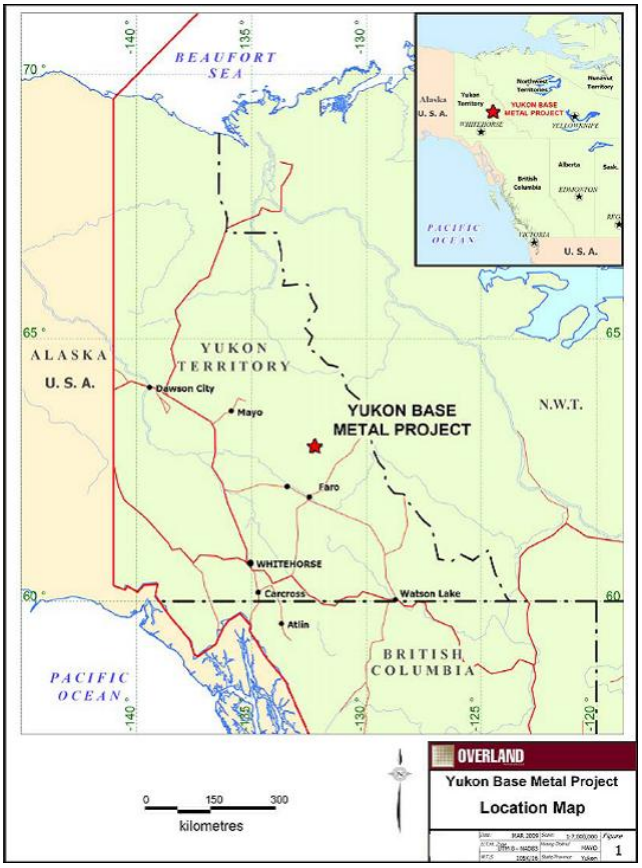
## INTRODUCTION

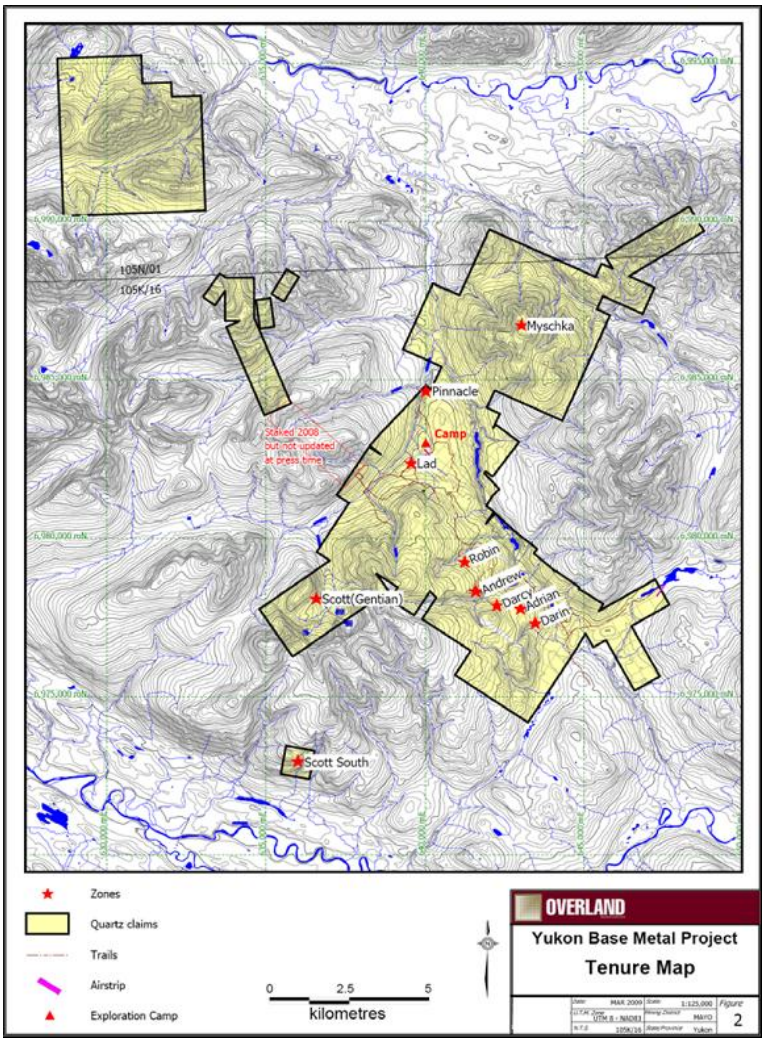
This report was prepared to document the geological, geochemical and diamond drilling surveys undertaken in 2008 to provide for government assessment requirements for the group of group of quartz mining claims collectively known by Overland Resources Limited as the Yukon Base Metal Project.



The various surveys were conducted for the explicit purpose of evaluating the potential of the group of claim blocks to host economically viable mineral deposits and advance the Andrew Zinc Deposit through feasibility.

For assessment purposes all work completed by the Company to 20 September 2008 will be applied for in the certificate of work for those claims listed.

All information and data documented in this report was obtained by employees or consultants employed by Overland Resources Yukon Ltd., except for the core assay analysis, which were outsourced to ALS Chemex of Vancouver B.C.



## PROPERTY DESCRIPTION AND LOCATION

The Yukon Base Metal Project is situated 110 km north of the town of Faro, Yukon (Figure 1) and consists of 567 full and fractional Quartz Mineral Claims covering approximately 10 800 hectares within the Mayo Mining District (Figure 2). The Project is located within NTS map sheet 105K/16. The coordinates of the approximate center of the property are 62° 55' 33" N latitude and 132° 13' 7" W longitude (NAD 83, UTM Zone 8, 641 070 mE and 6 980 155 mN).

## Claim Status

The Quartz Mineral Claims that comprise the Yukon Base Metal Project are owned 90% by Overland Resources Yukon Limited and 10% by 18526 Yukon Inc. Overland Resources Yukon Limited has the responsibility of permitting, claim maintenance, assessment filing and reporting and associated fees.

The claims lie on crown land, and surface rights belong to the crown. They do not lie within or near any park, special management zones, first nation settlement lands or land selections. However, they are situated within lands considered as traditional hunting and trapping areas by several first nation bands.

All claims are currently in good standing.

## ACCESS, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, PHYSIOGRAPHY

### Access

The Yukon Base Metal Project is accessible by helicopter and short take off and landing-capable fixed-wing aircraft via a 400m unsealed airstrip located at 132°14’20” W and 62°56’20” N (UTM NAD83; 640,090mE and 6, 982,690mN). Heavy equipment and bulk

supplies can be delivered to the property via an 85km winter trail which was re-established in winter 2008 from the North Canol Road at Dragon Lake.

## Climate

Temperatures at the Yukon Base Metal Project typically range from 8$^{o}$C to 26$^{o}$C in the summer and from -30$^{o}$C to +6$^{o}$C in the winter. Annual precipitation ranges from 120mm to 200mm, including 0.8m to 1.5m of snow accumulation in the winter months.

## Local Resources

No local communities or towns are within 50km of the Yukon Base Metal Project and as such all resources must be bought into the project area. Personnel for construction, mining, exploration, labour and support are available in the communities of Faro, Ross River and Watson Lake as well as the Territorial capital of Whitehorse. Faro and Ross River are 100km southwest and 115km south of the property respectively.

## Infrastructure

Infrastructure near the Yukon Base Metal Project includes the Canol Road and Robert Campbell Highway. The Canol Road extends for 458km from the Yukon-Northwest Territories border to Johnson's Crossing on the Alaska Highway south of Whitehorse. Northeast of the Pelly River at Dragon Lake, the Canol road comes to within 60km of the Yukon Base Metal Project where the winter access trail into the property begins.

Both Ross River and Faro are serviced by electrical transmission lines sourced from the Aishihik hydroelectric facility to the west.

## Physiography

The Yukon Base Metal Project is located within the South Fork Range of the Yukon Plateau, east of the Tintina Trench and west of the MacKenzie Mountains. The property occupies the west side of a wide valley, where elevations range from 1,000m to 1,800m above sea level. Several east flowing creek valleys cut moderate slopes across the Yukon Base Metal Project.

The vegetation at the Yukon Base Metal Project is alpine to sub-alpine with lower elevations being dominated by black and white spruce stands, typical of the Northern Boreal Forest.

## HISTORY

### Previous Work

Between 1967 and 1969 an exploration program was undertaken by Atlas Exploration in the area currently covered by the Yukon Base Metal Project (Adamson, 1968, 1969; Smith, 1967). Following preliminary exploration in 1967, 162 claims centered on mineral showings underlying the LAD claims were staked. Throughout 1968 and 1969, Atlas Exploration undertook line-cutting (63km), geophysical surveys (ground magnetic, air magnetic, and EM), geochemical surveys, geological mapping (1:400 and 1:200 scales), and trenching (hand and bulldozer). It was during this period that the winter trail and airstrip were first established on the property.

Atlas Exploration concluded their activities in 1969 and area and all but 42 of the claims lapsed.

Interest in the remaining claims was transferred to CIMA Resources and in 1977 they drilled two short holes totalling 15.32m on the LAD showing. These holes intersected mineralization near surface with the best results from drill hole 77-1 returning 5.3% Pb, 4.7% Zn and 3.9 oz/t Ag over 1.2 m (Soloviev et al., 2003). The claims were subsequently allowed to lapse.

