1.0 INTRODUCTION

The Eureka property consists of 349 contiguous mineral claims located in the west-central Yukon. The property is under option from Strategic Metals Ltd. which Golden Predator has the right to acquire 100% undivided interest in the property.

Eureka is situated in the Tintina Gold belt, a broad arcing zone of gold and silver deposits that extends from the Yukon through to Alaska. This zone is bound by the Tintina fault to the north, northeast and the Denali fault to the south, southwest. Important deposits which lie within similar geological settings include the White Gold deposit, the Pogo deposit, the Fort Knox deposit, and many other mineral occurrences.

This report describes the work done through the 2010 field season between May 29th and July 4th. This includes road building, camp building and the subsequent drilling program throughout the field season.

2.0 PROPERTY LOCATION, CLAIM DATA AND ACCESSIBILITY

2.1 Location

The property is located in the west-central Yukon (figure 2-1) at latitude 63°32' north and longitude 138°52' west on NTS map sheet 115O/07, and 115O/10. It consists of 349 mineral claims (table 2-1) registered to the Dawson Mining recorder, under ownership of Strategic Metals Ltd. Claim registration data is listed below, while the individual locations of each can be located on figure 2-2.

2.2 Access

The property is accessed via the Hunker Creek-South Klondike road system, which leaves the Klondike highway approximately 20 km east of Dawson City. The gravel road is maintained by the territorial government, and the entire 90 km distance from the highway to the property is accessible by two-wheel drive vehicles. Access to various parts of the property, including drill sites, is provided by a network of 4-wheel drive roads and bulldozer trails.

3.0 HISTORY AND PREVIOUS WORK DONE

Creeks draining the Eureka property have been producing placer gold since the Klondike Gold rush of 1898. Extensive hand mining using shafts and ground sluicing was carried out until the 1940's, after which time the production records ceased during the course of World War II. In 1959 mining in the Eureka and Black Hills creek area resumed with the emergence of modern mining methods. Reported gold production from 1978 to 2006 is 68,830 and 94,506 oz Au, respectively (Mining Inspection Division, 1998 and Placer Mining Section, 1983, 1985 and 1991).

3.1 Dawson Eldorado Mines Ltd. / Wealth Resources Inc.

Prior to 1988 hard rock exploration is poorly documented. The earliest hard rock exploration well documented was done on the Reka claims by Dawson Eldorado Mines Ltd. and Wealth Resources Inc. The aforementioned companies carried out reconnaissance-level geological and geochemical surveys of the claims. The work was carried out between, and on either side of the right and left forks of Eureka Creek, just north of Childs Creek. The reconnaissance work consisted of mapping and soil sampling this vicinity around Eureka creek. The claims were staked to cover the potential source area of exceptionally anomalous Geological Survey of Canada (GSC) stream sediment sample taken at the headwaters of Eureka Creek. Said sample returned 89 ppb gold, 38 ppm arsenic, 0.85 ppm antimony and 110 ppb mercury. The resulting exploration identified three areas where north trending breccias zones coincide with gold-in-soil anomalies containing values up to 496 ppb (van Angeren, 1988).

3.2 Pacific Mariner / Wealth Resources

The Reka claims were allowed to lapse despite encouraging results, and were re-staked as the Clara claims by Pacific Mariner/Wealth Resources. Work done over the 2 years (1992-1994) included a soil sampling program, and ground geophysics. Some bulldozer and excavator trenching was performed in 1994 across both gold in soil anomalies, and VLF-EM conductors. This program was designed to test north trending breccia fault zones, which were believed to be conduits for mineralizing fluids (Southam 1995).

3.3 Archer Cathro

A comprehensive study of the placer gold from Eureka Creek and Childs Gulch was conducted by Archer Cathro during winter 1998-1999. Gold recovered from the upper reaches of both creeks is described as a mixture of coarse and fine grains with average fineness increasing downstream from 640 to 735. The gold grains are generally angular. Some contain inclusions of dark quartz while others are attached to larger white quartz fragments. All of these attributes suggest the gold is near source.

3.4 Nordac Resources Ltd.

The results of the placer gold study prompted Nordac Resources Ltd. (now Strategic Metals Ltd.) to stake the initial 72 Eureka claims and a number of adjoining Armenius claims to cover potential lode source areas early in 1999. Later that spring Nordac formed the Eureka Joint Venture with Expatriate Resources Ltd. and staked an additional 314 claims.

