3) permeability tests were conducted on compacted samples of fine-grained (-¾ inch) silty, sandy colluvial matrix. Results indicate that the material is very impervious with an average permeability value of 5×10^{-9} cm/sec. This value is suitable for the construction of a low permeability core zone within the tailings embankment or leach pad foundation. However, it would likely have to be blended with residual soils to satisfy moisture-density requirements and may require the removal of oversize clasts. Coarser grained colluvium would also be suitable for use as random fill in embankment construction.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

3.4 RESIDUAL SOILS

- The residual soil materials generally comprise highly weathered, fine gravelly sands with some silt. Particle-size analyses indicate a wide range of values for the various silt, sand and gravel fractions due to varying degrees of in-situ weathering with depth and host rock alteration. Sand and gravel contents range from 12 to 90 percent and 0 to 86 percent, respectively. Fines (silt) contents range from 2 to 40 percent. Mean values for each of the silt, sand and gravel fractions are 12, 62 and 26 percent, respectively. These values are considered to be typical of most of the residual soil materials.

- The residual soil is typically heavily weathered and oxidized. This results in very weak, angular particles. Consequently, handling and compaction of this material will have a significant effect on the particle-size distribution. Particle-size analyses on samples after compaction reveal an increase in fines content of approximately 5 to 15 percent. This is advantageous in achieving higher density, stronger, less pervious compacted fill during embankment construction.

- Natural moisture contents range from 5 to 35 percent, with an average value of 10 percent. Typical values generally range from 8 to 12 percent. Higher values represent heavily altered and weathered clay gouge-like materials found primarily in the deposit area. Tests on frozen samples of residual gravelly sand in the deposit area indicate total moisture contents of approximately 25 percent. This material is generally stable and free draining when thawed.

- Atterberg limits tests reveal a very low to medium plasticity material. Plasticity indices range from 0 to 23 percent with an average value of 12 percent. Lower values are typical of slightly plastic silty fine sands (ML classification) found in the Casino valley. Higher values represent

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

medium plasticity, heavily weathered silty and sandy clays (CL classification) found in the deposit area. The plastic limits of the residual soils are much greater than the natural moisture contents.

- Compaction tests reveal very consistent moderate to high maximum densities which will provide for dense, strong compacted fill. Maximum dry density values range from 1.96 to 2.17 g/cm^3 (19.2 to 21.2 kN/m^3) with a mean value of 2.10 g/cm^3 (20.6 kN/m^3). Optimum moisture contents range from 7 to 12 percent with an average value of 9 percent. Natural moisture contents are generally at or slightly less than optimum which is favourable for construction. Excellent compaction is achieved at moisture contents between -3 and +2 percent of the optimum moisture content.

- Laboratory AEP permeability tests were carried out on various compacted samples of residual soil. Tests were performed at various levels of compactive effort and at different moisture contents. Samples tested at natural moisture content and 100 percent compactive effort (approximate maximum dry density) reveal consistent, very low permeability values ranging from 1 x 10^{-9} to 7 x 10^{-7} cm/s, with a geometric mean value of 2 x 10^{-8} cm/s. The variability is a result of the varying degrees of weathering or oxidation resulting in the break-up of particles during laboratory compaction.

  Permeability tests carried out at different moisture contents indicate no significant change in permeability. Very dry samples, however, do exhibit an increase in permeability by approximately one order of magnitude, as shown for sample 9052-B1 on Table 3.2.

  Permeability tests carried out on samples at different compactive efforts indicate an increase in permeability as the degree of compaction or density decreases. Permeability values range from 1 x 10^{-8} to 3 x 10^{-6} cm/s, with

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

a geometric mean value of 4 x 10^{-7} cm/s, and are approximately one order of magnitude greater than results for 100 percent compactive effort.

These results indicate that the residual soils would be suitable for the construction of a low permeability core zone within the tailings embankment, heap leach pad or other compacted earthfill structures provided some break-up of the residual particles is achieved during field compaction. The residual soil may also be combined with colluvium and/or broken rock to provide random fill for embankment construction.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

SECTION 4.0 - OBSERVATIONS

4.1 GENERAL

The results and observations of the geotechnical test trenches, laboratory testwork and surficial mapping were used to provide information on the distribution and types of surficial materials, foundation conditions and potential borrow sources. The results were also correlated with air-photo interpretation and vegetation to help delineate surficial materials and foundation conditions over the entire project area. This information will be used to provide preliminary siting and layouts of the various minesite components and requirements for more detailed geotechnical investigations. The following are discussions of results and observations. The distribution of surficial materials, vegetation types and potential borrow areas are shown on Drawing No. 1831.102. Typical geotechnical soil profiles are shown on Figure 4.1.

4.2 VEGETATION

A preliminary vegetation study was carried out during the test trench program to help correlate surficial materials and foundation conditions. The results correlate very well and indicate four distinct vegetation types corresponding to specific surficial materials and foundation conditions. The distribution of surficial materials and vegetation types are shown on Drawing No. 1831.102 and on Figure 4.1. The results are discussed below for each vegetation type:

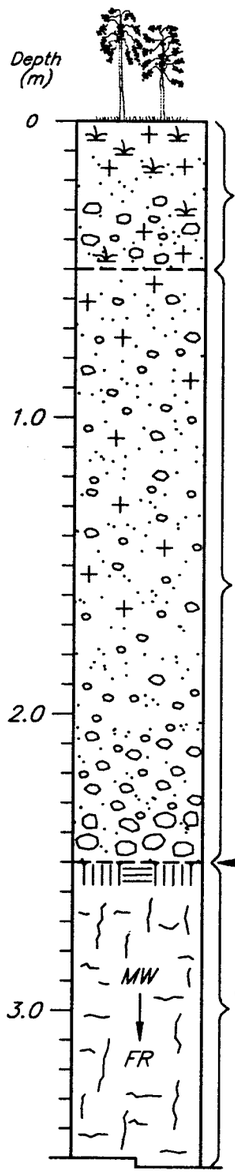
(i) Aspen and Poplar

Groves of deciduous aspen and poplar dominate well-drained, south and southeast-facing slopes along Casino Creek valley. Surficial materials in these areas typically comprise well-drained, heavily weathered residual sandy soils overlying broken bedrock, as shown on Soil Profile No. 1 of Figure 4.1. Some areas may comprise a thin veneer of surficial colluvium

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

1831.B7

1 RESIDUAL SOIL/BEDROCK



VEGETATION: (NTS)
- Deciduous aspen/poplar stands with thin moss and forest litter cover.