In 1968 Hudson Bay Mining and Smelting staked the SOLO claims 4km north of the LAD claims, comprising the north central portion of the present day Myschka claim group located at the north end of the Yukon Base Metal Project. From 1968 to 1969 Hudson Bay Mining and Smelting conducted grid soil sampling and geological mapping but the claims were allowed to lapse. An area covering the southern portions of the present day Myschka claims was staked in 1990 by Noranda Exploration Co. Ltd. as the RUSH claims. Select grab sampling on these claims returned values up to 3017 g/t Ag, 75% Pb, 0.2% Zn and 0.9% Sb (Yukon Minfile #105k/090, 1996) but the claims were allowed to lapse once again.

Anomalous drainages identified in a Geological Survey of Canada regional geochemical survey (Open File #2174) released in 1989 prompted Ron Berdahl, of Whitehorse to further investigate the area. Berdahl staked the ANDREW 1-10 claims in 1996 after encountering a large kill (devegetated) zone. Grab samples taken from several showings associated with the kill zone yielded up to 19.2% Zn and 74.6% Pb (Berdahl, 1997).

The MYSCHKA 1-16 claims were staked in 1998 by Viceroy Resource Corporation, transferred to NovaGold Resources Inc. in 1999 and subsequently allowed to lapse. As the MYSCHKA claims were lapsing, 18526 Yukon Ltd. re-staked the LAD 24 and 26 claims as SCOTT 1 and 2 and conducted more geochemical sampling and trenching on the ANDREW claims. In September 2000 18526 Yukon Ltd. staked the SCOTT 3-34 claims and conducted soil and rock geochemical surveys on the newly staked ground (Berdahl, 2002).

Noranda Inc. optioned the ANDREW claims from Berdahl in August 2000 and staked AMB 1-68, 70 and 72-104 claims adjoining the ANDREW claims to cover historic showings to the north. In the winter of 2000/2001, Noranda carried out airborne magnetic and electromagnetic surveys over the area, covering the newly staked AMB claims as well as the ANDREW and previously staked SCOTT claims to the west. From July to October 2001, Noranda undertook an exploration program, including drilling 15 holes totalling 2,717.7 m (Huard and Savell, 2002).

Noranda then staked AMB 115-162 claims, on the NE and SE side of the ANDREW claim block to cover a Zn-in-soil geochemical anomaly extending up to 1.2km to the southeast from the Andrew Zinc Deposit.

In 2001 the present day SOPHIA claims were staked by 18526 Yukon Ltd. and optioned to Klad Enterprises Ltd. who re-staked the MYSCHKA 1-16 as well as the MYSCHKA 17-96 surrounding the Sophia Claims.

In 2002 Noranda Inc. conducted in further soil geochemical sampling and drilled eight diamond drill holes totalling 1838.3m (Huard and Savell, 2003). Klad Enterprises Ltd. undertook a campaign of geological mapping concurrent with collecting rock silt and soil specimens on the MYSCHKA property.

Noranda Inc. terminated its option agreement on the property in 2003, coincident with the takeover of Noranda by Falconbridge Inc. Similarly, Klad Enterprises Ltd. allowed its interest to lapse in the MYSCHKA property.

In February 2007, Overland Resources Yukon Ltd. secured an option agreement to acquire 90% interest in the Yukon Base Metal Project. From May through November 2007, Overland reprocessed geophysical data, conducted regional geological mapping and geochemical surveying (1300 soil, 200 rock chip and several regional stream

sediment samples) and drilled 2,867m in 10 holes. The surface sampling extended the zinc in soil geochemical anomaly 2.5km southeast of the Andrew Zinc Deposit.

Additional mineralised zones were identified elsewhere on the property at the Gentian and Scott zones.

### Historical Mineral Resource Estimate

In March, 2007 Overland published an inaugural Mineral Resource estimate for the Andrew Zinc Deposit utilising the historical Noranda drill data from 2001-2002 of 5.9Mt @ 5.8% Zn, 2.0% Pb, 9.5 g/t Ag and 14.9 g/t Ge.

In 2008 Overland Resources published a revised Mineral Resource estimate based on the Noranda and Overland Resources drill data of 5.04Mt @ 7.47% Zn, 1.72% Pb, 5.43g/t Ag and 17.43g/t Ge, classification of this resource are presented in Table 1.

**Table 1: Reported Mineral Resource for Andrew Zinc Deposit (3% Zn cut-off)**

| CLASSIFICATION | TONNES | Zn (%) | Pb (%) | Ag (g/t) | Ge (g/t) |
|---|---|---|---|---|---|
| **MEASURED** | 88,000 | 7.2 | 1.0 | 4.9 | 26.3 |
| **INDICATED** | 4,101,000 | 7.7 | 1.8 | 5.7 | 18.5 |
| **INFERRED** | 856,000 | 6.6 | 1.3 | 4.1 | 11.7 |

Overland Resources conducted an aggressive exploration program in 2008 designed to advance the Andrew Zinc Deposit through feasibility and define additional resources elsewhere on the property.

This program consisted of mapping, prospecting, collection of soil, silt and reconnaissance rock samples, and diamond drilling. A total of 23,424.7m from 135 drill holes were completed in 2008. Six prospects outside the Andrew Zinc Deposit were drill-tested.

## GEOLOGICAL SETTING

### Regional Geology

The Yukon Base Metal Project covers an area underlain by marine and deep water derived clastic rocks of the western Selwyn Basin. The definition of the Selwyn Basin in this report follows that of Gordey and Anderson (1993) in reference to Late Precambrian to Middle Devonian off-shelf deposition of sediments restricted by the Cassiar platform to the southwest and the Mackenzie shelf to the east. The basin is considered part of

Ancestral North America and records several episodes of pericratonic rifting with subsequent subsidence. Generally, the basin fill comprises shale, limestone, chert and grit that have been subdivided across the basin into many formations and distinct facies that may or may not be time-equivalent. Regional geological mapping of the area (Gordey, 2008; Gordey and Makepeace, 2001) provides a framework for the regional and property-scale descriptions below.

The western portion of the basin (where the Andrew Zinc Deposit is located) is underlain by Precambrian (Hyland Group; Yusezyu and Narchilla formations), Lower-Middle Cambrian (Gull Lake Formation), Cambrian-Ordovician (Rabbitkettle-Menzie Creek formations), Ordovician-Silurian (Road River Group; Duo Lake and Steel formations), and Devonian to Mississippian (Earn Group; Prevost Formation) sequences (Figure 4). The sedimentary rocks were subsequently intruded by Cretaceous granite, quartz monzonite and granodiorite plugs assigned to the Selwyn Plutonic Suite. Collectively, they record a quiescent, subsiding continental margin punctuated by transgressive and regressive cycles, rifting, a receptacle for orogenic detritus from the north, collision of allochthonous terranes, mountain building and magmatism (Gordey and Anderson, 1993).

Large-scale dextral offset along the Tintina Fault, located 100 km southwest of the Yukon Base Metal Project, is understood to be the last major structural event to affect the region (Gabrielse et al., 2006). Reactivation of early Cretaceous contraction-related structures evidently occurred and faults cutting Selwyn Plutonic suite rocks are likely also related to this event.

## Property Geology

The table below (Table 2) summarizes the descriptive lithological codes and rock types on the Yukon Base Metal Project. Where known (e.g. distinctive maroon mudstone is unique to Narchilla Fm.), these rock types are assigned to regional stratigraphic groups or formations. Other rock types are ambiguous (e.g. sandstone) since they are found throughout the stratigraphic pile.

