INTRODUCTION

Expatriate Resources Ltd. has a 100% interest in the Goal Net property which protects volcanogenic massive sulphide (VMS) targets selected from old assessment reports and a regional geochemical data base documenting results of 1973 exploration by a joint venture managed by Archer, Cathro & Associates Limited. The property is composed of 1053 claims staked between 1994 and 1997.

Expatriate's exploration began in 1995 and work that year consisted of geological mapping, prospecting and soil sampling in three parts of the property (Goal, Net 1 and Net 2 Grids) from fly camps (Wengzynowski, 1996).

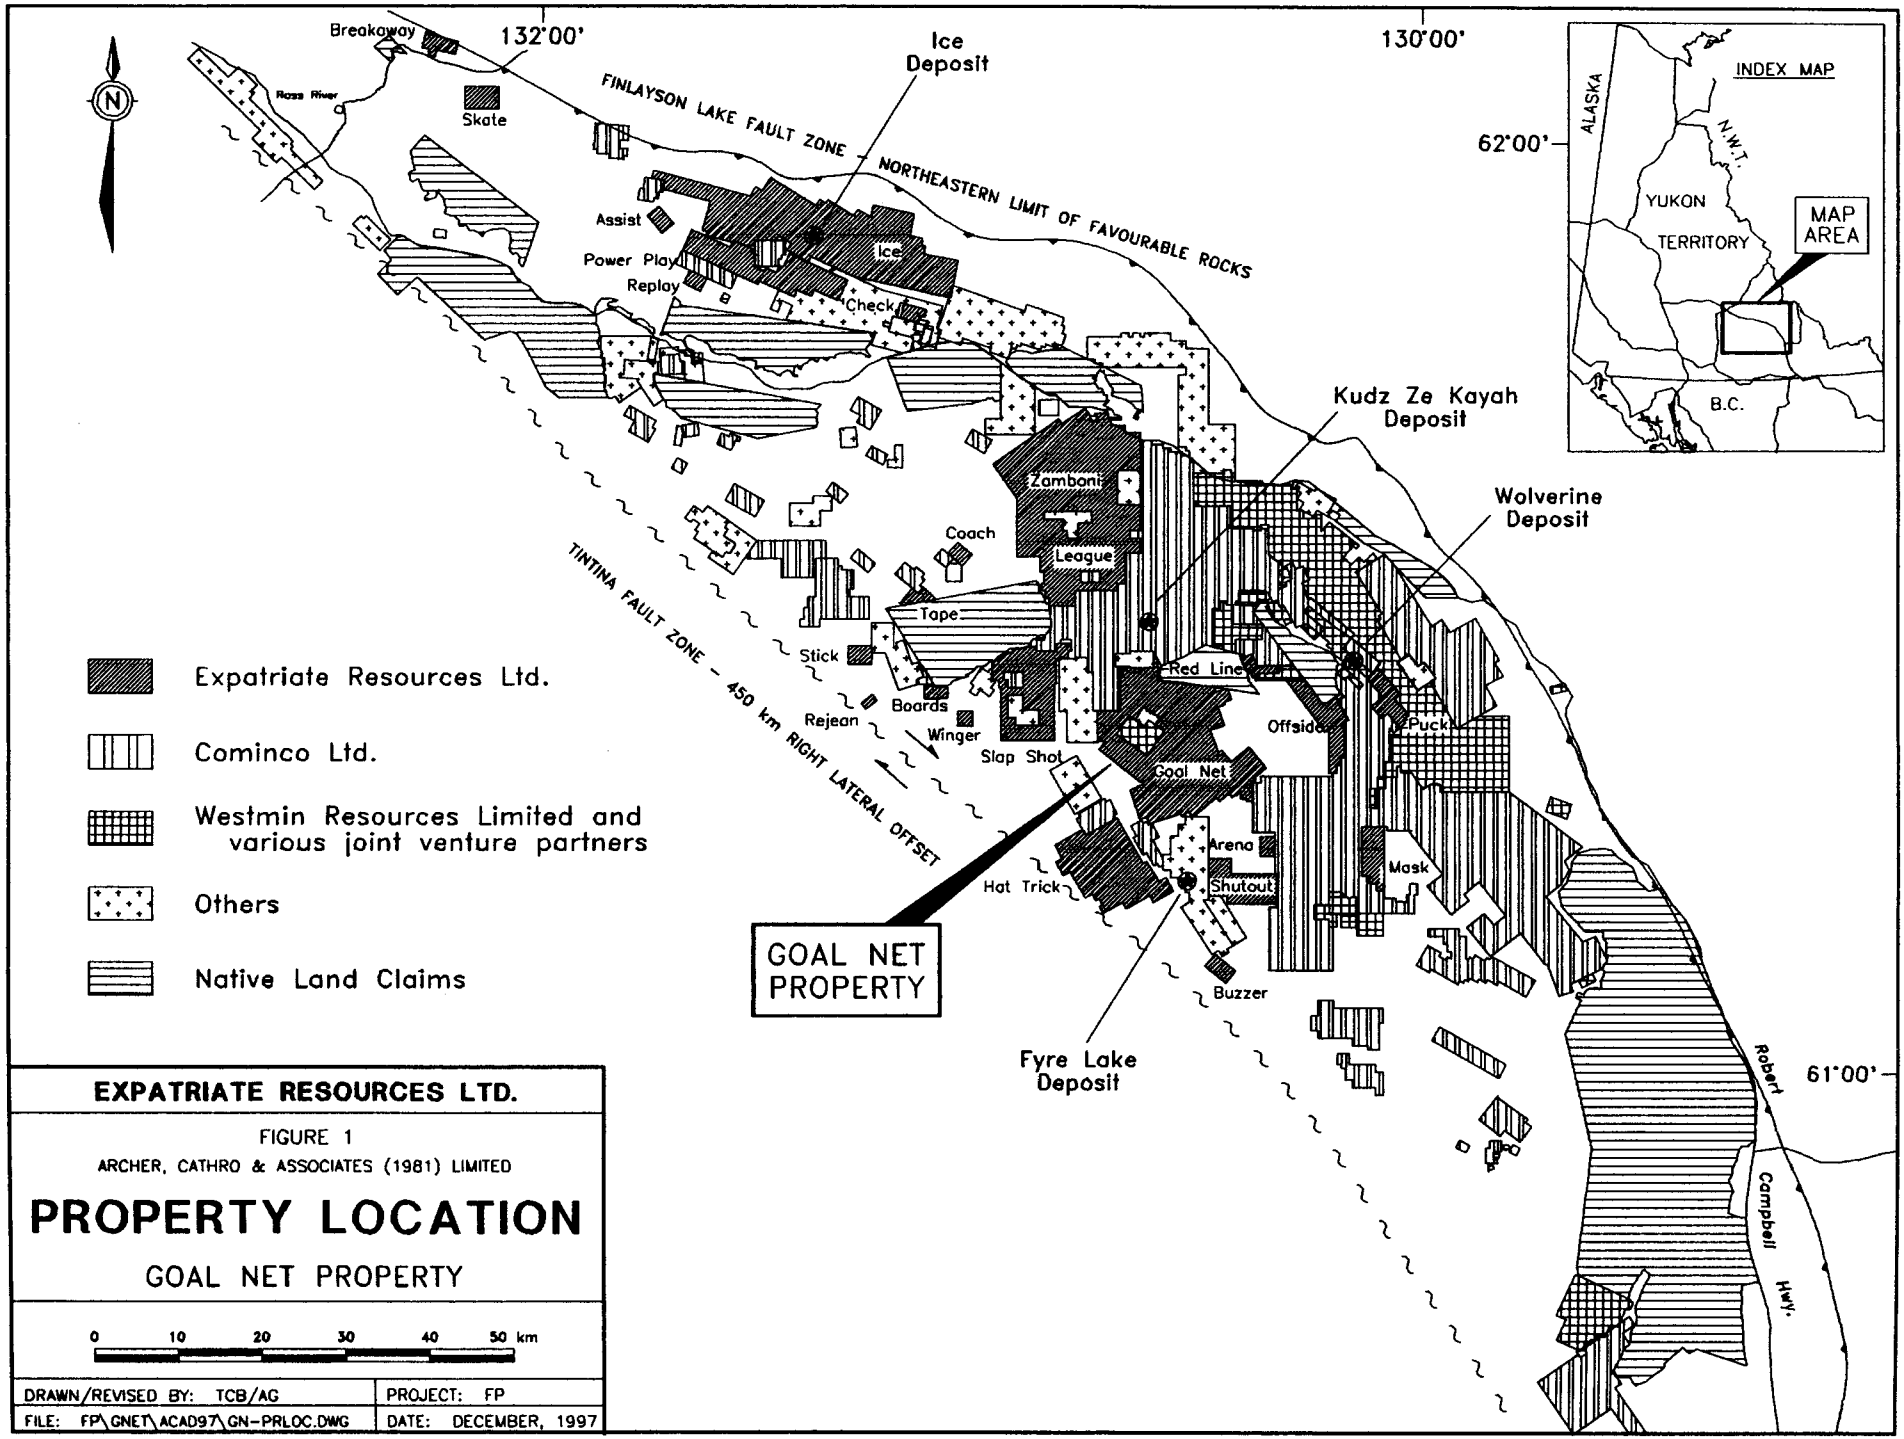

The 1996 exploration program started in spring with airborne magnetic and electromagnetic surveys over the entire property (Aerodat, 1996) and ground magnetic and MaxMin surveys on the Net 1 grid (Power and Lee, 1996). Work continued throughout summer with crews working from Expatriate's base camp at Finlayson Lake and from fly camps located on various parts of the property. The summer work consisted of reconnaissance and grid soil geochemistry, geological mapping, prospecting and claim surveys (Burgert, 1997).

In 1997 an integrated exploration program was carried out which included systematic follow-up work on targets identified in 1996. Three crews conducted geological mapping, prospecting, soil geochemical surveys and hand trenching on twelve targets within the claim block. This work was completed from a series of fly camps. The program was managed by Archer, Cathro & Associates (1981) Limited and supervised in by the author. Appendix I contains the Author's Statement of Qualifications.

PROPERTY, LOCATION AND ACCESS.

The property is located in southeastern Yukon at latitude 61°20'N and longitude 131°32'W on NTS map sheets 105G/7 and 105G/8 (Figure 1). It is comprised of 1053 mineral claims (Figures 2 to 5) registered with the Watson Lake Mining Recorder in the name of Archer, Cathro & Associates (1981) Limited which holds them in trust for Expatriate Resources Ltd. Claim registration data are listed below.

*Expiry dates include 1997 work filed for assessment credit but not yet accepted.

The property lies 25 km south of the Robert Campbell Highway and 230 km northeast of Whitehorse. In 1997 access was by helicopter from Expatriate's base camp at the Ice property 75 km to the northwest. Helicopter support was provided by a Bell 206B Jet Ranger contracted from Trans North Helicopters of Whitehorse.

During the 1996 and 1997 exploration programs most claim post locations, grid control points and hand trenches were surveyed using Trimble Geoexplorer GPS units. Field readings were corrected using base station data from Westmin Resources Limited's camp at Wolverine Lake and the Department of Northern Affairs (Forestry) of Whitehorse. Corrected GPS survey data appear in Appendix II.

GEOMORPHOLOGY

The property covers rugged terrain in the Pelly Mountains about 20 km southwest of Wolverine Lake. Creeks draining the property are tributaries of the North River and Money Creek, both of which eventually flow into the Liard River. Several lakes are located on the property, the largest of which is North Lake.

Elevations range from 1200 m in the North River valley, which bisects the property, to 2100 m atop peaks southeast of North Lake. Valley bottoms are typically broad and flat and are blanketed with Pleistocene deposits of glacial till. Topographic relief everywhere else on the property is steep, typically 20 to 40°, with occasional impassable cliffs. Outcrop is most abundant in creek cuts, along ridge crests and in north-facing cirques.