During summer 1999, Nordac and Expatriate explored the properties with geological mapping and geochemical surveys. All claims comprising the Armenius property and some of the Eureka claims were later allowed to lapse.

3.5 Viceroy Resource Corporation

In February 2002 Viceroy Resource Corporation optioned the Eureka property and drilled three RC percussion drill holes totaling 290 m at the Allan Showing, and a single hole of 90 m at the Wealth Showing. The option was allowed to expire, as it did not meet expectations.

In January 2003, as part of a corporate reorganization, Expatriate assigned its rights over the Eureka property to StrataGold Corporation.

In 2006, Strategic and StrataGold signed an agreement that gave Strategic the option to earn a 100% interest in the property by funding that year's exploration program.

3.6 Strategic Metals

Strategic explored two of the three known zones on the property (Wealth and Childs showings) in the summer of 2006. Exploration consisted of 1151 meters of excavator trenching, and 823 meters of reverse circulation (RC) drilling. Five trenches across the Wealth showing exposed quartz breccias and associated alteration halos. Subsequent drilling in 2006 focused on the trenches and exposed breccias of the Wealth showing. Drill highlights can be seen below in table 3-1.

During 2006 three trenches were excavated at the Childs showing designed to better test gold-bearing zones exposed in a previous bulldozer trench. Results yielded weakly elevated gold content.

In 2009 Strategic Metals did an extensive soil sampling grid (Figure 3-1) in an effort to better define and possibly expand the gold-in-soil anomalies. This program consisted of 3609 soil samples at 50x100m spacing throughout the central part of the property, and a smaller grid to the North West corner, as well as some road samples.

To follow up on the soil samples, 18 trenches totaling approximately 4200 meters were dug; four at the Allan showing, three were at the Childs showing, and 11 trenches were dug in areas with no previous showings. Highlights from the 2009 trenching program can be seen in table 3-2 below.

*Highlights are defined by a cutoff of 0.3 g/t gold over a minimum width of 3 m.

The highlights from 2009 were the basis for a number of Golden Predator's 2010 27 drill holes, as mentioned in the section 6.2.

4.0 GEOMORPHOLOGY

The property lies within rolling low mountains and hills, where creeks have incised an old peneplain. Elevations range from 560 m at the confluence of Eureka Creek and the Indian River, to more than 1300 m, where a north to northeast ridge bisects Eureka Creek and Black Hill Creek.

This area escaped the latest glaciations, which resulted in v shaped river incised valleys, limited exposed outcrop and meteoric oxidation which extends several meters from surface. Surficial deposits consist mainly of a thin veneer, generally windblown loess. Dendritic drainage systems are prevalent through the area, which results in radial fluvial fans off the sides of highland domes.

Permafrost is common on north slopes, as well as drainage floors. Stunted spruce is indicative of permafrost areas, as well as a thick moss covering. Ridge tops, and south facing slopes are generally devoid of any permafrost. In 2004, the Eureka area was burned extensively, which left little mature vegetation on the ridge tops. Where vegetation is mature, poplar is dominant in the valley bottoms which give way to black spruce and willows. Ridge tops are generally buck brush, willow and juniper. Labrador tea and fireweed (primary successive burn species), are the dominant flowering plants.

5.0 GEOLOGY

5.1 Regional Geology

The Eureka property is located within the Yukon-Tanana Terrane (YTT). This region, and much of the Klondike, is underlain by moderately metamorphosed late-Paleozoic rocks. The district is dominated by regional scale thrust faults which cut these metamorphic rocks. Post-thrust/accretion, Mid to Late Cretaceous volcanic flows and granitic plutons are common in the southern and western parts of the district.

The following is largely taken from J. Mortensen's open file 1996-1(G) describing the regional geology of the Klondike and Sixtymile Districts.

The regional geology around the Yukon-Tanana terrain consists of assemblages of supracrustal rocks, as well as suites of metaplutonic rocks. The Nasina assemblage (Late Devonian (?) to mid-Mississippian) consists mainly of fine grained $\pm$ carbonaceous quartz-muscovite-chlorite schist and quartzite. Locally abundant interlayered mafic schist and amphibolites and marble layers are present in the Nasina assemblage as well. Hornblende-biotite granodiorite gneiss locally occurs within the Nasina assemblage, as do smaller lenses of feldspar and quartz-feldspar augen schist, thought to be meta-porphyry sills and/or transposed dykes.

