INTRODUCTION

Expatriate Resources Ltd. has a 100% interest in the Goal Net property which protects volcanogenic massive sulphide (VMS) targets selected from old assessment reports and a regional geochemical data base documenting results of 1973 exploration by a joint venture managed by Archer, Cathro & Associates (1981) Limited. A total of 1043 claims was staked between summer 1994 and fall 1996. Expatriate conducted geological mapping, prospecting and soil sampling in three parts of the property (Goal, Net 1 and Net 2 Grids) in summer 1995.

The 1996 exploration program began in spring with airborne magnetic and electromagnetic surveys over the entire property and ground magnetic and Maxmin surveys on the Net 1 grid. Work continued throughout summer with crews working from Expatriate's base camp on Finlayson Lake and from fly camps located on various parts of the property. The summer work consisted of reconnaissance and grid soil geochemistry, geological mapping, prospecting and claim surveys. The program was managed by Archer Cathro and participated in by the author. Appendix I contains the Author's Statement of Qualifications.

The main body of this report describes geological, geochemical and claim surveys. Airborne magnetic and electromagnetic survey results were reported together with results from other properties in "Report on an Electromagnetic and Magnetic Survey" by Aerodat Inc. dated June 13, 1996, copies of which have been filed as a separate document. Ground magnetic and Maxmin survey results are reported in "Field Report - Net Maxmin/mag Survey" by M.A. Power dated April 19, 1996 which is included in Appendix II.

PROPERTY, LOCATION AND ACCESS

The property is located in southeastern Yukon at latitude 61°20'N and longitude 131°32'W on NTS map sheets 105G/7 and 105G/8 (Figure 1). It is comprised of 1043 contiguous mineral claims (Figures 2 to 5) registered with the Watson Lake Mining Recorder in the name of Archer, Cathro & Associates (1981) Limited which holds them in trust for Expatriate Resources Ltd. Claim registration data is listed below.

*Expiry dates include 1996 work filed for assessment credit but not yet accepted.

In 1996 access was by helicopter from Expatriate's base camp on Finlayson Lake (Km 232 on the Robert Campbell Highway). The property lies 25 km south of the base camp and 230 km northeast of Whitehorse. Helicopter support was provided by a Bell 206B Jet Ranger and an Aerospatiale 350B contracted from Kluane Helicopters of Haines Junction, Yukon. The helicopters were stationed at Expatriate's base camp for the summer.

During the 1996 exploration program most claim post locations were surveyed using Trimble Geoexplorer GPS units. Field readings were corrected using base station data from Westmin Resources Limited's camp at Wolverine Lake. GPS survey data appears in Appendix III.

GEOMORPHOLOGY

The property covers an extensive area of rugged terrain in the Pelly Mountains about 20 km southwest of Wolverine Lake. Creeks draining the property are tributaries of the North River, Money Creek and Wolverine Creek, all of which eventually flow into the Liard River. Several lakes are located on the property, the largest of which is North Lake.

Elevations range from 1200 m in the North River valley, which bisects the property, to 2100 m atop peaks southeast of North Lake. Valley bottoms are typically broad and flat and are blanketed with Pleistocene deposits of glacial till. Topographic relief everywhere else on the property is steep, typically 20 to 40°, with occasional impassable cliffs. Outcrop is most abundant in creek cuts, along ridge crests and in north-facing cirques.

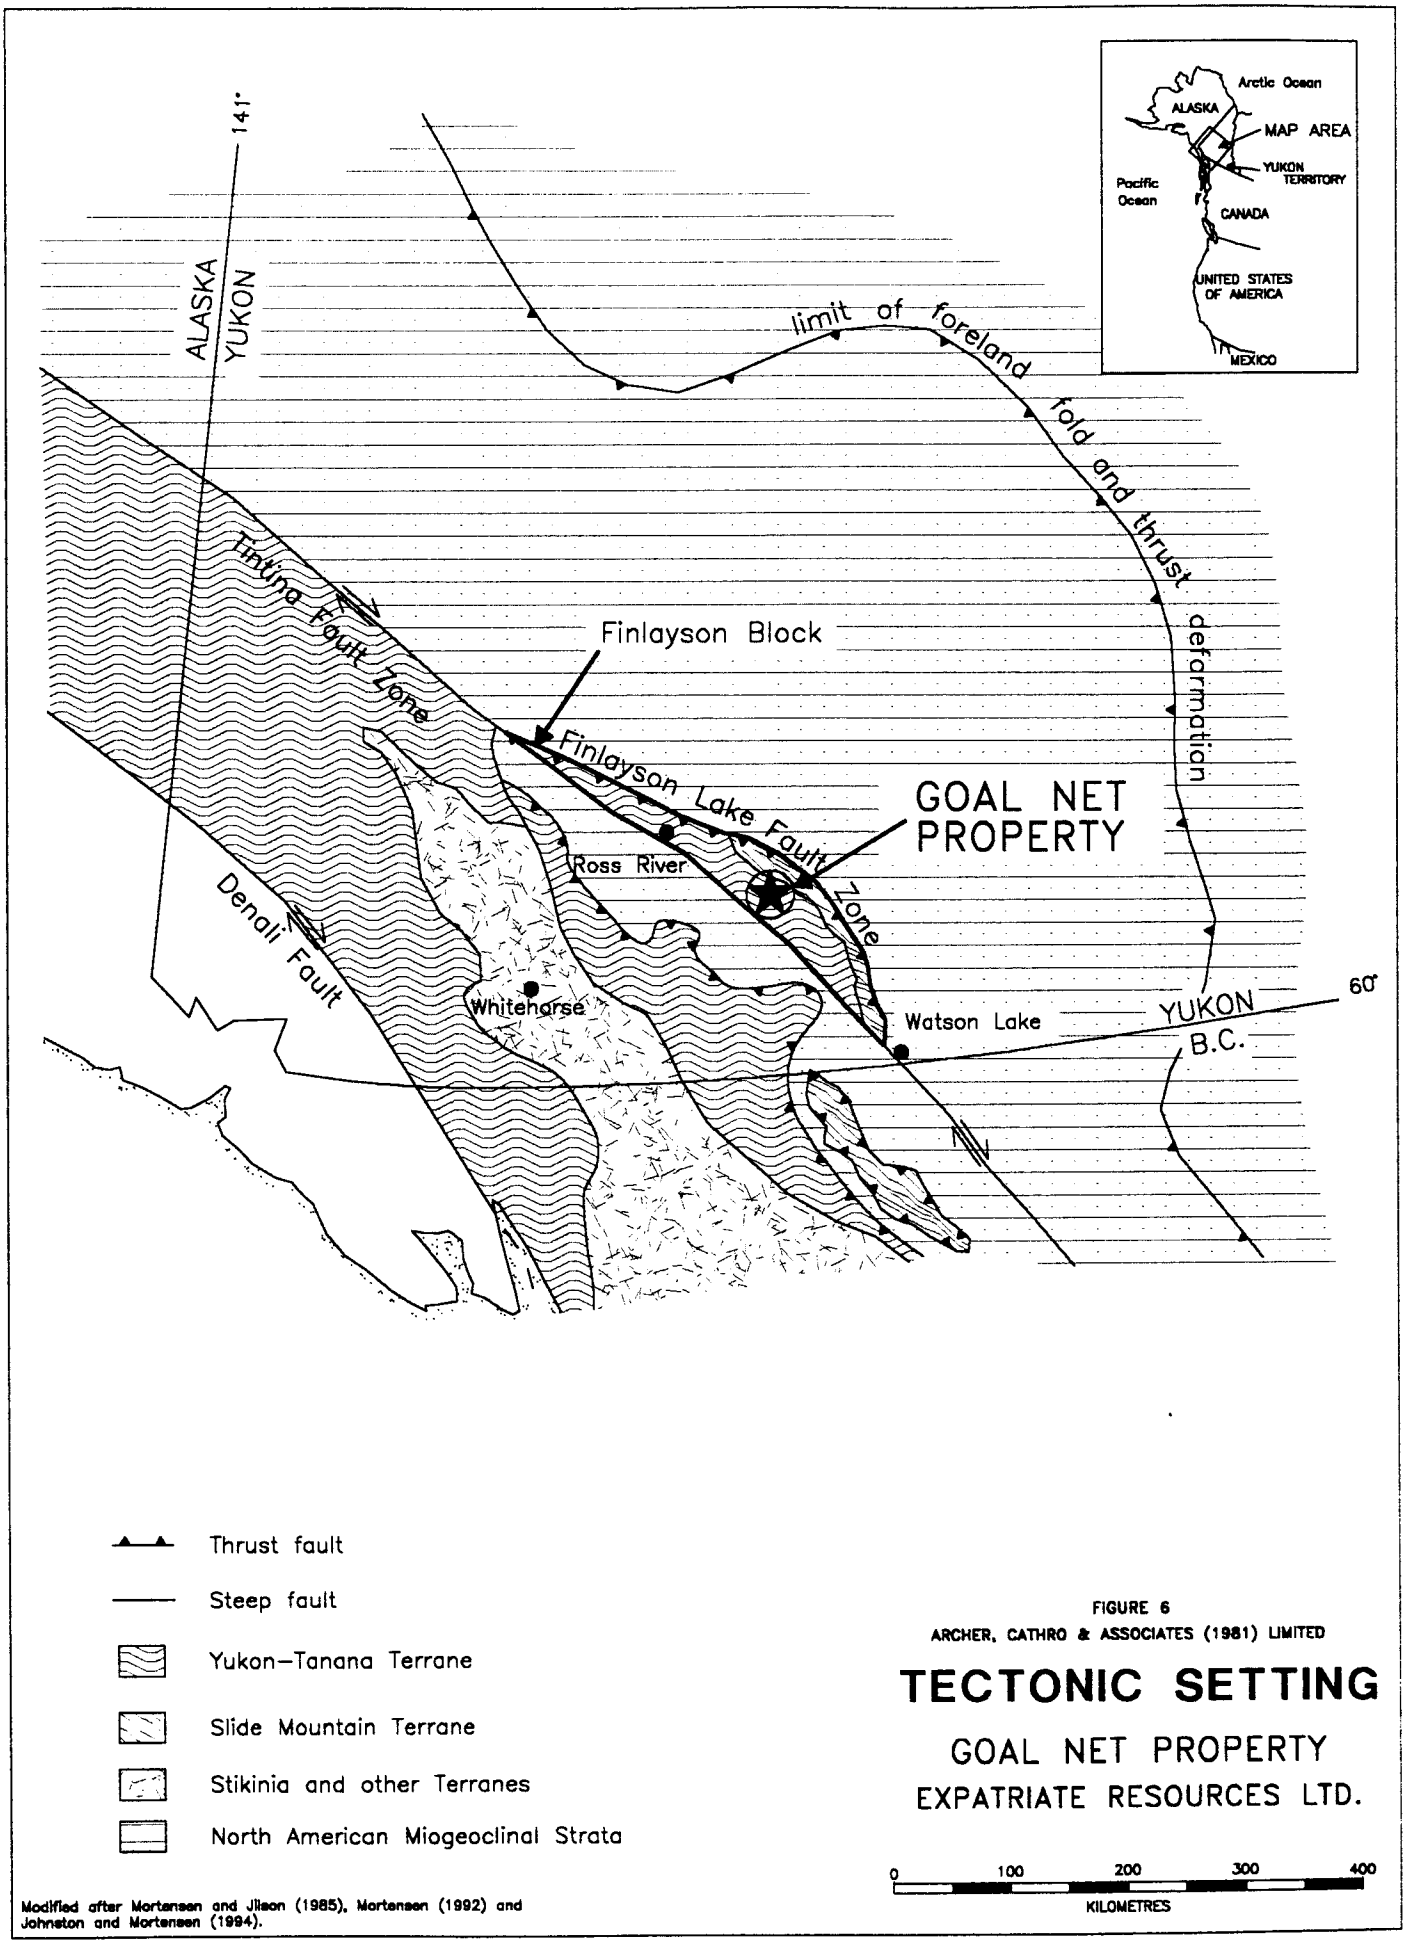
Vegetation consists of dense buckbrush in the valley bottoms which gives way to moderately dense growths of balsam and black spruce on lower slopes, buckbrush, willow and moss above 1550 m and eventually scattered buckbrush, alpine grass and lichen at elevations exceeding 1700 m. Steep talus slopes and cliffs are vegetated only by lichen.

