INTRODUCTION

Diamond drilling was conducted in 2006 to provide an accurate assessment of the potential of the Corduroy Ridge area, located 4 km east of the Division Mountain coal deposit. Excavator trenching in 1996 and follow-up reverse circulation drilling in 1999 provided encouraging results but coal quality values from analyses of the samples that were collected then were suspect due to contamination.

The Division Mountain area is located 85 km north-northwest of Whitehorse in south central Yukon Territory. Access is by a 31 km four-wheel drive road leaving the Klondike Highway at Braeburn. The main area of exploration interest lies 20 km west of the highway and the Yukon Energy Corporation electrical transmission grid. This point is 280 km by road from a year-round deep sea port at Skagway, Alaska.

Exploration at Division Mountain has been directed toward outlining sufficient resources to support an export thermal coal mine and/or a 20 MW to 50 MW generating station for a period in excess of twenty years. Exploration on the property between 1972 and 1999 consisted of 10.2 km of excavator trenching, 64 diamond drill holes totaling 10,555 m and 20 reverse circulation percussion drill holes totaling 1869 m. A March 9, 2005 resource evaluation by Norwest Corporation (Becker, 2005) calculated a National Instrument 43-101 compliant Measured and Indicated Resource of 51.6 million tonnes of High Volatile "B" bituminous coal. Calculated weighted averages for Division Mountain raw coal are 2.4% residual moisture, 27.9% ash content, 26.3% volatile matter, 43.6% fixed carbon, 0.45% sulphur and a calorific value of 5140 cal/g on an air dried basis.

The 2006 exploration program at Corduroy Ridge consisted of four diamond drill holes totalling 805.9 m in length. This report documents the results of that work. The 2006 program was managed by Archer, Cathro & Associates (1981) Limited on behalf of Cash Minerals Ltd.

Territorial Coal Exploration Licences encompassing the Division Mountain and Corduroy Ridge areas were acquired by Cash Minerals Ltd. in October 1992. These are held under renewable three year terms.

PROPERTY, LOCATION AND ACCESS

The Corduroy Ridge coal prospect is located in Whitehorse Mining District in south central Yukon, 20 km southwest of Braeburn, Yukon at 61°19'N and 135°57'W on NTS map sheet 105E/05 (Figure 1). Braeburn is 100 km by all-weather highway from Whitehorse and 280 km from the deep sea port of Skagway, Alaska.

Because the 2006 diamond drilling was carried out during the period of spring break up, access was by helicopter from the Klondike Highway at the Braeburn airstrip. Access at other times of the year is by a rough 20 km four wheel drive road leaving the Klondike Highway at Braeburn. Accommodation for the exploration crew was at the permanent Division Mountain base camp located near the Nordenskiold River, about 9 km northwest of the Corduroy Ridge area. Crew travel between the camp and drill was by ATV.

2006 PROGRAM

The 2006 exploration program on the Corduroy Ridge coal prospect consisted of four diamond drill holes (Holes 06-96 to 06-99) totalling 805.9 m. Drilling was carried out between May 8 and June 14, 2006. The work was managed by Archer Cathro and supervised by the author.

Appendix I contains the Author's Statement of Qualifications. The following Archer Cathro personnel were involved in the program:

Rob Carne	Project supervisor
Dirk Moraal	Site manager
Alex McKinnon	Truck driver for camp demob
Wes Huston	Truck driver for camp demob
Martine LeLevier	Cook

Drilling was contracted to Superior Diamond Drilling Inc. of Peachland, B.C. using a Mandrill 1200 wireline-equipped diamond drill. The drill and all related equipment were removed from the site at the close of the program. A summary of the drilling is given below.

Helicopter support was provided by Trans North Helicopters and Capital Helicopters from their bases at Whitehorse, Yukon using a combination of Bell 206, Bell 205 and AStar 350B2 helicopters, depending on availability.

All core sampling and core logging was done on site. Coal intervals were collected in whole and sent to the SGS Canada Inc. Mineral Services laboratory in Delta, B.C. for coal quality analyses. The drill core is stored on the property at the camp location.

GEOLOGY

Geomorphology

Topography in the Division Mountain area is characterized by rolling hills and broad river valleys with local regions of moderate to steep relief along northerly trending ridges (Figure 2). Elevations range between 670 and 1680 m. Most of the area is mantled by glacial till and outwash between 1 and 60 m thick. Permafrost is generally restricted to poorly drained areas of moderate to dense vegetation. Natural bedrock exposure is less than 5%, especially within the generally recessive coal measures.

