SUMMARY AND RECOMMENDATIONS

The Mucho property is owned 100% by Cash Resources Ltd. and consists of 36 mineral claims (728 hectares) located 135 km east of Ross River in east-central Yukon Territory. There is all-season road access to Finlayson Lake which lies 60 km southwest of the claims while helicopter support is available from a permanent base in Ross River.

The property lies in the southwestern Selwyn Basin. It covers an extensive metamorphic halo developed in tightly folded Upper Proterozoic to Lower Ordovician stratigraphy peripheral to a Cretaceous granitic plug.

Topography in the area is strongly influenced by glaciation and most of the property is underlain by rugged cirques, till covered plateaus or talus slopes. Soil development is immature.

Exploration in 1994 consisted of grid soil geochemistry, geological mapping and prospecting in the core of the property. Soil sampling outlined a strongly coincident east-west trending silver-lead-zinc anomaly that is 1900 m long and up to 500 m wide. The anomaly is still open in most directions and is cored by areas of high copper and gold values. Numerous mineral occurrences are located within and adjacent to the area of anomalous soil response. Pyrrhotite, galena, sphalerite, chalcopyrite and arsenopyrite occur in varying quantities within massive sulphide lenses, shears and veins and as disseminations and fracture fillings in skarns. Mineralization is found in all lithological units. Thirty-seven float specimens and chip samples collected from skarn, shear and massive sulphide occurrences within a 1500 by 500 m area in the western and central part of the soil grid yielded an arithmetic average of 83 g/t silver, 1.54% zinc, 1.13%

lead, 0.14% copper, and 0.24 g/t gold. Twelve vein specimens taken from a 400 by 300 m area toward the east end of the grid averaged 786 g/t silver, 4.63% lead, 3.71% zinc, 0.10% copper and 0.08 g/t gold.

Preliminary modelling suggests potential for a multi-element bulk-tonnage deposit that would be suitable for open pit mining or higher grade underground targets similar to those found elsewhere in the southern Yukon such as the former mines at Ketza River (gold-bearing manto) and Sa Dena Hes (zinc-lead-silver skarn). The Ketza River Mine contained a pre-production reserve of 250,000 tonnes of oxide ore grading 12.5 g/t gold and 390,000 tonnes of sulphide ore grading 8.6 g/t gold. Over three million grams of gold were produced between 1988 and 1990. Proven and probable reserves at Sa Dena Hes when production commenced in July 1991 were reported as 3.9 million tonnes grading 12.7% zinc, 3.9% lead and 48 g/t silver (Curragh, 1990).

Exploration at Mucho in 1995 should consist of 1300 m of large diameter diamond drilling in five to seven holes testing mineralization along the trend of the main soil geochemical anomaly. The drilling should be done in conjunction with additional grid and contour soil sampling, geological mapping and prospecting over the remainder of the property. The program is estimated to cost approximately $450,000, as shown in the proposed budget on the following page.

Respectfully submitted,

B. Wengzynowski.

W. Wengzynowski, B.A.Sc.

PROPOSED 1995 BUDGET
MUCHO PROPERTY

Diamond Drilling - 1300 m @ $120/m	$156,000
Helicopter - Bell 206B 150 hrs @ $700/hr, fuel included	105,000
Labour - geologist, geological assistant, one fieldman and a cook for 60 days, plus final report and head office supervision	77,000
Field Costs - 450 mandays @ $90/day	40,500
Analytical Costs - 200 soils and 500 rock samples geochemically analyzed by ICP plus assays as needed	10,000
Transportation and Shipping	7,000
Communication, Drafting and Printing	2,000
Assessment Filing	1,000
Management	19,000
Sub-Total	$417,500
GST	29,225
Total	$446,725

INTRODUCTION

The Mucho property is owned 100% by Cash Resources Ltd. It was acquired to cover a previously reported, lead-zinc soil geochemical anomaly and related silver-rich float occurrences that were identified during a review of prospective silver targets, conducted by Archer, Cathro & Associates (1981) Limited on behalf of Cash Resources in spring 1994. The first eight claims were staked on June 7, 1994 while the remaining twenty-eight were staked on August 30.