REGIONAL GEOLOGY

The Goal Net property is located within the Finlayson Block, a 380 by 60 km area comprised primarily of the Yukon-Tanana and Slide Mountain geologic terranes (Figure 6). These terranes represent the innermost of the accreted or "suspect" terranes in the Canadian Cordillera (Mortensen and Jilson, 1985). The northeastern margin of the block is the Finlayson Lake Fault Zone, a complex zone of steep and shallow faults related to transpressive suturing. The southwestern boundary of the block is the Tintina Fault, a major strike-slip fault with at least 450 km of dextral displacement during Late Cretaceous and/or Early Tertiary time (Tempelman-Kluit et al, 1976).

Regional mapping of the Finlayson Lake area was completed by the Geological Survey of Canada (GSC) in the mid to late 1970's (Tempelman-Kluit, 1977, 1979). More recent regional studies have been published by Mortensen and Jilson (1985) and Mortensen (1992). The following discussion of the regional geology (Figure 7) is based partly on the published work and partly on unpublished mapping completed in 1996 (Tempelman-Kluit, personal communication, 1996).

The Yukon-Tanana Terrane consists largely of Paleozoic continental margin and/or arc stratigraphy deposited on a continental basement of uncertain origin (Mortensen, 1992). The Yukon-Tanana Terrane in the Finlayson Lake area contains three major packages, collectively termed the Layered Metamorphic Sequence. The lowermost unit consists of garnet-mica schist with interbanded marbles, calc-silicates and calcareous schists near the top. The middle unit is a carbonaceous quartzite, schist or phyllite with rare conglomerates and locally extensive felsic and mafic volcanic interbands. Radiometric dating of the felsic metavolcanics in the Finlayson Block has consistently resulted in Late Devonian to Mississippian crystallization ages. Immediately



Modified after Mortensen and Jilson (1985), Mortensen (1992) and Johnston and Mortensen (1994).

Modified after Mortensen and Jilson (1985)

south of Finlayson Lake, large isolated outcrops of marble and quartzite which are poorly dated as Early Pennsylvanian to Early Permian (Tempelman-Kluit, 1979) form the uppermost unit of the Yukon-Tanana Terrane.

This sequence of units is generally correlative with a similar stratigraphic sequence in ancestral North America (Mortensen and Jilson, 1985; Tempelman-Kluit, personal communication, 1996). The lowermost is correlated with the Lower Cambrian Atan Group and the middle carbonaceous assemblage is correlated with the offshelf, Silurian-Devonian Nasina quartzite assemblage. The felsic volcanics are most similar to locally extensive Mississippian siliceous volcanics in the North American stratigraphy. Local calcareous phyllites and massive greenstones near the top of the lower unit are lithologically similar to the Kechika Group and Lower Paleozoic alkalic and potassic greenstones, respectively.

Gneiss and augen gneiss invariably occur low in the Yukon-Tanana succession beneath either the lowermost calcareous unit or the middle carbonaceous unit. Mortensen and Jilson (1985) considered the gneisses to be metamorphosed Mid-Paleozoic plutonic rocks. Conversely Tempelman-Kluit (personal communication, 1996) considers these gneisses to be at least in part recrystallization of earlier stratigraphy. Radiometric dating of the gneisses has consistently resulted in Late Devonian to Mississippian ages (Mortensen, 1992). The gneisses occur in structural culminations with diameters on the order of 10 km and structural relief up to about 1 km.

The Devonian-Mississippian Simpson Suite (Mortensen, 1992) forms thick intervals of hornblende granodiorite and quartz monzonite higher in the Yukon-Tanana stratigraphic sequence. Mortensen and Jilson (1985) interpreted this suite as intrusive. Tempelman-Kluit (1979, 1996) mapped the suite as an allochthonous slice emplaced on top of the structural pile.

Slide Mountain Terrane consists of Late Devonian to Late Triassic disrupted oceanic crust (Mortensen, 1992). Lithologies include massive and sheared greenstone, chert and mafic to ultramafic plutonic rocks occurring as fault-bounded slices along thrust faults and steep faults. These units are most abundant near the northeastern edge of the Finlayson Block but are also found throughout it.

Younger units unconformably overlie units from Slide Mountain, Yukon-Tanana and North American Terranes. Mesozoic clastic rocks are Late Triassic, immature sediments containing cobbles from both Slide Mountain and Yukon-Tanana Terranes. Young volcanic rocks consist of Late Cretaceous to Tertiary felsic volcanic flows and volcaniclastic deposits. They are usually found in close proximity to the Tintina Fault Zone.

Mesozoic intrusive activity in the Finlayson Block includes two suites. The first is comprised of several unmetamorphosed Early Jurassic mafic and intermediate composition plutons. The second suite consists of Late Cretaceous two-mica quartz monzonite and granite (Mortensen and Jilson, 1985).