Regional Geology

The Division Mountain area lies within Whitehorse Trough, a northwest trending, fore-arc basin comprised of Mesozoic volcanic and sedimentary rocks. Bounded by the Omineca Crystalline Belt to the east and the Coast Plutonic Complex to the west, the Whitehorse Trough constitutes the northern end of the Intermontane Belt of the Canadian Cordillera.

During Late Triassic time an island arc assemblage consisting of a 7,000 m thick succession of Lewes River Group aphyric to augite-phyric basaltic andesite flows, breccias and tuff, conglomerate, wacke, limestone and shale was deposited within Whitehorse Trough. Succeeding Jurassic basin-fill stratigraphy is more complex due to disconformities and hiatus in sedimentation and to diachronous or interfingering relationships in the shallow water and nearshore facies. In general, two coal bearing sequences are present: Lower to Upper Jurassic conglomerate and sandstone turbidites of the marine to deltaic Laberge Group; and, Upper Jurassic to Cretaceous conglomerate, sandstone and mudstone of the largely alluvial Tantalus Formation.

Stratigraphy

Generalized geology of the Division Mountain area is given on Figure 2. A cross section through the Corduroy Ridge area generated from 2006 diamond drill and 1999 reverse circulation drill data is shown in Figure 3.

The Laberge Group in the Division Mountain area is represented by the shallow marine Lower Member of the Tanglefoot Formation and the fluvial-deltaic, coal bearing Upper Member of the Tanglefoot Formation. The lithologically distinctive Lower Member serves as an easily

recognizable base for the overlying coal measures. Brown weathering black mudstone, with wispy siltstone to fine sandstone laminae in the form of low amplitude cross-stratification, alternates with thick (>10 m) intervals of massive brown weathering calcareous sandstone. A Lower to Middle Jurassic depositional span is recorded elsewhere in Whitehorse Trough for the unit but since this sequence is likely diachronous, being a record of a nearshore facies that migrated with basin fill, the precise age of the Lower Member in this area will remain unknown until it can be locally constrained by paleontological data.

Middle to Upper Jurassic Tanglefoot Formation Upper Member strata in the Division Mountain area record a complex fluvial-deltaic depositional environment. In general the unit consists of upwardly fining sequences of alternating sandstone-conglomerate beds and black shale or shaly mudstone, the latter commonly associated with coaly shale or coal seams. A section measured at Red Ridge, northwest of Division Mountain consists of 15 sedimentary cycles, each on the order of approximately 10 m thick. From base to top, a typical cycle consists of:

- a scour-based arkosic pebble conglomerate containing fossils, twigs and branches lying transverse to paleoflow along 1 to 2 m trough foresets;
- conglomerate lags infilling troughs as lenticular beds;
- a fining-upward zone of medium to fine grained arkose containing trough cross-beds which exhibit an upward decrease in set size;
- grey organic rich shale or shaly mudstone containing leaves, grasses and *Metasequoia* needles and twigs;
- coaly shale to shaly coal, commonly rich in coalified twigs and branches;
- banded coal; and,
- either a transition back to grey shale or an abrupt termination by the basal pebbly conglomerate bed of the next cycle.

The depositional environment was one of a rapidly aggrading flood-dominated delta. Cross-bedded conglomerate-sandstone cycles represent point-bar deposits from a high energy fluvial system. Paleocurrent variance supports a meandering river interpretation. Of particular interest is that, despite the generally coarse-grained nature of the channel sandstones and conglomerates, the overbank deposits and related coals are relatively thick and demonstrate remarkable lateral continuity. The coal seams were deposited in long-lived delta plain swamps that served as collection sites for transported organic material and for generation of peat bogs. Toward the Tanglefoot-Tantalus contact, coal becomes less abundant. Instead, grey shale and coaly shale predominates as much thinner beds than the coal seams lower in the succession.

Resistant beds of thick-bedded chert pebble conglomerate of the Upper Jurassic to Lower Cretaceous Tantalus Formation cap the Tanglefoot Formation Upper Member coal bearing sequence, forming prominent topographic highs in the region. Depositional environment of the Tantalus Formation appears to be one of an active flood plain. Coal has previously been mined at the base of the Tantalus conglomerates 100 km to the north of Division Mountain in the

Carmacks region. Coal float has been found in the vicinity of gopher holes in areas underlain by the Tantalus Formation at Division Mountain and Red Ridge but to date none has been found in bedrock.