The 1994 exploration program was funded by Cash Resources and consisted of grid soil geochemical sampling, geological mapping and prospecting. The work was done by two-man crews operating from tent camps on the property during the periods July 3 to 10 and August 15 to 19, 1994.

Appendix I includes the Author's Statement of Qualifications while field personnel are listed in Appendix II.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The property is located 135 km east of Ross River in east-central Yukon Territory at latitude 62°01'N and longitude 129°52'W on NTS map sheet 105I/4 (Figure 1). It consists of 36 contiguous mineral claims (Figure 2) registered with the Watson Lake Mining Recorder in the name of Archer, Cathro & Associates (1981) Limited which holds them in trust for Cash Resources Ltd. Data concerning claim registration is listed below.

Claim Name	Grant Number	Expiry Date*
Mucho 1-8	YB49303-YB49310	June 9, 1995
9-36	YB55951-YB55978	September 6, 1995

*The expiry dates do not include assessment credits for work done in 1994.

Access from Whitehorse to the Mucho area is provided by 180 km of paved highway (Klondike Highway) to Carmacks followed by 320 km of all-weather chip seal/gravel road (Robert Campbell Highway) to Finlayson Lake which is located 60 km southwest of the property (Figure 3). In 1994 air support was provided by Trans North Air Bell 206B helicopters operating from a permanent base at Ross River or a Cominco Ltd. exploration camp on Finlayson Lake. The closest lake suitable for float-equipped aircraft is Ptarmigan Lake which is located 3 km due west of the property and 57 km northeast of Finlayson Lake. In 1967 Atlas Exploration Limited constructed a 56 km winter road from the west end of Finlayson Lake to Pelly Lakes, 20 km west of the property. The road has not been used for many years and its present condition is unknown.

HISTORY AND PREVIOUS WORK

The area of interest was first staked as the Nar claims in September 1966 by Atlas Exploration to cover one of many silver-lead-zinc-copper showings discovered during a regional prospecting program. In summer 1967 a joint venture between Atlas Exploration and Mitsui Mining & Smelting Co. Ltd. conducted geological and geochemical surveys over parts of the claim block. This program outlined a 500 by 350 m coincident lead-zinc soil geochemical anomaly plus several mineralized float occurrences, specimens from which reportedly assayed as high as 4045 g/t silver, 9.5% lead and 14.2% zinc (Brock, 1967a and b). The property was transferred, optioned and restaked several times during the 1970's but, aside from a few prospecting traverses, no additional exploration was done.

Silverquest Resources Ltd. (later renamed Cash Resources Ltd.) staked the Max 1-4 claims over what is now the western part of the property in 1988 but allowed the claims to lapse the following year without exploring them.

GEOMORPHOLOGY

The claims are centred on Nar Mountain which lies along the southwest margin of the Logan Mountains, some 100 km northeast of the Tintina Trench. Creeks flowing north, south and west off the property are tributaries of the Woodside River which is part of the Yukon River watershed while a creek draining the east side of the property flows into the Yusezyu River which is part of the Mackenzie River watershed.

Geomorphology in the area is strongly influenced by Pleistocene to recent, valley and alpine glaciation which has cut broad U-shaped valleys flanked by hanging valleys ending in cirques. Glaciofluvial till blankets the floors of the larger valleys while lateral and terminal moraines plus large landslides are common features in the upland valleys. Local elevations range from 1050 m on the shores of Ptarmigan Lake to 2000 m at the peak of Nar Mountain.

Treeline in the area is about 1300 m with willow, alder and spruce on the lower slopes, gradually giving way to buckbrush and stunted spruce and finally grass and lichen above 1500 m. Bedrock is rare on south-facing slopes, except where deep incisions have been made by drainages, but is common along ridge crests and in north-facing cirques.

Soil development on south-facing slopes typically consists of a few centimetres of humus covering 30 to 100 cm of mixed B and C horizon material. Talus slopes and immature soils predominate on north-facing slopes. The upper limit of glacial material coincides with a prominent bench at about 1740 m on the south slope of Nar Mountain. Depth of till cover on the bench is unknown; however, a small hand pit dug at the base of slope bottomed in till at a depth of 0.75 m.