Structurally Yukon-Tanana schists and gneisses contain a pervasive, flat- to gently-dipping foliation. Close examination of this fabric indicates that it commonly is a closely spaced crenulation cleavage. Large scale folds related to this fabric can rarely be mapped in the field. In most cases bedding and earlier fabrics are transposed into near parallelism with this dominant fabric. Later crenulation cleavages are present only locally. Some of the Cretaceous intrusions have a mild deformation fabric, others are massive and do not contain a foliation.

Thrust faults within the Finlayson Block juxtapose lithologic sequences with similar deformation fabrics. Thrusting postdates the Late Paleozoic Slide Mountain lithologies and predates the Cretaceous intrusives. Recent mapping also suggests, but does not definitively prove, the presence of major late extensional faults juxtaposing differing sequences (Tempelman-Kluit, personal communication, 1996). East-northeast trending, steep normal faults disrupt all earlier deformation fabrics.

Metamorphic grades range from lower greenschist facies to middle amphibolite facies. Contact hornfels around plutonic units occur locally.

Metamorphism and deformation are tentatively correlated with transpressive suturing of these suspect terranes with ancestral North America. Suturing is restricted to the time interval of post-Triassic continuing into the Cretaceous. Whether deformation is continuous or sporadic has not been fully verified at present.

The discovery of the Kudz Ze Kayah and Wolverine VMS deposits within the Finlayson Block in the last few years (Johnston and Mortensen, 1994) has refocussed exploration activities in the area. Both deposits occur within metasedimentary and metavolcanic sequences of the Yukon-Tanana Terrane and are associated with felsic volcanics present in the middle unit of that terrane.

REGIONAL MINERALIZATION

A total of fifty-one mineral occurrences have been reported within the Finlayson Block (DIAND, 1995). Of these, twenty-one are known or suspected to be volcanogenic in origin while veins, skarns and asbestos occurrences comprise most of the remainder. Although the better known volcanogenic occurrences are thought to be of the Kuroko-type, some Besshi-type mineralization is also present (Morin, 1981; Johnston and Mortensen, 1994) and the recently discovered Ice Deposit appears to be Cyprus-type. Two occurrences have definite economic potential, the Kudz Ze Kayah and Wolverine Deposits (Figure 7). These Kuroko-type occurrences are the main "type-deposits" for Expatriate's exploration in the district and are briefly described below.

The Kudz Ze Kayah (ABM) Deposit lies within Yukon-Tanana Terrane near the centre of the block (Cominco Exploration, 1995; Whiteway, 1995). It is a VMS deposit hosted by an overturned assemblage of felsic pyroclastics, aphanitic massive rhyolites and metasiliclastic rocks belonging to the middle unit of the Layered Metamorphic Sequence. Although both the sulphides and wallrocks are highly strained and exhibit pervasive schistosity, compositional layering in the vicinity of the deposit is relatively undeformed with a consistent, shallow northerly dip. Sphalerite, chalcopyrite and galena are the main economic minerals while the gangue includes various mixtures of magnetite, barite, pyrrhotite, pyrite and carbonate. The deposit averages about 18 m thick and has been traced 700 m along strike and up to 400 m downdip. Open pit mineable ore reserves are reported to be 11 million tonnes grading 5.9% zinc, 0.9% copper, 1.5% lead, 130 g/t silver and 1.3 g/t gold (Schultze, 1996). Preliminary studies suggest that satisfactory

lead, zinc and copper concentrates can be produced using conventional flotation processes (Cominco Exploration, 1995). The mineralization responds well to magnetic and electromagnetic surveys but geochemical response is somewhat erratic because the entire deposit is covered by 2 to 10 m of glacial till.

The Wolverine Deposit is located 25 km east of the Kudz Ze Kayah property near a contact between Yukon-Tanana and overlying Slide Mountain rocks. It consists of the Wolverine and Lynx Zones which are hosted by rhyolitic metavolcanics and argillites lying within the middle unit of the Layered Metamorphic Sequence. The mineralization consists primarily of semi-massive to massive pyrite and sphalerite with varying amounts of galena, chalcopyrite, tetrahedrite and native gold. The surface expression of the Wolverine Zone is marked by a vegetation kill zone containing weakly malachite-stained argillite while the Lynx Zone is blanketed by glacial till. Westmin has traced the deposit 700 m along strike and up to 450 m downdip and it is still open. The mineralization averages 6.1 m thick and dips shallowly to the north. Both zones contain significantly more zinc and precious metals than Kudz Ze Kayah. The current geological inventory is reported to be 5,311,000 tonnes grading 12.96% zinc, 1.41% copper, 1.53% lead, 359.1 g/t silver and 1.81 g/t gold (Westmin News Release, November 30, 1996). Soil geochemistry outlined weakly to moderately anomalous values along the projected surface trace of the deposit while magnetic surveys easily traced a laterally extensive, banded iron formation which occurs about 80 m up-section from the massive sulphide horizon. Interpretation of electromagnetic results is complicated by the presence of graphite within the argillite.

REGIONAL GEOCHEMISTRY

Published geochemical data for the Finlayson Lake area are limited to reconnaissance scale stream sediment sampling conducted in the late 1980's by the GSC (Hornbrook and Friske, 1988; Friske et al, 1990). The sampling was done at an approximate density of one sample per 10 sq km Each sample was analyzed for twenty elements including common indicator elements for VMS deposits such as copper, lead, zinc, silver and arsenic. Anomalous results were obtained from creeks draining some previously known VMS occurrences (DIAND, 1995, Yukon Minfile 105G/32, 34 and 40) but many others, including the streams draining the Wolverine Deposit, produced near background values. Anomalous results were also obtained from several drainages where there were no known mineral occurrences. Follow-up exploration has since located showings in many of the anomalous creeks with the most significant discovery to date being the Kudz Ze Kayah Deposit.

Expatriate was able to supplement the published reports with private data summarizing results of 1973 exploration managed by Archer Cathro on behalf of a joint venture (Cathro, 1973). The reconnaissance prospecting and geochemical sampling program explored for lead-zinc mineralization in the lower unit of the Layered Metamorphic Sequence but because the data provides relatively uniform coverage over the entire region, it is also suitable for evaluating areas underlain by the favourable middle unit. The Archer Cathro samples included approximately 5000 soils and stream sediments collected at a density of approximately one sample per sq km. They were all analyzed for lead, zinc, copper and molybdenum. As might be expected, this closer

spaced sampling outlined many more areas of anomalous geochemical response than the government survey. Almost all of the known volcanogenic occurrences showed up as anomalies on this survey, including Kudz Ze Kayah and Wolverine.

The following table illustrates regional geochemical backgrounds for the metals and anomalous thresholds used for target selection.

GEOCHEMICAL BACKGROUNDS AND ANOMALOUS THRESHOLDS

		Anomalous Thresholds (ppm)			Peak
	Background	Weak	Moderate	Strong	Value
Copper	25	50	100	200	1720
Lead	30	50	100	200	>4000
Zinc	80	200	500	1000	>4000
Molybdenum	<1	2	5	10	65

The Goal Net property was staked to protect numerous moderately to strongly anomalous stream sediment and soil geochemistry targets selected from the Archer Cathro data.

Copper, lead and zinc are major metals in most VMS occurrences in the Finlayson Lake area and are obvious indicator elements. Molybdenum is present in anomalous quantities in the banded iron formation overlying the Wolverine Deposit (Meade, personal communication, 1995) and appears to be slightly enriched in the felsic metavolcanic rocks. Based on the geochemical signature in the vicinity of known occurrences its presence can be used to distinguish copper anomalies associated with volcanogenic mineralization from those derived from ultramafic rocks.

REGIONAL GEOPHYSICS

The only published geophysical data for the Finlayson Lake area resulted from airborne magnetic surveys conducted in 1961 by the GSC on behalf of the Department of Mines and Technical Surveys. The surveys were flown with fixed-wing aircraft at a nominal elevation of 300 m above ground level on east-west lines spaced approximately 1.6 km apart. Results are presented on a 1:250,000 scale map (DMTS, 1961) and in more detail on a series of 1:50,000 maps.

The largest, most intense areas of positive magnetic response are associated with obducted ultramafic rocks belonging to the Slide Mountain Terrane. Within the Campbell Range Belt where dips are usually moderate to steep, the anomalies are narrow and elongate while in the remainder of the block where the ultramafic rocks occur along shallowly-dipping thrust faults, they are much broader.

