
This map illustrates the results from a Gocad Mining Suite Targeting Workflow for the K - Block Survey Area.

The results outside of the survey limits (black curve) have been masked.

A total of 121 possible targets (above 98 % cut-off level) that were identified using this process.

High valued areas are those with multiple favourable geologic and geophysical attributes.

Targets were initially ranked by mean targeting score. The number of cells in each target region were used to further rank those regions with identical mean targeting scores. Rankings by this method are shown as black numbers centred over each target region centroid.

Note that 2 target regions (target_ID # 6 and 58) were identified during the targeting process that lay just outside of the survey boarder. As such, they were excluded from the target ranking process but their centroid poition has still been indicated with a ranking of 000 for reference.

The Colour Legend is binned by targeting score.