GEOLOGY

The Mucho area has been mapped at 1:250,000 scale by the Geological Survey of Canada (Gordey and Anderson, 1993). The claims lie within the Selwyn Basin geological terrane about 10 km north of a major thrust fault that forms the boundary between Selwyn Basin and allochthonous rocks of the Cassiar Platform. Stratigraphy in the vicinity of the property is deformed by tight upright folds that are the same age as the thrust fault and exhibit west-northwest trending axes. Post deformation high angle normal faults are developed both parallel and perpendicular to axial trends.

Figure 4 illustrates mapping in the core of the property by Cash Resources' geologists in 1994 plus GSC mapping for the remainder of the claim block. Local stratigraphy consists of clastic and carbonate sedimentary rocks, some of which exhibit intense hydrothermal alteration associated with a Mid-Cretaceous granitic plug (Nar Pluton). Four primary lithological units have been identified on the property and are described as follows from oldest to youngest.

Yusezyu Formation (PY) consists of Upper Proterozoic medium to thick bedded, grey-blue limestone with thin interbeds of black and maroon, weakly ferruginous chert and mudstone. This unit forms a fault-bound wedge in the southwest corner of the property.

Gull Lake Formation (ϵ_G) is predominantly Lower and Middle Cambrian orange-brown weathering, moderately recessive shale and siltstone with minor interbedded arkose. In the lower part of the section tan to grey weathering calcareous siltstone is also present. Gull Lake stratigraphy is exposed in the core of anticlines in the centre and northeast corner of the property. Rocks belonging to this unit in the centre of the property are often strongly skarnified and gossanous.

Rabbitkettle Formation is comprised of Upper Cambrian and Lower Ordovician tan to grey-blue, wavy banded limestone (ϵO_{R2}) in the eastern and southwestern parts of the property. This unit also includes resistant, white to buff weathering, moderately to strongly silicified and skarnified rocks (ϵO_{R2A}) in the north-central part of the property. These rocks are believed to be thermally metamorphosed equivalents of the limestone but are separated from it by a north-trending high angle fault.

Selwyn Plutonic Suite (K_{S2}) rocks are limited to the Nar Pluton, a 20,000 sq m orbicular body located along a ridge crest in the northwest part of the property. This undeformed plug ranges in composition from a biotite granite to granodiorite. It intrudes both the Rabbitkettle and Gull Lake Formations and is believed to be responsible for the thermal metamorphism. The limit of the metamorphic aureole has not yet been defined. Nearby intrusions with similar mineralogy have been dated between 80 and 96 mya (Gordey and Anderson, 1993).

Fold deformation is constrained to the period between Mid-Jurassic and Mid-Cretaceous (Gordey and Anderson, 1993). Local folds are tight with limbs dipping as steeply as 78°.

There are two main fault sets, one subparallel to fold axes and the other oblique. Small scale structures include joints and extensional fractures, many of which are mineralized. Joints are typically tri-planar and orthogonal with respect to bedding. Fractures cut stratigraphy and exhibit strikes varying from 150 to 170° and dips from 70E to 80W.

MINERALIZATION

In 1994, a total of 66 rock samples were collected during prospecting traverses most of which were conducted over the core of the property. All samples were sent to Chemex Labs Ltd. located in North Vancouver, B.C. where they were crushed and ring pulverized then routinely analyzed for 32 elements using the induced coupled plasma technique (ICP) and gold by fire assay followed by neutron activation. Samples that exceeded geochemical detection limits were later assayed for gold, silver, lead, zinc and/or copper, as required. Selective pulps were also analyzed geochemically for tungsten, tin, tantalum and niobium. Appendix III contains the Certificates of Analysis while Figure 5 shows sample locations.

Mineralization has been discovered throughout the property and in all of the major units. It is most abundant within the Gull Lake Formation in the western and central parts of the claim block where it occurs as ubiquitous veinlets and as disseminations, massive sulphide lenses and shears in and adjacent to skarn zones. Mineralized shears and veins have been recognized in the Yusezyu and Rabbitkettle Formations while disseminated and fracture mineralization have been discovered in intrusive float. The various types of mineralization are described with respect to their lithological hosts as follows.