A series of secondary positive anomalies was also recorded over Yukon-Tanana rocks but until recently they had no obvious explanation. Prospecting and mapping have now shown that magnetite occurs locally within schists of the middle unit of the Layered Metamorphic Sequence. The greatest documented concentration of magnetite is found in the hanging wall of the Wolverine Deposit where it forms several thin horizons approximately 80 m up-section from the massive sulphide mineralization. Magnetite is also a significant constituent of the mineralization at Kudz Ze Kayah. The Goal Net property covers numerous areas of very strong magnetic response which reflect the presence of fault-bounded ultramafics of the Slide Mountain Terrane and Cretaceous plutons. More subtle anomalies scattered throughout the property are potential VMS targets.

PROPERTY GEOLOGY AND MINERALIZATION

General

Figure 8 illustrates general property geology which includes rocks belonging to the Yukon-Tanana and Slide Mountain Terranes plus the Mesozoic Plutonic Suite. The Slide Mountain rocks are primarily confined to large klippe that are thrust over the other units. Rocks of the Layered Metamorphic Sequence underlie about 60% of the claim block. Geology and mineralization in eight parts of the property, where most of the detailed mapping and prospecting have been done, are described as follows.

Blade 1-30 Claims

Bedrock exposure is excellent on the ridges and peaks but rare in the valley bottoms. Six rock types have been recognized and are described below. The first five are part of the Layered Metamorphic Sequence while the last belongs to the Slide Mountain Terrane. Rocks generally dip gently (10 to 15°) southward.

Quartzite is the most common unit in the area. It typically weathers brown, orange, or dark grey. Degree of foliation is variable but the rocks are usually highly friable. Compositional banding parallels foliation and ranges from a few millimetres up to 20 cm in thickness. Fresh surfaces are white, light grey or black, depending on graphite content which ranges up to 20%. Muscovite and biotite are common along foliation planes. A 0.3 square metre area of malachite stained quartzite was discovered on a cliff face at UTM 6800860N and 409820E. No primary copper minerals were seen in the rock and a chip sample across the zone (N110135) yielded a surprisingly low 468 ppm copper. All other metals returned background values.

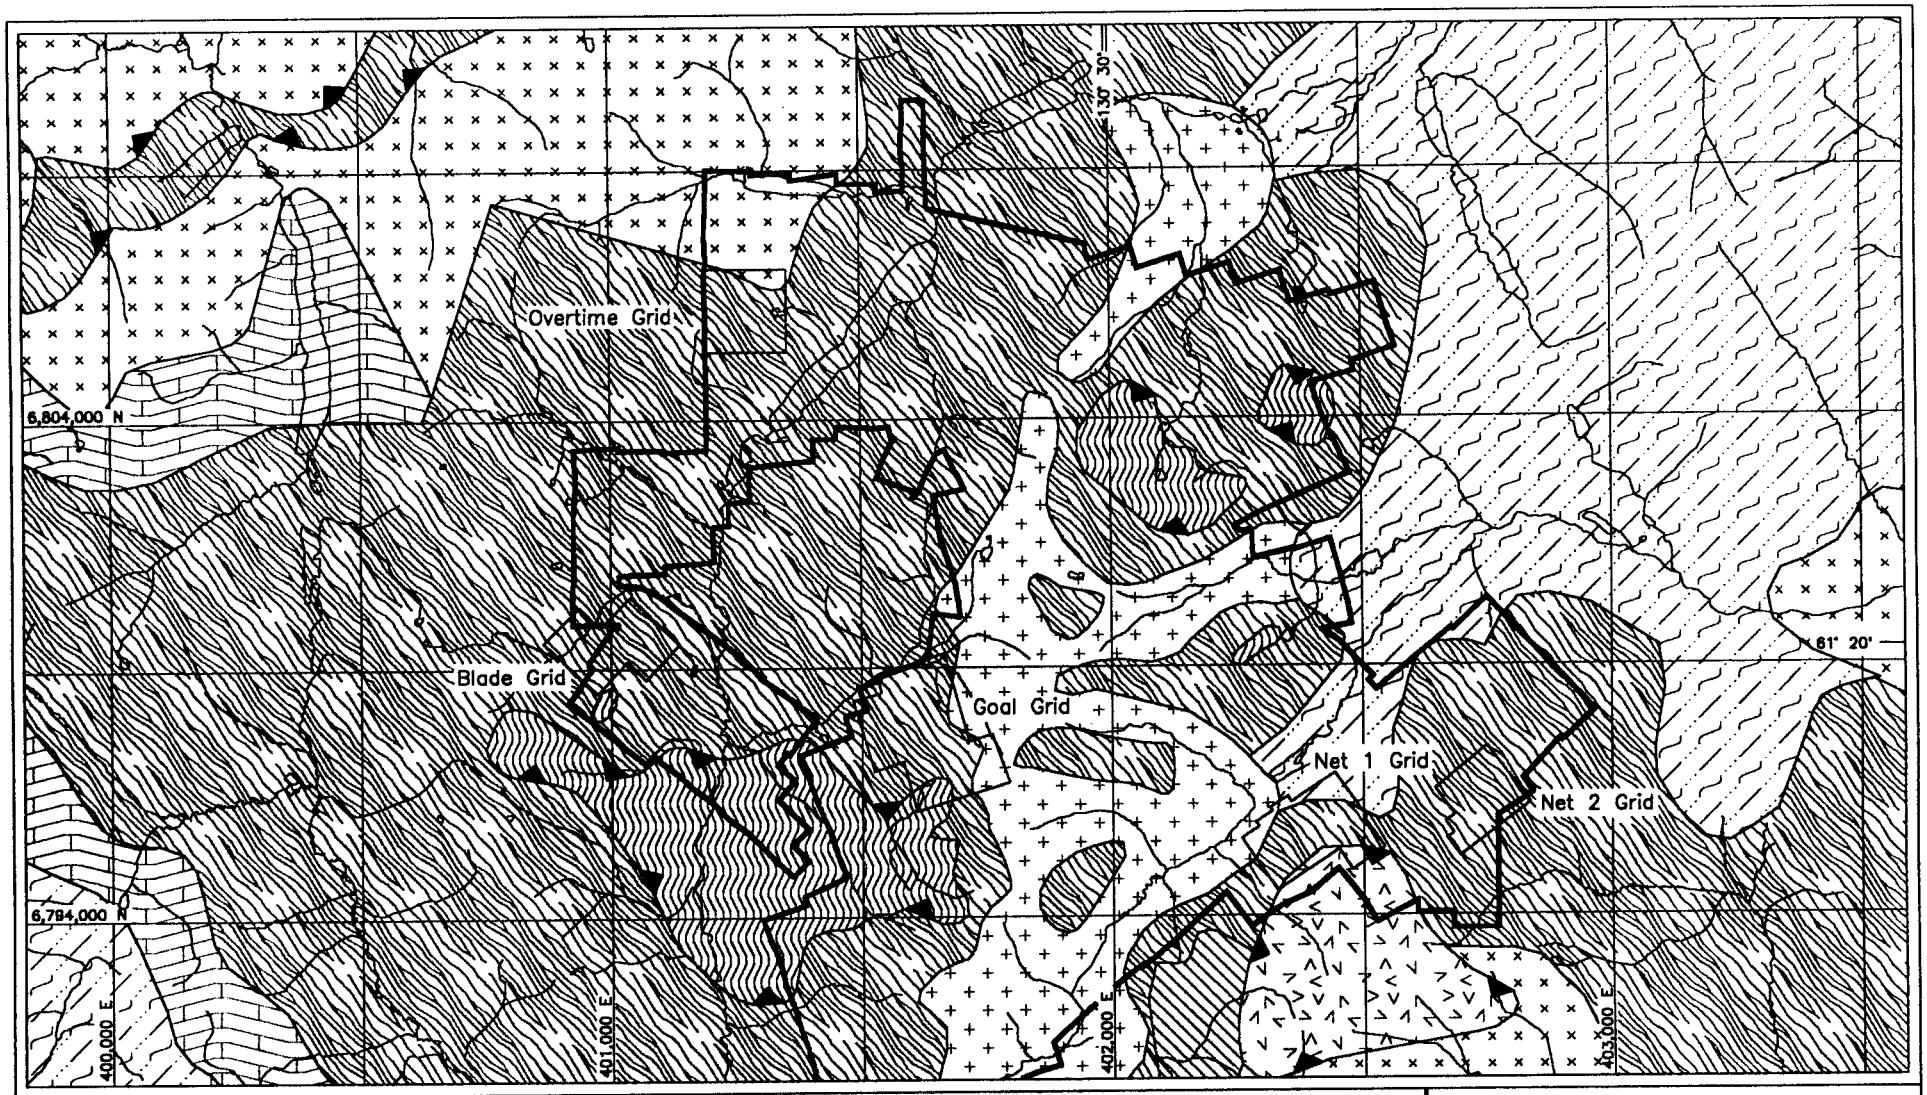

FIGURE 8

Archer, Cathro & Associates (1981) Limited

PROPERTY GEOLOGY

GOAL NET PROPERTY

EXPATRIATE RESOURCES LTD.