TOPSOIL/COLLUVIUM:
- Moist silty topsoil over well graded sandy, gravelly colluvium with silt and organics. (well drained, dry)

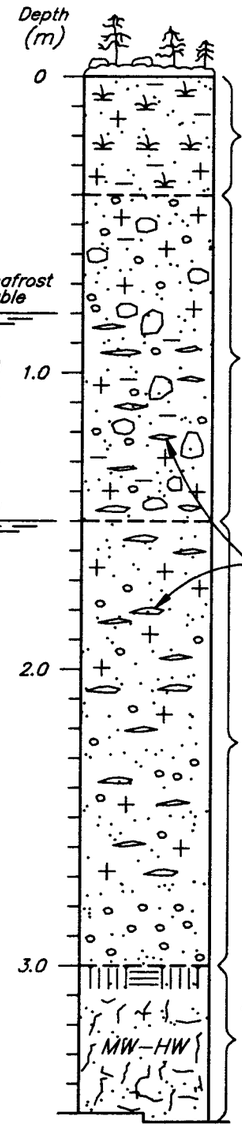
RESIDUAL SANDS:
- Heavily weathered, weak, angular residual sand and fine gravel with trace to some silt. Material is well drained and dry to slightly moist.

← Contact varies from 1.5 to 3.5 m.

BEDROCK:
- Hard, mod. weathered to fresh, blocky, broken, coarse grained granodiorite.

Notes:
- Typical of non-frozen, well drained, south and east-facing slopes and along ridges at higher elevations along Casino Valley.
- Potential borrow source materials.

2 PERMAFROST-COLLUVIUM/RESIDUAL SOIL/BEDROCK



VEGETATION: (NTS)
- Scrub birch willow with very thick moss and grass cover. (no trees)

TOPSOIL:
- Very moist organic-rich, silty clayey top-soil with peat layers.

COLLUVIUM (PARTIALLY FROZEN):
- Moist, well graded colluvium comprising gravel and cobble clasts supported in matrix of silty sand with fine gravel and clay.
- Ice lensing common in permafrost areas.

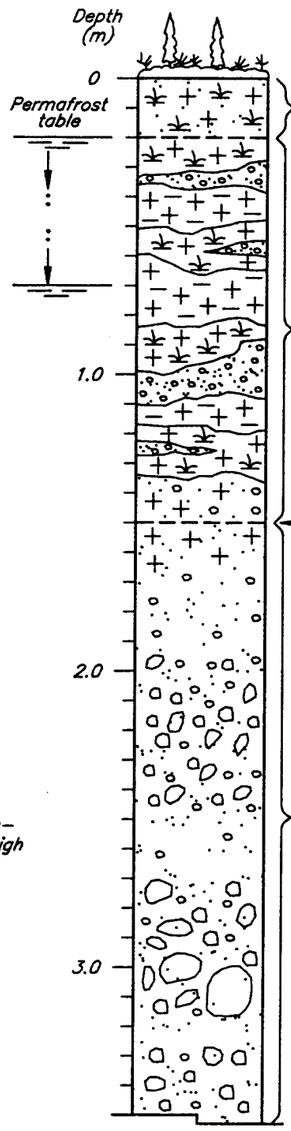
← Ice lenses (typ.)

RESIDUAL SANDS (FROZEN):
- Moist, heavily to extremely weathered residual silts and sands with some gravel. (occasional wet silty clay gouge zone)
- Thin ice lenses and ice crystals common in permafrost areas. (medium to high saturation)

BEDROCK:
- Moderate to heavily weathered, weak, blocky granodiorite/porphyry/breccia. Some v. weak, friable alteration/shear/fault zones.

Notes:
- Typical of tree-less, permafrost regions in the deposit area and along north-facing slopes in Casino Valley.
- Materials too wet for use as construction material.

3 PERMAFROST-ORGANIC (PEAT) TOPSOIL/ALLUVIUM



VEGETATION: (NTS)
- Sparse, stunted black spruce, sphagnum moss, sedge grass. Hummocky tussock fields.

ORGANIC TOPSOIL:
- Organics, mosses, grasses and roots.

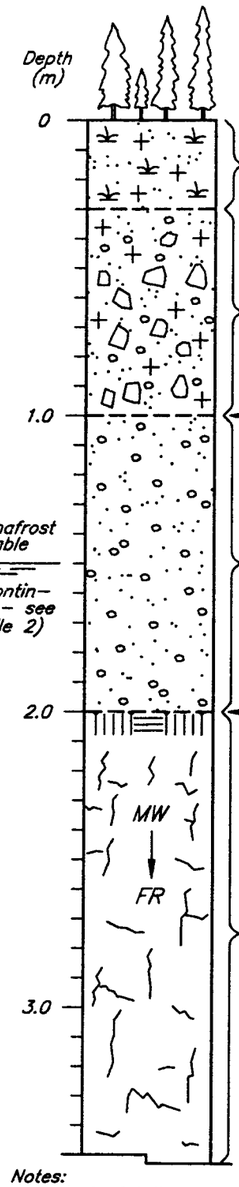
INTERBEDDED ORGANICS AND ALLUVIUM (FROZEN):
- Interbedded clayey silts, peats and sandy gravels.
- Ice-rich, hard, saturated.
- Very soft and wet when thawed.

← Contact varies from 1.5 to 2.5 m.

ALLUVIAL SANDS AND GRAVELS:
- Interbedded alluvial (fluvial) sands and sandy gravels with some cobbles. (alluvial materials near surface in non-frozen areas adjacent to creeks)

Notes:
- Typical of stunted black spruce, thick moss and hummocky terrain (permafrost) found along valley bottoms and the base of slopes.

4 COLLUVIUM/RESIDUAL SOIL/BEDROCK



VEGETATION: (NTS)
- Tall spruce on slopes; stunted black spruce at base of slopes. (permafrost)

ORGANIC TOPSOIL:
- Organics, silty soil with roots. (thick moss and peat in permafrost)

WELL GRADED COLLUVIUM:
- Silty sand and gravel with clay and rock fragments.

← Contact varies from 0.5 to 1.5 m.

RESIDUAL SAND AND GRAVEL:
- Heavily weathered, weak, angular residual sand and fine gravel with some silt.

← Contact varies from 1.0 to 3.0 m.

BEDROCK:
- Fresh to mod. weathered, broken, blocky granodiorite.

Notes:
- Typical of tall spruce stands found along east and west-facing slopes along Casino Valley.
- Permafrost is discontinuous and occurs primarily along north-facing slopes.
- Potential borrow source materials.