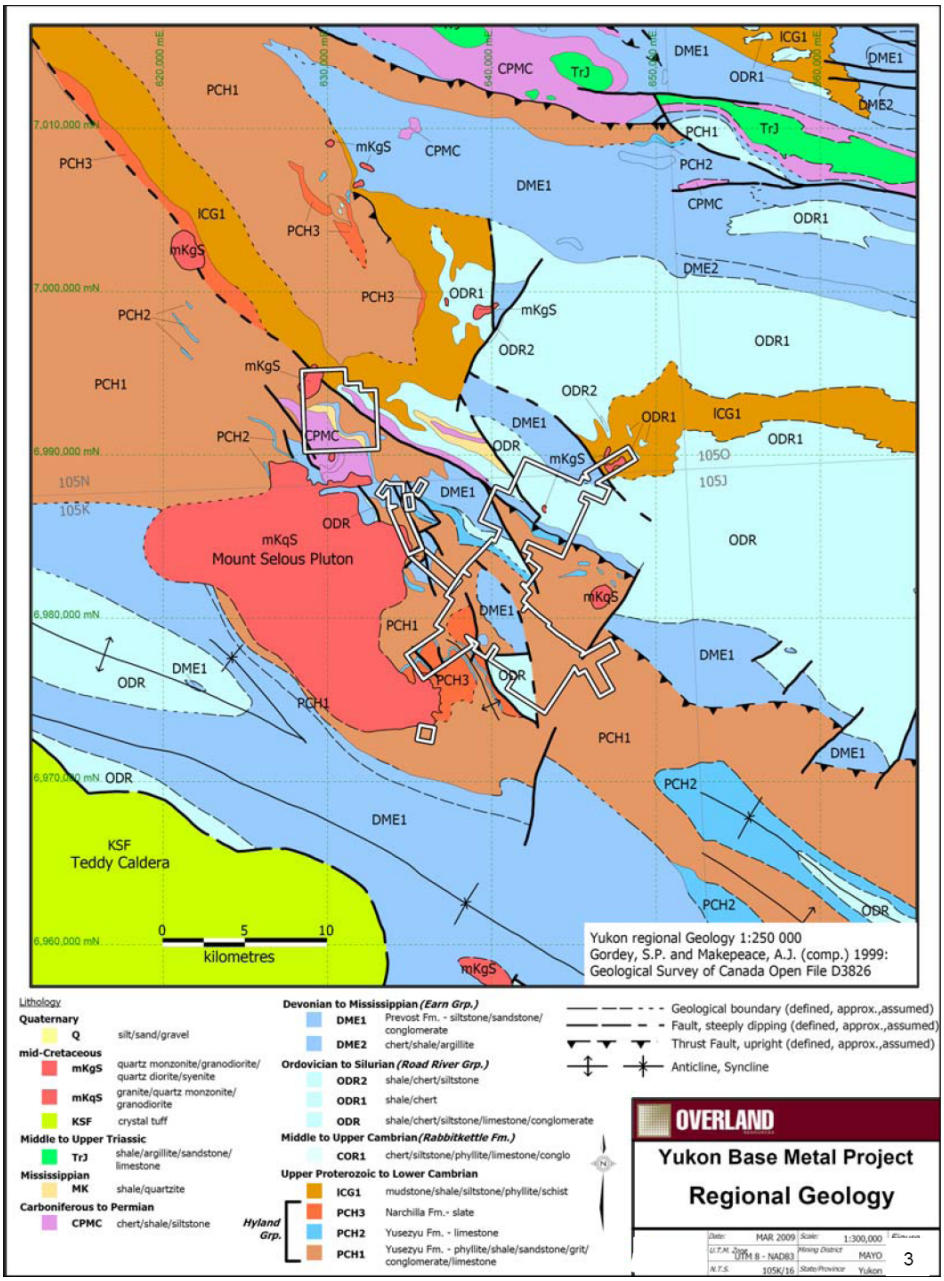


**Table 2: Summary of Lithologic Units used for Logging and Mapping**

| | | |
|---|---|---|
| **UNCONSOLIDATED - Pleistocene and recent** | | |
| Ogv | Overburden | undivided glacial tills, colluvium, alluvium |
| **SELWYN PLUTONIC SUITE - mid-Cretaceous** | | |
| Fg | granitic rock | Undifferentiated |
| Fgd | Granodiorite | medium-grained, unfoliated |
| Fpo | Porphyry | feldspar (locally with amphibole or quartz)-phyric igneous rock with fine-grained grey groundmass, commonly in metre to 10-metre wide dykes |
| Ida | Diorite | green-grey, medium-grained |

| | | |
|---|---|---|
| **EARN GROUP (DME) - Devonian and Missippian** | | |
| Sbx | sedimentary breccia | Conglomerate (Sedimentary Breccia): black, monomict to polymict, locally with chert pebble clasts, commonly carbonaceous |
| Scg | Conglomerate | generally with white and grey chert pebbles in a fine-grained grey groundmass, locally sand-rich, poorly bedded |
| Sms_bk | mudstone – black | black, carbonaceous mudstone with rare more coarse-grained laminations |
| Ssh_bk | shale – black | black, fine-grained, fissile, carbonaceous |
| **ROAD RIVER GROUP (ODR) - Ordovician and Silurian** | | |
| Sct | Chert | Undifferentiated: thin to medium-bedded, green, grey, black |
| Sct_bk | chert – black | thin-bedded, fine-grained |
| Sct_gy | chert – grey | thin-bedded, fine-grained |
| **HYLAND GROUP – Proterozoic and lower Cambrian** | | |
| **Narchilla Formation (PCH3)** | | |
| Sms_gn | mudstone – green | pale green with maroon interbeds locally, typically with strong slatey cleavage |
| Sms_rd | mudstone – red | maroon with pale green silty interbeds typically with strong slatey cleavage |
| **Upper Yusezyu Limestone Formation (PCH2)** | | |
| Sls | Limestone | pale light brown, light grey to black, massive to bedded, locally silicified, silty or brecciated |
| Sst_cct | sandstone - calcareous | typical sandstone but with strong reaction to HCl indicative of calcite cement |
| **UNDIVIDED SEDIMENTARY ROCKS OF HYLAND, ROAD RIVER AND EARN GROUPS** | | |
| Sms | Mudstone | undivided and interbeded various coloured mudstone |
| Sms_gy | mudstone – grey | light grey mudstone, typically with slatey cleavage, commonly as interbeds within sandstone-dominated sequences |
| Spy | Phyllite | pale brown to grey, locally with porphyblasts or crenulations |
| Sqt | Quartzite | quartzite or quartz-rich sandstone: medium to coarse-grained, locally with minor biotite and common opalescent blue clast, generally silica cemented |
| Ssh | Shale | grey to black, fine-grained, fissile |
| Slt | Slate | undivided: typically grey to black with well-developed slatey cleavage |
| Ssl | Siltstone | dark to light grey, finely bedded |
| Ssl_cct | siltstone - calcareous | dark to light grey, finely bedded, strong to moderately calcareous |
| Sst | Sandstone | undivided sandstone: variable cement and clast content |
| **METASOMATIC (post early Cretaceous contractional event)** | | |
| V | Vein | undivided massive vein, typically comprising calcite, dolomite and quartz |
| Vgln | vein + galena | stockwork: comprising irregular carbonate-quartz veins with galena |
| Vglnspl | veins + galena + sphalerite | stockwork: comprising irregular carbonate-quartz veins with sphalerite and galena |
| Vspl | vein + sphalerite | stockwork: comprising irregular carbonate-quartz veins with sphalerite |

| | | |
|---|---|---|
| Zbxv | vein breccia, stockwork | stockwork: barren stockwork vein dominated unit with undifferentiated wallrock, carbonate-quartz predominant |
| **METAMORPHIC AND TECTONIC** | | |
| Xhf | Hornfels | biotite-bearing sedimentary rock, generally proximal to plutonic rocks |
| Xsc | Schist | strongly deformed undivided sedimentary rock with pervasive schistosity |
| Xsz | shear zone | strongly deformed undivided rock with strong tectonic shear fabric, local mylonite |
| Zbx | fault breccia | comprising angular slickensided fragments and lesser gouge |
| Zfzg | fault gouge | comprising gouge-dominated fault rock with lesser fragments |

## Sedimentary Rocks

The Yukon Base Metal Project is located in the upper sheet of the Sheldon Thrust which crops out 7km north-northeast of the Andrew Zinc Deposit (Gordey, 2008). This thrust juxtaposes older Hyland group rocks over younger Road River and Earn group rocks.

Assigning rock units on the Yukon Base Metal Project to stratigraphic formations is problematic due to the similarity of rock types among groups, lack of exposure below tree-line and abundant structural complication. Exceptions to this are the distinctive maroon and green laminated mudstones of the Narchilla Formation, and carbonaceous to graphitic, locally pyritic mud-matrix turbidites of the Earn Group that contain distinctive chert clasts sourced from the underlying Road River Group.

Description of the local geology is based on Gordey (2008) and data collected during the 2008 exploration program. The interpreted bedrock geology of the Yukon Base Metal Project (Map 1) is a modified version of Gordey (2008) and includes interpretation of mapping data from Atlas, Noranda and Overland as well as the airborne magnetic data.

The stratigraphic determination is mostly based on the distinctive units described above. Lithologies in the immediate area have been assigned to the Hyland, Road River, and Earn Groups and to the Selwyn Plutonic Suite.

## Igneous Rocks

To the west, two-mica granite, quartz monzonite and granodiorite of the Mt Selous Pluton is exposed. At the contact between the Mt Selous Pluton and the Narchilla formation the mudstone is black and displays a strong cleavage with 1-2 mm diameter andalusite (?) porphyroblasts. Locally sedimentary rocks near the intrusive contact are

biotite hornfelsed. A granite plug in the northeastern side of the property is interpreted to be the same age and cogenetic with the Mt. Selous pluton to the west.

### Structural Geology

The property-scale structural geology is dominated by kilometre-scale structures related to early Cretaceous northeast-directed contraction (i.e. thin-skinned detachment tectonics). Structures include thrust faults, normal faults, folds and penetrative axial-planar cleavage. The regional-scale Sheldon Thrust is located about 7 km northeast of the Andrew Zinc Deposit where Hyland group rocks overlie Earn and Road River group rocks across a southeast-dipping frontal thrust ramp. As such, most of the property is underlain by Hyland Group rocks comprising a displaced thrust sheet above a flat detachment.

Several strong linear features occur on the property and are highlighted by topographic lineaments and/or linear features on the airborne magnetic image. In drill core from the various zones that have been drilled, numerous faults occur. These typically comprise fault breccia and fault gouge. They represent the last structural event recorded on the property.

### Mineralization

Mineralization on the Yukon Base Metal Project is predominantly of the massive sulphide zinc-lead-silver breccia hosted open infill type. Significant mineralization occurs at the Andrew Zinc Deposit and the Darcy Zinc Deposit. Smaller mineralizing systems have been demonstrated at the Adrian and Darin zones which lie within a 2.5 km-long zinc in soil geochemistry anomaly.

Minor mineralization is exposed at the LAD and Pinnacle zones but drilling has so far failed to delineate significant mineralized widths. These zones are characterized by replacement scarn style mineralisation containing variable pyrrhotite, chalcopyrite, sphalerite and galena.

## 2008 EXPLORATION PROGRAMME

Surface work in 2008 included extension of the soil grid initiated by Noranda, prospecting and geological mapping on the Andrew, Adrian, Darcy, Darin, Gentian, Lad, Robin and Scott zones, as well as the Myschka and B-Claims, silt sampling on the B-Claims, and trenching in the Robin zone. The 2008 program included the collection of

1262 soil samples, 9 silt samples, 57 rock samples, 5,364 drill core samples including QA/QC (Table 3).