SCALE: 1: 150,000	FILE: GN-GEOL.DWG	
DRAWN: TCB	PROJ: FP	DATE: FEB 1,1987

Rusty weathering quartzite containing minor disseminated, fine-grained pyrite occurs on the southern wall of a cirque at UTM 6797880N and 409270E. A sample across the rusty zone (N110134) returned background values for all metals.

Biotite-chlorite±quartz schist occurs in several distinct bands and as interfoliations within the quartzite. This rock contains abundant epidote and is flat green on fresh and weathered surfaces. It is well foliated and fissile, and is likely metamorphosed intermediate or mafic volcaniclastic. The only mineralization found in the unit is occasional fine-grained pyrite within a 3 m thick section of rusty schist located at UTM 6798670N and 409060E near a contact with the underlying quartzite. Sample N110133 was taken across the rusty section and returned a slightly elevated copper value of 312 ppm with background values for all other metals.

Felsite occurs near the centre of the map area. It is white on fresh surfaces and weathers orange to rusty brown. The unit is only weakly foliated and is probably of rhyolitic composition. Finely disseminated pyrite is common.

Paragneiss is found as interfoliations in quartzite, occasionally in association with the biotite-chlorite±quartz schist. It is variably foliated indicating different degrees of strain. On the northern edge of the map area, foliations are weak and widely spaced (1 m) producing outcrops that weather into large, blocky boulders. In other areas the gneiss is highly foliated and fissile. Quartz and feldspar comprise most of the unit while biotite ranges from 5 to 25%.

Ultramafic forms prominent craggy peaks near the western edge of the map area. This rock weathers dark grey to brown and is typically dark green with pistachio green stringers on fresh

surfaces. It is tough, massive and serpentinized. Groundmass consists primarily of olivine with serpentine up to 5%. Fine-grained magnetite was also observed as euhedral octahedra up to 3mm diameter in talc veins. Radial masses of forest green prismatic actinolite (up to 5 cm in length) are also present locally. Pervasive quartz-carbonate alteration has produced prominent buff orange weathering outcrops in some areas.

Greenstone is found in a few areas near the ultramafic and is believed to be serpentinized volcanic. It is dark green on fresh and weathered surfaces and exhibits moderate foliation.

Goal 1-24 Claims

Rocks are weakly to moderately foliated with generally shallow dips of about 17° toward the southwest. Six main rock units recognized in this area are described in the following paragraphs. The first two are part of the Layered Metamorphic Sequence, the third belongs to the Simpson Suite, the fourth is assigned to the Slide Mountain Terrane and the last two are phases of the Mesozoic Plutonic Suite.

Undifferentiated paraschist is brown, buff, grey or rusty weathering, interbanded mafic and felsic phyllites and schists that locally grade up to gneiss. Most of the unit is comprised of buff, fine-grained quartzite with or without biotite. Buff to grey-brown, medium-grained, moderately foliated quartz-muscovite schist and green to grey-green, fine-grained biotite-chlorite±amphibole schist are interbanded within the quartzite. Traces of pyrrhotite, pyrite, galena, sphalerite and chalcopyrite are disseminated throughout the section. Although numerous samples of this material were analyzed, most returned near background values for all metals. The most promising

target is a 1 m thick horizon containing foliaform pyrite, sphalerite and galena. A specimen from the horizon (N110152) returned 2.4% zinc and 0.13% lead. The horizon outcrops immediately beneath a ridge crest at UTM 6797970N and 416720E.

Biotite-chlorite±quartz schist is dark green, grey or black weathering, fine-grained and thinly foliated. Locally, very fine-grained feldspar segregations occur along foliation planes. Typical schist contains about 1% disseminated pyrite and pyrrhotite. A quartz-rich end member comprises approximately 10% of the unit. This rock is sucrosic in appearance and moderately foliated. It is often mineralized with up to 3% disseminated pyrrhotite and pyrite plus rare, fine-grained galena, sphalerite and chalcopyrite.

Narrow bands of amphibole schist are also found within the biotite-chlorite±quartz schists. These rocks are light green-grey weathering, moderately foliated and dark green on fresh surfaces. They contain minor interstitial biotite, chlorite and epidote plus calcite along micro-fractures developed perpendicular to foliation.

Paragneiss is light blue-grey to brown, fine grained and weakly to moderately foliated. Mineral composition ranges from 40 to 80% quartz, 10 to 40% biotite, 0 to 20% feldspar, 0 to 10% amphibole and 0 to 5% garnet.

Ultramafic occurs as lenses along the contact between overlying paraschist and underlying biotite-chlorite±quartz schist.

Quartz monzonite is light grey to pale orange weathering, massive to weakly foliated and grey to buff on fresh surfaces. Mineral composition ranges from 40 to 50% feldspar, 10 to 30% quartz, 10 to 20% muscovite and 10 to 30% biotite.

Blastomylonitic muscovite-quartz porphyry forms narrow dykes and sills predominantly within biotite-chlorite±quartz schist.

Goal 66-86 Claims

Four rock types have been recognized in this area. The first two belong to the Layered Metamorphic Sequence, the third is from the Simpson Suite and the last is part of the Slide Mountain Terrane.

Paragneiss is well-foliated and weathers dark grey to black or rusty-brown. Its main mineral components are quartz, feldspar, and muscovite. Traces of disseminated pyrite and pyrrhotite are common within many horizons. One 5 m thick, quartz-rich layer contains up to 2% pyrite.

Multicolored quartzite conformably overlies the paragneiss. It ranges from black and graphitic to tan and micaceous. Rusty patches are developed where the quartzite contains minor disseminated pyrite.

Muscovite±biotite granite lies lowest in the section and has a subhorizontal contact with the overlying paragneiss. It is weakly to moderately foliated and weathers in large, blocky boulders. Granite sills are common in the paragneiss near the contact between the units. Minor pyritization also appears along the intrusive contact.

Ultramafic unconformably overlies the paragneiss and quartzite. It is dark green and highly serpentinized.

Goal 103-319 Claims

These claims are underlain by rocks of the Layered Metamorphic Sequence which are intruded by quartz-feldspar porphyry sills and a quartz monzonite stock belonging to the Mesozoic Plutonic Suite.

Chlorite schist is lustrous, dark green and wavy banded. Altered feldspar and traces of finely disseminated sulphides, including chalcopyrite, occur in the schist matrix. Coarser pyrite is found along fractures while tourmaline is developed in some fractures and along foliation planes.

Muscovite-chlorite schist is a pearly, light brown or olive coloured, fine grained, well banded unit that forms blocky talus. Minerals are segregated into chloritic and quartzofeldspathic bands with biotite replacing chlorite in some cases.

Biotite-chlorite schist is lustrous, dark brown, fine- to medium-grained, moderately laminated, moderately fissile and blocky fracturing. Interfoliated layers of coarse biotite and chlorite are developed in a weakly feldspathic matrix.

A siliceous phyllonite is dark grey, fine grained, well laminated and highly fissile with a slaty texture. The foliation planes have a bright pearly lustre and greasy feel because of muscovite along parting surfaces. Some sections of this unit contain thick siliceous bands which may represent a highly developed flaser fabric. The phyllonite is interlayered with other lithologies including: muscovite schist, micaceous marble and pyritic rhyolite. The muscovite schist is a light brown, well banded, moderately fissile unit comprised of medium-grained muscovite in a fine-grained carbonate-quartz-feldspar groundmass. Micaceous marble is dull black to medium grey,

finely banded, medium grained, granular, blocky fracturing and carbonaceous. The pyritic rhyolite is translucent to rusty brown, extremely siliceous, very fine grained, massive and contains finely disseminated pyrite grains.

Intrusive rocks consist of massive quartz monzonite which is part of a large stock and a 3 to 5 m thick quartz-feldspar porphyry sill which intrudes the schist.

Two small scheelite occurrences are known in the map area. One of the occurrences was discovered in 1978 and is known as the Chapman Showing (Cathro, 1978). It consists of scheelite within calc-silicate altered, recessive weathering, highly deformed, discontinuous limy bands in thin quartz-muscovite schist. The other showing was discovered in 1980 (Cathro, 1981). It includes coarse scheelite in a banded calc-silicate altered quartz-muscovite schist adjacent to a large shear zone containing abundant quartz veins. Traces of finely disseminated scheelite are also found in schists below the main showing.