General Notes:
1. All depth intervals are average and approximate only.
2. Material descriptions may vary depending on location. (See Drg. No. 1831.101 and Table 2.1 for details)

Feb. 16, 1994

CASINO PROJECT
TYPICAL GEOTECHNICAL SOIL PROFILES

FIGURE 4.1

CAD FILE: \PROJECT\1831\PG\B7 Plot scale 1=1 STD.1

overlying residual soil. Topsoil is very thin and comprises an organic mat of forest litter, grasses, roots and very thin moss. The residual (and colluvial) materials in these areas will provide excellent borrow sources for embankment construction.

(ii) Alpine Tundra

At higher elevations, along north-facing slopes near Patton Hill and gentle slopes along the upper reaches of Canadian and Casino Creeks, vegetation is comprised primarily of treeless, alpine tundra-like shrubs, assorted willows and thick mosses. Much of this area is underlain by permafrost as indicated by active processes of solifluction (annual creep of saturated soils), cryoturbation, polygonal ground and down-slope striping. Soil profiles in these areas typically comprise a thin veneer of poorly developed organic and ice-rich colluvium overlying in-situ, heavily weathered residual soils or bedrock, as shown on Soil Profile No. 2 of Figure 4.1. Broken, blocky bedrock underlies a thin cover of moss and lichen at higher elevations along Patton Hill, with coarse blocky talus lying at the base of steep slopes.

(iii) Valley Bottom Peat Bogs

Lowland areas along Casino, Meloy, Brynelsen and Austin Creek valleys and along north-facing slopes adjacent to Casino valley, comprise acidic, nutrient-poor, peat bogs supporting black spruce, sphagnum moss and scrub birch willow vegetation. These areas are typically poorly drained with abundant string bogs, very thick moss and hummocky sedge grass tussock fields. Sparse, stunted black spruce trees up to 2.5 metres tall are common. The thick sphagnum moss and organic-rich peat vegetation provides an excellent insulating layer for permafrost which is typically found at shallow depths. Trench excavations reveal extensive permafrost and ice-rich, fine-grained peaty sediments immediately underlying the moss cover, as shown on Soil Profile No. 3 of Figure 4.1.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

(iv) White Spruce and Birch

Thick stands of tall white spruce and birch with some aspen are characteristic of east and west-facing slopes along Casino Creek valley. Soil profiles in these areas typically comprise well graded colluvium with a fine-grained, moist silty matrix, overlying residual sandy soils in part and/or broken bedrock, as shown on Soil Profile No. 4 of Figure 4.1. Permafrost is discontinuous in these areas and is mainly restricted to north-aspect slopes and shaded draws.

4.3 PERMAFROST

Permafrost, or perennially frozen ground, is discontinuous along Casino valley and is restricted primarily to valley peat lands, north-facing slopes and local shaded areas. Permafrost is extensive over the Casino deposit area. The distribution of permafrost is shown on Drawing No. 1831.102. Significant results are summarized below:

- Permafrost in Casino Creek and tributary valleys primarily occurs along valley bottoms and in shaded draws. These areas are characterized by the deposition of fine-grained, low permeability fluvial sediments, including stratified silts, clays and fine sands which has resulted in the development of saturated and frozen ice-rich soils. Flood plain deposits along Casino Creek valley comprise organic silts and silty fine sands and commonly overlie coarser-grained alluvial sands and gravels at depth.

- Colluvial and alluvial fans along the base of slopes and tributary valleys are also frozen and comprise fine-grained, ice-rich sediments as indicated by sparse stunted black spruce.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

- Permafrost is also common along north-facing slopes adjacent to Casino Creek valley. These areas are marked by well developed solifluction ridges and the absence of trees, indicating permafrost at shallow depths.

- Depths to the permafrost table along the Casino Creek valley range from approximately 0.2 to greater than 3 metres. Along the valley bottom the thick layer of moss and peat provides an insulative layer for permafrost resulting in very thin active layers (depth of thaw) and shallow depths to permafrost of approximately 0.3 to 0.5 metres. The permafrost acts as an impervious barrier to groundwater flow resulting in abundant surface water and peat bogs supporting limited vegetation and tree growth.

- Permafrost is prevalent in the Casino deposit area. Along shallow slopes permafrost is common, resulting in the development of abundant fine-grained organic, colluvial and residual soils and ice wedges in broken rock. Frequent buried layers of frozen, ice-rich peats and colluvium are also common. The ice-rich soils exhibit very low strengths and flow when thawed in open excavations.

- The permafrost table lies at shallow depths along valley slopes north of Patton Hill and at lower elevations along the upper reaches of Casino and Canadian Creek valleys, including Heap Leach Site No. 2. Thermal testing in existing drill holes in the deposit area, carried out by the Geological Survey of Canada, indicate significant variation in depths to permafrost of from 3 to 72 metres. The thickness of permafrost in the deposit area is not known but is also expected to vary considerably.

- Ground ice is not expected to be significant in bedrock due to the well-drained nature of the steep slopes and the low in-situ fracture spacing in the bedrock at depth.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

- Permafrost is absent along south-facing slopes and along ridges at higher elevations along Casino Creek valley, including the potential Waste Rock Storage and Plantsite areas. These areas are characterized by well-drained colluvial and/or residual sandy soils supporting stands of tall spruce and poplar, respectively.

- Permafrost is also absent along some areas of the Casino valley as evident by the presence of tall grasses and willows, and the absence of thick mosses. These areas are discontinuous and likely result from the historic shifting of the creek channel which acts to maintain a thawed region under the creek.

Permafrost is an important factor when considering the location, design, construction and performance of all minesite components. The presence of ground ice in the deposit area may affect stability, groundwater flow and mining operations. The variability of permafrost and types and amounts of ground ice will require further, more detailed subsurface investigations. These investigations will include ground temperature profiling and will be carried out in the deposit area and at selected locations for each of the minesite components.

4.4 ALLUVIUM

Alluvial materials in the Casino project area are found in creeks and along flat valley bottoms. The alluvium is generally coarse grained and comprises interbedded sands and gravelly sands with cobbles and small boulders. The distribution of alluvial materials is shown on Drawing No. 1831.102. Significant results are summarized below:

- Coarse-grained alluvium comprising cobbly sands and gravels with some small boulders lies near surface along Casino Creek valley. The alluvium is typically overlain by frozen organic-rich soils which comprise

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

approximately 90 percent of the valley. Near Casino Creek itself the alluvium lies at surface and is not frozen.

- Stratified, fine-grained, alluvial sands and clayey silts typically lie near surface along tributary valleys to Casino Creek, including Meloy, Brynelsen and Austin Creek valleys. These valleys are also characterized by extensive permafrost resulting in highly saturated, ice-rich sediments.