The Permian Klondike Schist (mid-Permian), which comprise a variety of felsic schists thought to be derived from felsic tuffs, cherty tuffs and tuffaceous cherts. Between these felsic units are no-carbonaceous, fine-grained micaceous quartzites and quartz-feldspar-muscovite-biotite schist, derived from siliclastic protoliths. Granitic orthogneiss containing coarse potassium feldspar augen forms the Mt. Burnham orthogneiss and the central southern portion of the Fiftymile Batholith. In the Klondike District, the augen schist unit grades structurally downwards into a biotite-bearing quartz monzonitic gneiss of the Sulphur Creek orthogneiss.

Multiple biotite quartz monzonite intrusions intersect the metamorphic rocks of the YTT, such as the Jim Creek pluton.

Metamorphic rocks of the YTT are unconformably overlain by unmetamorphosed sedimentary and volcanic rocks of mid-late Cretaceous. Lower units generally consist of sandstones and pebble conglomerates of the Carmacks group.

5.2 Structural Geology

The rocks of the Nasina and Klondike Schist assemblages, and associated orthogneiss units have gone through deformation and metamorphism which is thought to have occurred following the accretion of the YTT to the North American plate. Four phases of deformation are observed in layered rocks of the YTT within the Klondike district. Phase I involved Mid-Permian regional scale metamorphism which resulted in penetrative foliation approximately parallel to original bedding. This fabric trends roughly northwest and dips gently to the northeast. Small scale

Regional Geologic Units

UPPER CRETACEOUS

uKC1: CARMACKS: augite olivine basalt and breccia; hornblende feldspar porphyry andesite and dacite flows; vesicular, augite phytic andesite and trachyte; minor sandy tuff, granite boulder conglomerate, agglomerate and associated epiclastic rocks (Carmacks Gp., Little Ridge Volcanics, Casino Volcanics)

uKC3: CARMACKS: medium-bedded, poorly sorted, coarse- to fine-grained sandstone, pebble conglomerate, shale, tuff, and coal; massive to thick bedded locally derived granite or quartzite pebble to boulder conglomerate (Carmacks Gp.)

UPPER JURASSIC & LOWER CRETACEOUS

uJKT: TANTALUS: massive to thickly bedded chert pebble conglomerate and gritty quartz-chert-feldspar sandstone; interbedded dark grey shale, argillite, siltstone, arkose and coal; at one locality includes red-weathering dacite to andesite flows at base (Tantalus)

CARBONIFEROUS AND PERMIAN

CPK1: KLONDIKE SCHIST: tan to rusty and black weathering muscovitic and/or chloritic quartzite and quartz-muscovite-chlorite schist; quartz and/or feldspar augen-bearing quartz-muscovite (chlorite) schist; includes augen gneiss and amphibolite (Klondike Schist)

DEVONIAN, MISSISSIPPIAN AND(?) OLDER

DMN2: NASINA: marble (Nasina assem.)

DMN3: NASINA: quartzite, micaceous quartzite, quartz muscovite (chlorite; feldspar augen) schist, and minor metaconglomerate and metagrit as in (1), but may locally include significant Nisling Assemblage

LATE DEVONIAN TO MISSISSIPPIAN

DMqPW: PELLY GNEISS SUITE - SOUTHWEST: foliated equigranular medium-grained muscovite quartz monzonite; moderately to strongly foliated K-feldspar augen-bearing quartz monzonitic to granitic gneiss (S. Fifty Mile Batholith, Mt. Burnham Orthogneiss.)

isoclinal folds were also developed at this time. The Phase II event occurred between Mid-Permian and Late Triassic and formed close spaced crenulation cleavage. At least three different sub-phases of crenulation cleavage are observed. The latest may be associated with the development of thrust faults which are constrained to the period between Late Triassic and Early Jurassic. The onset of this faulting is also coincident with the emplacement of serpentinite bodies along the faults and small scale isoclinal folding, link banding and warping. The final phase of deformation is coeval with the emplacement of Cretaceous intrusive bodies which resulted in broad low amplitude folding that masks and overprints the Phase I foliation. Steep faults are developed adjacent to some Cretaceous intrusions and are major controls for much of the drainage. Displacement on these structures is unknown but is believed to be minor.

5.3 Property Geology

Although no detailed mapping was performed on the claim block in 2010, generally due to the lack of bedrock exposure, the 27 hole RC drilling program delineated some dominant lithologies.