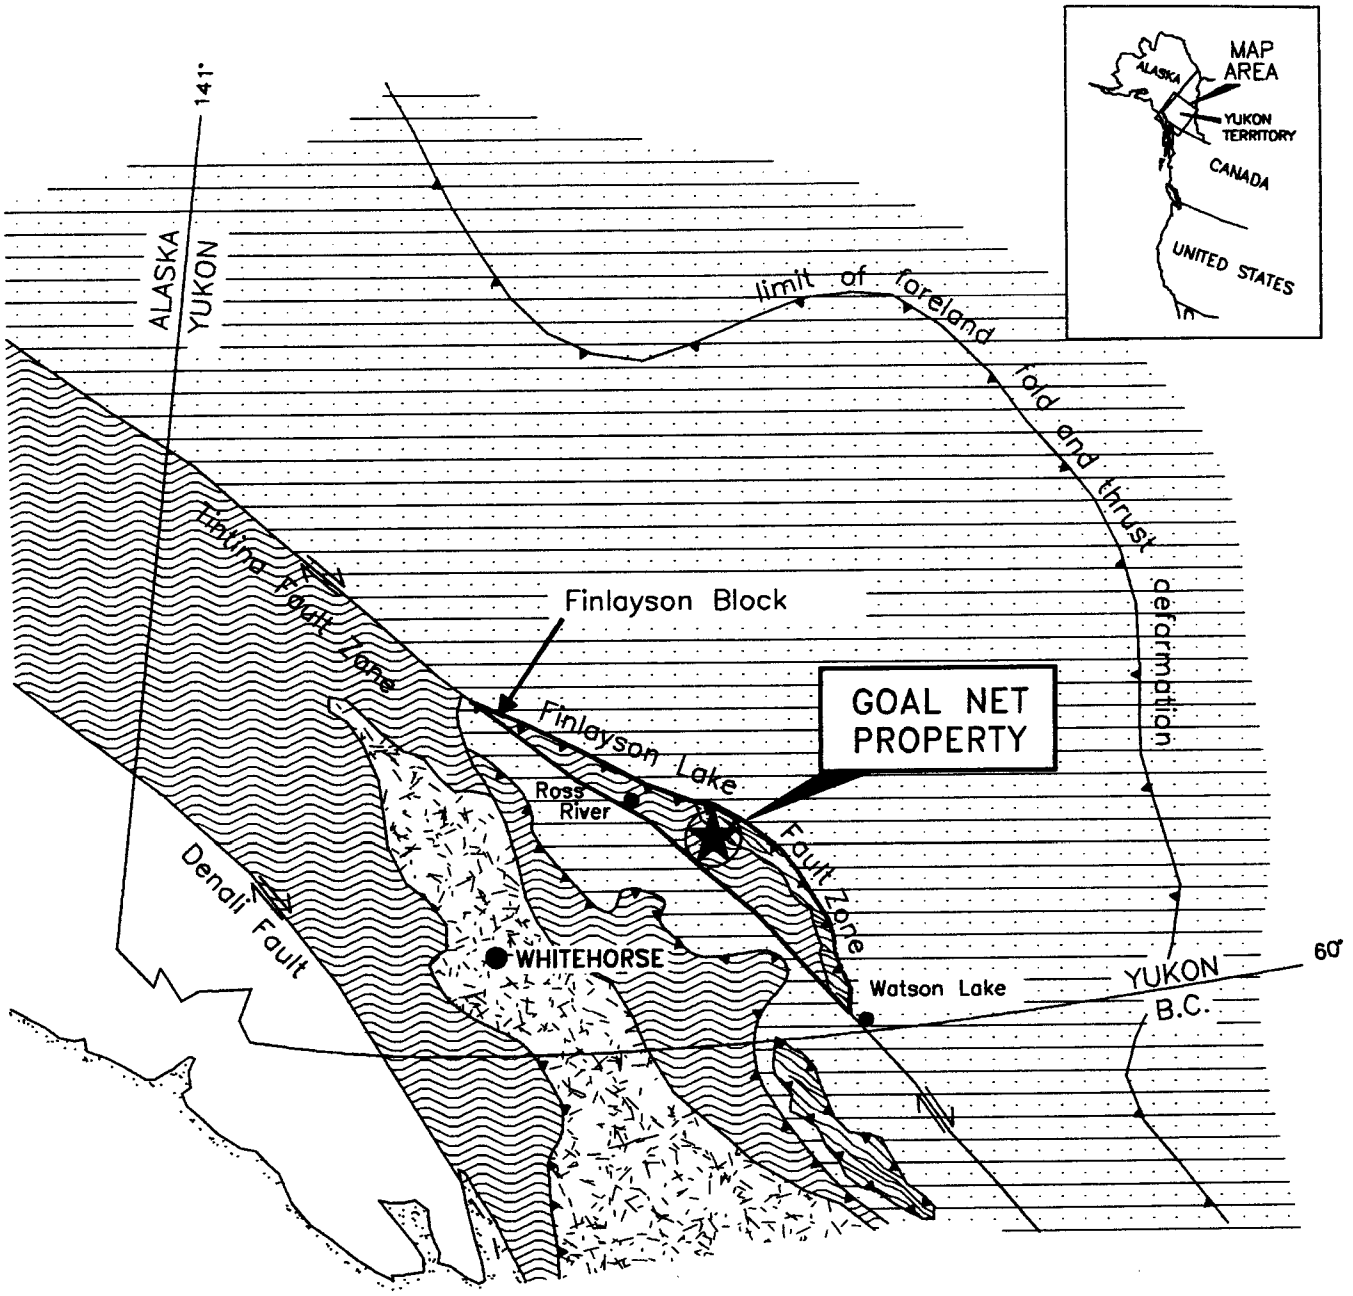

Vegetation consists of dense buckbrush in the valley bottoms giving way to moderately dense growths of balsam and black spruce on lower slopes, then buckbrush, willow and moss above 1550 m and eventually scattered buckbrush, alpine grass and lichen at elevations exceeding 1700 m. Steep talus slopes and cliffs are vegetated only by lichen.

REGIONAL GEOLOGY

The Goal Net property is located within the Finlayson Block, a 380 by 60 km area comprised primarily of the Yukon-Tanana and Slide Mountain geologic terranes (Figure 6). These terranes represent the innermost of the accreted or "suspect" terranes in the Canadian Cordillera (Mortensen and Jilson, 1985). The northeastern margin of the block is the Finlayson Lake Fault Zone, a complex zone of steep and shallow faults related to transpressive suturing. The southwestern boundary of the block is the Tintina Fault, a major strike-slip fault with at least 450 km of dextral displacement during Late Cretaceous and/or Early Tertiary time (Tempelman-Kluit et al, 1976).

Regional mapping of the Finlayson Lake area was completed by the Geological Survey of Canada (GSC) in the mid to late 1970's (Tempelman-Kluit, 1977, 1979). More recent regional studies have been published by Mortensen and Jilson (1985) and Mortensen (1992). The following discussion of the regional geology (Figure 7) is based partly on published work and partly on unpublished mapping completed in 1996 (Tempelman-Kluit, personal communication, 1996).

The Yukon-Tanana Terrane consists largely of Paleozoic continental margin and/or arc stratigraphy deposited on a continental basement of uncertain origin (Mortensen, 1992). The Yukon-Tanana Terrane in the Finlayson Lake area contains three major packages, collectively termed the Layered Metamorphic Sequence. The lowermost unit consists of garnet-mica schist with interbanded marbles, calc-silicates and calcareous schists near the top. The middle unit is a carbonaceous quartzite, schist or phyllite with rare conglomerates and locally extensive felsic and

mafic volcanic interbands. Radiometric dating of the felsic metavolcanics in the Finlayson Block has consistently resulted in Late Devonian to Mississippian crystallization ages. Immediately south of Finlayson Lake, large isolated outcrops of marble and quartzite which are poorly dated as Early Pennsylvanian to Early Permian (Tempelman-Kluit, 1979) form the uppermost unit of the Yukon-Tanana Terrane.

This sequence of units is generally correlative with a similar stratigraphic sequence in ancestral North America (Mortensen and Jilson, 1985; Tempelman-Kluit, personal communication, 1996). The lowermost is correlated with the Lower Cambrian Atan Group and the middle carbonaceous assemblage is correlated with the offshelf, Silurian-Devonian Nasina quartzite assemblage. The felsic volcanics are most similar to locally extensive Mississippian siliceous volcanics in the North American stratigraphy. Local calcareous phyllites and massive greenstones near the top of the lower unit are lithologically similar to the Kechika Group and Lower Paleozoic alkalic and potassic greenstones, respectively.

Gneiss and augen gneiss invariably occur low in the Yukon-Tanana succession beneath either the lowermost calcareous unit or the middle carbonaceous unit. Mortensen and Jilson (1985) considered the gneisses to be metamorphosed Mid-Paleozoic plutonic rocks. Conversely, Tempelman-Kluit (personal communication, 1996) considers these gneisses to be at least in part recrystallization of earlier stratigraphy. Radiometric dating of the gneisses has consistently resulted in Late Devonian to Mississippian ages (Mortensen, 1992). The gneisses occur in structural culminations with diameters on the order of 10 km and structural relief up to about 1 km.

The Devonian-Mississippian Simpson Suite (Mortensen, 1992) forms thick intervals of hornblende granodiorite and quartz monzonite higher in the Yukon-Tanana stratigraphic sequence. Mortensen and Jilson (1985) interpreted this suite as intrusive. Tempelman-Kluit (1979, personal communication, 1996) mapped the suite as an allochthonous slice emplaced on top of the structural pile.

Slide Mountain Terrane consists of Late Devonian to Late Triassic disrupted oceanic crust (Mortensen, 1992). Lithologies include massive and sheared greenstone, chert and mafic to ultramafic plutonic rocks. These units are most abundant near the Finlayson Lake Fault Zone along northeastern edge of the Finlayson Block where they are referred to as the Campbell Range Belt. Smaller ultramafic bodies within the Finlayson Block are enigmatic, with some mappers considering them to be thrust bounded slices of the Slide Mountain Terrane and others proposing they were intruded as sills into stratigraphy of the Yukon-Tanana Terrane.

Younger units unconformably overlie units from Slide Mountain, Yukon-Tanana and North American Terranes. Mesozoic clastic rocks are Late Triassic, immature sediments containing cobbles from both Slide Mountain and Yukon-Tanana Terranes. Young volcanic rocks consist of Late Cretaceous to Tertiary felsic volcanic flows and volcaniclastic deposits. They are usually found in close proximity to the Tintina Fault Zone.

Mesozoic intrusive activity in the Finlayson Block includes two main suites. The first is comprised of several unmetamorphosed Early Jurassic mafic and intermediate composition plutons. The second suite consists of Late Cretaceous two-mica quartz monzonite and granite (Mortensen and Jilson, 1985).

Structurally Yukon-Tanana schists and gneisses contain a pervasive, flat- to gently-dipping foliation. Close examination of this fabric indicates that it commonly is a closely spaced crenulation cleavage. Large scale folds related to this fabric can rarely be mapped in the field. In most cases bedding and earlier fabrics are transposed into near parallelism with this dominant fabric. Later crenulation cleavages are present only locally. Some of the Cretaceous intrusions have a mild deformation fabric, others are massive and do not contain a foliation.

Thrust faults within the Finlayson Block juxtapose lithologic sequences with similar deformation fabrics. Thrusting postdates the Late Paleozoic Slide Mountain lithologies and predates the Cretaceous intrusives. Recent mapping also suggests, but does not definitively prove, the presence of major late extensional faults juxtaposing differing sequences (Tempelman-Kluit, personal communication, 1996). East-northeast trending, steep normal faults disrupt all earlier deformation fabrics.

Metamorphic grades range from lower greenschist facies to middle amphibolite facies. Contact hornfels around plutonic units occur locally.

Metamorphism and deformation are tentatively correlated with transpressive suturing of these suspect terranes with ancestral North America. Suturing is restricted to the time interval of post-Triassic continuing into the Cretaceous. Whether deformation is continuous or sporadic has not been fully verified at present.

The discovery of the Kudz Ze Kayah and Wolverine Deposits within the Finlayson Block in the last few years (Johnston and Mortensen, 1994) has refocussed exploration activities in the

area. Both deposits occur within metasedimentary and metavolcanic sequences of the Yukon-Tanana Terrane and are associated with felsic volcanics present in the middle unit of that terrane.

During the 1996 field season regional mapping was done in the vicinity of the Kudz Ze Kayah Deposit by government mappers at 1:50,000 scale (Murphy and Timmerman, 1997). This work confirmed the general stratigraphic position of the Kudz Ze Kayah Deposit and assigned it to an undifferentiated felsic schist unit (Unit 3f). Murphy continued mapping to the south and east in 1997 to determine the regional extent of this favourable stratigraphy (Murphy, 1997). This work covered about two-thirds of the Goal Net property, specifically the western portion of the claim block due south of Kudz Ze Kayah. As a result of this program Murphy has identified a mafic volcanic unit (Unit 2m) and a second felsic metavolcanic unit (Unit 1f), both of which are located deeper in the Layered Metamorphic Unit and have potential to host VMS deposits.

REGIONAL MINERALIZATION

A total of fifty-one mineral occurrences have been reported within the Finlayson Block (DIAND, 1995). Of these, twenty-one are known or suspected to be volcanogenic in origin while veins, skarns and asbestos occurrences comprise most of the remainder. Although the better known volcanogenic occurrences are Kuroko-type, some Besshi-type mineralization is also present (Morin, 1981; Johnston and Mortensen, 1994) and the recently discovered Ice Deposit is Cyprus-type. Figure 7 shows the location of the Kudz Ze Kayah, Wolverine and Fyre Lake Deposits which are the main "type-deposits" for Expatriate's exploration at the Goal Net property. The three deposits are briefly described below.