- Significant deposits of alluvial sandy gravels with cobbles also occur along the upper reaches of Canadian Creek northwest of the deposit area. Historic placer workings in the area report overburden depths of up to 13 metres. These conditions may not be suitable for heap leach pad construction.

4.5 COLLUVIUM

Surficial colluvium in the Casino project area is typically found along steep slopes near Patton Hill and along north and west-facing slopes within Casino Creek valley. Colluvium is very thin or absent along south-facing slopes and along ridge lines where residual, weathered soils predominate. The distribution of colluvium over the project area is shown on Drawing No. 1831.102. Significant results are summarized below:

- Colluvial materials found along slopes in the Casino valley comprise a fine to medium-grained sand with some silt and trace clay supporting coarse gravel to cobble-size clasts of broken rock fragments.

- The colluvium varies in thickness from approximately 0.5 to 2.0 metres and generally increases down-slope.

- In poorly drained areas such as at the base of slopes, in shaded draws, and in permafrost areas, the colluvium is moist to very moist and is not considered suitable for use as embankment fill or in leach pad construction.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

Well-drained and coarse-grained material at higher elevations, however, may be suitable as random fill or mixed with underlying residual soils for use in embankment construction.

- Colluvium in the deposit area comprises coarse blocky talus (scree) along the base of steep slopes. The talus generally increases in thickness down-slope resulting in the formation of talus fans. These areas may provide sources of rockfill for embankment construction. Along upper reaches of Canadian and Casino Creek valleys, blocky talus overlies frozen, ice-rich and organic-rich colluvium.

4.6 RESIDUAL SOILS

Residual soils in the Casino project area typically comprise heavily weathered, iron oxidized, and decomposed sand with some fine gravel and silt. The material is derived from heavy in-situ weathering of host granodiorite bedrock resulting in very weak, angular particles. The distribution of the residual soils is shown on Drawing No. 1831.102. Significant results are summarized below:

- Residual soils along slopes in Casino valley are typically well drained and non-frozen with moderately low moisture contents. The residual soils coarsen with depth to broken rock as weathering processes decrease.

- Along south and east-facing slopes and along ridges at higher elevations the residual material lies at surface and provides the best potential sources of borrow for embankment fill. A veneer of fine-grained residual silty sands is typically found near surface and provides an excellent source of relatively impervious compacted fill for use in embankment core zones, heap leach pad foundations, effluent/seepage collection ponds, and other minesite structures.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

- Some residual soils in the deposit area comprise heavily to extremely weathered and altered sandy silts and sticky, gouge-like, plastic clayey silts. These zones are apparently related to alteration and preferential weathering along weak steeply dipping shear and fault zone structures.

- Frozen residual soils in the deposit area are characteristically hard and partially saturated with only approximately 5 to 10 percent excess ice content. The ice is present as fine interstitial ice crystals and very thin (1-2 mm) discontinuous ice lenses.

4.7 BEDROCK

Bedrock in the Casino valley area comprises fresh to slightly weathered, blocky, hard, competent coarse-grained, intrusive rock. The bedrock forms part of the Dawson Range Klotassin Batholith and is comprised primarily of coarse-grained granodiorite with minor quartz diorite. A few trenches on either side of Casino Creek intersected hard, fresh, fine-grained quartz-rich gneiss and quartzite rocks of the Yukon Metamorphic Complex. The Yukon Group represents an older suite of metamorphic rocks which were intruded by the Dawson Range intrusives. The bedrock surface is variable and is related to the depth of weathering of the overlying residual soils and/or varying thicknesses of surficial colluvium. Depths to bedrock (refusal) vary from approximately 1 to 4 metres along slopes and ridges in Casino valley. Bedrock was not intersected in the valley up to depths of approximately 3.5 metres.

Bedrock in the deposit area comprises broken, fine blocky granodiorite, quartz monzonite, Patton porphyry (dacite), and latite breccias. The bedrock is overlain in part by talus (scree) and organic-rich colluvium. Depth to bedrock varies considerably due to local variations in preferential weathering along shear, alteration and fault zones. Depths generally increase down-slope from approximately 0 to 10 m at higher elevations, to greater than 30 metres at lower

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

elevations and along alteration zones. Average overburden depths are reported to be approximately 8 metres.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

SECTION 5.0 - GEOTECHNICAL IMPLICATIONS

5.1 GENERAL

The results of the investigations and laboratory testwork were used to assess the geotechnical implications for the various potential minesite components. The geotechnical implications are discussed for each of the components with respect to foundation conditions, seepage control and borrow materials for embankment, heap leach pad or effluent/seepage collection pond construction. Preliminary geotechnical aspects affecting design and layout are discussed in the following sections for each component along with recommendations and requirements for further work. A discussion of potential concrete aggregate sources is also included.

5.2 TAILINGS OR SOLUTION CATCHMENT FACILITIES

A total of four (4) preliminary alternative sites for tailings/solution storage were reviewed within Casino Creek valley, as shown on Drawing No. 1831.101. The valley type topography present at all sites is advantageous for tailings storage as it allows natural control and confinement of seepage within one valley. This results in monitoring and collection of all seepage at a "single-point" downstream of an embankment. A comparative assessment of each site will be carried out upon determination of ore reserves and tailings or effluent storage requirements. Preliminary indications suggest a large deposit requiring significant storage. This leads to Tailings Site No. 4 as the preferred alternative and provides the focus for these geotechnical investigations.

Significant geotechnical implications, including foundation conditions and potential borrow source areas, are summarized below:

- Appreciable quantities of residual soil materials are available along slopes and ridges adjacent to Casino Creek valley for tailings embankment construction. Finer-grained residual silty sands found along ridges at higher

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

elevations provide excellent sources of dense, relatively impervious compacted fill material for core zone or leach pad construction. Coarser material and broken bedrock at depth could be easily bladed and/or ripped with heavy equipment to provide additional material for zoned embankment construction.

- Significant borrow sources of alluvial sands, gravels and cobbles are available along valley bottoms. These materials are competent, granular and free draining and would provide excellent structural fill for embankment construction. The presence of shallow permafrost in finer-grained and organic-rich sediments away from creek channels would require extensive stripping, melting and stockpiling to allow access and drainage of underlying coarse-grained alluvial materials.

- Surficial deposits of well-graded colluvium, residual sands and broken rock provide additional borrow sources of random fill for embankment construction. These materials are found primarily along well-drained slopes east of Casino Creek valley.