Goon 1-68 Claims

Work in this area consisted of reconnaissance prospecting traverses during which an occurrence of massive pyrrhotite and pyrite with minor chalcopyrite was discovered at UTM 6807210N and 418140E. Most of the mineralization occurred as talus fragments but two, 3 m wide outcrops were also located. Rocks in the area are strongly hornfelsed and occasionally skarnified. Where exposed this mineralization appears to be conformable with stratigraphy but its exact nature is uncertain. No detailed geological mapping was done. Specimens of the massive sulphides (N110344) assayed up to 0.51% copper, 2.2 g/t silver, 550 ppm cobalt and 443 ppm nickel.

Net 1-28 Claims

Of the five main rock types mapped in this area, three belong to the Layered Metamorphic Sequence, one is part of the Slide Mountain Terrane and the other forms a Cretaceous intrusion.

Well-foliated, micaceous paraschist varies in colour from light tan to dark grey, depending on graphite content. It is interfoliated with quartzite, cream to white felsic metavolcanic and pinkish grey biotite gneiss. Fine-grained, dark grey limestone containing abundant silicate bands and lenses up to 5 cm thick also occurs within the paraschist. This assemblage represents a favourable succession for VMS deposits.

The paraschist hosts a stratabound sulphide occurrence that was discovered in 1990 (Dodge, 1990). The showing consists primarily of float, specimens of which have returned up to 1.41% copper, 1.65% zinc and 0.48% lead. In 1996 mineralization was found in bedrock at the bottom of a 0.6 m deep hand trench. It consists of a 0.3 m interval containing up to 15% pyrite with minor sphalerite. Specimens collected from the mineralized horizon assayed up to 2.7% zinc (N110177) but a 1.5 m long chip sample across the mineralization and adjacent wallrocks (N110176) returned only 0.01% zinc. A second trench located 15 m along strike to the east failed to reach bedrock while a third trench located 20 m along strike to the west reached unmineralized bedrock at a depth of 0.6 m. Four other trenches were dug nearby in the vicinity of anomalous soil sample sites. Only two reached bedrock and neither encountered significant mineralization.

Muscovite-chlorite-biotite quartzite and biotite-chlorite±quartz schist are pale to medium green and finely laminated. These units overlie the paraschist and may either be a retrograded felsic gneiss or a metamorphosed chloritic tuff. They are variably hornfelsed and exhibit fine purplish biotite in thin bands.

Greenstone of the Slide Mountain Terrane is thrust over the Layered Metamorphic Sequence on the ridge southeast of the area of interest. The unit consists of silvery green, highly foliated and fissile biotite-chlorite phyllite that contains abundant epidote. It is believed to be metamorphosed basaltic tuff or volcanoclastic.

Weakly foliated muscovite±biotite granite occurs in outcrops immediately northwest of Cleaver Lake. It is part of a large stock and is mineralogically similar to Cretaceous intrusions mapped elsewhere in the region.

NHL 1-52 Claims

All of the structural/stratigraphic units observed in this area are essentially flat-lying. They include three rock types from the Layered Metamorphic Sequence, two belonging to the Slide Mountain Terrane and a Cretaceous intrusive.

Biotite amphibolite is the oldest unit in the area. It is typically dark green and thinly banded. Interlayered with the amphibolite are up to 20 m thick intervals of dark grey carbonaceous quartzite and medium to pale brown felsic volcanic.

Quartzite overlies the amphibolite. It is light tan coloured and is interlayered with cream felsic volcanic. The volcanic ranges from siliceous metarhyolite to micaceous quartz-muscovite schist, both of which are extremely hard and weather tan to cream white with rusty-orange patches.

Extremely muscovite-rich felsic volcanic weathers to produce distinctive red, orange, and yellow soil that closely resembles soil derived from a mineralized horizon at Expatriate's Hat Trick property. Disseminated pyrite grains and foliated pyritic bands are visible in unweathered specimens of the unit. Samples of typical muscovite-rich felsic volcanic (N110329 & N110330) returned background values for all metals while an angular float boulder containing 1 to 2% pyrite with minor sphalerite (N110200) assayed 0.073% zinc.

Slide Mountain Terrane rocks are found in the eastern part of the map area. They include a medium to dark brown, thickly-bedded sediment that is structurally overlain by dark green massive greenstone. The greenstone is highly magnetic and probably includes altered ultramafic and basalt.

The stratigraphic units are intruded by a fine- to coarse-grained, poorly foliated, muscovite-biotite granite of Cretaceous age. The uppermost part of the granite contains screens of metasediment.

Overtime 1-50 Claims

This area is centred on an east-facing cirque which offers excellent bedrock exposures. Eight rock types have been mapped with the first seven belonging to the Layered Metamorphic Sequence and the last to the Mesozoic Plutonic Suite.

Much of the property is underlain by undifferentiated paraschist similar to that mapped on the Goal 1-24 claims. Biotite gneiss bands composed of up to 90% biotite are interfoliated with the paraschist. These layers range from 0.3 to 10 m in thickness and may represent metamorphosed mafic dykes. Along the crest of the south wall of the cirque (UTM 6806920N

and 413210E) is a 1 m thick, rusty horizon bearing 1 to 5% pyrite. Samples collected from the horizon (N110106 & N110107) returned background values for all metals.

A mixed package of interlayered felsite, greenstone and black graphitic quartzite occurs in the paraschist along the same wall of the cirque as the rusty horizon. This package is about 30 m thick. A specimen of the black quartzite with a rusty coating on fracture surfaces (N110108) returned moderately anomalous zinc while a sample of the greenstone bearing pyrite grains up to 1 cm in diameter (N110109) returned background values for all metals.

Immediately overlying the mixed package is a 2.5 m thick section of paraschist containing 1 to 15% grey to tan stratabound sphalerite at UTM 6806870N and 412630E. Chip samples taken across the richest part of the mineralized horizon (N110201 to N110208) averaged 2.7% zinc and 0.83 g/t silver over 1.2 m, including 12.3% zinc and 2.4 g/t silver over 0.2 m.

A second felsite unit was located on the northwestern cirque wall. It contains ovoid quartz and feldspar phenocrysts and may be a metamorphosed quartz-feldspar porphyry. The felsite weathers rusty and forms a prominent orange gossan. The source of the limonite is occasional finely disseminated pyrite grains. A sample of this rock (N110130) returned background values for all metals. A 0.2 m long fragment of orange limonite boxwork float with abundant malachite coatings was found nearby. Hand trenching failed to reveal its source.

Near the western limit of the map area is a subcrop of leucocratic paraschist bearing finely disseminated pyrite grains that are weathering to produce orange soil. The host rocks are light green-grey and well foliated. Specimens of this rock (N110127 to N110129) returned background values for all metals.

North of the cirque the predominant rock type is unfoliated to weakly foliated hornblende-biotite diorite which weathers into large, blocky boulders. This unit is part of a stock that is believed to be Jurassic in age. No mineralization was observed in the diorite.

PROPERTY GEOCHEMISTRY

General

Reconnaissance soil sampling was done across the entire property while grid soil sampling was conducted on specific targets where anomalous results had previously been identified. The reconnaissance samples were collected at approximately 100 m intervals on contour controlled lines or along claim lines, except where frozen ground or steep topography prevented sampling. Grid samples were taken at 100 m intervals along lines spaced 100 m apart using slope corrected baselines for control. All sample sites are marked by 0.5 m wooden lath while baselines are marked with 1.0 m lath. Sample numbers and, where appropriate, grid coordinates are inscribed on aluminum tags that are stapled to the lath.

Sample locations for both 1995 and 1996 geochemical programs are shown on Figures 9 to 12. The 1996 Certificates of Analysis are in Appendix IV while those from 1995 were previously reported (Wengzynowski, 1996).

Analyses for copper are shown on Figures 13 to 16, lead on Figures 17 to 20 and zinc on Figures 21 to 24. Anomalous thresholds for these metals plus three other VMS indicator elements are tabulated below.

	Anomalous Threshold Values (ppm)			
Element	Weak	Moderate	Strong	Extreme
Copper	50	100	200	400
Lead	50	100	200	400
Zinc	200	500	1000	2000
Molybdenum	2	5	10	20
Silver	1	2	5	10
Cobalt	50	75	100	200

Results from specific grids and targets are discussed in the following text while their general location is shown on Figure 25. The table on the following page shows the approximate dimensions for each anomaly, which metals are most representative of the anomaly, and the peak values for six VMS indicator elements.

Overtime Grid

The grid covers an east-facing cirque and adjacent talus slopes. The geological setting is favourable for Kuroko-type VMS mineralization. A sphalerite showing located on the south wall of the cirque lies within an area of moderately anomalous zinc response. A strong zinc anomaly in the southwestern corner of the grid coincides with the projected surface trace of the mineralized horizon but no outcrop was found in that area.