The Kudz Ze Kayah (ABM) Deposit lies within Yukon-Tanana Terrane near the centre of the block (Cominco Exploration, 1995; Whiteway, 1995). It is a VMS deposit hosted by an overturned assemblage of felsic pyroclastics, aphanitic massive rhyolites and metasiliclastic rocks belonging to the middle unit of the Layered Metamorphic Sequence. Although both the sulphides and wallrocks are highly strained and exhibit pervasive schistosity, compositional layering in the vicinity of the deposit is relatively undeformed with a consistent, shallow north dip. Sphalerite, chalcopyrite and galena are the main economic minerals while the gangue includes various mixtures of magnetite, barite, pyrrhotite, pyrite and carbonate. The deposit averages about 18 m thick and has been traced 700 m along strike and up to 400 m downdip. Open pit mineable ore reserves are reported to be 11 million tonnes grading 5.9% zinc, 0.9% copper, 1.5% lead, 130 g/t silver and 1.3 g/t gold (Schultze, 1996). Preliminary studies suggest that satisfactory

lead, zinc and copper concentrates can be produced using conventional flotation processes (Cominco Exploration, 1995). The mineralization responds well to magnetic and electromagnetic surveys but geochemical response is somewhat erratic because the entire deposit is covered by 2 to 10 m of glacial till.

The Wolverine Deposit is located 25 km east of the Kudz Ze Kayah property near a contact between Yukon-Tanana and overlying Slide Mountain rocks. It consists of the Wolverine, Sable and Lynx Zones which are hosted by rhyolitic metavolcanics and argillites lying within the middle unit of the Layered Metamorphic Sequence. The mineralization consists primarily of semi-massive to massive pyrite and sphalerite with varying amounts of galena, chalcopyrite, tetrahedrite and native gold. The surface expression of the Wolverine Zone is marked by a vegetation kill zone containing weakly malachite-stained argillite while the Lynx and Sable Zones are blanketed by glacial till. Westmin has traced the deposit 700 m along strike and up to 450 m downdip. The mineralization averages about 6 m thick and dips shallowly to the north. The Sable Zone, which lies about 1500 m to the southeast, was discovered in late 1997 when two holes yielded high grade intersections over narrow widths. All three zones contain significantly more zinc and precious metals than Kudz Ze Kayah. The most recent geological inventory is reported to be 6,237,000 tonnes grading 12.66% zinc, 1.33% copper, 1.55% lead, 370.9 g/t silver and 1.76 g/t gold (Westmin News Release, January 15, 1998). Soil geochemistry outlined weakly to moderately anomalous values along the projected surface trace of the deposit while magnetic

surveys easily traced a laterally extensive, banded iron formation which occurs about 50 m up-section from the massive sulphide horizon. Interpretation of electromagnetic results is complicated by the presence of graphite within the argillite.

The Fyre Lake Deposit is located 3 km southwest from the southern edge of the Goal Net property. It is a Besshi-type VMS deposit hosted by chloritic±actinolite±quartz schist belonging to the middle unit of the Layered Metamorphic Sequence. The host stratigraphy is structurally overlain by phyllitic metasediments with a basal unit of quartz-chlorite-mica schist (Roberts, 1997). Drilling to date has identified three mineralized horizons within the Kona East and West Zones. Massive and semi-massive sulphide mineralization is contained within a 6 to 80 m section that has a drill-inferred length of 1500 m over an average width of 250 m (GCNL, 1997). Kona East intersections on the Lower Horizon averaged 1.2% copper, 0.12% cobalt and 0.77 g/t gold over 7 m while those found in the Upper Horizon averaged 1.9% copper, 0.12% copper and 0.53 g/t gold over 13 m (Columbia Gold Mines Ltd., News Release, December 2, 1996). Average grades and widths for Kona West mineralization are not yet available and Columbia Gold Mines Ltd. is currently in the process of establishing a resource estimate for the deposit as drilled to date.

REGIONAL GEOCHEMISTRY

Published geochemical data for the Finlayson Lake area are limited to reconnaissance scale stream sediment sampling conducted in the late 1980's by the GSC (Hornbrook and Friske, 1988; Friske et al, 1990). The sampling was done at an approximate density of one sample per 10 sq km. Each sample was analyzed for twenty elements including common indicator elements for VMS deposits such as copper, lead, zinc, silver and arsenic. Anomalous results were obtained from creeks draining some previously known VMS occurrences (DIAND, 1995, Yukon Minfile 105G/32, 34 and 40) but many others, including the streams draining the Wolverine Deposit, produced near background values. Anomalous results were also obtained from several drainages where there were no known mineral occurrences. Follow-up exploration has since located showings in many of the anomalous creeks with the most significant discovery to date being the Kudz Ze Kayah Deposit.

Expatriate was able to supplement the published reports with private data summarizing results of 1973 exploration managed by Archer Cathro on behalf of a joint venture. The reconnaissance prospecting and geochemical sampling program explored for lead-zinc mineralization in the lower unit of the Layered Metamorphic Sequence but because the data provide relatively uniform coverage over the entire region, it is also suitable for evaluating areas underlain by the favourable middle unit. The Archer Cathro samples included approximately 5000 soils and stream sediments collected at a density of approximately one sample per sq km. They were all analyzed for lead, zinc, copper and molybdenum. As might be expected, this closer

spaced sampling outlined many more areas of anomalous geochemical response than the government survey. Almost all of the known volcanogenic occurrences showed up as anomalies on this survey, including Kudz Ze Kayah, Wolverine and Fyre Lake.

The following table illustrates regional geochemical backgrounds for the metals and anomalous thresholds used for target selection.

GEOCHEMICAL BACKGROUNDS AND ANOMALOUS THRESHOLDS

		Anomalous Thresholds (ppm)			Peak
	Background	Weak	Moderate	Strong	Value
Copper	25	50	100	200	1720
Lead	30	50	100	200	>4000
Zinc	80	200	500	1000	>4000
Molybdenum	<1	2	5	10	65

Copper, lead and zinc are major metals in most VMS occurrences in the Finlayson Lake area and are obvious indicator elements. Molybdenum is present in anomalous quantities in the iron formation overlying the Wolverine Deposit (Meade, personal communication, 1995) and appears to be slightly enriched in the felsic metavolcanic rocks. Based on the geochemical signature in the vicinity of known occurrences its presence can be used to distinguish copper anomalies associated with volcanogenic mineralization from those derived from ultramafic rocks.

REGIONAL GEOPHYSICS

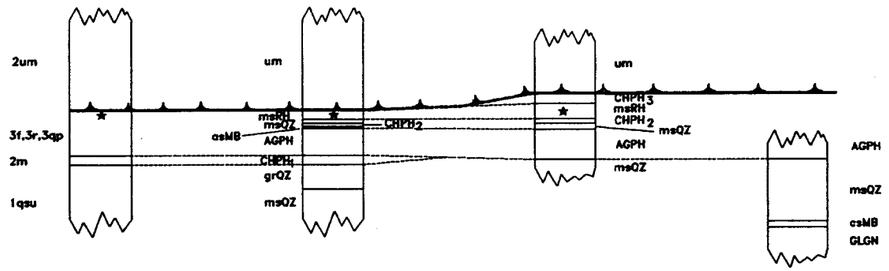

The only published geophysical data for the Finlayson Lake area resulted from airborne magnetic surveys conducted in 1961 by the GSC on behalf of the Department of Mines and Technical Surveys. The surveys were flown with fixed-wing aircraft at a nominal elevation of 300 m above ground level on east-west lines spaced approximately 1.6 km apart. Results are presented on a 1:250,000 scale map (DMTS, 1961) and in more detail on a series of 1:50,000 maps.

The largest, most intense areas of positive magnetic response are associated with obducted ultramafic rocks. Within the Campbell Range Belt where dips are usually moderate to steep, the anomalies are narrow and elongate while in the remainder of the block, where the ultramafic bodies dip shallowly, they are much broader.

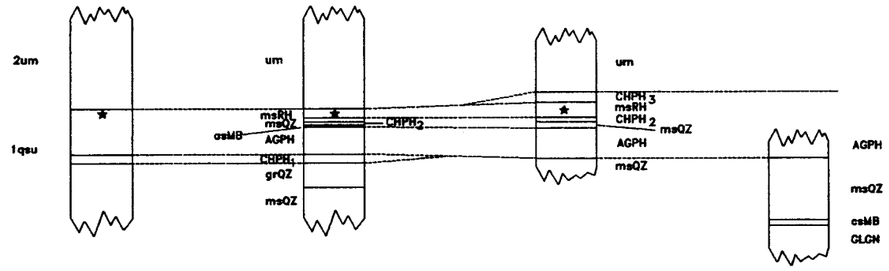

A series of secondary positive anomalies was also recorded over Yukon-Tanana rocks but until recently they had no obvious explanation. Prospecting and mapping have now shown that magnetite occurs locally within schists of the middle unit of the Layered Metamorphic Sequence. The greatest documented concentration of magnetite is found in the hanging wall of the Wolverine Deposit where it forms several thin horizons approximately 50 m up-section from the massive sulphide mineralization. Magnetite is also a significant constituent of the mineralization at Kudz Ze Kayah and Fyre Lake.

The Goal Net property covers areas of very strong magnetic response which closely coincide with flat-lying ultramafic bodies. In 1997 sub-horizontal magnetite horizons were discovered in felsic metavolcanic stratigraphy underlying some of the ultramafic bodies. These represent prime VMS targets while more subtle anomalies elsewhere on the property may also be significant.

STRATIGRAPHIC COLUMN AND STRUCTURAL INTERPRETATION

GOAL NET PROPERTY

DRAWN/REVISED BY: LCP/AG	PROJECT: FP
FILE: FP\GNET\ACAD97\MISC\STR-COL.DWG	DATE: DECEMBER, 1997

PROPERTY GEOLOGY

The Goal Net property occupies approximately 22,000 hectares in the central portion of the Finlayson Block. Detailed geological mapping was conducted in well exposed parts of the property between 1995 and 1997 by L.C. Pigage Consulting Limited and Expatriate geologists, as shown in general on Figure 8 and more detailed on Figures 9 to 12. The following section describes the main lithologies, their structural and stratigraphic relationships, their correlations with units mapped by Murphy in 1996 and 1997, and the primary structural features.

The main lithologies include metasedimentary and metavolcanic units belonging to the Layered Metamorphic Sequence and a variety of intrusive units. Most stratigraphy is relatively flat lying and exhibits a well developed foliation that trends northwesterly and dips gently to the northeast. Local variations from the general trend are described under specific targets in the Property Geochemistry and Mineralization section.

Although stratigraphic relationships between layered units observed on the property are well established, the actual position of those units within the Layered Metamorphic Sequence and the relationship between the layered units and an ultramafic intrusive unit are uncertain. Three structural interpretations proposed by Pigage are presented on stratigraphic columns (Figure 13). The main difference between these interpretations is the mechanism by which the ultramafic was emplaced on top of the layered stratigraphy. Interpretation 1 (the model adopted in the remainder of this report) assumes the ultramafic bodies are a klippe of Murphy's Unit 2 that are structurally emplaced by thrust faulting. This interpretation is supported by earlier mapping done by Tempelman-Kluit (1977)

and Mortensen (1985). Interpretation 2 involves redefining the underlying stratigraphy as Unit 1 rather than Unit 3 and having the ultramafic intruded as a conformable sill near the contact between Units 1 and 2. Finally, Interpretation 3 assumes that the ultramafic was emplaced as a sill within Unit 3.

Twelve units are mapped on the property. Seven are Mississippian or older stratigraphic units while the remainder are coeval or younger intrusions. The units are described as follows in approximate order of formation.

LITHOLOGY

Stratigraphic Units

Calc-Silicate Marble (csMB) is the lowest metasedimentary unit exposed in the map area. It is grey to white and coarsely crystalline with narrow (5 to 15 cm) green calc-silicate interbands constituting about 5% of the unit. The calc-silicate bands contain hornblende and epidote and are generally contorted and boudinaged. Muscovite-biotite schist and biotite-chlorite-actinolite phyllite are occasionally interbanded with the marble.

Quartzite (msQZ) conformably overlies the marble and is grey to tan, non-calcareous and slightly micaceous. Diffuse colour banding and foliations are well developed. Some foliations exhibit a purple tinge due to the presence of fine grained disseminated hornfels biotite. Thin selvages of pale green retrograde chlorite after hornfels biotite occur adjacent to some fractures. Narrow bands ($\leq$1m) are locally rusty weathering where pyrite and pyrrhotite are present. The quartzite unit is about 100 m thick and contains interbands of marble (10 cm to 5 m), chlorite-actinolite$\pm$calcite phyllite ($\leq$15m) and most importantly yellow to rusty weathering pyritic muscovite-quartz phyllite ($\leq$20 m) that is believed to be felsic volcanic in origin.