- Foundation conditions along abutment slopes in Casino Creek valley are characterized by a thin veneer of colluvium and/or residual soil overlying bedrock at shallow depths. Blocky granodiorite bedrock was intersected at shallow depths along abutment slopes at Tailings Site Nos. 1, 3 and 4. Trenches excavated on the east slope at Tailings Site No. 2 terminated in frozen colluvium and residual soils. Foundation preparation along abutment slopes would likely involve excavation or blasting (in permafrost areas) to bedrock and backfilling with impervious compacted fill wherever required to minimize foundation seepage losses.

- Foundation conditions in Casino Creek valley are characterized by frozen organic and ice-rich sediments and peats overlying thick stratified deposits of relatively pervious coarse-grained alluvial sands, gravels and cobbles.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

Trenches excavated in non-frozen areas encountered alluvial materials to depths greater than 3.5 metres. Various design alternatives for foundation preparation include the excavation of alluvial materials to bedrock and replacement with compacted fill or constructing a seepage cutoff wall. The construction of a semi-pervious foundation with downstream seepage collection would be an alternative if depths to bedrock are considerable and if thawed foundation strengths of overburden are adequate to provide long-term stability.

More detailed sub-surface investigations will be required at the preferred tailings storage facility site to evaluate the following geotechnical and hydrogeological conditions:

- The thickness and characteristics of overburden and the quality of bedrock.
- Detailed information on the stratigraphy and in-situ density of the overburden materials.
- The collection of overburden samples at depth for laboratory index and compaction testwork.
- Water tests in selected formations to obtain information on hydraulic conductivities and groundwater pressures in the overburden and bedrock.
- Installation of groundwater monitoring wells.
- Installation of thermistors in permafrost areas to determine ground temperature profiles and seasonal variations.
- Possible additional test pits to obtain site-specific information on potential borrow source materials.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

5.3 WASTE ROCK STORAGE

A potential Waste Rock Storage site is located south of Patton Hill, as shown on Drawing No. 1831.101. This site is advantageous for waste rock storage since it lies on a south-aspect slope which contains no permafrost and is located in the Casino Creek catchment. Surficial materials at the site comprise coarse boulder talus (scree) overlying well-drained residual sand along upper portions of the slope, and colluvium, comprising sand and broken rock with some silt, overlying residual soil along lower portions of the slope. Bedrock lies at shallow depths ranging from 1 to 4 metres. These conditions have the following geotechnical implications:

- Blocky boulder talus (scree) and well-drained, competent residual sands provide relatively high foundation strengths for waste rock loading.

- The absence of permafrost on the south-facing slope is advantageous in providing long-term foundation stability and minimizing surface settlements.

- Stripping would likely not be required due to large boulder scree which would provide an excellent contact with overlying waste rock.

- Any seepage losses would be confined to the Casino Creek catchment and contained by the tailings facility downstream.

A comparative assessment of various alternative sites will be carried out to determine the best site for waste rock storage. Additional geotechnical and hydrogeological investigations would then be carried out to provide information on foundation stability and seepage for preliminary design.

5.4 OPEN PIT

The approximate location of the deposit area is shown on Drawing No. 1831.101. Overburden materials in the deposit area are characterized by frozen, ice-rich

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

colluvium and residual soils overlying bedrock at variable depths. These conditions have the following geotechnical implications for open pit development:

- Blasting may be required in permafrost areas during pit development to remove ice-rich overburden at lower elevations.

- Pit slopes excavated in colluvium and heavily to extremely weathered and altered residual soils will likely require shallow angles of approximately 2H:1V or less.

- Sediment control berms and staged pre-production stripping may be required to control and minimize sediment transport from thawing ice-rich overburden. Wide benches may also be required along the overburden/bedrock contact to contain thawing overburden during open pit development.

- The presence of ice-bonded rock near surface will thaw during pit development, resulting in increased groundwater inflows and reduction of pit slope stability near surface.

Additional detailed geotechnical and hydrogeological investigations will be required in the open pit area and include the following:

- Oriented drill holes for rock mass classification and to determine orientations of discontinuities and geologic structures affecting pit slope stability.

- Installation of thermistors to obtain detailed information on ground temperature profiles to determine thicknesses and extent of permafrost and its subsequent affects on pit slope stability.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

- Permeability and groundwater pressure testing to estimate pit inflows, hydraulic gradients and groundwater pressures affecting pit slope stability.

- Installation of groundwater monitoring wells for the collection of baseline groundwater quality data.

5.5 PLANTSITE

The proposed plantsite area is located southeast of Patton Hill in the vicinity of the existing airstrip, as shown on Drawing No. 1831.101. This area may also be utilized as a heap leach pad site, as discussed in Section 5.6. Surficial materials in this area are characterized by well-drained residual sands over blocky, fresh granodiorite bedrock along south and west-facing slopes, and frozen organic ice-rich colluvium over residual sand and granodiorite bedrock along north and east-facing slopes. These conditions have the following geotechnical implications:

- The residual sands provide an excellent source of low permeability, dense compacted backfill for millsite structures. Significant deposits of residual materials are also available nearby along slopes north of camp.

- Heavy and vibrating structures such as crushers etc. may be founded at shallow depths on hard, competent granodiorite bedrock.

- Potential quarry sources of fresh granodiorite are available to crush for concrete aggregate and non-frost-susceptible drainage gravel for millsite foundation structures.

- Permafrost areas may be excavated or blasted to competent bedrock at shallow depths of 1 to 2 metres for foundation preparation.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

5.6 HEAP LEACH PADS

Three (3) preliminary alternative sites for heap leach pad construction are shown on Drawing No. 1831.101. Preliminary design objectives for all sites would involve the construction of a starter embankment to provide initial confinement stability and possible in-heap solution storage as the northern climate requires. This would allow the ore to be placed in lifts upstream or upslope of the embankment prior to leaching. Drainage and liner systems would be installed to contain and convey the leachate to collection ponds downstream of the embankment.

Foundation conditions are similar at Heap Leach Site No.'s 1 and 2. Permafrost lies at shallow depths along north and northeast-facing slopes. Materials comprise frozen, ice-rich colluvium overlying residual sands. Non-frozen colluvium overlies residual sands and bedrock at shallow depths along south and southwest-facing slopes. Bedrock lies at shallow depths along abutment slopes at both sites. Bedrock was not intersected in the valley bottoms at either site. These sites are advantageous in providing confinement and "single-point" monitoring and collection of all seepage and leachate solutions. Site No. 2 however is located in Canadian Creek valley, outside the proposed Casino valley development area, and would require additional environmental protection measures.