A small anomalous centre was outlined along strike to the north immediately west of the cirque. It produced extremely high zinc (up to 2460 ppm) and lead (up to 5070 ppm) values with weakly to strongly anomalous copper and arsenic response. The area is talus covered and prospecting has not explained this anomaly.

A third cluster of high zinc and lead values is located along the northern edge of the grid. This area is distinguished by extremely anomalous silver (up to 24.6 ppm) and molybdenum (up to 21 ppm) values.

Blade Grid

This area exhibits relatively subdued geochemical response and lack of encouraging geology making it a low priority VMS target. The most anomalous cluster of values is located immediately uphill from a malachite stained cliff face above the 1996 campsite. This cluster is 400 by 300 m and contains weakly to moderately anomalous copper, lead, zinc and molybdenum values.

Goal Grid

Most of the grid was done in 1995 and the only new work was four lines that extend westward from the 1995 grid to better define the area of anomalous response. The target is a broad zone of roughly coincident, weakly to moderately anomalous copper, lead and zinc values with a 1400 by 600 m core containing scattered strongly anomalous values. The geochemical pattern over much of the grid appears to reflect downslope dispersion from a mineralized source high on the ridge. A small showing of stratified pyrite and sphalerite was discovered near the centre of the anomaly but this showing is too small to account for the extensive geochemistry response.

Net 1 Grid

The geochemical anomaly and area of favourable stratigraphy are located on a heavily vegetated lower slope adjacent to a broad, glacial till covered valley. Zinc response occurs across the entire area while lead, copper and molybdenum are more localized. The highest zinc values are in the vicinity of hand trenches where VMS mineralization was discovered. Some of the highest copper and lead values are found along the western edge of the grid. A patch of high cobalt and moderate copper values in the northeastern corner of the grid is likely caused by serpentinized ultramafic.

Net 2 Grid

This target is centred on a ridge comprised of relatively flat lying stratigraphy which includes felsic metavolcanic. Almost the entire grid is anomalous for zinc. The peak values are found in the southwestern corner and centre of the grid, and coincide with moderately to strongly anomalous lead and copper response. Float samples from streams draining the area have assayed up to 5.98% zinc, 1.55% lead, 82 g/t silver and 0.86 g/t gold (Wengzynowski, 1996) but prospecting has not yet located the source.

Target A

Weakly to moderately anomalous copper and zinc response was obtained from two reconnaissance sample lines located uphill from massive pyrrhotite-pyrite-chalcopyrite float described in the Geology and Mineralization section for the Goon 1-68 Claims. Cobalt values were low in soil but strongly anomalous in the mineralized float.

Target B

Copper, zinc and molybdenum response occurs across the entire target while anomalous lead values are confined to an area of gossanous micaceous mud that reportedly resembles the mud flow downhill from the lead-zinc-copper-silver showing at the Hat Trick property. The area is underlain by favourable geology and has only been superficially prospected and sampled.

Target C

Moderately to strongly anomalous copper values with weak zinc support are scattered over a broad area. This is a low priority target because most of the anomalous area is underlain by Cretaceous intrusive rocks.