Carbonaceous Quartzite (grQZ) occurs as interbeds (up to 80 m thick) within the msQZ unit described above. It is dark grey, fine grained and pervasively foliated as defined by abundant brown biotite hornfels. Interbedded in lesser amounts with the carbonaceous quartzite are intervals of muscovite-quartz phyllite, biotite-chlorite phyllite and argillaceous marble.

Chlorite Phyllite ($CHPH_1$, $CHPH_2$, $CHPH_3$) is a mafic greenstone (1 to 40 m thick) that occurs conformably throughout the metasedimentary and metavolcanic stratigraphy in most parts of the property. Subunits are correlated to parts of Murphy's Units 2 and 3. The rocks are commonly olive-green, pervasively foliated and comprised of chlorite, biotite, actinolite and minor calcite. Quartz, garnet and epidote are also present in isolated localities. Occasionally the rocks are altered to pale tan quartz-carbonate-muscovite phyllite.

Feldspar Augen Phyllite/Carbonaceous Phyllite (AGPH) is a 50 to 90 m thick sequence of intimately interbanded tan to brown, feldspar augen phyllite and black carbonaceous phyllite. The feldspar augen phyllite is likely strained felsic volcanic. It consists of pervasively foliated feldspar, biotite, muscovite and quartz surrounding feldspar augens that are ≤ 1 cm across and constitute 1 to 5% of the unit. Locally the phyllite exhibits silver-tan to maroon alteration and is very fissile. Extremely quartz rich members are aphanitic, slightly micaceous, massive and resistant. Fresh exposures are pale cream to off-white while others are orange and rusty weathering. The carbonaceous phyllite is grey to black and often exhibits an irregular brown and orange patchy surface coating. This member is micaceous, highly fissile and constitutes about 30% of the unit.

Sandy Marble (asMB) is between 1 and 10 m thick and conformably overlies the AGPH unit. It is dark grey, thinly laminated and contains argillaceous partings which define foliation. Lithologically this unit ranges between a marble and a calcareous quartzite. In some locales it exhibits thin, foliaform, rusty weathering horizons containing disseminated pyrite.

Metarhyolite/Quartz Phyllite (msRH) occurs beneath the ultramafics (um) in most parts of the claim block. It includes black carbonaceous quartzite and phyllite interlayered with pale pink to grey, aphanitic, siliceous metarhyolite and rhyolitic phyllite. Metarhyolite interbands are greater than 5 m thick in places and locally weather rusty-orange. Some sections within this unit are lithologically similar to the AGPH unit.

Intrusive Units

Grass Lakes Augen Orthogneiss (GLAG) is the oldest intrusive unit (Mississippian) mapped on the property. It occurs at the base of the oldest metasediments and as narrow sills within them. The rocks are generally well foliated, grey weathering and competent. Augen include white feldspar up to 1 cm across and lesser quartz.

Grass Lakes Granite Orthogneiss (GLGN) is also Mississippian in age and occurs as large stocks and smaller sills within the metasedimentary rocks. It weathers grey to cream with an orange tint and typically forms large massive angular blocks. Fresh surfaces are tan to cream, fine grained and equigranular. Muscovite, biotite, quartz and feldspar comprise the main mineral assemblage. Mica defines moderately developed foliation but only constitutes about 5% of this unit.

Pyroxenite Ultramafic (um) occurs mostly as large thrust bounded klippe along ridge tops in the eastern part of the claim block. It consists of medium-grained, strongly magnetic, serpentinized, dark brown and green pyroxenite. The age of this unit is uncertain but is probably Mississippian.

Biotite Muscovite Granite (bmGR) is Cretaceous in age and is found in large stocks. This unit is grey to brown, medium- to coarse-grained and generally equigranular. It weathers to form large slabs or blocks and is usually unfoliated.

Quartz Feldspar Porphyry (qfP) comprises narrow Cretaceous to Tertiary dykes and plugs in the eastern and southern parts of the property. It is pale greenish grey and unfoliated. Biotite, pink feldspar and quartz phenocrysts up to 1 cm across are disseminated throughout a medium-grained feldspar matrix.

CORRELATIONS

The units described in the previous paragraphs have been correlated using Interpretation 1 (Pigage, 1997) with those identified by Murphy as illustrated on Table I.

TABLE I

Murphy	Pigage

Unit 2	$CHPH_1$
Unit 3	AGPH msQZ $CHPH_{2,3}$ asMB msRH
2 um	um
MGg	GLGN GLAG
Kg	bmGR
Td	qfP

STRUCTURE

The dominant structural fabric on the property is a pervasive, nearly flat-lying foliation which is subparallel with compositionally layering. Based on regional mapping (Murphy and Timmerman, 1997), Phase 1 foliation has been almost completely overprinted by Phase 2. The dominant Phase 2 foliation is generally axial planar to recumbent isoclinal folds, and forms gentle basin and dome patterns throughout the property. Crenulation cleavage is also present. Outcrop scale isoclinal and sub-isoclinal folding is preserved and clearly exhibited by quartz sweats and siliceous horizons in numerous exposures across the property. Phase 3 deformation consists of broad open folds which generally trend to the northwest.

The only regional scale fault is the suspected thrust which is believed to have emplaced the ultramafic bodies atop the layered units. Smaller scale, late stage brittle faulting affects most units. These faults are usually steeply dipping and east- to northeast-trending. Fractures associated with these features are randomly oriented and often infilled with quartz±carbonate vein material.

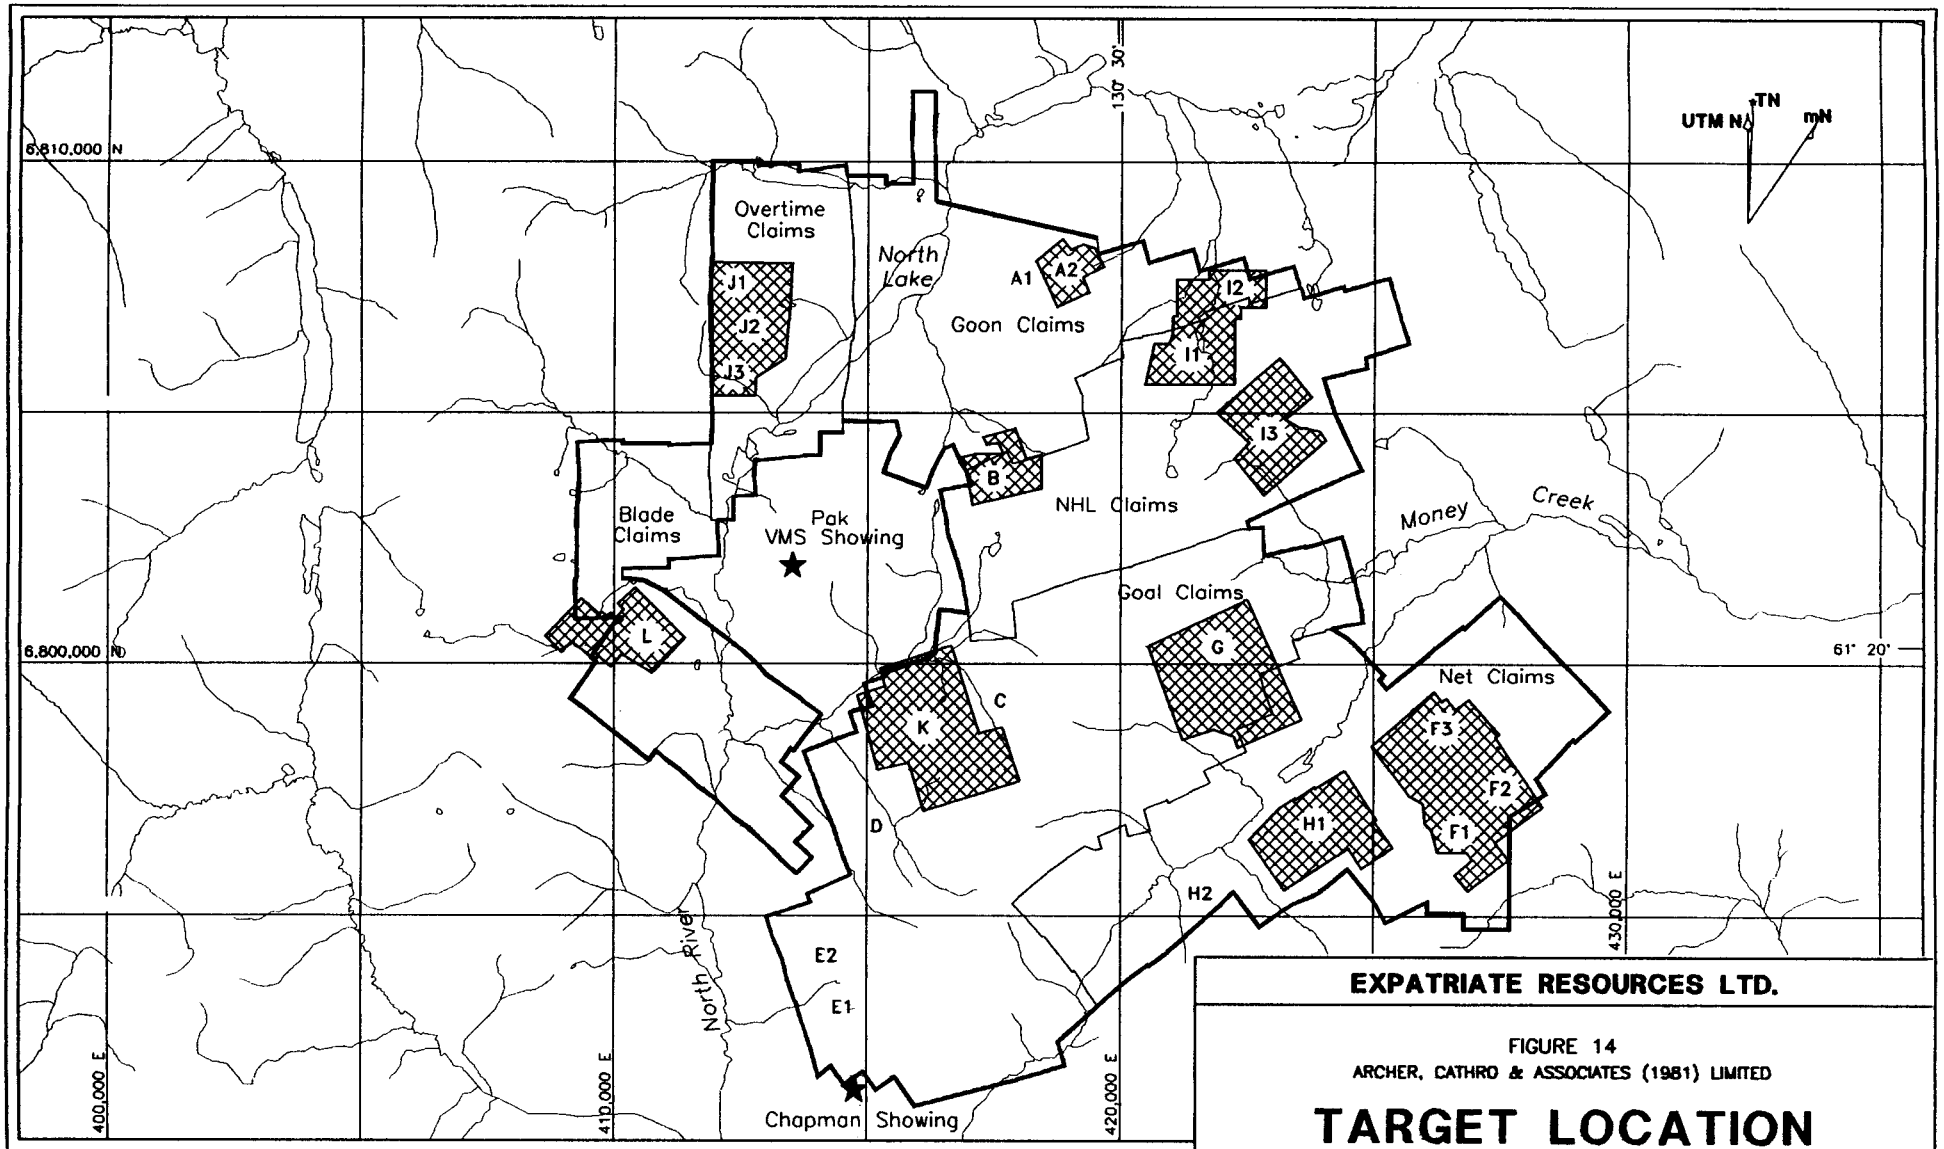

PROPERTY GEOCHEMISTRY AND MINERALIZATION

Geological mapping, reconnaissance and grid soil sampling, and prospecting from 1995 to 1997 have identified twelve targets (A to L) on the Goal Net property (Figure 14). Regional geological mapping has outlined three favourable VMS host lithologies (Unit 1f, 2m, 3f) within the Layered Metamorphic Sequence. Unit 3f consists of felsic metavolcanics hosting the Kudz Ze Kayah and Wolverine Deposits, while Unit 2m is composed of mafic metavolcanic rocks containing the Fyre Lake Deposit. Although no deposits have been discovered in Unit 1f, these felsic metavolcanic rocks are associated with strong soil geochemical anomalies and foliaform mineralization on other Expatriate properties in the Finlayson Block and are considered to be a favourable host for VMS mineralization. Table II categorizes individual targets on the Goal Net property into prospective mineralization types and assigns them to probable host units.