Foundation conditions at Heap Leach Site No. 3 in the vicinity of the proposed Plantsite area are characterized by non-frozen, well-drained residual sands and/or well-graded colluvium overlying bedrock at shallow depths. This site is advantageous due to better foundation conditions and southerly exposure, however would likely require more difficult and costly measures for seepage monitoring, leachate collection and leach ore confinement.

These conditions have the following implications for leach pad construction:

- Extensive earthworks may be required at Site No. 1 to obtain flatter slopes to provide stability for liner systems and to allow drainage for leachate

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

collection. Flatter slopes at Site No.'s 2 and 3 would require minimal earthworks.

- Heap leach Site No.'s 1 and 3 both drain into the Casino Creek catchment which is advantageous in controlling seepage losses within the tailings impoundment located downstream.

- Borrow sources of residual sands and broken granodiorite rock are locally available at all sites along well-drained south-facing slopes for initial embankment or foundation construction.

- Shallow depths to bedrock along abutment slopes at Site No.'s 1 and 2 and along the flat slope at Site No. 3 provide favourable conditions for embankment foundation preparation. Drilling would be required to determine depths to bedrock in the valley bottoms at Site No.'s 1 and 2. The thick deposits of coarse-grained alluvial along Canadian Creek may preclude Site No. 2 for heap leach storage due to difficulties in controlling seepage and leachate collection.

- Foundation conditions are generally favourable for the construction of a drainage/liner system. Variable depths of permafrost and thicknesses of overburden at Site No.'s 1 and 2, however, may result in differential thaw settlement of ice-rich materials, resulting in extensive work to stabilize prior to liner installation.

The selection of the preferred site(s) for leach pad construction will depend on leachable ore reserves, open pit limits and permitting requirements. A comparative assessment of the alternative sites would then be carried out to determine the preferred site for more detailed investigations. These investigations would include drilling along the starter embankment and additional test pitting for more detailed overburden and permafrost characterization.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

5.7 CONCRETE AGGREGATE

The absence of significant clean sand and gravel deposits suggests that concrete aggregate will need to be processed from crushed quarry rock on site. Alluvial sand and gravel deposits along Casino Creek valley may be suitable for use as fine aggregate for concrete structures in the tailings facility area. Sources of coarse concrete aggregate for millsite structures will likely be obtained locally from crushed rock. The fresh, hard, blocky, coarse-grained granodiorite rock found extensively over the project area will provide an excellent source of aggregate. Potential quarry sources of fresh granodiorite are abundant in the proposed millsite area. Alluvial sands and gravels in Canadian and Casino Creeks would likely require too much processing to economically obtain sufficient quantities for concrete aggregate. It is recommended that large bulk samples of fresh granodiorite rock and alluvial sands and gravels be obtained for further concrete aggregate testwork. This would include grain-size analyses, alkali reactivity, soundness and abrasion testing.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

SECTION 6.0 - CONCLUSIONS

The preliminary surficial geotechnical investigations carried out at the Casino project area generally indicate favourable conditions for the various potential minesite components. Surficial materials typically comprise well-graded colluvium overlying residual sands and bedrock along slopes and at higher elevations, and thick stratified deposits of alluvial silty sands and cobbly sands and gravels along valley bottoms. Bedrock was intersected at shallow depths of from 1 to 4 metres over most of the project area and comprises blocky, hard, fresh to moderately weathered granodiorite. Bedrock was not intersected along Casino Creek valley. Surficial materials in the deposit area comprise thick sections of residual soils and significant depths of weathering of up to 30 metres along weak alteration and shear zones. An average overburden depth of 8 metres is estimated for the deposit area from exploration drilling.

Permafrost is extensive over the project area. Slopes near Patton Hill and along the upper reaches of Canadian and Casino Creek valleys are characterized by organic and ice-rich colluvium and residual soils at shallow depths. Permafrost is also found extensively along valley bottoms, in shaded draws and on north-facing slopes along Casino Creek and tributary valleys. These areas are identified by treeless slopes, thick hummocky moss, and sparse, stunted black spruce trees at the base of slopes and along valley bottoms.

Vegetation provides an excellent indicator of underlying surficial materials. Tall stands of deciduous aspen and poplar found along south and southeast-facing slopes, and along ridges at higher elevations indicate significant deposits of well-drained in-situ heavily weathered residual sands overlying broken bedrock. These materials provide excellent potential borrow sources of dense, strong, low-permeability compacted fill for embankment or leach pad construction. Tall, thick stands of coniferous white spruce with mixed birch and aspen are present along east and west-facing slopes along Casino and tributary creek valleys and indicate moist, well-graded colluvium overlying residual sands and/or bedrock at shallow depths.

Association of Consulting Engineers of Canada
Association des Ingénieurs-Conseils du Canada

Much of the colluvium in these areas is suitable or may be mixed with underlying residual soils and broken rock to provide potential borrow sources of random fill for earthworks construction. Surficial materials in permafrost areas along valley bottoms are characterized by frozen ice-rich organics (peat) and fine-grained alluvial silty sediments overlying coarse-grained, free-draining stratified alluvial sands, and cobbly sands and gravels. The coarse-grained alluvial materials may be suitable as structural fill or filter zones in embankment construction. Non-frozen areas adjacent to creeks comprise coarse-grained alluvial (fluvial) cobbly sands and gravels near surface.

The results of these investigations provide preliminary information on the surficial materials and foundation conditions over the entire Casino project area. This information will be used for conceptual studies and selections of the various minesite components for additional, more detailed geotechnical and hydrogeological investigations.

LEGEND

- Residual sand over bedrock, materials well drained and dry. Deciduous aspen and poplar tree vegetation.
- Colluvium over residual sand and/or bedrock. Tall spruce with birch tree vegetation.
- Permafrost – frozen, organic–rich topsoil (peat and muck) over colluvium or alluvium, typical of valley bottoms and north–facing slopes. Stunted black spruce and thick hummocky moss vegetation.
- Alluvial sands and gravels with cobbles and small boulders. Recent, non–frozen creek deposits.
- Tree line (approximate)
- Surficial materials / vegetation contact (approximate)
- Exploration access road (major)
- Exploration access trails (minor)

Morphology

c	Channel
p	Plain, floodplain
h	Hummocky
d	Delta
v	Veneer (up to 1m thick)
b	Blanket (from 1 to 3m thick)
(f)	Frozen (permafrost)
	Colluvial/talus fan
	Bedrock outcrop
	Solifluction (annual thaw down–slope creep)
	Down–slope striping (annual thaw channel erosion)

e.g.1 Cv/RS/R(f) — Veneer of colluvium over residual soil over bedrock, frozen (permafrost)

e.g.2 Cv/RS//Cb R — Veneer of colluvium over residual soil over bedrock (major); or a blanket of colluvium over bedrock (minor)