Gull Lake Formation

Mineralized fractures are found in all rock types comprising this formation and range from hairline to 1 cm in width. Outcrop exposures are rare but, where observed, the veinlets appear to be developed most favourably along the orthogonal joint set at a density of about $50/m^3$. This

type of mineralization has not been systematically sampled as most float specimens and bedrock exposures are strongly oxidized. Sulphide minerals, in decreasing order of abundance, are pyrrhotite, galena, sphalerite, chalcopyrite and pyrite. The fractures do not exhibit alteration envelopes and do not usually contain gangue minerals.

Skarn zones are found throughout the Gull Lake Formation. They are typically rusty weathering, pale to dark green on fresh surfaces and conformable with bedding. The two most common matrix mineral assemblages are chlorite-epidote and diopside. Sulphide minerals include pyrrhotite with varying amounts of sphalerite, galena and chalcopyrite, all occurring as fine-grained disseminations, blebs and fracture fillings. Mineralized skarn float is found within a 1200 by 500 m area in the central and western parts of the property. Specimens returned up to 380 g/t silver, 3.96% lead, 7.61% zinc and 0.30% copper. Gold values are only weakly anomalous (up to 42 ppb).

Semi-massive to massive pyrrhotite has been identified in several gossanous outcrops within a 500 by 300 m area along the contact between the Gull Lake and Yusezyu Formations. It typically consists of spheroidal-weathering boulders, up to 30 cm in diameter, surrounded by strongly fractured, in situ limonite matrix. Although the orientation of the outcrops appears to be conformable with bedding, this is difficult to confirm due to deep weathering and possible slumping in the area. The massive pyrrhotite boulders were not systematically sampled however specimens returned generally low values for all metals except iron. Randomly oriented fractures up to 10 cm wide are common within the gossanous outcrops. A composite sample from twelve galena-bearing limonitic fractures taken over a 35 sq m area assayed 398 g/t silver and

1.03% lead with weakly anomalous values for copper (193 ppm), zinc (308 ppm) and gold (383 ppb). Transported gossans up to 20 cm thick are developed downhill from some of the massive sulphide mineralization.

Mineralized shear zones are found in skarns adjacent to the massive sulphide-bearing gossans and less frequently within the gossans themselves. These structures dip steeply to the northeast and strike 160°.

Shears within the gossans contain massive sulphide lenses comprised of pyrrhotite plus 5 to 20% galena, 1 to 5% black-jack sphalerite and trace to 2% chalcopyrite. A chip sample across the largest of the pyrrhotite lenses (20 by 0.35 m) returned 353 g/t silver, 0.8 g/t gold and moderately anomalous values for lead (5900 ppm), zinc (1850 ppm) and copper (971 ppm).

All shears discovered to date in the skarns are mineralized with 5 to 15% galena, trace to 20% arsenopyrite, trace to 20% chalcopyrite, 2 to 10% sphalerite and minor pyrrhotite. The mineralization pinches and swells, reaching maximum widths of 0.5 m. Chip samples from four shears located 60 m apart yielded assays up to 312 g/t silver, 5.39% lead, 2.58% zinc, 3.46% copper and 7 g/t gold over widths varying from 0.1 to 0.5 m.

Yusezyu Formation

Mineralized shears within this unit resemble those in the Gull Lake Formation. They dip steeply to the northeast and strike 160°. Most contain narrow, lensy massive pyrrhotite bodies ranging from 5 to 10 cm in width and 5 to 10 m in length. The largest shear is marked by a 3 m wide, 100 m long gully containing abundant massive pyrrhotite float with lesser galena and sphalerite. There are only a few outcrops in the gully and most are strongly oxidized. However,

one massive sulphide exposure was located and a 0.4 m chip sample across it assayed 195 g/t silver, 5.39% lead, 2.58% zinc with lower values for copper (600 ppm) and gold (37 ppb).