TARGET LOCATION

GOAL NET PROPERTY

SCALE 1:150,000

0 1000 3000 5000m

DRAWN/REVISED BY: TCB/AC	PROJECT: FP
FILE: FP\GNET\ACAD97\MISC\GN-TARGL.DWG	DATE: DECEMBER, 1997

General

Grid soil sampling has been performed on nine of the twelve targets over the past three years. Survey control on the grids is provided by slope corrected baselines that are cut to line-of-sight and marked at 100 m intervals with 1 m lath bearing aluminium tags inscribed with grid coordinates. Soil sampling was done at 100 m intervals on lines spaced 100 m apart. Sample sites are shown with 0.5 m lath and attached aluminium tags upon which are written grid coordinates and sample numbers.

Where possible, reconnaissance soil samples were taken at 100 m intervals along contour and claim lines. These sample sites are marked by either 0.5 m lath with aluminium tags displaying the sample numbers or orange flagging with the sample numbers written in felt pen.

All soil samples were sent to Chemex Labs Ltd. of North Vancouver where they were dried, screened to -80 mesh, digested in nitric-aqua regia and geochemically analyzed for 32 elements using the Induced Coupled Plasma (ICP) technique. Select pulps were analyzed for gold by fire assay and Atomic Absorption or tungsten using a tri-acid digestion followed by Atomic Absorption. Soil sample locations are illustrated on Figures 15 to 18 while contoured results for lead, zinc and copper are shown on Figures 19 to 30. Table III lists the anomalous thresholds for the contoured elements. Certificates of Analysis for 1997 data appear in Appendix III and those for earlier years are in previous reports (Wengzynowski, 1996 and Burgert, 1997).

TABLE III

Element	Anomalous Threshold Values (ppm) Weak	Moderate	Strong
Lead	50	100	200
Zinc	200	500	1000
Copper	50	100	200

Rock specimens and chip samples were collected from various locales within each target area. These locations are shown on the Mineralization Compilation maps, Figures 31 to 34, which also illustrate the areas of moderate or strong soil geochemical response for lead, zinc and copper.

Targets

Target A covers a west-facing cirque and upland plateau in the North Lakes area. Outcrop is rare except on cliffs near the headwall of the cirque. Talus or glacial till blanket bedrock in most parts of the target. Soil development is poor aside from a few areas on the plateau where bedrock is weathering in-situ.

Reconnaissance soil sampling and prospecting along contour and claim lines identified two specific areas of interest, one located in the cirque (A1) and the other on the plateau (A2).

Close spaced contour soil samples taken within the cirque (A1) generally returned low values even though massive and semi-massive pyrrhotite, pyrite and chalcopyrite skarn mineralization was found in several locations. The first showing was discovered in a talus chute along the headwall of the cirque in 1996. A specimen taken that year (N110344) returned 0.51% copper, 2.2 g/t silver, 550 ppm cobalt and 443 ppm nickel. Follow-up traverses in 1997

located other talus showings. A selected massive sulphide specimen (058246) returned 45.0 g/t silver, 3.50% copper, 0.09% zinc and 430 ppm cobalt while a 40 cm chip sample (058245) from a massive, fine-grained pyrrhotite float boulder yielded 1.0 g/t silver, 0.14% copper and 125 ppm cobalt. Although sulphide rich mineralization has not been observed in-situ, it is believed to be associated with garnet-diopside-calcite±hornblende±epidote skarn zones developed within Murphy's Unit 1. Samples (N111906 and N111913) were taken from 10 cm thick limonitic lenses exposed in skarn outcrops on a cliff and returned up to 8.4 g/t silver, 1.10 g/t gold, >1% copper and 116 ppm cobalt. There are a series of these lenses but they are all strongly contorted and none was traced for more than 5 m along strike.

Sampling over a 2400 by 1400 m grid on the plateau outlined an 800 by 800 m area comprised of coincident moderately to strongly anomalous zinc-copper values (A2). The strongest values are in a 500 by 300 m core surrounding a 50 by 20 m kill zone containing mineralized float. Peak soil values for zinc and copper were 6790 and 2160 ppm, respectively. Anomalous lead values are clustered in the core with peak values to 252 ppm. Although this target has not been systematically prospected, mineralization was discovered during the soil surveys. Foliaform disseminated galena, sphalerite and chalcopyrite occur in biotite-chlorite-garnet±quartz schist within a small outcrop near the head of the geochemical anomaly. A sample (058224) of this material yielded 103.0 g/t silver, 2.59% lead, 2.51% zinc and 840 ppm copper. Abundant strongly pitted, chalcopyrite rich quartz-carbonate float is scattered throughout the kill zone. The mineralization and pits are aligned parallel to foliation. Much of the float is coated

with malachite and azurite. Unfoliated white quartz vein float containing patchy disseminated chalcopyrite was also found within the kill zone. None of the mineralized float was sampled.

Target B lies in the same package of rocks as the Pak VMS showing located about 3.5 km to the southwest (Figure 14). The Pak showing consists of a massive pyrrhotite horizon with sphalerite and chalcopyrite laminae in isoclinally folded felsic and mafic metavolcanic rocks. The horizon is traceable for about 150 m along strike and varies between 0.3 and 2.5 m thick. A 3 m chip sample reportedly returned 34.3 g/t silver, 0.70% lead, 1.70% zinc and 0.7% copper while specimens yielded up to 54.9 g/t silver and 4.3% copper (DIAND, 1997). The showing is held by Westmin Resources Limited and Atna Resources Ltd.

Target B is situated along a ridge crest and in an adjacent north-facing cirque. Outcrop is common on cliffs below the ridge crest but most of the area is till or talus covered. Yellow, clay altered zones were mapped near the ridge crest and in a saddle at the head of the cirque. Although steep terrane precluded systematic sampling or detailed mapping on the upper zone, soil sampling was done on a 1200 by 1200 m grid in the alteration zone at the head of the cirque. Nearby soil samples taken along a claim line in 1996 were significantly elevated in copper, zinc and molybdenum. The grid survey outlined a 1200 by 1000 m area of anomalous copper response with values up to 656 ppm. The strongest part of the anomaly is situated immediately below the saddle and it appears that much of the anomaly is due to downslope or glacial dispersion. Zinc response is coincident with copper but most values are only weakly anomalous. Scattered

samples within the cirque yielded up to 3040 ppm zinc. Lead response is more localized than copper or zinc with the highest values (up to 840 ppm) occurring in a 600 by 300 m cluster near the top of the clay altered zone. The lead anomalies are most likely derived from the felsic metavolcanics in Murphy's Unit 3 but the highest zinc and copper response is in an area underlain by mafic metavolcanics assigned to Unit 2m.

Only limited prospecting has been carried out on this target. Sucrosic muscovite quartzite float containing foliaform disseminated sphalerite and galena was located near the base of the cliffs within the cirque. A specimen (N111976) returned 6.0 g/t silver, 0.75% lead and 1.02% zinc.

Target C has only received cursory exploration and consists of a large gossan bleeding out from a saddle into an eastern-facing cirque. Bedrock exposure is excellent on the western side of the saddle but non-existent on the east. The area is underlain by quartz-muscovite-biotite schist which is intruded by unfoliated dykes, sills and plugs.

Soil sampling along claim and contour lines outlined moderately to strongly anomalous copper values with weak zinc support in the vicinity of the gossan. No mineralization was discovered and examination of the gossan showed that it consists of crushed quartz and muscovite mixed with bright red-orange soil. This colour is typically associated with iron weathering from biotite schists elsewhere on the property. Abundant unmineralized white quartz vein material is also present in the vicinity of the gossan.

Target D has only been explored by two contour lines spaced 200 m apart. Two samples taken on the lower line returned strongly anomalous zinc values (1715 ppm) but near background values for other metals. A series of samples collected over a length of 600 m on the upper line also yielded moderate to strong zinc response. The highest zinc value (1570 ppm) also has strong copper support (226 ppm).

No detailed mapping or prospecting has been done in the area. A strong airborne magnetic anomaly lies uphill from the anomalous sample sites but this is likely explained by ultramafics mapped by Murphy.