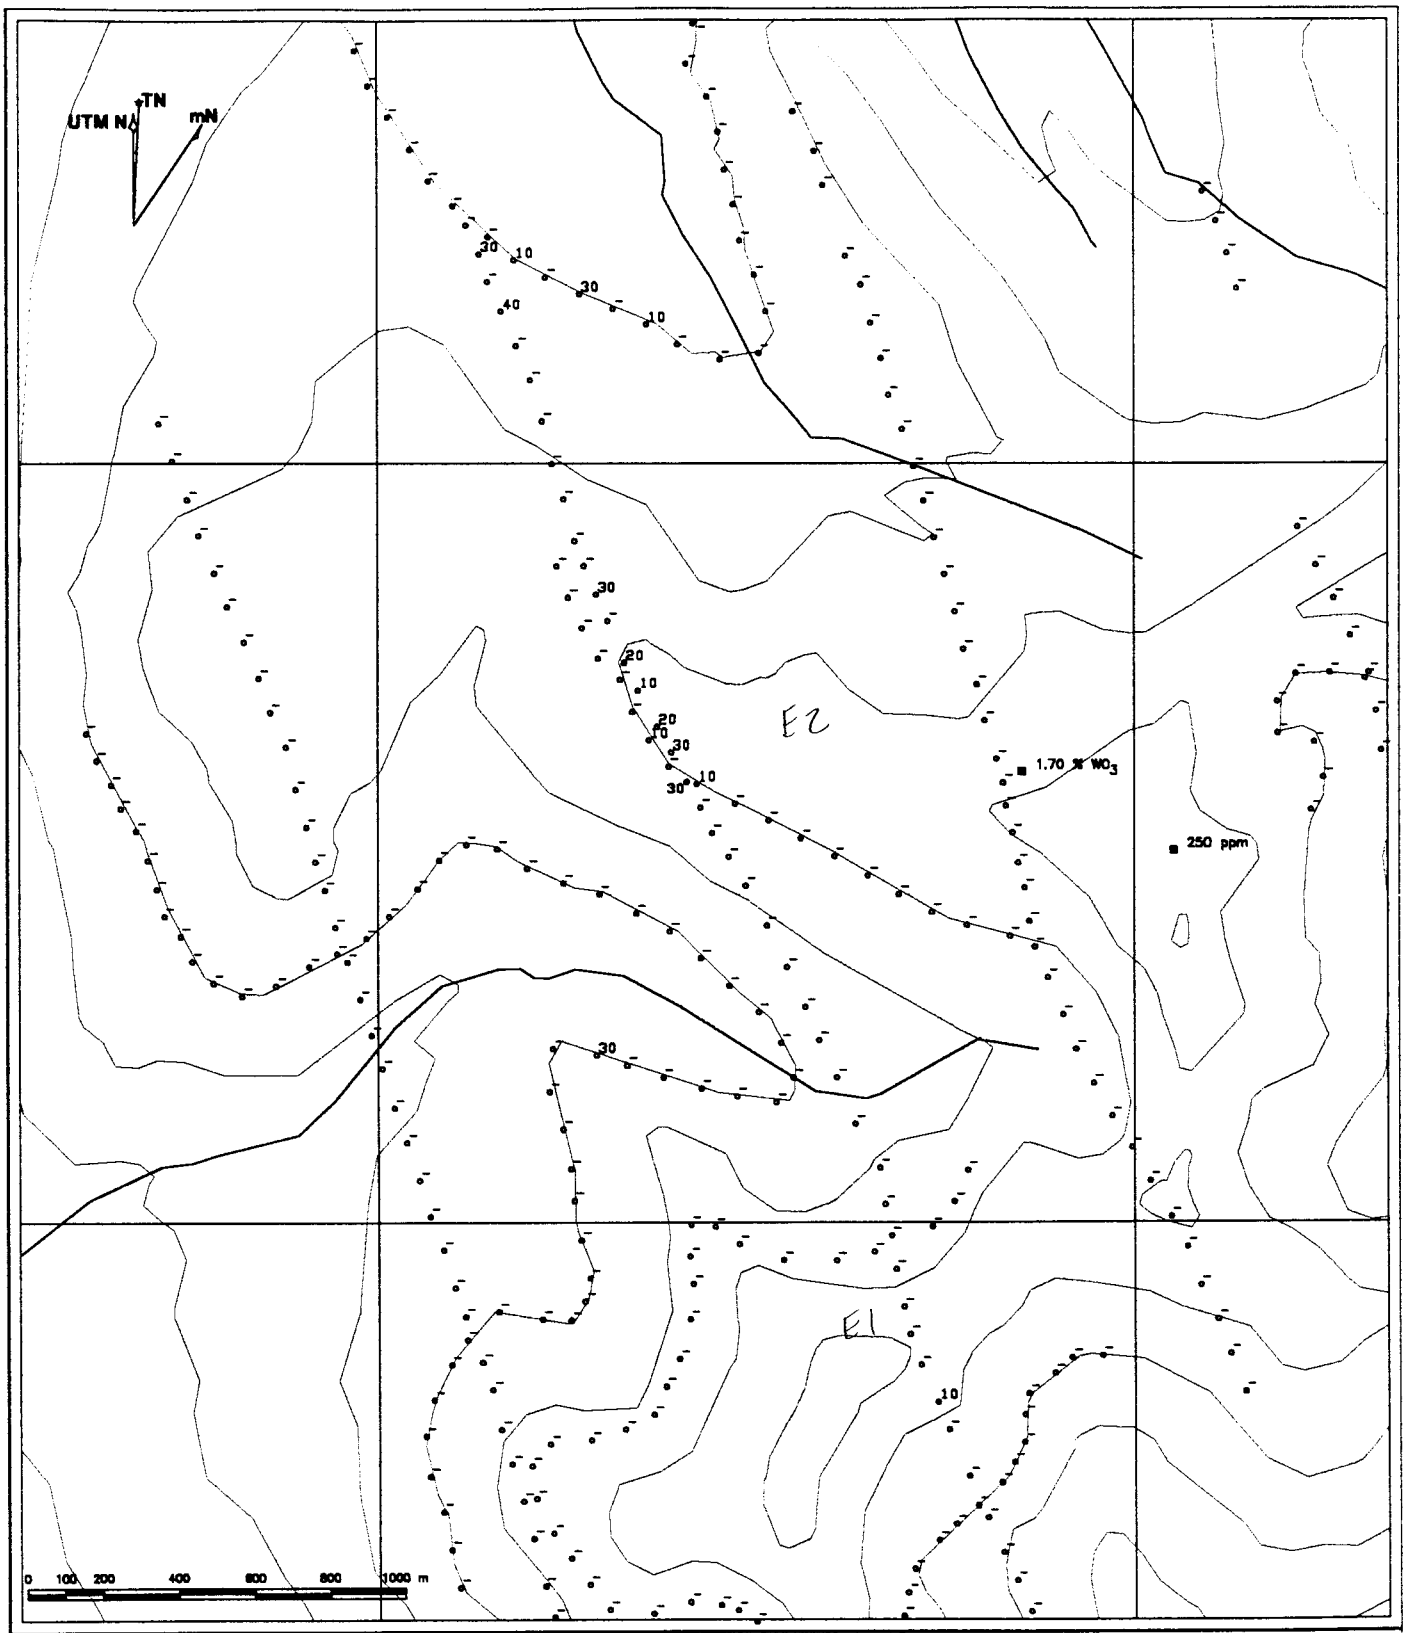
Target D

This is a very specific target identified on a single reconnaissance line. It is strongly anomalous for zinc but returned near background values for all other metals.

Target E

Moderately to strongly anomalous copper response occurs across an extensive area that is underlain by Layered Metamorphic Sequence and Slide Mountain Terrane rocks. Two areas are of specific interest. The first is located in the northern part of the anomaly where copper is strongly supported by cobalt. This may reflect high background in ultramafic but may also be a valid Besshi-type VMS target similar to the nearby Fyre Lake Deposit. The second area is centred on the old Chapman Showing where chalcopyrite and tungsten were discovered in Layered Metamorphic Sequence rocks. This area is characterized by copper with molybdenum support.

Probably the most interesting aspect of Target E is the associated tungsten response. Previous workers had identified two small showings (see Geology and Mineralization Section for Goal 103-319 Claims). The 1996 soil sampling identified a cluster of anomalous tungsten values (10 to 30 ppm) about 2 km north of the old showings (Figure 26). More importantly, prospecting



32 Soil sample location with tungsten value in ppm

Soil sample location with tungsten value less than detection limit

170 ppm Rock sample location with tungsten value as indicated

≥ 20 ppm W

≥ 10 < 20 ppm W

FIGURE 26

DRAWN: TCB	PROJ: FP	DATE: 2/4/1997

nearby located a gabbroic dyke with about 10% disseminated pyrrhotite, a specimen of which (N110036) was submitted for routine ICP analysis and yielded a high tungsten response. A subsequent assay of the sample pulp returned 1.7% WO_3. No follow-up work has been done on this showing.

Target F

This anomaly is defined by a single reconnaissance sample line and lies about 200 m northwest of the Net 2 grid. It is moderately to strongly anomalous for zinc and lead and is likely an extension of the anomaly on the grid.

Target G

Copper response occurs over a broad area underlain by rocks of the Layered Metamorphic Sequence and Slide Mountain Terrane. Localized extremely anomalous zinc and lead values indicate good VMS potential. The area has only been tested with widely spaced reconnaissance lines and the anomalies have not been followed up by detailed prospecting or mapping.

Target H

Strongly anomalous copper values were located on a reconnaissance line about 600 m southwest of the Net 1 Grid. The area is heavily vegetated and outcrop is rare. Weak zinc and molybdenum support suggests that the source of the anomaly is an extension of the favourable units exposed in trenches on the Net 1 Grid.

Target I

This target was identified on two reconnaissance lines spaced 800 m apart. Strongly anomalous zinc and molybdenum values were obtained on both lines. The western line also exhibits strong copper, moderate silver, and weak lead support while the eastern line has strong lead with weak copper. The area is shown as being underlain by Layered Metamorphic Sequence and Slide Mountain Terrane rocks but no detailed mapping or prospecting have been done. This is an excellent VMS target.

CONCLUSIONS AND RECOMMENDATIONS

Work in 1995 and 1996 has shown that the Goal Net property has excellent VMS potential. Much of the property is underlain by rocks belonging to the middle unit of the Layered Metamorphic Sequence which hosts Kuroko-type deposits at Wolverine and Kudz Ze Kayah to the east and north and a Besshi-type deposit at Fyre Lake to the southwest.

Preliminary prospecting has located several areas of sub-economic VMS mineralization on the property while soil geochemistry has identified numerous excellent targets that have not yet been explained.

The next phase of exploration should be done from a number of fly camps and consist of detailed mapping, prospecting and hand trenching plus grid sampling in the vicinity of the better reconnaissance targets. Property scale mapping and reconnaissance soil sampling should be continued using looping traverses radiating out from the fly camps. Ground geophysics may be necessary after grid soil results are obtained in order to help define specific drill targets.

Stratigraphic drilling is already warranted to test anomalies and mineralization on the Overtime, Goal, Net 1 and Net 2 Grids.

Respectfully submitted,

Re: Field Report - Net Maxmin / mag survey

This memorandum describes the Maxmin and magnetic field surveys performed on the Net Property from March 23 to April 12, 1996.

a. Crew and equipment. The survey party consisted of Jeff Mitchell (Geophysicist), Phil Chidgzey (Crew chief) and Ron Stack (Tech). J.M. replaced P.C. on 01 April following an injury. The crew was equipped with 2 Omni Plus proton precession magnetometers, and Omni IV base station magnetometer and a Maxmin I-10 with MMC. All data was stored in the instruments in RAM and dumped to a laptop computer at the end of the survey day.

b. Grid. A total of 32.1 line-km of grid was picketed. Lines were spaced 100 m apart and stations picketed with full length tagged lathe at 25 m intervals. The base line was slope corrected; survey lines were not slope corrected. Portions of the grid were wiped out by avalanches during the course of the survey and this accounts for the discrepancy between the coverage in the magnetic field and Maxmin survey. The coordinates of selected points were determined with hand-held GPS and will be used to register the grid relative to NAD27.

c. Data. Digital data is included with this report in XYZ format and as raw dump files. Corrected data are plotted on the attached plots. This includes stacked profiles for the 220, 880 and 3520 Hz Maxmin data and a contour map of the magnetic field data. Terrain corrections have been applied to the Maxmin data to correct the in-phase channel. A base level shift in the in-phase data apparently caused by a shift in the chainage marker on the reference cable has also been removed. Magnetic field data has been corrected for temporal geomagnetic fluctuations.

d. Preliminary results. Strong magnetic field anomalies were recorded on the south end of the grid, particularly on lines 10100E to 10400E. Unusual Maxmin anomalies were recorded on Lines 10100E and 10200E at the south end as well. These are frequency invariant and thus are either due to a magnetic feature or to unremoved terrain effect. I will discuss these responses with the geophysicist on his return to clarify this matter. Ron Stack discovered mineralized float near the end of Line 10400E; a specimen will be forwarded separately from this report (and the digital data) as it may contain pyrrhotite. No significant anomalies were detected in the north part of the grid.

Respectfully submitted,
AMEROK GEOSCIENCES LTD.

GPS DATA

Goal Net Property

GPS Survey Coordinates

Data Quality: Standard = The surveyed positions were recorded in 3D mode and were differentially corrected. The reported UTM coordinates are within 1 to 5 meters of their actual locations; Poor = >25% of the surveyed positions were recorded in 2D mode; Uncorrected = The surveyed positions were not differentially corrected; N/S = No survey data available.

Base Station: W = Westmin Resources Limited base station at Wolverine Lake; WL = Ministry of Environment, Lands and Parks base station at Williams Lake; DL = Ministry of Environment, Lands and Parks base station at Dease Lake; RR = Department of Renewable Resources (Forestry) base station at Whitehorse.