Rabbitkettle Formation

Mineralized veins occur within the limestone on a north-facing cliff in the eastern part of the property. Three vein types are observed: 1) strongly manganiferous carbonate with a semi-massive sphalerite core and disseminated sphalerite, galena and arsenopyrite toward the margin; 2) massive fine-grained galena with manganiferous limonite selvages; and, 3) brecciated manganiferous carbonate with varying amounts of malachite, azurite, galena, sphalerite and chalcopyrite. The veins dip steeply to the east or west and strike between 150 and 170°. They range from 5 to 100 cm in width but have only been traced along strike for 2 to 10 m because outcrops are rare and prospecting is difficult on the steep slopes. Eight samples from veins across a 400 m section of the cliff returned an arithmetic average grade of 1140 g/t silver, 5.90% lead, 5.28% zinc, 0.14% copper and 0.01 g/t gold. The highest grade specimen assayed 5451 g/t silver, 1.78 lead, 15.20% zinc, 0.74% copper and 0.57 g/t gold.

Nar Pluton

This unit has received only cursory prospecting. A specimen of rusty weathering intrusive float collected from the west end of the property in 1994 assayed 72 g/t silver, 2.66% lead, >1% zinc and low values for copper (140 ppm) and gold (<0.03 g/t).

Although most types of mineralization on the property contain low quantities of tungsten, tin, tantalum and niobium, occasional high values have been obtained from some shears and veins. Analyses range up to 0.24% tungsten, 0.25% tin, 12 ppm tantalum and 32 ppm niobium.

SOIL GEOCHEMISTRY

A total of 214 soil samples were collected from a 1900 by 500 m grid near the centre of the property while two soil and eight stream sediment samples were taken during peripheral prospecting traverses. Grid control was provided by a baseline that followed a pre-existing claim line. The baseline is marked at 50 m intervals with 1 m wooden lath bearing aluminum tags inscribed with the grid coordinates. Soil samples were collected at 50 m intervals along compass- and topofil-controlled lines aligned perpendicular to the baseline and spaced approximately 100 m apart. All sample locations in the eastern portion of the grid are indicated with 50 cm wooden lath bearing aluminium tags inscribed with the sample number and grid coordinate. The initial sampling in the western part of the grid was completed at 100 m intervals with sites marked as described above while infill sample locations are marked with orange flagging. All samples were sent to Chemex Labs Ltd. where they were screened to -80 mesh and then geochemically analyzed for 32 elements using the induced coupled plasma technique (ICP) and gold by fire assay with a neutron activation finish. Appendix III contains the Certificates of Analysis while Figure 5 shows sample locations.

Figures 6 to 10 illustrate results for silver, lead, zinc, copper and gold, respectively, while Table 1 below lists threshold values and peak values for each metal.

TABLE 1
SELECTED GEOCHEMICAL DATA

Metal	Threshold Weak	Moderate	Strong	Peak Value
Silver	2 ppm	5 ppm	10 ppm	107 ppm
Lead	200 ppm	500 ppm	1000 ppm	>10,000 ppm
Zinc	500 ppm	1000 ppm	2000 ppm	4,300 ppm
Copper	100 ppm	200 ppm	500 ppm	849 ppm
Gold	25 ppb	50 ppb	100 ppb	292 ppb

Silver, lead and zinc show a high degree of correlation with the majority of the moderately to strongly anomalous values occurring in an east-west trending band that is up to 500 m wide and extends the length of grid. The anomaly is open in all directions in the western part of the grid and along strike to the east where it has narrowed to about 200 m wide. Some of the apparent weakening and discontinuity toward the eastern end of the grid may be caused by glacial till cover. Antimony results have not been plotted but are closely associated with silver.

Copper results are highest in the western part of the grid and are only weakly correlated with lead, zinc and silver. Moderately anomalous values are clustered in a 700 by 300 m area within which there are several strongly anomalous spot highs.

Gold geochemistry has outlined a 900 m long east-west trending zone of moderately anomalous values containing a 300 by 200 m strongly anomalous core. The high gold values lie along the north side of the grid and are outside the main anomalous trend. The only metals that gold is strongly correlated with are arsenic and bismuth.