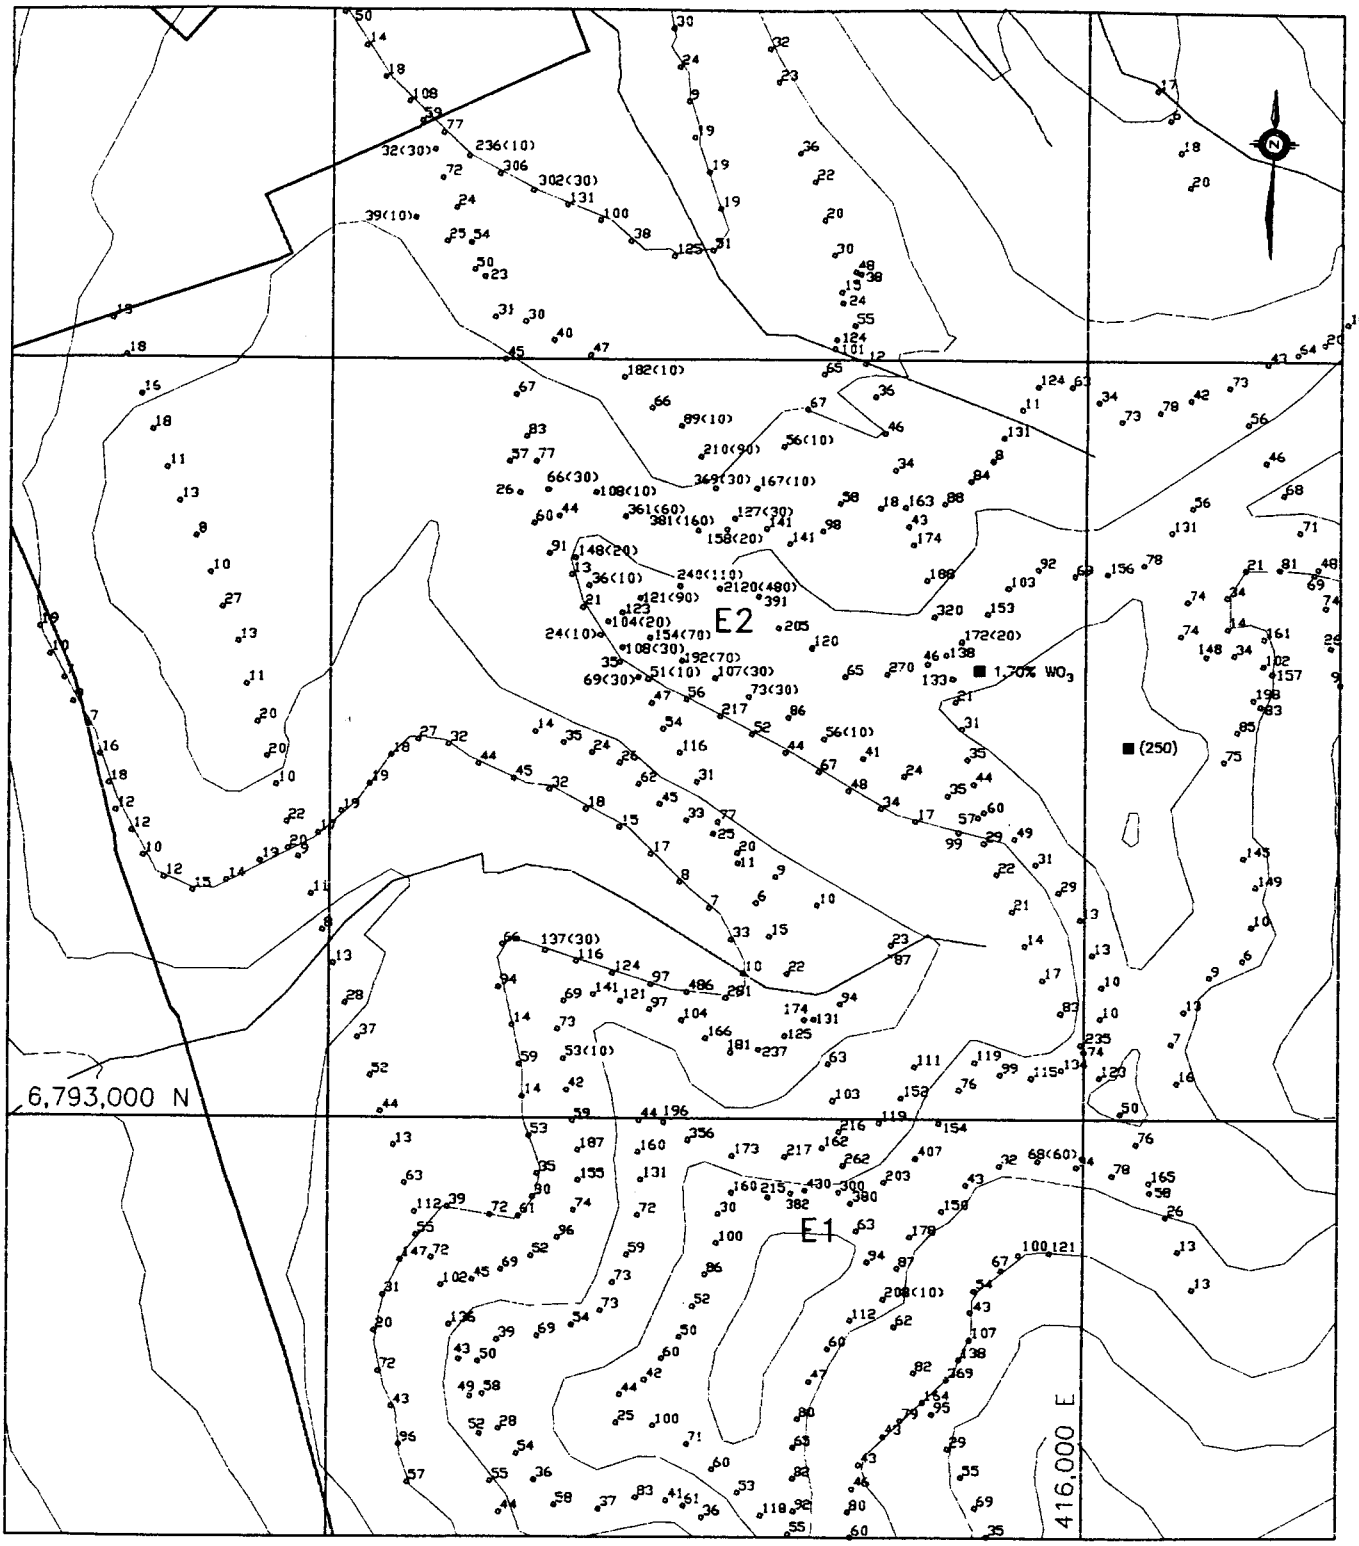

Target E covers several ridges in the extreme southern part of the property. Cliffs are common at higher elevations but talus and till blanket lower slopes and cirque floors. Many north-facing slopes are snow covered until mid to late summer. The target area is dominantly underlain by two sequences of ultramafic rocks, one of which is described by Murphy as a metagabbro. The ultramafics are overlain by an extensive mafic metavolcanic sequence (Unit 2m) which is in turn overlain by a thin package of felsic metavolcanic schists (Unit 3). A large Cretaceous stock borders the eastern part of the target while small Tertiary dykes are found in the centre of the area. Extensive soil sampling along contour and claim lines has identified two specific targets, E1 and E2.

E1 is highlighted by a 500 m string of strongly anomalous copper values (up to 430 ppm) taken along a northwest-facing slope. This sample line is topographically the highest of four lines defining the anomaly. Cursory prospecting within this anomaly discovered malachite and azurite stained mafic metavolcanic float (N111970) which assayed 1.4 g/t silver and 0.27% copper.

E2 lies about 3 km north of the Chapman showing (Figure 14) where scattered copper mineralization and two weak scheelite occurrences are reported in calc-silicate altered quartz-muscovite schist (Cathro, 1978 and 1981).

In 1996 reconnaissance soil sampling north of the Chapman showing identified several areas of anomalous copper response and prospecting located another tungsten occurrence. This showing consists of disseminated pyrrhotite and scheelite in an isolated skarn outcrop, a specimen from which (N11036) returned 1.7% WO_3. Several soil samples taken downhill from the skarn yielded moderately to strongly anomalous copper response but the best tungsten value was only 20 ppm.

In 1997 close spaced soil contour sampling was done over a 12 sq km area covering the previously discovered tungsten showings and nearby reconnaissance copper anomalies. This work outlined several clusters of moderately to strongly anomalous copper values. The most promising area (E2) lies about 500 m west of the tungsten skarn found in 1996 (Figure 35). It is located near the top of a northwest-trending ridge and consists of a 600 by 600 m area defined by coincident, strongly anomalous copper-tungsten response with peak values of 2120 and 480 ppm, respectively. The sample that produced the peak values also returned 18 ppm silver and 280 ppb gold. The soil at this site is iron rich but no mineralization was observed. E2 lies within a positive magnetic anomaly which may be caused by pyrrhotite in a skarn zone. The centre of the magnetic anomaly lies about 300 m to the west in an area that has not been soil sampled. No follow-up prospecting was done at E2 because results were obtained after the crew left the project area.

DETAILED COPPER-TUNGSTEN GEOCHEMISTRY TARGET E

GOAL NET PROPERTY

Scale 1:20,000

DRAWN/REVISED BY: AG	PROJECT: FP
FILE: FP\GNET\ACAD97\MISC\GN-CU-W.DWG	DATE: DECEMBER, 1997

Chalcopyrite-bearing float was found during soil sampling in one of the other clusters of anomalous copper response located near E2. The mineralization occurs as disseminations and foliaform wisps within quartz-biotite-chlorite schist (Unit 2m). A sample of this material (058227) returned 8.0 g/t silver and 1.04% copper.

Target F is underlain by a 350 m thick succession of metasedimentary and mafic to felsic metavolcanic rocks correlated with Units 2 and 3. Prospecting and grid soil geochemical surveys conducted within a 3000 by 2000 m area outlined three specific targets: F1, F2 and F3. The soil sampling covers a large northwest-facing cirque and adjacent south- or west-facing talus slopes. Bedrock exposure is good in the upper part of the cirque where cliffs are prevalent. Till and talus blanket the lower slopes and cirque floor. The entire target area lies within a relatively strong but poorly defined magnetic high. There are no EM conductors or resistivity lows in the area.

F1 is one of the largest soil geochemical anomalies on the property. It spans both sides of a northwest-trending ridge and, using the combined moderate copper, lead and zinc thresholds, covers an 1800 by 700 m area. Zinc is the most widely dispersed metal followed by lead and copper. Peak values for the three metals are 4700, 492 and 322 ppm, respectively. The anomaly is likely derived from a mineralized horizon either within or immediately below cliffs near the ridge crest. Numerous lead-zinc and copper float occurrences have been identified within the anomaly. Galena and sphalerite are most common in quartz-muscovite schist exhibiting varying degrees of carbonate alteration. The sulphides occur as thin foliaform wisps or disseminations. Specimens (935422, 058235, 935425) returned up to 83.0 g/t silver, 2.19% lead, 5.98% zinc and

0.47% copper. Mafic schist occasionally contains disseminated pyrite with minor chalcopyrite but none of this material was sampled. Magnetite-bearing muscovite-biotite schist float was also discovered along the banks of the creek draining the main cirque on the northwestern edge of the anomaly.

F2 is located about 1000 m northeast of F1 and is centred on a ridge crest along the north wall of the cirque. This 1300 by 600 m anomaly is defined predominately by zinc values with smaller lead clusters and sporadic copper response. Peak values for zinc, lead and copper are 3620, 500 and 210 ppm, respectively. The signature and setting of this anomaly is analogous to F1, however no mineralization has been located to explain it.

F3 is situated on a west-facing slope in the northwest corner of the grid. This anomaly is 500 by 100 m and trends north, parallel to topography. Peak values for lead, zinc and copper were 4960, 1025, and 274 ppm, respectively. No prospecting has been performed in this area.

Target G is a on a steep-sided northeast-trending ridge near the headwaters of Money Creek. Bedrock exposure is good. Stratigraphy includes multiple felsic metavolcanic horizons within quartzites, phyllites and gneisses correlative to Units 1 and 3. The basal lithology is foliated granite.

Grid and contour soil sampling covers a 2600 by 2000 m area centred on the ridge crest. Copper response is most extensive and outlines a 2000 by 1500 m arcuate anomaly which crosses the ridge crest and extends into cirques on either flank. The shape of the anomaly is consistent with a source horizon within the shallow northeast-dipping stratigraphy. Smaller clusters (up to

300 by 300 m) of coincident, moderate to strong lead-zinc response occur within the copper anomaly. Several of these clusters coincide with a large yellow-green clay altered zone exposed in a prominent saddle and an adjacent cirque. The alteration zone roughly parallels stratigraphy. A 2.0 m deep hand pit excavated into the zone bottomed in bright yellow muscovite rich clay, samples of which returned near background geochemical values. Strongly pyritic, clay altered muscovite schist and ferricrete breccia float were discovered nearby. Samples had high iron contents and were weakly elevated in zinc. A single fragment of banded sphalerite rich quartz-muscovite schist float (058219) found stratigraphically above the clay altered zone, yielded 1.0 g/t silver and 8.55% zinc.

Hand trenches were also excavated in the north-facing cirque across areas of anomalous soil response. Trench 1 was dug immediately uphill from a sample site that had yielded 62 ppm lead, 810 pm zinc and 60 ppm copper. Bedrock consists of rusty weathering quartz biotite schist from which four chip samples (N112206-209) returned an arithmetic average of 0.51% zinc over 6.5 m. Trench 2 is located at the head of the strongest combined lead (694 ppm)-zinc(1750 ppm)-copper (353 ppm) anomaly. Only small patches of bedrock were exposed which consist of biotite-quartz schist with chalcopyrite-bearing quartz veinlets. A specimen (N112213) of this material returned 0.6 g/t silver, 0.01% zinc and 0.05% copper. Trench 3 was excavated near the top of the cirque in the vicinity of the sphalerite-bearing float (058219). Approximately 5 m of stratigraphy was exposed consisting mainly of quartz biotite and quartz muscovite schist. Chip samples returned low values but a specimen (N112214) containing about 15% fine grained foliaform pyrite yielded 1.2 g/t silver, 0.16% zinc and 0.24% copper.