**Table 3: Surface Samples Collected during the 2008 Program**

| Sample Type | Total* | ALS Chemex Analytical Code |
|---|---|---|
| Rock | 57 | ME-MS61 |
| Soil | 1262 | ME-MS41 |
| Silt | 9 | ME-MS41 |

*includes ~10% QA/QC samples

Silt samples were collected from favourable locations in creeks and rivers, with moss-mat samples collected where no silt was available due to creek conditions. Samples were placed in paper kraft bags and dried in camp prior to shipping. Sample locations were marked with blue and orange flagging tape and a metal tag indicating sample number, date and sampler. Descriptive notes including sample location, type, volume and depth, slope, downstream direction, colour, texture, and petrology of float/bedrock were recorded on site. Samples were sent to the ALS Chemex preparation facility in Terrace, BC and subsequently to the Vancouver laboratory for analysis via aqua regia digestion and Inductively Couple Plasma Atomic Emission Spectroscopy (ICP-AES).

Standard, reconnaissance-style soil samples were collected at 50m intervals and 200m line spacing. Soil sample locations were marked with orange and blue flagging and all sample sites were marked with a Tyvek tag with the sample number marked on the tag with a china marker. Soil samples were taken from B-horizon soils wherever possible but locally permafrost was encountered forcing collection of smaller amounts of material. Characteristics of the sample site were recorded on a sample form for later reference. A field duplicate soil sample was collected about every 20th sample and sample blanks were inserted every 20th sample.

Rock and silt samples were marked in the field by a combination of pink and blue flagging plus a small aluminum tag on which has been inscribed the sample number, the type of sample, the initials of the sampler, and the date the sample was taken. Characteristics of the rock sample were recorded on a sample form and the data from these forms has been included in Appendix D. All rock, soil and silt samples were located using a hand-held GPS.

Reflex EZ-Shot down-hole survey tools were used to measure dip and azimuth readings at 50 foot increments to track drill-hole deviation. A Real Time Kinetic (RTK) GPS was

used to survey all of the Andrew Zinc Deposit drill-hole collar locations that had been completed by July 14th, 2008.

A magnetic declination of 25° E was used for all compass measurements. Structural measurements are all reported utilizing the right-hand rule. All maps and UTM coordinates are referenced to the 1983 North American Datum (NAD-83; Zone 8).

## Geochemistry

### Silt Geochemistry

In 2008, nine grab-style silt samples were collected from drainages on the B-claims (Table 4, Map 2). Assays returned variable Zn, Pb and Ag values, with sample G0669352 the most anomalous in Zn at 1580 ppm. An additional five samples from 2008 returned high to moderately anomalous values (265-723 ppm), while lead was moderately anomalous at best (> 30 ppm). A thematic map highlighting anomalous Zn, Pb and Ag sample locations is shown in Map 2.

**Table 4: 2008 Silt Geochemistry**

| Sample No. | Ag (ppm) | Ba (ppm) | Cd (ppm) | Cu (ppm) | Mn (ppm) | Pb (ppm) | Zn (ppm) |
|---|---|---|---|---|---|---|---|
| G0669351 | 1.0 | 410 | 0.5 | 56 | 206 | 39 | 115 |
| G0669352 | 0.5 | 1100 | 15.4 | 173 | 3970 | 34 | 1580 |

### Soil Geochemistry

A total of 1262 soil geochemical samples were collected as part of the exploration programme conducted during 2008.

#### Robin Zone

The Robin zone comprises an east-west trending Zn in soil anomaly 850 x 300 m that is centred about 1km due north of the Andrew Zinc Deposit (Map 6). The anomaly is defined from Atlas-era (1960s) soil data that was compiled in 2008 into digital form.

During the 2008 season, 47 soil samples were collected along an ATV trail that passes through the center of the anomaly to test validity of the historical data. Additionally, some of the north-south soil lines which were completed during expansion of the 2007 grid covered part of the Robin zone. The modern results did not corroborate the 1960s soil data.

## Rock Geochemistry

A total of 50 rock samples were collected within the project area during the 2008

### Darin Zone

A total of 4 rock samples (Table 5) were taken in and around the Darin zone during the 2008 field season with samples returning values up to 2.5% Pb (sample 8494) and 1.7% Zn (sample H031511). Mineralisation consists of massive galena in quartz-calcite veins hosted in locally intense quartz +/- carbonate stockwork cutting medium- to coarse-grained, quartz sandstone.

**Table 5: Darin Zone Significant Mineralization**

| Sample # | Easting (NAD83) | Northing (NAD83) | Sample Type | Zn (ppm) | Pb (ppm) | Ag (ppm) | Cu (ppm) | Ge (ppm) | Mn (ppm) |

### Scott Claims (including Gentian Zone)

The Scott 3-34 claims encompass targets known as the Gentian zone (Scott kill zone), Bordeleau showing and Red Precipitate creek. A total of 4 rock samples were taken within the Scott claims during the 2008 field season with values returning up to 3.3% Zn and 2140 ppm Pb (sample G0668606) from the Gentian zone (Table 6).

**Table 6: Gentian Zone Significant Mineralization**

| Sample # | Easting (NAD83) | Northing (NAD83) | Sample Type | Zn (ppm) | Pb (ppm) | Ag (ppm) | Cu (ppm) | Ge (ppm) | Mn (ppm) |

**Hugo Creek Area**

A total of 3 rock samples were taken along Hugo Creek during the 2008 field season with the highest grade sample returning 314 ppm Pb, 1320 ppm Zn (sample G0668602).

**Robin Zone**

During the 2008 season, a total of 11 rock samples were collected within the Robin zone. None of the rock samples returned significant assay results for Zn or Pb. A single sample returned 1,000 ppm Cu reflecting the occurrence of chalcopyrite and malachite (Table 7).

**Table 7: Robin Zone Significant Mineralization**

| Sample # | Easting (Nad83) | Northing (NAD83) | Sample Type | Zn (ppm) | Pb (ppm) | Ag (ppm) | Cu (ppm) | Ge (ppm) | Mn (ppm) |
|---|---|---|---|---|---|---|---|---|---|
| M271747 | 640990 | 6979361 | Float | 222 | 84.3 | 0.4 | 1000 | -0.05 | 198 |

Two trenches for a total of 272m were excavated using a 312 Caterpillar excavator. Trenches #1 and #2 were oriented and excavated along azimuths of 025$^{o}$ and 030$^{o}$, respectively (Map 6). This orientation was chosen to cross cut the inferred bedding orientation at a high angle. A total of 162m was trenched, 2m wide and 0.5 to 1.5m deep. Geological stations were recorded within the trench using a handheld GPS. In the following description, all location references are measured from the southwest end of the trench.

**B-Claims**

The B-Claims comprise 100 contiguous claims approximately 7 km northwest of the Andrew camp. The area was staked to surround an RGS (Regional Government Survey) silt sample returning highly 1170 ppm Zn.

Four rock samples were collected on the B-claims.

**Myschka Claims**

During the 2008 field program several representative samples and measurements were taken to confirm previous work. In summary, the Myschka is surface sample grades do not warrant further work.

## DIAMOND DRILLING

A total of 23,424.7m was drilled in 135 holes by Overland Resources Yukon Ltd. during the 2008 exploration program. The drilling consisted of infill and geotechnical drilling on

the Andrew Zinc Deposit and drill testing of six exploration targets including the Adrian, Darcy, Darin, Gentian, Lad, and Robin zones. All holes were inclined to better represent the true thickness of the mineralization and drilled using NTW tools except when the drilling conditions required reducing to BTW to complete the drill hole.

All drill core was shipped to camp via helicopter and was logged for geological and geotechnical characteristics (recovery, RQD, RMR, Q value and magnetic susceptibility) and subsequently photographed. Mineralized intervals were sampled by the geologist.

Reflex EZ-Shot down-hole survey tools were used to gather dip and azimuth readings at 50 foot increments to track drill-hole deviation. A Real Time Kinetic (RTK) GPS was used to survey all of the Andrew Zinc Deposit drill-hole collars that had been completed by July 14th, 2008.

**Sample Preparation, Analysis and Security**

Sampling during the 2008 season was performed using standard geosciences practices and procedures. All drill core samples were cut using petrol powered water-cooled core saws. Sample widths were a maximum of 1.5 m and a minimum of 0.7 m, selected on the basis of lithological, alteration or mineralization boundaries. Core recovery was good although intensely fractured locally through fault zones and near surface. Results from the 2008 exploration program are considered reliable.

In 2008, drill core was sawn longitudinally with one half submitted for analysis and the other half remaining on site for reference. All samples were individually bagged in 12 x 20” poly ore bags labeled with unique sample numbers and containing corresponding lab-specific assay tags. Sample bags were then sealed with plastic zip-ties and batched in woven nylon “rice” bags.

All samples were flown off-site via fixed wing aircraft to Whitehorse, YT, and shipped via commercial carrier to ALS Chemex Labs in Terrace, BC. Samples were shipped in rice bags pre-printed with shipping information and a unique project specific code. All rice bags were sealed with a unique numbered heavy duty zip-tie. No rice bags delivered to ALS Chemex Terrace showed any evidence of tampering. Pulps were prepared in Terrace and chemical analysis was carried out by ALS Chemex of North Vancouver, BC, an ISO 9001:2000 accredited laboratory.