Quartz-muscovite-sericite schist is pale grey/green to dark grayish green thinly foliated unit. This unit displays schistose and weak-strong foliation. Thickness within this lithology ranges from less than 1 meter to 10 meters. This is the most abundant rock type observed on the property. Chlorite or biotite were often present as well.

Quartzite is generally white to white/grey and has moderate foliation. Variable quantities of muscovite and biotite define foliation planes when present. Ridge crests on the property generally have quartzite capping the ridge.

The majority of this property, including all 3 showings (Wealth, Allen and Childs) is underlain by these two distinct lithologies of the lower Paleozoic Nasina assemblage. These units generally form beds greater than 10 meters in thickness; however lenses of quartzite situated within well foliated sections of the schist recognized in the geologic log. When foliation is present it strikes predominantly north north-west, which is thought to represent axial planar crenulation foliation and lineation related to east to east north east folding. Fractures are best developed within the massive and brittle quartzite units.

6.0 WORK DONE 2010

Work completed by Golden Predator Canada Corp. in 2010 included an extensive reverse circulation drilling program totaling 2961 meters of the Wealth and Childs Showings, as well as road construction (minor) and drill pad building (minor).

6.1 Road building

A minor road was needed to access Eu-10-16RC. A D6 with Total Crawler Services was brought in to do this work, as well as build the corresponding drill pad.

6.2 Drilling

RC Drilling was confined to the Wealth and Childs showings. 27 holes comprise 2961 m were completed, testing the down dip continuity of arsenopyrite, and pyrite veins partially brecciated and clay altered breccia systems exposed by trenching in 1999 and 2006. Expansion of some significant results from Strategic Metals 2009 drilling program was also carried out. Golden Predator was also interested in searching for a North South extension in the mineralized drill intercept located by Viceroy in 2002 on the Wealth showing.

Drilling was performed by Orbit and Garant from High River Alberta using a RIG 201 MPD 1000 Track Mounted Drill. Drilling was conducted dry with samples collected over 1.52 m intervals. A 1/8 box splitter (?) enabled the collection of a 12.5% split for assay purposes, and 87.5% reject bag to be stored at the drill site for further analytical or metallurgical use. Samples were taken under the supervision of a 12 hour shift geologist/field assistant on site. Duplicate samples were taken through a tree tiered riffle splitter once every 36 samples. When minor water was encountered, the hole could be kept dry for another 30 m or so. Once water production became extensive, the hole was called off. Every time water was intersected it was kept track of to eliminate any sources of contamination. A list of drill hole collars can be found in Table 6-1.

6.3 Sampling

Samples were sent to ALS Chemex's prep lab in Whitehorse and then forwarded to their ISO 9001 certified preparation facility in Terrace, B.C. The pulps were analyzed at ALS's ISO 9001 certified laboratory in Vancouver. Approximately 5% of the pulps are sent for secondary check assays at Stewart Groups Eco Tech laboratory in Kamloops, B.C. Blanks, commercial standards and duplicate samples were included in each batch. To determine Au levels at the ppb level detection limit 5-10,000 ppb (5-1000 ppb at Stewart Group) 30 g samples are fire assayed then digested in aqua regia solution and analyzed by atomic absorption. At Eco Tech, values over 1,000 ppb are re-assayed by fire assay and then digested with aqua regia and then re-analyzed by an atomic absorption instrument (detection limit 0.03 g/t). At ALS Chemex, values over 10 g/t gold are re-assayed by fire assay followed by a gravimetric finish (50 ppb lower detection limit).

Other elements are analyzed by a 35 elements package (ME-ICP41) whereby the sample is dissolved in an aqua regia acid solution and then analyzed by ICP. Additional check-analyses are carried out by the lab which did not receive the original sample.

Golden Predator employs high standards of protocol with respect to the handling and chain of custody of its samples. All sampling is conducted under the supervision of the Company's project geologist and the chain of custody from the drill to the sample preparation and logging facility is continually monitored by the project geologist. Samples are shipped to the lab by qualified couriers or Company personnel under locked bags with independent identification lock numbers. Data verification of the analytical results includes a statistical analysis of the duplicates, standards and blanks that must pass certain set parameters for acceptance to insure accurate and verifiable results

Commercial standards were used by the company to test the accuracy and precision of the lab equipment. A low grade, medium grade and high grade standard were picked and placed at random intervals within each sample batch.