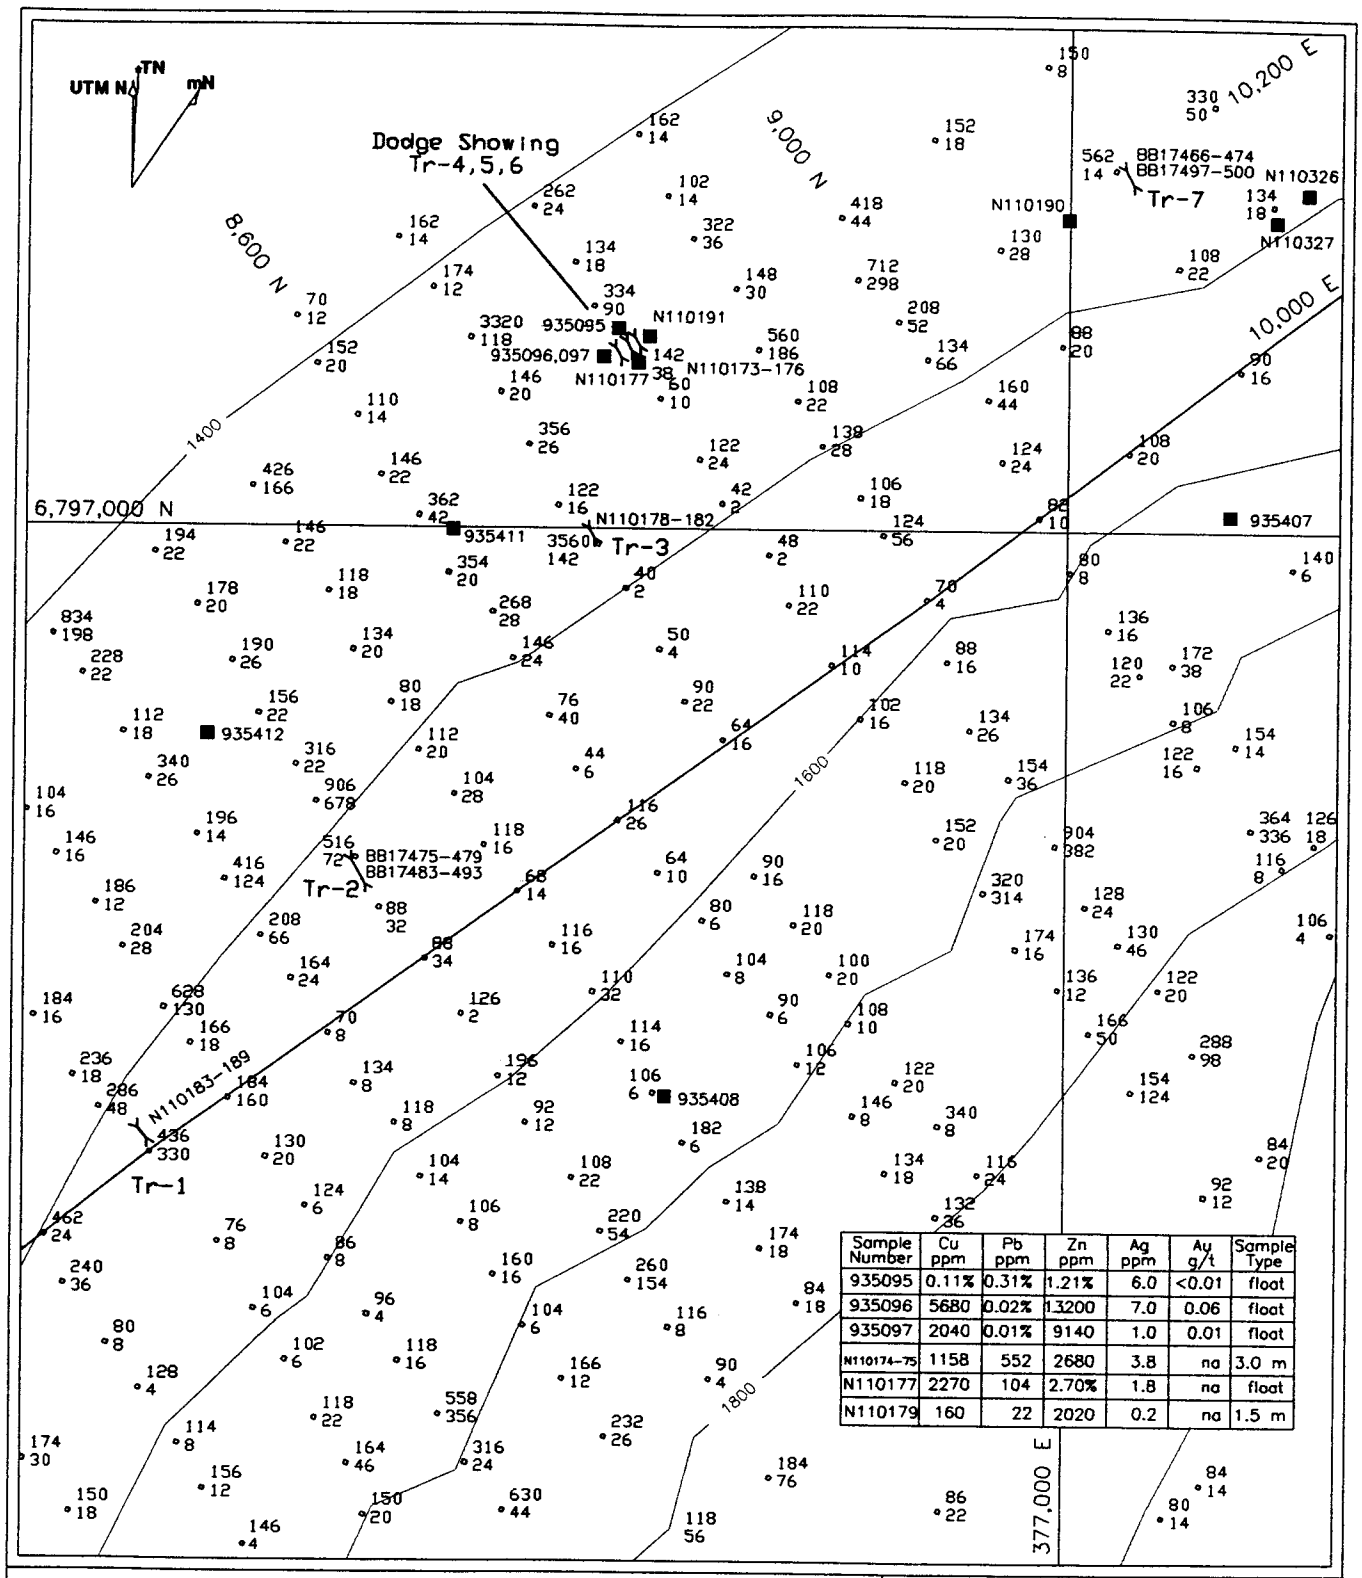

Magnetite- and chalcopyrite-bearing float was discovered near the upper edge of the geochemical anomaly in the eastern part of the cirque. The chalcopyrite forms thin wisps and blebs (1 to 2% of the rock) parallel to foliation while the magnetite occurs as medium-grained foliaform disseminations. A specimen (N112267) returned 0.21% copper. The float was traced uphill to a bedrock source consisting of a 4 m thick magnetite rich (10 to 15%) quartz-biotite-garnet gneiss horizon. The lower 1 m contains irregular concentrations of chalcopyrite and about 5% magnetite. This horizon has not been explored along strike but may represent an iron formation similar to the one at the Wolverine Deposit. It is likely the cause of a moderately intense magnetic anomaly defined by the airborne surveys.

Several small pieces of coarsely crystalline silicified skarn float containing fine grained, banded, partially oxidized sphalerite and galena were discovered at the base of cliffs approximately 1000 m west of the clay altered zone. A specimen (058221) returned 57.0 g/t silver, 4.40% lead and 2.94% zinc. This area was not thoroughly explored.

Prospecting was also performed about 1 km east of the soil grid in an area where contour sampling returned strongly anomalous lead, zinc and copper values. Stratabound sphalerite and galena were discovered within large (30 by 50 by 100 cm) felsic schist boulders being shed from cliffs above the sample site. A 50 cm chip sample (N112167) taken across one of the slabs produced 11.4 g/t silver, 0.86% lead and 0.29% zinc.. Select specimens (058217-218) yielded up to 24.0 g/t silver, 1.02% lead and 4.46% zinc. The felsic schist horizon is approximately 3 m thick at this location and pinches to about 50 cm some 300 m to the west where it disappears under talus. The horizon could not be traced to the east because of impassable cliffs.

Target H covers a series of northwest-facing slopes and cirques on a northeast-trending ridge. Most of this area is talus covered and soil development is poor. A pyroxenite ultramafic body sits atop the ridge and is underlain by metasedimentary and felsic and mafic metavolcanics belonging to Unit 3. Two specific areas of interest (H1 and H2) are located within the target area.

H1 is centred on a stratabound sulphide showing located in 1990 by a prospector who conducted hand trenching plus minor backpack diamond drilling (Dodge, 1990) . The showing is located at a break-in-slope near the valley bottom amongst alder and buckbrush. Float specimens reportedly assayed up to 0.48% lead, 1.65% zinc and 1.41% copper. Grid soil geochemical surveys performed by Expatriate cover a 2200 by 1400 m area extending uphill and along strike from the showing. Moderately anomalous lead, zinc and copper values form a 1400 m long southwest-trending zone which parallels the slope slightly uphill from the sulphide occurrence. Seven hand trenches were excavated along an 1100 m portion of the anomalous trend, as illustrated in Figure 36. Three trenches (Tr-4, 5 and 6) were dug along strike from the old showing at about 15 m intervals. Weakly disseminated sphalerite and galena were encountered within quartz-biotite-muscovite schist bedrock. Two chip samples (N110174-175) from one trench averaged 3.8 g/t silver, 0.05% lead, 0.27% zinc and 0.12% copper over 3.0 m while specimens returned up to 2.70% zinc.

Sample Number	Cu ppm	Pb ppm	Zn ppm	Ag ppm	Au g/t	Sample Type

TRENCH LOCATION TARGET H

GOAL NET PROPERTY

0 100 200 300m

DRAWN/REVISED BY: TCB | PROJECT: FP

FILE: C:\FP\GNET\ACAD97\TRLOC-H.DWG | DATE: DECEMBER, 1997

Tr-7, located 400 m northeast of the Dodge showing, consists of four hand pits excavated along a 15 m section upslope from a sample site that yielded 562 ppm zinc. Bedrock was not encountered in any of the pits and samples taken from pit profiles returned only weakly anomalous values for silver, lead, zinc and copper. Finely laminated barite-magnetite float was located in the vicinity of this trench site in 1996 but was not traced to source.

Tr-1, 2 and 3 are situated 700, 400 and 100 m southwest of the Dodge showing, respectively, and again consisted of a series of hand pits excavated uphill from anomalous soil sample sites. Pits at Tr-1 exposed unmineralized quartz-muscovite-biotite schist bedrock, samples of which returned low values. At Tr-2 four pits were excavated along a 23 m section of the slope. No bedrock was uncovered but samples from the base of the soil profile in the upper two pits were anomalous, returning up to 844 ppm zinc and 271 ppm copper. A 1.5 m chip sample (N110179) taken from Tr-3 returned 0.20% zinc. This trench was centred on a soil sample site which had yielded 3560 ppm zinc and 142 ppm lead.

Two other sulphide occurrences were discovered in the H1 area. A single fragment of chalcopyrite-bearing chert float was found uphill from the Dodge showing near the ultramafic and metasedimentary contact. This specimen (935408) returned 22.0 g/t silver, 0.55% lead, 0.58% zinc and 0.83% copper. The other occurrence is located 2 km to the east on the other side of a ridge. It consists of galena rich quartz-muscovite schist float, a specimen of which (935414) returned 77.0 g/t silver, >1.00% lead and 0.64% zinc.

H2 is composed of anomalous reconnaissance contour soil samples located about 2 km southwest of H1 on a northwest-facing slope. A series of samples taken over a 700 m length near the base of the slope produced moderately to strongly anomalous copper values with a peak of 412 ppm. Contour samples from further up the slope are also moderately anomalous. Lead and zinc response are near background in all samples. This anomaly has not been systematically prospected.

Target I is located in the northeastern part of the claim block and covers a number of excellent soil geochemical anomalies. It spans a series of ridges and cirques near the headwaters of Money Creek and the North River. Stratigraphy consists of a 400 m thick package of quartzites with interlayered felsic and mafic metavolcanic rocks sandwiched between a basement granite gneiss and an overlying ultramafic unit. The potential VMS host lithologies are correlated to Murphy's Unit 3f and include laterally extensive magnetite and more localized rhodochrosite horizons. Prospecting has identified multiple, shallowly-dipping magnetite horizons and has traced them intermittently for strike lengths of up to 500 m around the periphery of the ridge. Strong airborne magnetic anomalies in this area have been explained by the ultramafics capping the ridges, however the anomalies may be due in part to the underlying magnetite horizons.

In 1997 grid soil sampling was done in two parts of the target area where reconnaissance samples taken along claim lines had produced strongly anomalous values. This work identified three specific areas of interest (I1, I2 and I3). I1 and I2 are on the north grid which covers a 2000 by 1500 m area on the floor of a north-facing cirque, while I3 is on the southerly grid which tested an 1800 by 1600 m area on a southwest-facing slope.

I1 is consists of partially overlapping clusters of moderately anomalous copper-lead-zinc values within the southern part of the cirque. The combined moderate thresholds outline a north-trending anomaly approximately 1000 m long and 100 to 500 m wide. The narrowest section of the anomaly borders a lakeshore and is lead and zinc rich, while the wider part is at the base of cliffs and is elevated in copper and zinc. Clusters of less intense zinc and copper response have also been outlined to the west of the main trend and form an intermittent band approximately parallel to topography. The lead-zinc core of the main anomaly has not been systematically prospected but work immediately uphill from the copper rich portion discovered chlorite phyllite float with foliaform chalcopyrite and cuprite. This material is locally abundant at the base of the cliffs and specimens (059507-508) returned up to 19.0 g/t silver, 0.03% lead, 0.88% zinc and 2.53% copper. Foliaform sphalerite and galena float (2 to 5 cm thick) was discovered above the cliffs in orange weathering, carbonate altered quartz-muscovite schist but none of this material was sampled. Quartz-chlorite schist mineralized with disseminated magnetite (10 to15%) was found in the same area.

Several other showings were found adjacent to the grid in the southern part of the cirque. Magnetite rich calc-silicate float containing pyrite, galena and minor sphalerite was discovered in a steep talus chute near the southwestern edge of the grid. A specimen (058244) returned 16.0 g/t silver, 3.99% lead, 0.03% zinc and 0.09% copper. Massive, fine grained magnetite was also found in the area but was not sampled. Stratabound sphalerite and galena float was located some 600 m south and upslope from the grid at the base of a cliff composed of quartz-biotite-muscovite

schist and quartz-chlorite schist. Most of the float occurs within a 20 by 20 m area and consists dominantly of thin (5 to 10 cm) rotten, pitted schist slabs with abundant manganese and hydrozincite coatings. Sulphides are present on some fresh surfaces in float and outcrop, but none of this material was sampled. The apparent source of the mineralization lies approximately 80 m stratigraphically below a magnetite-bearing horizon.

I2 is located about 500 m northeast of I1 and covers part of a western-facing, till-covered slope. Soil sampling identified an approximately 650 by 200 m north-northeast trending lead-zinc-copper anomaly. Peak values were 3060 ppm lead, 1015 ppm zinc and 86 ppm copper. Prospecting prior to soil sampling discovered one piece (10 by 10 by 7 cm) of strongly pitted and hematite stained quartz-muscovite schist float (059509) which returned 18.2 g/t silver, 0.89% lead and 0.15% zinc. The soil anomaly approximately coincides with a strong magnetic anomaly which may be a result of thick ultramafic till that blankets most of the area.