In 2008, samples were analyzed for 51 elements by aqua regia digestion and ICP-AES (inductively coupled plasma atomic emission spectroscopy) or ICP-MS (mass

spectroscopy). Values returning greater than 10,000 ppm Zn or Pb or 100 ppm Ag from the initial analysis were rerun using aqua regia digestion and atomic emission spectrometry optimized for higher concentrations. Results from this second tier of analysis that returned greater than 20% Pb or 30% Zn were analyzed via four acid digestion and potentiometric titration.

**Data Verification**

QA/QC carried out during the 2008 exploration program involved inclusion of analytical blanks, core duplicates and three standards in the drill core sample stream submitted to the laboratory. Results of this program are detailed below in the Data Verification section. ALS Chemex institutes an additional QA/QC program that involves the inclusion of additional blanks, standards and duplicates into the sample stream within the laboratory. It is the opinion of the authors that sample preparation, security, and analytical procedures were adequate during the 2008 exploration program.

**Adrian Zone**

A five hole, 810m diamond drill program designed to test anomalous soils and continuity of surface mineralization at depth was completed in 2008. Table 8 lists the significant mineralization encountered during the drill program in the Adrian zone. Trace mineralization was intersected in all five holes with the best results returning 4.7% Zn over 2 m in hole AD08-004. Mineralization occurs as disseminated or vein-hosted fine to coarse grained sphalerite in strongly silicified coarse grained sandstone. The relation of true thicknesses to core lengths is not known.

**AD08-001**

AD08-001 targeted the subsurface extension of the Dawson Showing. This hole encountered an upright sequence of Narchilla Formation red mudstone above Yusezyu sandstone on the western limb of an anticline. From 77.3m to 77.8m depth trace sphalerite and 1% galena hosted in a quartz-calcite vein is present cutting a black mudstone horizon. Weak to moderate stockwork containing trace to 1% sphalerite cutting sandstone occurs from 80.6–90.8 m and from 124.1m to 142.0m depth. A quartz-calcite cemented breccia was intersected from 107.8m to 112.4m with 0.5% to 1% sphalerite occurring as disseminated flecks and minor stringers. The breccia also contained trace galena, pyrrhotite and 1% disseminated pyrite.

**AD08-002**

AD08-002 was drilled in the Adrian zone to test the extent of vein-hosted sphalerite and galena mineralization found in a surface showing coincident with anomalous Zn in soil geochemistry. The hole intersected alternating beds of sandstone and grey mudstone, with minor sedimentary breccia and calcareous siltstone. Trace fracture filling and stringers of sphalerite are present throughout the hole. Locally, quartz-sphalerite veins, and rare quartz-sphalerite-galena veins characterize zones of stronger mineralization. Sheared mudstone beds bound rare intervals of silicified sandstone with disseminated sphalerite.

**AD08-003**

AD08-003 was drilled to test the zinc soil anomaly, as well as to test the weak mineralization encountered in AD08-002. The hole was collared in strongly silicified sandstone with minor sphalerite and trace galena in moderately to highly oxidized quartz/calcite veins from 0.4m to 7.1m. The hole drilled through sections of highly silicified sandstone and grey mudstone to 100.3m, where it encountered green and maroon mudstone (Narchilla Fm.) to 111.2m. The hole consisted of moderate to highly sheared maroon mudstone to the end of the hole at 150.6m.

**AD08-004**

AD08-004 targeted the zinc soil anomaly. The hole collared in silicified sandstone with 0.5% light red-orangey-yellow sphalerite associated with quartz/calcite veining, from 14.0m to 38.0m. There is a concentrated section of 3% sphalerite from 25.8m to 34.6m. The hole contains unmineralised grey mudstone from 64.3–97.0m and silicified sandstone to the end of the hole at 176.8m. Minor reddish-orange sphalerite occurs from 112.6m to122.5m in association with quartz/calcite veining.

**AD08-005**

AD08-005 encountered trace amounts of sphalerite and galena throughout the hole over five intervals: 14.7m to 35.0m, 42.6m to 43.2m, 97.2m to 97.7m, 108.0m to 108.6m and from 130.0m to 130.4m. Mineralization is typically hosted within quartz-calcite veins in medium to coarse sandstone, but trace amounts also occur within veins in fine-grained mudstone. Final depth of 149.96m.

**Table 8: Significant Intercepts in 2008 Adrian Zone Drill Holes**

| Hole-ID | From (m) | To (m) | Interval (m) | Zn (%) | Pb (%) | Ag (ppm) |
|---|---|---|---|---|---|---|
| AD08-001 | 76.40 | 77.90 | 1.50 | 0.0 | 1.7 | 2.5 |
| AD08-002 | 121.28 | 123.28 | 2.00 | 1.7 | 0.1 | 0.4 |
| AD08-004 | 15.26 | 34.76 | 19.50 | 1.3 | 0.0 | 0.2 |
| | 25.76 | 27.76 | 2.00 | 4.6 | 0.0 | 0.7 |
| | 32.76 | 34.76 | 2.00 | 4.7 | 0.0 | 0.6 |

### Discussion

Mineralization was intersected in all five holes with the best results returning 1.3% Zn over 19.5 m in hole AD08-004. Mineralization occurs as disseminated or vein-hosted fine to coarse grained sphalerite predominantly hosted in strongly silicified, coarse grained sandstone.

Breccia intensity at the Adrian zone is greatly reduced when compared to elsewhere on the project. The style of mineralization and alteration, however, are similar indicating that a hydrothermal system is present at Adrian.

Drilling at the Adrian zone is consistent with the soil geochemical anomaly suggesting that the anomaly is real and an artefact of near surface mineralization. Significantly, the drilling to date has only tested 280m of strike length along the 600m-long soil anomaly. More intense mineralization may occur at depth or upslope of the zinc in soil anomaly. Further drilling is recommended at the Adrian zone to test upslope of the geochemical anomaly and additional mineralization at depth.

## Andrew Zinc Deposit

During 2008 drilling was primarily an infill program at 25 m drill centres. Significant 2008 results are summarized in Table 9.

**Table 9: Significant Intercepts in 2008 Andrew Zinc Deposit Drill Holes**

Composited values calculated using a 1% Zn or 1% Pb cut-off with up to 3 m of included waste. Minimum composite length is 1 m and additional 1% Pb cut-off composites were included into the table where the Pb values were not reflected by the Zn based compositing.

**Discussion**

Section 1800mE is typical of the eastern portion of the system. Here the body dips variably to the north, shallowing from -60º to -45º at a depth of 1050 RL. Increased drill density in the east has shown that the eastern portion of the mineralized vein system dips more shallowly compared to the western portion of the deposit, where the dip is more consistent at -70º near surface. The stockwork in the east typically ranges from 30m to 50m thick. Holes AN08-111 and AN08-120 increased the confidence in near surface mineralization eastward to section 1850mE.

A weakly developed stockwork was encountered in holes AN07-023 and AN07-025 on section 1900mE indicating that there is potential for the system to continue to the east. There is an opportunity to increase the deposit size eastward if the natural pinch and swell of the system is consistent with observations elsewhere in the zone.

Through the central portion of the zone the mineralized zone bends between 1100 RL and 1200 RL. This is not post-emplacement structural folding, but apparently inherited from the form of the fault focusing the mineralizing fluids.

## Darcy Zinc Deposit

Seventeen diamond drill holes for 2820m of core were drilled at the Darcy zone in 2008. Drilling in this area was designed to test an extensive Zn in soil anomaly, linear devegetated zones and mineralization encountered in 2001 (hole AN01-08) which returned 7.5% Zn over 5.55m.

The second hole of the 2008 program (DY08-002) intersected two mineralized intervals including 13.6% Zn over 28.29m and 11.9% Zn over 43.89m. A further 15 holes were subsequently drilled and significant results are presented in Table 10. Drill core from Darcy Zinc Deposit hole DY08-004 was oriented to better understand structural controls on the mineralization and its orientation. The zone proved an elusive target, owing to irregular geometry and to abundant late faults which have dissected the area.

Three additional intersections were encountered to the north of the main Darcy Zinc Deposit.

### Discussion

Drilling to date has delineated a roughly tabular stockwork body which dips to the northeast. Its interpreted true thickness ranges from 20 to 30 m and it is open to the west and the east. In general, the stockwork appears to be concordant with bedding in the area and shows a preference for being hosted by sandstone.

Exploration along strike from the main Darcy zone mineralization is recommended.

**Table 10: Selected Significant Intercepts in 2008 Darcy Zone Drill Holes**

| Hole-ID | From (m) | To (m) | Interval (m) | Zn (%) | Pb (%) | Ag (g/t) |

## Darin Zone

A total of 1699m in 13 drill holes were completed on the Darin zone in 2008 to test anomalous Zn in soils. Nine of these holes intersected mineralization ranging from trace to 11.2% Zn over 11.15m in hole DN08-008.

**Table 11: Significant Intercepts in 2008 Darin Zone Drill Holes**

| Hole-ID | From (m) | To (m) | Interval (m) | Zn (%) | Pb (%) | Ag (g/t) |
|---|---|---|---|---|---|---|
| DN08-001 | 37.5 | 38.4 | 0.9 | 7.37 | 0.00 | 1.1 |
| DN08-004 | 102.54 | 103.7 | 1.16 | 3.19 | 0.19 | 8.0 |

| | 159.19 | 163.67 | 4.48 | 1.25 | 0.04 | 0.9 |

**DN08-001**

DN08-001 encountered a narrow interval of fault-bound Narchilla mudstone at the top of the hole above a mixed sequence of Yusezyu sandstone and mudstone. Mineralization was encountered in a weakly silicified stockwork hosted in sandstone; with the strongest mineralization at 36.7m to 38.4m which returned 7.4% Zn. A major fault structure was encountered at 117m, and required a switch to BTW-sized drill tools to progress deeper.