Small stocks, dykes and sills of porphyritic basalt, andesite and dacite intrude the Tanglefoot Formation coal measures. The presence of glassy chill zones and rare amygdaloidal textures are indicative of emplacement in a near-surface setting. Age of the intrusions is unknown but they are probably related to regionally extensive volcanic rocks of the Upper Cretaceous Carmacks Group, which unconformably overlie the Laberge and Tantalus stratigraphy in the Division Mountain area.

Structural Geology

Deformation in the Whitehorse Trough occurred primarily as flexural slip folding during the Middle Cretaceous. Synclinal and anticlinal axes trend north-northwest, parallel to the trough axis. Fold wavelengths are generally between 500 m and 2 km, although complex tight folds with wavelengths less than 3 m have been noted. The coal bearing Cairnes Syncline forms the core of the Division Mountain coal deposit. It trends 310° and plunges 9° to the northwest (Figure 2). The syncline limbs dip between 25 and 72°. Diamond drilling in 1997 concentrated on the coal rich east limb of the Division Mountain Syncline about 2 km south of the Cairnes Syncline. This syncline also trends approximately 310° with the east limb dipping 45 to 55° to the southwest. Exploration to date has not yet defined either the fold nose or the western limb of the Division Mountain Syncline.

The folded stratigraphy has only been slightly modified by northwest and northeast trending normal faults with minor dip slip displacements.

Trenching and reverse circulation drilling in the vicinity of Corduroy Ridge exposed northeast dipping coal and Tanglefoot Formation Upper Member stratigraphy. This is probably a fold repeat of the Division Mountain and Cairnes Syncline coal bearing sequences. Bedrock exposure is severely limited within the Tanglefoot coal measures due to glacial till cover, but the well exposed overlying Tantalus conglomerates suggest that a six kilometre long, steeply east dipping sequence of the Tanglefoot Upper Member stratigraphy may be present at Corduroy Ridge.

GEOLOGY OF THE COAL MEASURES

The four holes drilled at Division Mountain were oriented to provide a cross section across the coal bearing Upper Member of the Tantalus Formation. Location of the cross section is shown on Figure 2. Geology of the drill section with locations of coal samples taken from drill core are shown on Figure 3. Drill core geology is given in detail on the diamond drill logs (Appendix II). Complete analyses are given in the Certificate of Analysis (Appendix III). Intersected widths of

coal are close to probable true widths.

The four 2006 diamond drill holes at Corduroy Ridge provide a complete stratigraphic section across the upper 580 m of the Upper Member of the Tanglefoot Formation. The base of the unit was not exposed. Results of the drilling show that coal occurs in two settings within the Upper Member.

The top 380 m of the Upper Member was intersected by holes 06-96, 06-97 and the first 30 m of hole 06-98. Twenty-eight coal seams were intersected. Stratigraphy is dominated by medium bedded, well sorted sandstone with minor mudstone beds near the top. Numerous thin seams (<50 cm) of coal are present near the top of the unit, giving way downsection to episodic cyclic concentrations of thin to moderately thick (1.00 to 1.99 m) coal seams. Nine of the 28 seams contain low ash (<14%) coals that may be suitable for a direct shipping thermal coal product (Table II). The most significant intersections were **Seam 4** (2.06 m thick, 11.66% ash, 6754 Kcal/Kg calorific value) and **Seam 23** (1.97 m thick, 13.44% ash, 6503 Kcal/Kg calorific value).

A 200 m stratigraphic thickness of the middle part of the Upper Member was intersected by holes 06-98 and 06-99. Stratigraphy is dominated by medium to thick bedded sandstone with minor conglomerate giving way at depth to increasingly coarse grained sandstone and conglomerate. Coal seams are much less frequent, but generally thicker. Ash contents are significantly greater than those for seams higher in the section, reflecting thin inseam partings of sandy or shaly material. Significant intersections include **Seam 36** (5.65 m thick, 23.13% ash, 5608 Kcal/Kg calorific value), **Seam 37** (4.43 m thick, 18.93% ash, 6026 Kcal/Kg calorific value) and **Seams 34-35** (1.41 m thick, 19.02% ash, 5959 Kcal/Kg calorific value and 1.41 m thick, 24.54% ash, 5464 Kcal/Kg calorific value, respectively, which are separated by a 19 cm sandstone parting).