Assay certificates are compiled in appendix 3

7.0 MINERALIZATION

7.1 Types of Mineralization

Identifiable sulphides were rare and highly scattered throughout the drilling program, generally due to the deep penetration of meteoric water, and oxidation from hydrothermal fluids. Pyrite and arsenopyrite were the dominant sulphides present. Two main styles of gold mineralization dominate the property: 1) auriferous quartz breccias confined to the more massive quartzite beds; and 2) quartz veins with anomalous gold grades within, and surrounding the vein.

Quartz breccias are confined to the more massive quartzite beds and consist of gossanous/limonitic crackle breccias. Crackle breccias consist of angular fragments of quartzite and mesothermal quartz within a fine grained matrix, which is pervasively limonitic. Drill hole samples of brecciated zones generally show a positive correlation between gold, silver, arsenic and lower concentrations of molybdenum. Antimony and bismuth values were quite low.

Quartz vein material is generally white to off-white and heavily fractured. The dominant quartz veins were fine grained and regular, parallel to foliation. Veinlet stringers and hairline quartz veins are also intermittent throughout the property. Remnants of disseminated sulphides occur as weathered out pits, and rusty lineations within fractures. Fresh arsenopyrite was discernable in quartz veins from ~ 12-19m of hole EU-10-03RC. Many vein specimens exhibited crackle brecciation.

Previous work done on the Eureka property has delineated three showings of gold mineralization known as the Allen, Wealth and Childs showings (Figure 6)

7.2 Allen Showing

The Allen showing is located along a north trending ridge near upper Eureka Creek, in the centre of the property just north east of the Wealth showing (~800m). The zone contains brecciation and clay alteration, which returned a grab sample of 15 grams per ton (g/t). However, chip sampling by Nordac and Expatriate in 1999 across the altered/brecciated zone only returned 0.44g/t over 4 meters. None of the holes drilled by Viceroy in 2002 yielded significant gold grades.

7.3 Wealth Showing

The Wealth showing is located 800 meters SW from the Allen showing in the Eureka highlands. It lies within a 600 by 250 m gold-in-soil anomaly (>20 to 315 ppb Au). Five trenches excavated across the showing between 1999 and 2006 exposed north trending quartz breccias and associated alterations halos. Percussion drilling in 2006 consisted of seven holes drilled in the Wealth showing, with the highest grade being 2.34 g/t over 3.05 meters.

The 2010 drilling program on the Wealth Showing consisted of 23 reverse circulation holes (Eu-10-01RC to Eu-10-22RC, and Eu-10-27RC), totaling 2423 meters (Figure ?). Significant intersections are shown in table (7-1). Hole Eu-10-04RC yielded the highest grade intersection drilled on the Wealth showing in 2010. This hole was part of a 4 hole spread designed to test the gold bearing breccias mapped and sampled by Strategic Metals in 2009. Eu-10-04RC was located at the far eastern end of the trench, and drilled at 270 degrees at an inclination of -60, which can be seen in the section (Figure ?). Three other samples from hole Eu-10-04RC yielded anomalous gold grades of higher than .5 g/t. These samples were just up hole from the 2.440 g/t intersection at 70.10-71.63 m. Hole Eu-10-02RC, part of the same spread as Eu-10-04RC intersected 1.930 g/t over a 1.52m interval. Eu-10-02RC was drilled at 90 degrees with an

inclination of -50. Both these intersects are likely from the same auriferous lithology. Hole Eu-10-20RC intersected 2.170 g/t at a depth of 64.01 m over 1.52 m, and a .600 g/t intersect at 65.53 over 1.52 m.. This hole, as well as Eu-10-19RC were designed to intersect coinciding gold-in-soil and gold-in-silt anomalies. Eu-10-19RC was drilled at 90 degrees (due east) and Eu-10-20RC was drilled at 270 degrees, both holes were drilled at an inclination of -55 degrees. Hole Eu-10-19RC had one intersection worth noting, 0.524 g/t at a depth of 4.57-6.10 m, though the difference in depth between both the Eu-10-20RC and the Eu-10-19RC notable intersections suggests they are not part of the same vein system. EU-10-08RC intersected 1.52 meters of 1.720 g/t at a depth of 62.48 m. Surprisingly, this intersect is 20 m down hole of a 4.57 m section of breccia. Hole Eu-10-10RC intersected 1.150 g/t at 60.96 m for 1.52 m. Interestingly, this interval, and well over 10 m either side of this interval, is devoid of vein or breccia material. This hole was designed to intersect high gold-in-soil values and chips samples from trenching, as well as Strategic Metal's percussion drill holes PDH-ER-07,08,09 and 10, which all displayed anomalous gold grades including 2.34 g/t over 3.05 m.