**DN08-002**

Failed to encounter significant mineralization or stockwork zones. The hole encountered a fault bound wedge of Narchilla mudstone near the top of the hole and Yusezyu sandstone throughout the rest of the hole.

**DN08-003**

DN08-003 encountered mostly Yusezyu sandstone with a narrow, fault-bound interval of Narchilla mudstone near the bottom of the hole. Based on surface interpretation and a younging reversal noted during logging, this hole crosses the axial plane of a syncline. Minor barren stockwork was encountered in two intervals and no significant values were returned in the hole.

**DN08-004**

DN08-004 was drilled SW of DN08-001 along the same section line. Minor mineralization was encountered at 102.5m and is hosted within quartz-calcite veins and is also found as disseminations within coarse grained sandstone. Two narrow intervals of barren stockwork were encountered in the hole. Upright bedding indicators are

consistent with this hole passing through an upright western limb of a syncline. Final depth 156.9m

**DN08-005**

This hole is dominated by sandstone with interbedded mudstone, and short fault zones. Two short zones of sphalerite and galena mineralization were encountered near the bottom of the hole. The mineralization is hosted within quartz veins.

**DN08-006**

Sphalerite and minor galena mineralization were encountered in this drill hole over two intervals. The main mineralised zone was encountered from 44.1m to 57.5m. A second zone was encountered deeper in the drill hole from 101.1m to 101.6m with 0.5% sphalerite. Mineralization is hosted within quartz-carbonate veins. Several barren stockwork zones were encountered.

**DN08-007**

This hole encountered minor mineralized stockwork and an interval of shallow barren stockwork. This hole cored near the syncline hinge.

**DN08-008**

This hole intersected two significant intervals of mineralization including 10.5m of 3.6% Zn from surface and 21.2m of 4.8% Zn from 103.5m. The shallow interval is the same barren interval encountered in DN08-007 and illustrates the proximal nature of targeted drilling. The deeper interval is interpreted to be the same zone encountered in DN08-012 and is probably a bedding-concordant fault system.

**DN08-009**

This hole intersected several intervals of moderately strong stockwork. The only mineralization encountered was a vein of yellowy-brown sphalerite in stockwork at about 52m downhole. The main stockwork zone exposed at surface to the north was encountered in the bottom of this hole but it seems to pinch out.

**DN08-010**

This hole intersected several intervals of moderately strong stockwork including a broad interval at about 50m downhole. Significant mineralization, however, was not encountered.

**DN08-011**

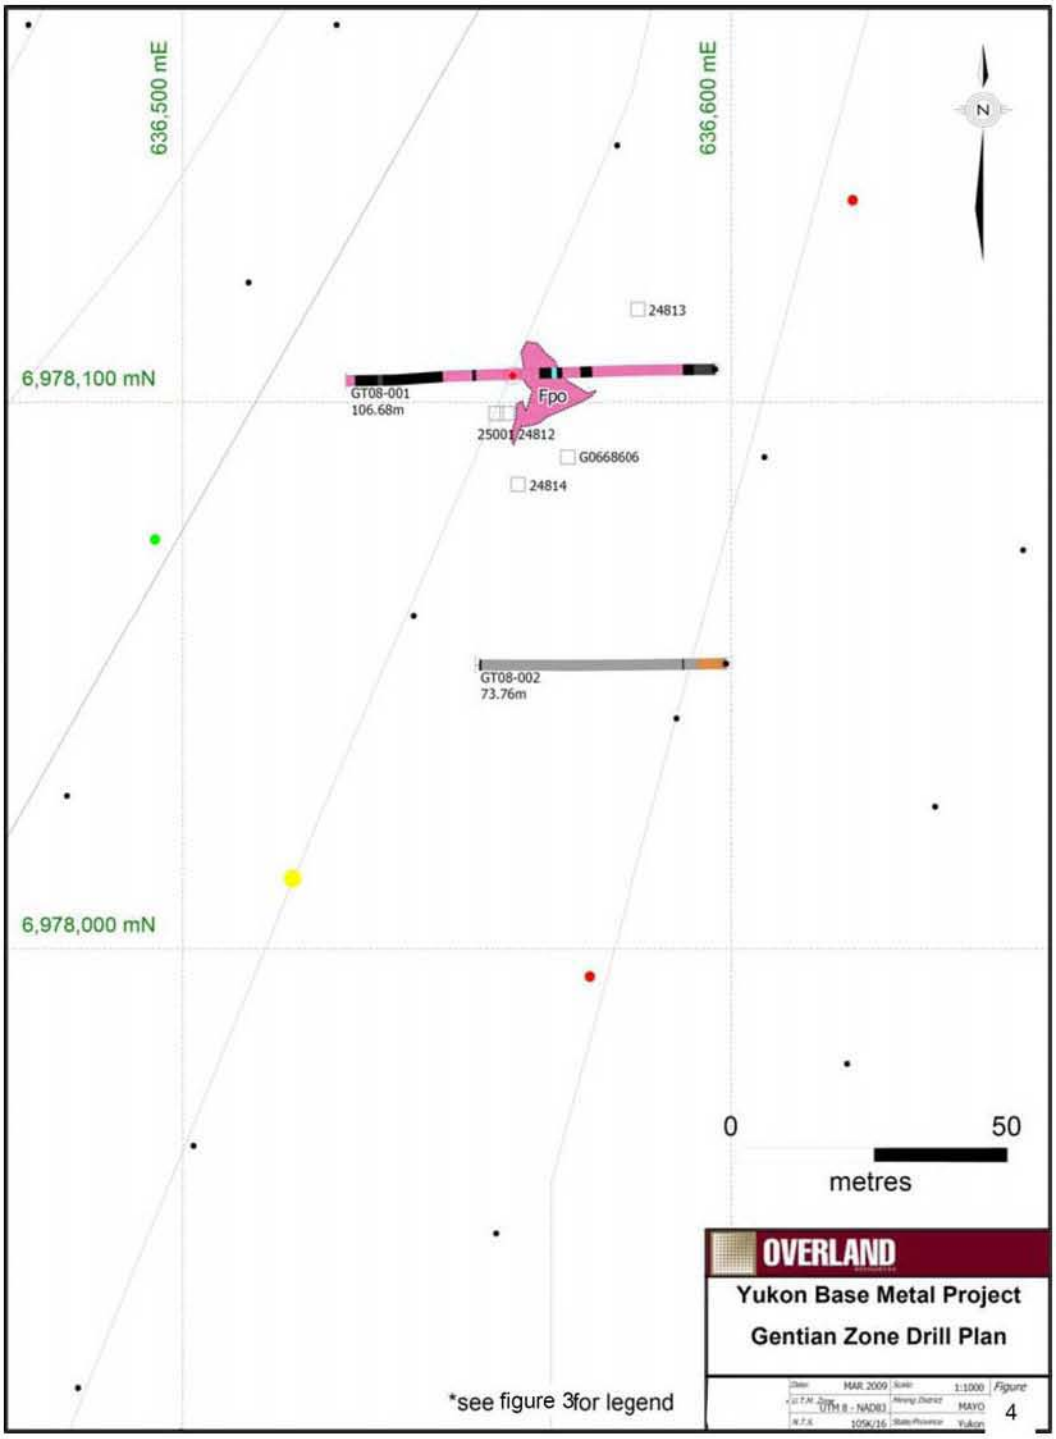
Several stockwork and breccia zones occur in this hole, but only trace sphalerite mineralization was intersected from 32.2m to 32.6m within Yusezyu formation.

**DN08-012**

A moderate quartz-calcite stockwork and breccia zone with trace to 2% sphalerite and galena was intersected from 15.4m to 35.6m. This zone is directly above a fault-bound zone of Narchilla mudstone. The zone is a similar width to the zone in DN08-008 but the grade is much lower.

**DN08-013**

This hole was drilled as an exploration as well as follow-up hole to DN08-008 along strike to the north. Minor mineralization was encountered at three separate zones within the drill hole from 7.4m to12.2m, 86.2m to 86.8m and from 151.2m to 161.5m. The highest grade found within any of these three zones was 3% sphalerite found from 10.7m to 12.2m.



### Discussion

Drilling at the Darin zone has delineated a new mineralised hydrothermal system about 270m long which shows many of the characteristics of the Andrew Zinc Deposit. The system trends northwesterly.

As evident in DN08-008 drilling has been conducted on the edge of the mineralised system. Drilling further to the south could result in the discovery of additional mineral resources.

## Gentian Zone

During the 2008 drill program, two holes were drilled within the Gentian zone totalling 180.4 m (Figure 8). No significant mineralization was intersected within these drill holes. These holes were designed to test the continuity of sphalerite and galena mineralization at depth beneath the Scott kill zone.

**GT08-001**

GT08-001 was drilled below sphalerite bearing float in the Scott Kill zone, in order to test the subsurface extent of the mineralization. The hole intersected abundant feldspar-amphibole porphyry dykes up to 20m thick but typically 5m to 10m thick intruding black mudstone and fine grained calcareous sandstone. Trace sphalerite mineralization was

observed occurring sporadically from 69m to 87m depth within chaotic sphalerite-galena-calcite veins. Sphalerite mineralization occurred entirely within sedimentary rock and rarely, occurred in abundances greater than 5% over 1.5m. Contacts between the porphyry and sedimentary rocks were commonly brecciated and locally cemented by calcite.