The only significant test of lateral continuity of coal seams at Corduroy Ridge was at the west end of the drill cross section where Seams 34-35, 36 and 37 were intersected at a shallow depth by 1999 reverse circulation hole 99-74, at a moderate depth from surface by hole 99-76 (which was twinned by hole 06-99) and at about 200 m down the dip from surface by hole 06-98 (Figure 3). All three seams decrease in aggregate thickness from roughly 15 m in hole 99-74 to only 1.85 m in hole 06-99, over a distance of 120 m down the dip. This lack of lateral continuity has been observed at the Division Mountain deposit, especially where conglomerates are present - an indication of relatively high energy depositional environments.

The base of the Upper Member of the Tanglefoot Formation, where the bulk of the Division Mountain reserves are located, was not intersected by the 2006 drilling on Corduroy Ridge. Holes 99-74 and 99-75 intersected an 80 m thick andesite sill. Similar intrusions occur near the base of the coal bearing stratigraphy at Division Mountain where there are significant coal seams at a deeper stratigraphic level, near the base of the Upper Member. This potential was not addressed by the 2006 drilling. A proposed 250 m diamond drill hole that would complete the

Coal seam with less than 14% ash (AD)

stratigraphic investigation of the Upper Member is shown on Figure 3.

The relatively thin Lower Member of the Tantalus Formation is the host of past-producing coal mines at Carmacks, some 100 km north of Corduroy Ridge. These strata have never been directly tested by drilling or trenching at Division Mountain although there are several recorded occurrences of associated coal float in the region. A 160 m deep diamond drill hole that would test this interval is shown on Figure 3.

Coal seams intersected by the 2006 diamond drilling dip to the northeast at 63°. This attitude is concordant with the overlying well exposed Tantalus Formation conglomerates. At the southwest end of the diamond drill section (Figure 3), dips of the coal seams and enclosing stratigraphy flatten to about 20°, a much more favourable attitude for surface extraction. This flattening may simply be a homoclinal feature on the east limb of a much larger anticline that underlies the Klusha Creek (Figure 2), or it may be evidence of a smaller scale anticline-syncline pair on the flank of the larger fold. This type of structural setting allows for the relatively low stripping ratio for the Division Mountain deposit where the host Cairnes Syncline occurs as a parasitic fold on the east limb of the regional scale Division Mountain Syncline.

RECOMMENDATIONS

The methodology developed over 15 years of exploration at Division Mountain is bedrock mapping to define areas of interest, excavator trenching to reveal structural geology and the presence or absence of potentially economic thicknesses of coal, and diamond drilling to recover uncontaminated samples of coal for coal quality analyses. This is recommended as the best approach for further work at Corduroy Ridge. The initial phase of exploration should be detailed geological mapping of the Corduroy ridge area to identify specific areas that are potentially underlain by strata of the Tanglefoot Formation Upper Member. This should be followed up with excavator trenching on section lines spaced initially at 300 m with infill at 150 m as required to establish continuity. Only once the distribution of coal bearing stratigraphy is outlined and once the structural fabric has been identified, can diamond drilling can be efficiently employed to recover coal samples for analysis.

Respectfully submitted,

ARCHER, CATHRO & ASSOCIATES (1981) LIMITED

R. C. Carne, M.Sc., P. Geo.

APPENDIX I

AUTHOR'S STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

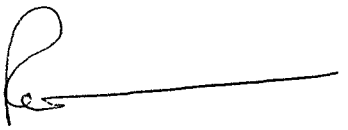
I, Robert C. Carne, geologist, with business addresses in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in Burnaby, British Columbia, hereby certify that:

1. I graduated from the University of British Columbia in 1974 with a B.Sc. and in 1979 with a M.Sc. majoring in Geological Sciences.

2. I am a Professional Geoscientist registered with the Association of Professional Engineers and Geoscientists of the Province of British Columbia (registration number 19868).

3. From 1974 to present, I have been actively engaged as a geologist in mineral exploration in British Columbia and Yukon Territory.

4. I have personally participated in or supervised the field work reported herein and have interpreted all data resulting from this work.



Robert C. Carne, M.Sc., P.Geo.