I3 is 1100 m long and consists of three clusters of coincident lead-zinc response which parallel stratigraphy and topography. Lead exhibits strong response in each of the three clusters with peak values up to 954 ppm. Zinc and copper are generally less intense and returned peak values of 1910 and 133, respectively. Only limited prospecting was carried out along the anomalous trend. Thinly banded massive and disseminated magnetite float was located in talus near the southeastern end of the anomaly. One piece of orange weathering, strongly pitted and leached schist was also found in the same area. This float specimen (N111991) returned 12.0 g/t silver, 0.40% lead, 0.11% zinc and 2.04 g/t gold.

Hand pits and hand trenches were excavated across the three strongest areas of geochemical response at I3, as illustrated on Figure 32. The first group of pits is located near the southeastern end of the anomalous trend at grid coordinate 9+500N, 10+200E. The soil sample from this site yielded 242 ppm lead, 740 ppm zinc and 19 ppm copper. Fourteen pits were excavated uphill from this station at approximately 5 m intervals to an average depth of 1 m. Most pits bottomed in what is believed to be broken and rotated bedrock. Two soil samples were taken from each pit, one from mid-level and the other from the base. Pits 1 to 7, representing the lower 35 m of the excavations, returned elevated values for silver, lead, zinc, copper and molybdenum but the upper pits returned near background values. The second series of pits is located at 9+800N, 10+200E where a soil sample yielded 340 ppm lead, 1070 ppm zinc and 48 ppm copper. Sixteen hand pits were dug along a 97 m section of the slope above the anomalous site and encountered similar material to that observed in the hand pits previously described. Soil samples taken from the lower nine excavations (representing 56 m of the section) returned strongly anomalous values for lead and zinc. Samples from the pits further uphill again returned sharply lower values. An 11 m long hand trench excavated on the knoll at 10+200N, 10+200E encountered unconsolidated angular rubble intermixed with soil. Eight soil samples taken along the trench floor returned values up to 1.2 g/t silver, 3470 ppm lead, 2340 ppm zinc and 33 ppm copper. No bedrock or mineralization was exposed in this trench.

Prospecting at a similar stratigraphic level as the main anomalous trend was done on cliffs 1000 m southwest across the valley. This work discovered disseminated to wispy foliaform pyrite, sphalerite and galena in yellow weathering muscovite schist and disseminated pyrite and

chalcopyrite in quartz-chlorite schist. Sulphide rich float (058213) from this showing yielded 3.0 g/t silver and 4.03% zinc. Prospecting could not trace the float to source, however a 15 to 20 m thick horizon of similar, blonde weathering muscovite schist was mapped above the mineralized float.

Two showings were also discovered at Target I outside the specific areas on interest. A thin bornite rich calc-silicate skarn lens was located 2 km southeast of I3. This lens is only 10 cm thick and 1 m long. A chip sample (N111915) across the widest section (10 cm) returned 56.4 g/t silver and 2.25% copper. The other showing consists of ferricrete breccia float located 3 km southwest of I1. This occurrence was discovered while tracing magnetite and overlying rhodochrosite horizons south from I1. Samples of ferricrete breccia float (059506) were slightly elevated in zinc (2900 ppm). Reconnaissance contour soil samples taken along the slope for a length of 600 m in the vicinity of this occurrence produced moderately to strongly anomalous lead values with moderate zinc support.

Target J is located on the Overtime claims in the western part of the property. Mapping, prospecting and grid soil sampling have been performed in and adjacent to an eastern-facing cirque,

7 km southwest of the Kudz Ze Kayah Deposit. Stratigraphy is mapped as Unit 3f in the core of the target area with orthogneiss at lower levels. Three specific areas of interest (J1, J2 and J3) have been outlined on the 2500 by 1500 m soil geochemical grid.

J1 is a 1000 by 400 m eastern-northeast trending, moderately anomalous zone of coincident silver-lead-zinc-copper response. Peak values obtained for these metals were 24.6, 7580, 3120 and 412 ppm, respectively. The anomaly is situated along a ridge crest near the western edge of the claim block. Three hand trenches were excavated across a mineralized float train 100 m north of the strongest soil response. Mineralized specimens in the float train are comprised of medium-grained banded galena and lesser sphalerite in a quartz-muscovite matrix that exhibits small scale folds. A float specimen (N112222) returned 35.0 g/t silver, 17.90% lead, and 2.23% zinc . Only one hand trench reached bedrock. It exposed an 80 cm thick section of grey banded quartzite containing foliaform sphalerite and galena with an interbed of unmineralized biotite-chlorite schist. Chip samples across the entire 80 cm width returned a weighted average of 2.0 g/t silver, 0.84% lead and 0.97% zinc, while the best mineralized 30 cm (N112225) yielded 4.2 g/t silver, 2.10% lead and 1.73% zinc. The base of the mineralized section was not exposed because the lower end of the trench caved in.

Strongly oxidized and probably leached foliated metavolcanic float was located within an isolated silver-lead-zinc anomaly 400 m north of the trenching area. One specimen (N112221) was found and returned 324.0 g/t silver, 0.46% lead, 0.38% arsenic and 0.80 g/t gold.

J2 extends from a ridge top down a south-facing slope about 600 m south of J1. The anomaly covers a 700 by 400 m area and is dominantly copper-zinc rich. A foliaform sphalerite-bearing outcrop discovered in 1996 is located within the anomalous area on a cliff along the ridge top. Mineralization consist of fine- and medium-grained, brown and black sphalerite in a bleached

quartz-muscovite schist. Chip samples (N110201-208) taken over a 1.2 m width returned a weighted average of 0.8 g/t silver and 2.70% zinc, including a 20 cm sample in the core which yielded 12.30% zinc. The mineralized horizon is traceable for about 10 m before it is obscured by talus.

J3 is a 200 by 100 m copper-zinc anomaly located at the southern edge of the grid. Peak values obtained were 399 ppm and 880 ppm respectively. This area has not been prospected.

Target K is centred on the original Goal 1-24 claims where a soil geochemical grid was established in 1995. The grid covers a 2800 by 2000 m area centred on a north-trending ridge. The main drainage in the vicinity of the target originates within a north-facing cirque. The headwall of this cirque offers the only significant bedrock exposure and consists primarily of flat-lying Unit 1 stratigraphy with a very small exposure of Unit 2.

Clusters of weakly to strongly anomalous lead, zinc and copper values are scattered across the entire 2200 by 1000 m grid. The geochemical pattern in most areas suggests downslope dispersion from a mineralized source high on the ridge. The strongest lead response is localized near the ridge crest in a 1200 m long northwest-trending anomaly.

Prospecting in 1995 and 1996 identified minor disseminations of pyrite, pyrrhotite, sphalerite, galena and chalcopyrite in a high percentage of the float at the base of the cliffs around the headwall of the cirque. In 1997 massive and semi-massive sulphide float was found in a 30 by 3 m float train in the same area. Typical specimens consist of fine-grained massive pyrrhotite with disseminated and patchy sphalerite, galena and chalcopyrite. Fine quartz fragments are also

present and define a weakly lineated fabric. Specimens are as large as 20 by 20 by 20 cm. Samples (N111986, N111988) returned up to 36.0 g/t silver, 1.66% lead, 6.04% zinc and 0.49% copper . Limited prospecting was unsuccessful in delineating the source of the float train, however a 1 m thick horizon containing foliaform pyrite, sphalerite and galena was located in outcrop uphill from the float, just below the ridge crest. A specimen from the horizon (N110152) returned 3.0 g/t silver, 0.13% lead and 2.40% zinc. The mineralized horizon was not traced along strike due to impassable cliffs.

Two hand trenches and a series of hand pits were excavated along the ridge top in the areas which produced strong lead-zinc geochemical response. Tr-1 is located within a saddle in the western part of the grid where a soil sample yielded 2530 ppm zinc. The trench did not reach bedrock and no mineralized float was encountered. Tr-2 is located along the ridge where a soil sample returned 2720 ppm zinc and 118 ppm copper. This trench cut obliquely across local foliation and uncovered strongly oxidized quartz-biotite-feldspar schist with weakly disseminated foliaform sphalerite in bands up to 4 cm thick. A 0.8 m chip sample (N112196) returned 0.8 g/t silver and 0.45% lead. Hand pits dug downhill from Tr-2 failed to reach bedrock and did not encounter mineralized float. Narrow float trains containing rusty limonitic schist fragments were observed in the vicinity of the hand pits. A specimen of this material (059505) returned 12.4 g/t silver, 0.62% lead and 1.96% zinc.

Two other areas of mineralization were located approximately 2 km downslope from the head of the cirque along the banks of a creek. The furthest downstream showing was discovered

during follow-up prospecting of a soil sample site which had yielded 312 ppm lead, 2280 ppm zinc and 129 ppm copper. It consists of two outcrops about 20 m apart in a till covered area. Coarse-grained, sucrosic biotite-muscovite-quartz-feldspar schist with disseminated brown sphalerite and abundant hydrozincite was located on the eastern bank of the creek adjacent to the soil sample site. No samples of this material were analyzed. An outcrop of rusty weathering metaquartzite with limonite filled fractures was discovered just downstream. Chip samples (N112258-261) taken across foliation over a 4.0 m width returned a weighted average of 1.7 g/t silver, 0.08% lead and 0.35% zinc. The second area of mineralization was discovered about 800 m upstream and consists of coarse granular quartz-biotite-muscovite schist with foliaform pyrite, pyrrhotite and sphalerite. One specimen (N111990) taken from a rusty weathering subcrop returned 12.0 g/t silver, 0.23% lead and 4.16% zinc.

Target L is located in the far western part of the property on the Blade claims and is centred on a north-trending ridge. Bedrock exposure is restricted mainly to the ridge top and cliffs immediately below it. Slopes on either side of the ridge below the cliffs are generally talus covered and soil development is poor. Most of the target area is underlain by Unit 1 schist and metaquartzite. The upper part of the ridge is capped by mafic metavolcanic stratigraphy of Unit 2.

Grid soil sampling covers a 1500 by 1500 m area, most of which is located on a northwest-facing slope. Copper response forms a 1000 m arcuate band around the ridge crest and

approximately coincides with the mafic metavolcanic rocks. Zinc and lead form clusters within the copper band with the strongest lead values scattered along the uphill edge of the anomaly. Cursory prospecting within the area of anomalous response discovered weak malachite staining on quartzite outcrop. Specimens returned only slightly elevated copper values.

SUMMARY AND RECOMMENDATIONS

Exploration on the Goal Net property has identified a number of exceptional VMS targets within the same stratigraphic package which hosts the nearby Kudz Ze Kayah, Wolverine and Fyre Lake Deposits. Geochemical response is stronger on some of the targets than is reported from the known deposits. Although several mineral occurrences have been discovered and VMS-related features (such as the magnetic horizons and clay altered zones) have been mapped, specific drill targets have not yet been defined.

The next phase of exploration should consist of detailed geological mapping and prospecting coupled with extensive hand trenching. The work should be performed from a series of fly camps between mid-June and September. The highest priority should be assigned to Targets E, F, G, I, J and K.

Respectfully submitted,

APPENDIX I

AUTHOR'S STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

I, W. Douglas Eaton, geologist, with business addresses in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in North Vancouver, British Columbia, do hereby declare that:

1. I graduated from the University of British Columbia in 1980 with a B.Sc. majoring in Geological Sciences.
2. From 1971 to present, I have been actively engaged in mineral exploration in British Columbia and Yukon Territory and on June 1, 1981, I became a partner in Archer, Cathro & Associates (1981) Limited.
3. I have been a Director of Expatriate Resources Ltd. since May, 1993.
4. I have personally participated in or supervised the field work reported herein and have interpreted all data resulting from this work.

W. Douglas Eaton, B.A., B.Sc.

APPENDIX II

GPS DATA

Goal Net Property

GPS Survey Coordinates

Data Quality: Standard = The surveyed positions were recorded in 3D mode and were differentially corrected. The reported UTM coordinates are within 1 to 5 meters of their actual locations; Poor = >25% of the surveyed positions were recorded in 2D mode; Uncorrected = The surveyed positions were not differentially corrected; N/S = No survey data available.

Base Station: W = Westmin Resources Limited base station at Wolverine Lake; WL = Ministry of Environment, Lands and Parks base station at Williams Lake; DL = Ministry of Environment, Lands and Parks base station at Dease Lake; RR = Department of Renewable Resources (Forestry) base station at Whitehorse.

F2 Target referred to in text

N111991 Rock sample location with sample number

Hand trench

Soil geochemical grid outline

093788

Moderate threshold for copper soil geochemistry

Moderate threshold for lead soil geochemistry

Moderate threshold for zinc soil geochemistry