#### GT08-002

GT08-002 was drilled 50m to the south of the Scott Kill zone in order to test for any subsurface mineralization, indicated by float mineralized with sphalerite in the kill zone. The hole intersected intercalated finely laminated black mudstone and calcareous siltstone. The hole was abandoned at 73.76m due to poor ground conditions; core was not recovered from 72.54m to 73.76m.

### Discussion

Trace mineralization was intersected beneath the Gentian kill zone and is similar in style to the mineralization observed at surface. Calcite-cement breccias within sedimentary rocks at the margin of the feldspar porphyry dykes were intersected and are interpreted to indicate hydrostatic brecciation caused by fluids heated by the intruding magma.

## Lad Zone

In 2008, two holes totalling 214.9m were drilled on the Lad zone (Table 12; Figure 5) to test semi-massive replacement style galena-sphalerite-pyrrhotite mineralization. Neither hole intersected significant mineralization. The holes were collared approximately 25m apart along strike of the mineralization observed at surface.

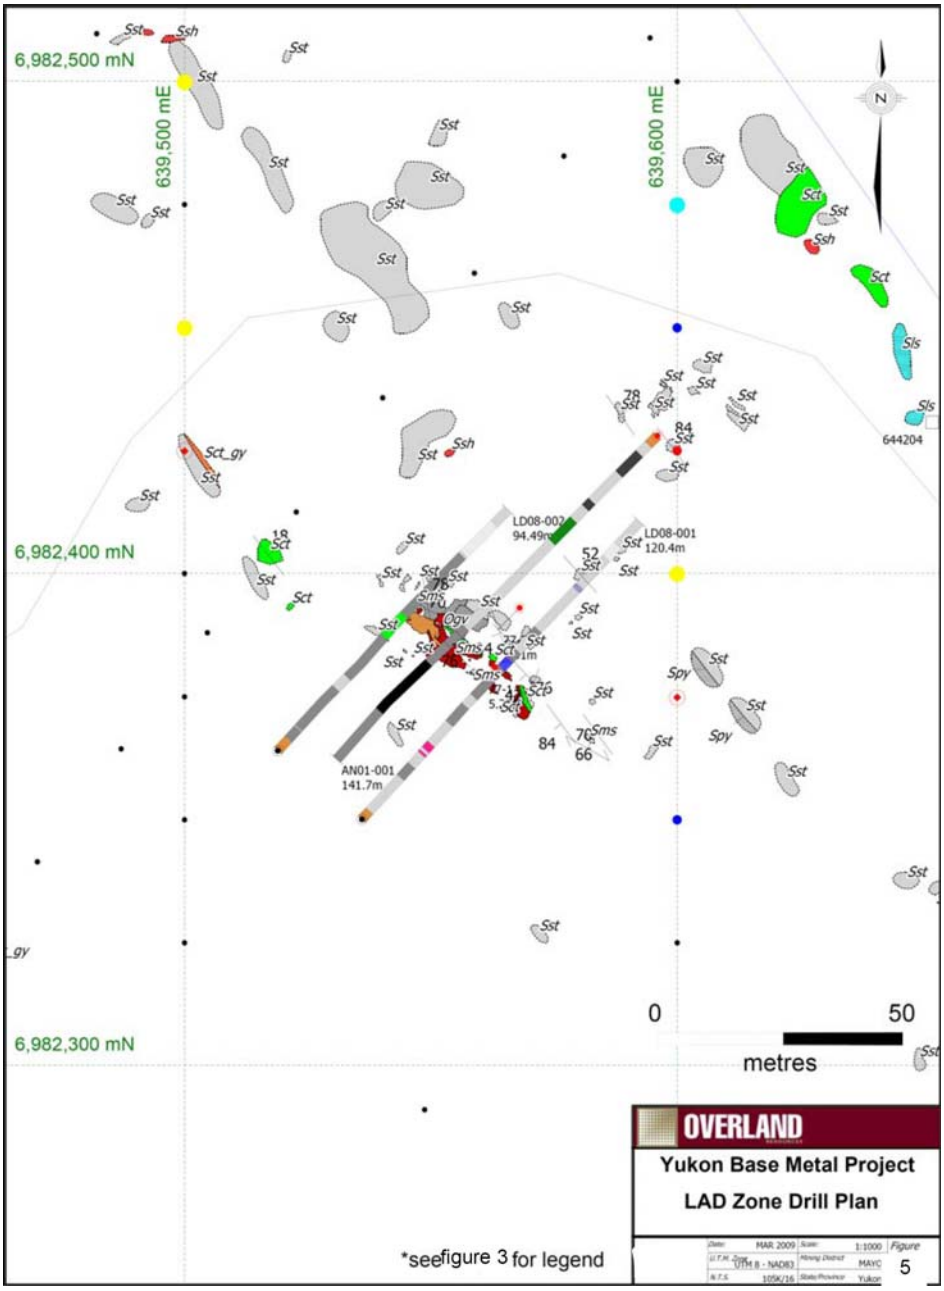


**Table 12: Summary of Lad prospect Diamond Drill Holes**

| Year | # of holes | Hole Numbers | Core Size | Total metres | Operator |
|---|---|---|---|---|---|
| 1977 | 2 | 77-1, 77-2 | unknown | 15.32 | CIMA |
| 2001 | 1 | AN01-01 | NQ2 | 141.7 | Noranda |
| 2008 | 2 | LD08-001 - LD08-002 | NTW | 214.89 | Overland |

#### LD08-001

LD08-01 was drilled to test the subsurface extent of replacement style and fractured hosted vein style galena and sphalerite mineralization observed on surface. The hole was drilled down-dip of the surface showing, 40m to the south-west.

This hole intersected 120.40m of interbedded mudstone and sandstone hosting pyrite and pyrrhotite veins, trace sphalerite veins, but no significant sulphide mineralization. The rock showed moderate silica flooding and chlorite alteration.

**LD08-002**

LD08-002 was drilled 15m to the north-east of LD08-001. Drilling proceeded through highly fractured mudstone, chert and rare interbedded sandstone. The mudstone showed moderate silica alteration and local reduction patches proximal to quartz veins.

Fractures had a common vein assemblage of pyrrhotite-pyrite-quartz, minor chalcopyrite, and trace galena and sphalerite. Geochemical results from this hole are generally low, although a 2m wide zone from 24.38 m returned 0.4% Zn and 0.4% Pb.

**Discussion**

Shallow drill-testing at the Lad prospect intersected only minor base metal mineralization. The distribution of mineralization could be highly irregular and podiform resulting in drill holes missing the strongly mineralized areas. Induced Polarization geophysics could be useful to delineate regions of increased sulphide concentration proximal to the Lad and would provide additional targets for further drill testing.

## Robin Zone

During the 2008 drill program, three holes were drilled into the Robin zone to test anomalous Zn values revealed from a soil sampling program in the late 1960s. The holes intersected Hyland Group sandstones and mudstones but none of the drill holes intersected significant mineralization and no samples were collected.

**Statement of Qualifications**

I, Hugh Alan Bresser hereby certify that:

1. I am a graduate of James Cook University of North Queensland (1992) with an Honours Bachelor of Science degree in Metalliferous and Economic Geology, and am a graduate of Queensland University (2004) with a Masters of Business Administration, and I have practiced my profession continuously since 1992.
2. I am a Member of the AusIMM.

Dated at Perth, Austrlalia, this_____day of _____.

# Appendix C: Statement of Expenditures

**STATEMENT OF EXPENDITURES**
**ANDREW PROPERTY**
**Fieldwork: March 15 - September 20, 2008**

## PROFESSIONAL FEES AND WAGES:

| | | |
|---|---|---|
| Eleanor Alesi, Geologist | | |
| 78.75 days @ $525/day | $ | 41,343.75 |
| Henry Awmack, P.Eng. | | |
| 9.27 days @ $650/day | | 6,025.50 |
| Darcy Baker, Project Geologist | | |
| 143.15 days @ $650/day | | 93,047.50 |
| Cam Bartsch, Geologist | | |
| 16.50 days @ $525/day | | 8,662.50 |
| Scott Berdahl, Geologist | | |
| 35.00 days @ $525/day | | 18,375.00 |
| Robin Black, Project Geologist | | |
| 150.12 days @ $650/day | | 97,578.00 |
| Wanda Carter, Geologist | | |
| 105.00 days @ $525/day | | 55,125.00 |
| Kelly Caulfield, Senior Sampler | | |
| 87.00 days @ $325/day | | 28,275.00 |
| Marcel Cerel, Cook | | |
| 78.50 days @ $450/day | | 35,325.00 |
| Ken Creemer, Sampler | | |
| 8.00 days @ $275/day | | 2,200.00 |
| Ken Creemer, Padbuilder | | |
| 26.00 days @ $400/day | | 10,400.00 |
| Amber Dales, Cook | | |
| 123.50 days @ $450/day | | 55,575.00 |
| Samantha Darling, Senior Sampler | | |
| 16.00 days @ $325/day | | 5,200.00 |
| Chris Deveau, Padbuilder | | |
| 81.50 days @ $400/day | | 32,600.00 |
| James Dick, Camp Manager | | |
| 34.00 days @ $400/day | | 13,600.00 |
| Harold Dick, Sampler | | |
| 109.73 days @ $275/day | | 30,175.00 |
| Jenni Dickinson, Project Geologist | | |
| 29.00 days @ $525/day | | 15,225.00 |
| Kelsey Dodge, Geologist | | |
| 26.00 days @ $525/day | | 13,650.00 |
| Thomas Dodge, Sampler | | |
| 57.00 days @ $275/day | | 15,675.00 |
| Thomas Dodge, Padbuilder | | |
| 43.00 days @ $400/day | | 17,200.00 |
| Matthew Eckfeldt, Geologist | | |
| 95.00 days @ $525/day | | 49,875.00 |
| Camille Eliott, Cook | | |
| 129.50 days @ $400/day | | 51,800.00 |
| Kristy Emery, Advisor | | |
| 244.25 days @ $115/hour | | 28,088.75 |
| Kristy Emery, Project Manager | | |
| 15.00 days @ $575/day | | 8,625.00 |
| Nicole Etzel, Senior Sampler | | |