7.4 Childs Showing

Four RC drill holes, Eu-10-23-Eu-10-26 were completed at the Childs showing, totaling 538 meters. Highlights of this drilling can be found in table 7-2. Eu-10-26RC yielded the highest grade sample found on the property to date, 6.620 g/t over 1.52 m. This hole was designed to intersect a breccia zone delineated by two trenches, T3 and T5 excavated in 2006. This intersect occurs just 1.52 m after a zone of heavy quartz veining. Two notable results came from Eu-10-23RC, at 6.10 m and 120.40 m, each lasting approximately 1.52 m. Hole Eu-10-24RC intersected .452 g/t gold at 96.1 for 1.52 m. Both of these holes were designed to confirm and expand on results from T4, a 2006 trench, which yielded an average grade of 0.72 g/t gold across approximately 4 m true width (Wengzynowski, 2006).

8.0 RECLAMATION

All reclamation on the property was completed as of October 2010. This included rehabilitating roads implemented by Golden Predator Canada Corp. All drainage ditches which were filled in for road purposes have been re-dug. The location of camp has been rehabilitated, as have drill pads used for the 2010 season. Throughout the second and third week of September, Golden Predator contracted Total Crawler Services to do the work with an EX 200 Hitachi.

9.0 CONCLUSIONS AND RECOMMENDATIONS

The main lithological package consists of quartz, muscovite, sericite, and/or biotite schists with some interbedded quartzite lenses of the Nasina Assemblage. Two set of structures, NS- and NNW-striking fracture systems, have been established, which are mostly in accordance with the regional structural setting. Gold mineralization is related to the intensity of alteration, brecciation, and oxidation. It occurs related with pyrite and arsenopyrite in auriferous quartz breccias, and massive quartz veins.

The 2010 RC-drilling program has successfully provided new Au-grade anomalous results at the Wealth showing, which confirmed previous drilling results recorded by Viceroy (2002), and Strategic Metals (2006; 2009). In addition, the four RC-holes drilled at the Childs Showing this year, have confirmed the continuity of the NS-striking mineralized breccias on the property.

Although the gold grades and widths encountered during 2010 drilling program are not economic, there appears to be good geological and assay continuity between section-lines drilled at the Wealth and Childs Showings.

Continued exploration work on the Eureka property is warranted given to the current gold prices. It should consist of additional drilling at the Childs Showing to identify continuity of the NS-striking breccia zones with results of 1.52m@1.19 g/t Au and 1.52m@6.62 g/t Au, in holes EU10-23RC and EU10-26RC respectively. In addition, gold mineralization results of 1999 and 2002 at the Allan Showing needs to be checked with an additional proposed drilling program.

Analytical Methods and Detection Limits

Geochemical Procedure - ME-ICP41

Trace Level Methods Using Conventional ICP-AES Analysis

Sample Decomposition: Nitric Aqua Regia Digestion (GEO-AR01)
Analytical Method: Inductively Coupled Plasma - Atomic Emission Spectroscopy (ICP - AES)

A prepared sample is digested with aqua regia in a graphite heating block. After cooling, the resulting solution is diluted to 12.5 mL with deionized water, mixed and analyzed by inductively coupled plasma-atomic emission spectrometry. The analytical results are corrected for inter-element spectral interferences.

NOTE: In the majority of geological matrices, data reported from an aqua regia leach should be considered as representing only the leachable portion of the particular analyte.

Fire Assay Procedure – Au-AA23 & Au-AA24
Fire Assay Fusion, AAS Finish

Sample Decomposition: Fire Assay Fusion (FA-FUS01 & FA-FUS02)

Analytical Method: Atomic Absorption Spectroscopy (AAS)

A prepared sample is fused with a mixture of lead oxide, sodium carbonate, borax, silica and other reagents as required, inquarted with 6 mg of gold-free silver and then cupelled to yield a precious metal bead.

The bead is digested in 0.5 mL dilute nitric acid in the microwave oven, 0.5 mL concentrated hydrochloric acid is then added and the bead is further digested in the microwave at a lower power setting. The digested solution is cooled, diluted to a total volume of 4 mL with de-mineralized water, and analyzed by atomic absorption spectroscopy against matrix-matched standards.