Compositional – Genetic Category

O	Organics: peat and muck (frozen in permafrost areas)
T	Talus: coarse, blocky broken rock.
C	Colluvium: various materials (silty sand and gravel with rock frags)
A	Alluvium: gravel, sand and silt with cobbles (stratified)
RS	Residual soil: in–situ, weathered, weak sandy material
R	Bedrock

TEST PIT LOG

TEST PIT No. SH-1
SHEET 1 of 1

PROJECT CASINO
PROJECT No. 1831
CATION OF TEST PIT 20m S of Core Shack
GROUND ELEVATION
DATE June 15/93
LOGGED BY MDG

NOTES Groundwater level, difficulty in digging, equipment used, etc.	DEPTH (m)	GRAPHIC LOG	DESCRIPTION AND CLASSIFICATION OF MATERIAL
Very easy digging w/ Hitachi UH09LC backhoe. Pit dug for new outhouse. ∴ terminated at 2.4m. Dry pit. Non-frozen.	0 SH-1-A. 0.7 1 2 2.4 3		0-0.7m SILTY (TILL-LIKE) COLLUVIUM Brown, firm, moist v.f. gravelly SILT w/ trace-some v.f. sand and clay. Poorly sorted, well graded. Contains occasional nodule of orange (residual) sandy clay - likely from residual, weathered soil. → Fine grained brown silty till-like colluvium. Angular gravel clasts to 1cm dia. Matrix supported. Est. low perm. Slightly plastic & sticky. Trace fine organics (roots). Non-frozen. 0.7-2.4m RESIDUAL, WEATHERED GRAVELLY SAND. Orange, dense, slightly moist fine gravelly SAND w/ some silt and clay → residual (weathered), decomposed rock ie. residual soil. Mat'l also contains occasional cobble size (10cm dia.) angular hard slightly weathered granodiorite rock fragment. Appreciable fines content, est. mod. low permeability. Non-frozen. Note: Loose, crumbly cream-grey colour granular gouge-like mat'l at end of pit. Comprises clayey fine-crs. SAND → GRANULAR FAULT / SHEAR GOUGE

TEST PIT LOG

TEST PIT No. 9008-A
SHEET 1 of 1

PROJECT CASINO
LOCATION OF TEST PIT
DATE JUNE 20, 1993.

PROJECT No. 1831
GROUND ELEVATION
LOGGED BY MDG

NOTES Groundwater level, difficulty in digging, equipment used, etc.	DEPTH (m)	GRAPHIC LOG	DESCRIPTION AND CLASSIFICATION OF MATERIAL
Hitachi backhoe UH09LC Very hard digging in frozen (permafrost) material. Trench walls melting and becoming very unstable as mat'l thaws to soupy mess. Permafrost table at approx. 0.45m. Materials below frozen and hard. Ice lensing prominent in both materials (esp. in finer grained silty sands and sandy silts). Occasional ice lense up to 5cm thick.	0 0.25 Permafrost Table 9008-A1 (frozen) 1 2 2.5 Bottom 3		MOSS / PEAT VEGETATION Thick moss over matted spongy fibrous, wet black peat. 0.25-0.9 GREY, FROZEN FINE GRAINED COLLUVIUM Grey very fine sandy SILT with trace-some clay. Ice-rich. Est. excess ice comprises 50-60% by volume as 1cm thick lenses spaced 2mm-5mm. Mat'l is frozen & very hard. Ice is well bonded to soil particles. Highly frost susceptible. 0.9 0.9-2.5m FROZEN RESIDUAL SILTY SAND Orange-brown (oxidized, weathered) residual silty SAND with some fine gravel. Mat'l frozen and contains abundant ice lenses (Est. 50% excess ice by volume). Residual mat'l coarsens with depth to fine gravelly SAND. Decrease in ice lensing. Est. 30% excess ice by volume. Mat'l is frozen and v. hard.

SHEET 1 of 3

PROJECT CASINO. — N. END OF TRENCH
LOCATION OF TEST PIT
DATE JUNE 18, 1993.

PROJECT No. 1831
GROUND ELEVATION
LOGGED BY MDG.

NOTES Groundwater level, difficulty in digging, equipment used, etc.	DEPTH (m)	GRAPHIC LOG	DESCRIPTION AND CLASSIFICATION OF MATERIAL
Hitachi backhoe UH09LC Easy digging in old (existing) trench. *No evidence of previous ice lensing in any materials therefore suspect trench was originally excavated in unfrozen ground. Trench is dry. Gravelly & sandy materials are free draining est. mod. high permeability.	0 0.5 1 9008-B1 2 3 3.7 4		0-0.1 ORGANICS & MOSSES with abundant roots. Deciduous (willow) vegetation suggests no permafrost. 0.1-0.5 GRAVELLY SAND (COLLUVIUM) Light brown-tan fine gravelly SAND with trace silt and fine organics (roots) → Recent colluvium (?). Loose, dry. No evidence of previous ice lensing. 0.5-3.7 RESIDUAL GRAVELLY SANDS. Orange-brown (oxidized, weathered), medium dense gravelly SAND with trace silt. Occasional small cobble Material is moist but not frozen. Sand is well graded. but poorly sorted. Occasional band of heavily weathered and stained mat'l. Some cobbly zones. Residual (weathered in place) sand. Coarsening at base to sand and gravel. Gravel is heavily weathered, weak and crumbly. Very dense at base but no cohesion. 3.7-4.5 COARSE COLLUVIAL SANDS & GRAVELS Moderate-heavily weathered, iron stained cobbly SAND and GRAVEL. Medium dense, dry. Stoney looking material. Clasts are angular and generally weak. (R1-R2), moderately weathered. Some clasts mod. hard quartz monzonite w/ limonite / hematite staining. Polylithic clasts