As expected, stream sediment samples collected from a creek draining the west end of the soil grid yielded anomalous values for most metals. Moderately to strongly anomalous results for silver (4.8 ppm), gold (40 ppb), zinc (512 ppm), lead (258 ppm) and copper (50 ppm) were also obtained from stream sediment samples taken from drainages in the northern part of the property which has not yet been grid sampled. Stream sediment samples from all other creeks returned near background values for all metals.

DISCUSSION AND CONCLUSIONS

Preliminary exploration on the Mucho claims has outlined a large zone of coincident silver-lead-zinc geochemical response plus smaller clusters of strongly anomalous gold and copper values. The anomalies extend to the grid boundaries in most areas and this, coupled with stream sediment sampling of peripheral drainages, suggests that favourable targets exist elsewhere on the property.

Mineralization has been discovered in all units on the property but the preferred host appears to be the Gull Lake Formation. High silver, lead, zinc, copper and gold assays are commonly associated with disseminated and fracture filling mineralization in skarn zones but have also been obtained from shears and massive sulphide lenses within and adjacent to the skarns. Prospecting and sampling in the area is frustrated by deep oxidation and poor exposure; however, 37 specimens and chip samples collected from a 1500 by 500 m area returned an arithmetic average grade of 83 g/t silver, 1.54% zinc, 1.13% lead, 0.14% copper and 0.24 g/t gold. Veins within unaltered Rabbitkettle Formation limestone along the northeast edge of the geochemical grid also produced high assays. Twelve specimens collected across a 400 m section averaged 786 g/t silver, 4.63% lead, 3.71% zinc, 0.10% copper and 0.08 g/t gold.

Although a specific model has not yet been established for the mineralization, results obtained to date indicate there is the potential for a bulk-tonnage, polymetallic deposit that could be mined by open pit methods or smaller, higher grade deposits suitable for underground mining. Similar lithologies of the same age elsewhere in southern Yukon host significant gold-bearing

mantos (Ketza River Mine) and zinc-lead-silver skarns (Sa Dena Hes Mine). The Ketza River deposit is located 135 km southwest of Mucho and contained a pre-production reserve of 390,000 tonnes of sulphide ore grading 8.6 g/t gold and 250,000 tonnes of oxide ore grading 12.5 g/t gold (Canamax, 1985). Over three million grams of gold were produced between 1988 and 1990. The Sa Dena Hes deposit lies 180 km south-southeast of Mucho and reportedly contained pre-production reserves of 3.9 million tonnes grading 12.7% zinc, 3.9% lead and 48 g/t silver (Curragh, 1990). The mine opened in July 1991 and processed 527,000 tonnes of ore before it ceased operation in December 1992 when its owner Curragh Resources entered receivership. The property was purchased by Cominco and Teck Corp. in 1994 but no decision has been announced concerning reopening.

LEGEND

CRETACEOUS

- Ks2 — Selwyn Plutonic Suite: (Nar Pluton) Biotite granite and granodiorite

UPPER CAMBRIAN AND LOWER ORDOVICIAN

- EOR2 — Rabbitkettle Formation: tan to grey-blue, wavy banded limestone and skarnified equivalents
- EOR2A — Rabbitkettle Formation: microcrystalline volcanic tuff with minor thinly interbanded, rusty weathering maroon mudstone

LOWER AND MIDDLE(?) CAMBRIAN

- EG — Gull Lake Formation: orange-brown weathering, moderately to non-calcareous, thin to thick bedded, white to grey-blue quartzite; moderately recessive shale and siltstone; local basal member of limestone conglomerate and limestone

UPPER PROTEROZOIC

- PY — Yusezyu Formation: medium to thick bedded, grey-blue limestone with thin interbeds of black and maroon weakly ferruginous chert and mudstone

- SOIL SAMPLE
- ROCK SAMPLE
- SILT SAMPLE
- OUTCROP
- GEOLOGIC CONTACT, KNOWN AND INFERRED
- FAULT TRACE, INFERRED
- MINERALIZED SHEAR
- MINERALIZED VEIN
- BEDDING ORIENTATION