LOCATION OF TEST PIT
DATE AUG. 21, 1993

PROJECT No. 1831
GROUND ELEVATION
LOGGED BY MDG

NOTES Groundwater level, difficulty in digging, equipment used, etc.	DEPTH (m)	GRAPHIC LOG	DESCRIPTION AND CLASSIFICATION OF MATERIAL
Cat D7 dozer.	0		Vegetation: Sparse (10-15 m spacing) thick, tall spruce trees with abundant thick willows and thick moss w/ grass. Apparent solifluction lobes in moss (from freeze-thaw cycle soil creep). Abundant large talus boulders of v. hard, fresh, crs. grained granodiorite up to 2m dia. (Boulders likely transported down-slope from solifluction). Slope poorly drained.
	0.3		0-0.3m ORGANIC-RICH TOPSOIL (VEGETATIVE MAT) Organic-rich topsoil comprising talus boulders, thick moss roots and some black, dry silt.
Fairly easy excavation in well graded stoney colluvium. Trench is dry, non-frozen. walls stable in moist colluvium & residual materials.	1		0.3-1.4m WELL GRADED, BROWN, DENSE COLLUVIUM Brown, dense, silty sand with some fine-med. gravel, trace clay matrix (approx 60%) supporting cobble to small boulder size fresh, v. hard crs. grained granodiorite clasts (approx. 40%). Cobble & boulder clasts are sub-rounded and range from 3-20 cm dia. Matrix is moist (approx. at optimum moisture content). Est. v. low plasticity, low in-situ permeability. Mat'l is well graded, v. poorly sorted, massive colluvium (transported down-slope).
Easy excavation in residual material.	1.4	HW	1.4-1.8m RESIDUAL SAND w/ SILT and GRAVEL Orange, med. dense, moist residual sand with silt and gravel. Material grades down from silty sand to HW, weak (oxidized) fine blocky badly broken granodiorite rock — weathering profile.
Refusal a. 1.8 m (Likely easily rippable).	1.8	SW-FR Blocky, Broken.	1.8m HARD, BROKEN SW-FR GRANODIORITE Broken, v. hard, SW-FR crs. grained, med. blocky granodiorite bedrock.

Hitachi backhoe UH09LC. Easy digging in colluvium (boney) and uniform residual sandy materials. Test Pit is dry, non-frozen. walls are stable.	0		Vegetation Abundant, thin (3" dia.) aspen and poplar, rare spruce. No permafrost. Soil is well drained. Vegetative mat is thin (10cm) and comprises moss / lichen and tree roots. 0-1.0m COLLUVIUM (TALUS) & RESIDUAL SAND Light orangish brown mixture of FR-SW granodiorite rock frags. and residual fine gravelly sand with some silt. (Estimate 70% rock, 30% matrix). Rock frags. are hard to v.hard, angular and range from 5-30 cm dia. Mat'l is clast and matrix supported. → Colluvium derived from erosion of hill and transport of talus blocks downslope w/ residual (reworked) gravelly sand matrix.
	1		1.0-1.3m RESIDUAL SILTY SAND Light orange-brown, loose to med. dense, dry silty residual sand with some very fine gravel.
Moderately difficult digging in SW-MW Granodiorite Bedrock at ~ 1.5m. (estimate easily rippable).	1.3	HW, weak, badly broken Granodiorite Bedrock	1.3-1.7m HW, WEAK, FRIABLE BEDROCK Heavily weathered and weak, friable, badly broken granodiorite bedrock. Heavily iron oxidized (limonite / hematite) throughout.
	1.7	SW-MW, mod. hard	1.7m SW-MW, BROKEN GRANODIORITE BEDROCK Slight to moderately weathered, mod. hard, badly broken granodiorite bedrock.

NOTES Groundwater level, difficulty in digging, equipment used, etc.	DEPTH (m)	GRAPHIC LOG	DESCRIPTION AND CLASSIFICATION OF MATERIAL
Hitachi backhoe UH09LC Very easy digging in EW, residual soils. Existing (old) trench - non-frozen.	0 1 2 3 4	Bottom	0-0.5m F.GR. COLLUVIUM / ALLUVIUM (same material as S. End of Trench). 0.5-2.0m EW, RESIDUAL SANDY SILT Yellow - lt. orange, extremely weathered, loose residual soil comprising sandy SILT with some clay and fine gravel. 2.0-3.5m EW GRANODIORITE - QUARTZ FRAGS. & CLAYEY MATRIX. Yellow - lt. orange, extremely weathered, friable, badly broken, crumbly, heavily altered Granodiorite bedrock. White angular rock frags. comprise competent quartz frags in white clayey matrix (Est. 50% frags : 50% matrix). Mat'l is very badly broken. Granular clay (gouge-like) zones abundant along trench wall. Clay is med. - highly plastic (sticky), v. soft and wet. Residual soils are loose to medium dense, v. moist to wet (high saturation). Estimate low permeability. WEATHERING: Minor shear / broken zones have apparently induced preferential weathering to white clays. The alteration of feldspars to clay in the granodiorite has likely induced accelerated weathering along weak zones.

Sample 9053-A1 from spoil pile adjacent to trench.

Mr. Frank Gish
Archer Cathro and Associates
P.O. Box 4127
Whitehorse, Yukon
Y1A 3S9

Dear Frank,

Enclosed are the listings of temperatures for the four holes that we measured for heat flow at Casino in July. Also included are plots of temperature vs. depth for each hole. Thermal gradients for the two deepest holes, 168 and 162 (703-2 and 703-4) are quite consistent at 20 and 23°C/km respectively. The gradients for the two shallow holes are less reliable, especially hole 124 (703-1). There is also a list of the core samples which we took for our thermal conductivity measurements.

Finally, there is a list of all the holes that we attempted to log, including those not used for heat flow, the depths at which they were blocked, the temperatures measured at the bottom, and approximate water depths. Collar elevations ranged from 1150 to 1375 m asl. The depth from surface to the water table varied considerably, from 3 to 170 m, and permafrost was present at depths from 3 to 72 m. Therefore ice plugged the tops of many holes we attempted to log, but we successfully logged five holes where the water table was below the lower boundary of permafrost. Blockages could be due to ice or caving rock, but we are assuming that the blockages at temperatures less than 0°C to be ice.

The presence or absence of ice-bonded rock may have an effect on the methods of mining and/or milling this deposit. Drilling or mining operations penetrating the boundary of ice-bonded rock into warmer areas may produce large amounts of ground water. The amounts of explosives needed to break up the rock may vary, depending on the amount of bonding by ice, so knowing the position of the water table will be important.

I would like to take this opportunity to thank you for your generous hospitality. We are very grateful for your assistance in choosing the holes to log, and for the use of a vehilcle for our work. We look forward to future cooperation.

Sincerely,

Wanda Bentkowski

Wanda Bentkowski

Attempted Holes
(temperature and water depth information)

Hole #	Depth(m)	Permafrost?	Temp.(°C)	Water Depth (m)
124	108.4	n		< 10
154	30.3	y ice on cable	-.452	30.3
165	8	y	-.076	8
168	570.2	n		150.4
152	3	y?	.001	3?