| | | |
|---|---|---|
| | 93.50 days @ $325/day | 30,387.50 |
| Stewart Harris, P.Geo. | | |
| | 0.31 days @ $650/day | 201.50 |
| Brittany Hilderman, Senior Sampler | | |
| | 117.50 days @ $325/day | 38,187.50 |
| Jodi Inkster, Sampler | | |
| | 44.00 days @ $275/day | 12,100.00 |
| Heather Jaggard, Geologist | | |
| | 110.50 days @ $525/day | 58,012.50 |
| Adele Johnston, Cook | | |
| | 9.00 days @ $450/day | 4,050.00 |
| Tiffany Lunday, GIS | | |
| | 4.00 hours @ $75/hour | 300.00 |
| Danielle MacPheat, Sampler | | |
| | 71.50 days @ $275/day | 19,662.50 |
| David Magill, Sampler | | |
| | 11.00 days @ $275/day | 3,025.00 |
| Rachael Marshall, Geologist | | |
| | 99.50 days @ $525/day | 52,237.50 |

**Objective:**

AD08-001 targeted the subsurface extension of the mineralized quartz-calcite stockworked outcrop of the Dawson prospect, coupled with anomalous Zn soils. Mineralization was present as trace sphalerite, pyrite, and lesser galena but continuous over large intervals generally as replacement sulphides within quartz veins hosted in sandstone and less commonly carbonaceous mudstone. Sandstones were commonly weakly to moderately stockworked.

**SUMMARY LOG:**

| | | Dark to medium grey well bedded mudstone. Mudstone dominated unit with 30-40% bedded fine-grained sandstone. This possibly is a larger scale sedimentary breccia unit with large sandy rip-ups and brecciated light grey mudstone beds in a black mud matrix. Bedding angles vary greatly in a short interval from 40°CA, to parallel to CA, to 55°CA. Angular to sub-angular brecciated clasts of tan mudstone or sandstone are located proximal to their host within a black mudstone matrix. Only minor quartz calcite veins are observed. An opaque white calcite-quartz vein contains galena which is replacing the vein quartz-calacite from 77.35 - 77.7 m at low angle to CA. Specks of trace 2-5 mm brown zoned honey sphalerite is observed dowhole from the galena minaleralization. Mineraliztion is dominantly found in sandstone with minor sphalerite in mudstone. |

| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AD08-002 was drilled in the Adrian zone to test the subsurface extent of galena and sphalerite veins found in outcrop. The hole was drilled perpendicular to bedding on surface, and did not encounter significant mineralization. There was no day shift drillers for July 20th and 21st.

| | | **SANDSTONE** |
| | | **The unit is dominantly a quartz rich sandstone with 0-8% feldspar grains less than 2mm in size, and 0-2% lithic fragments. Some intervals have 2-3mm subrounded quartz grains and rare opalescent quartz grains. Rarely the unit is a mud-supported sandstone with muddy and silty laminations. Generally the unit has very low bedding angles and is moderately cross-cut by quartz veining. Veins near the top of the unit have a rusty periphery. Trace sphalerite can be found within some quartz stringers. Trace disseminated pyrite. Some quartz veins have a dark hard periphery, possibly chlorite within quartz, and rarely a calcite core.Grain size decreases but the percentage of feldspar increases to 5% at 22.00m.** |

| | | **SANDSTONE** |
| | | The unit is a medium grained, moderately silicified quartz rich sandstone. The unit has approximately 1% feldspar grains locallized in short intervals. Occasional thick quartz veins cross-cut the unit and contain trace sphalerite. Sphalerite is also disseminated within a silicified sandstone interval bounded by sheared grey mudstone. Some intervals of the sandstone have quartz grains up to 2mm in size and also have irregular parallel lineaments oriented at approximately 50 degrees to core axis, possibly an alteration along a planar weakness. |

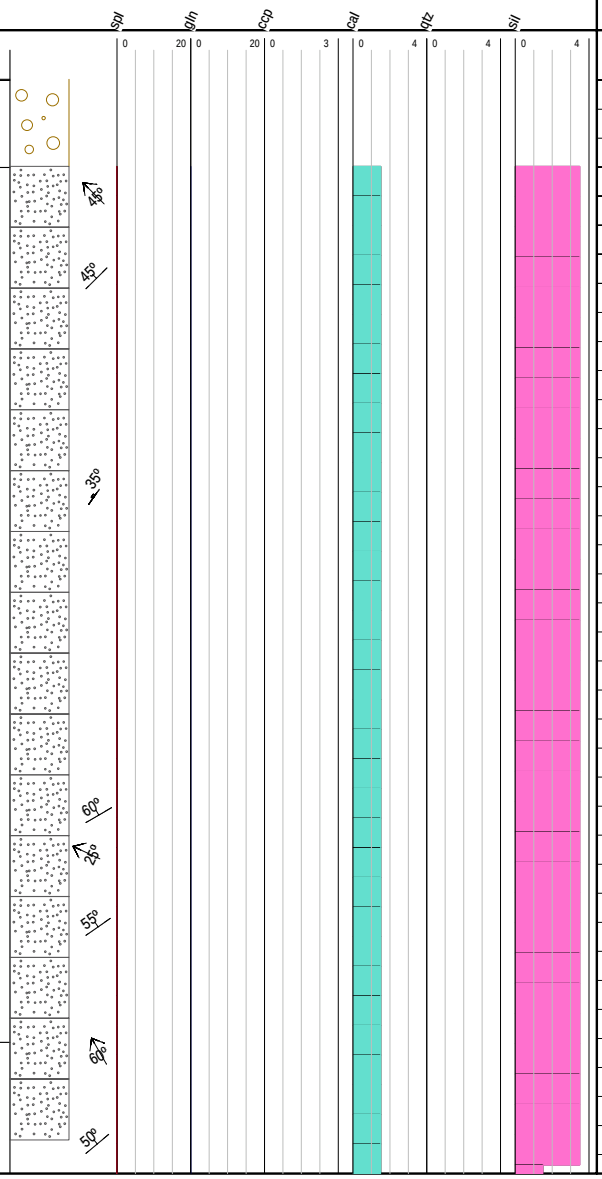
|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1179.0 m |
| **Hole:** | AD08-003 | **Azimuth:** | 65.0° |
| **Proposed:** | propAD08-D | **Dip:** | -50.7° |
| **Location:** | 642942 m East 6977858 m North | **Length:** | 150.57 m |
| **Area:** | Adrian_zone | **Date started:** | **Date completed:** |
| **Claim:** | AMB10 | 2008/08/03 | 2008/08/05 |
| **Logged by:** | J.Norris | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Hole AD08-003 is being drilled at an azimuth of 65 degrees and at a dip of -50 to further explore a zinc soil anomaly in the Adrian zone. Two holes have previously been drilled in this zone, including AD08-02 which was drilled along the same section as this hole will be. Hole AD08-002 intersected weak mineralization. This hole is planned to go to a depth of 150m.

**SUMMARY LOG:**



0m to 0.42m - Overburden
0.42m to 7.10m - Sandstone with minor sphalerite and trace galena
7.10m to 15.45m - Grey Mudstone
15.45m to 22.21m - Sandstone
22.21m to 39.43m - Grey Mudstone
39.43m to 48.00m - Sandstone
48.00m to 49.48m - Calcareous Sandstone
49.48m to 50.19m - Black Mudstone
50.19m to 100.30m - Sandstone
100.30m to 103.05m - Green Mudstone
103.05m to 105.46m - Maroon Mudstone
105.46m to 106.68m - Green Mudstone
106.68m to 108.01m - Sandstone
108.01m to 111.16m - Green Mudstone
111.16m to 150.57m - Maroon Mudstone
150.57m - End of Hole

| | | Sandstone |
| | | Highly silicified, fine to medium grained light grey, massive sandstone. The unit contains 15% quartz/calcite veining from 2mm to 3cm thick. The quartz/calcite veins weakly to moderately brecciate the sandstone in localized sections. The veins appear to have occured in several pulses, due to the cross-cutting relationships seen. The unit is very competent. There is very minor 2-4cm interbeds of finely laminated grey mudstone throughout. |
| | | There is minor amounts of sphalerite associated with the quartz/calcite veining. The sphalerite occurs as 2-5mm dark red to brown blebs are strongly altered and leached from the quartz/calcite veins, leaving 2-5mm sized vugs. Some of the veins have an orange staining due to the leaching of the sphalerite. Trace galena is seen as 1mm and sub-mm sized crystals, associated with the sphalerite. |
| | | 5.64m - The sandstone becomes moderately silicified and is a medium to dark green in colour, with 2-5% 1mm to 1cm quartz/calcite veinlets. It is likely that the very light grey colour of the upper portion of sandstone has experienced a much higher degree of alteration and silicification. |

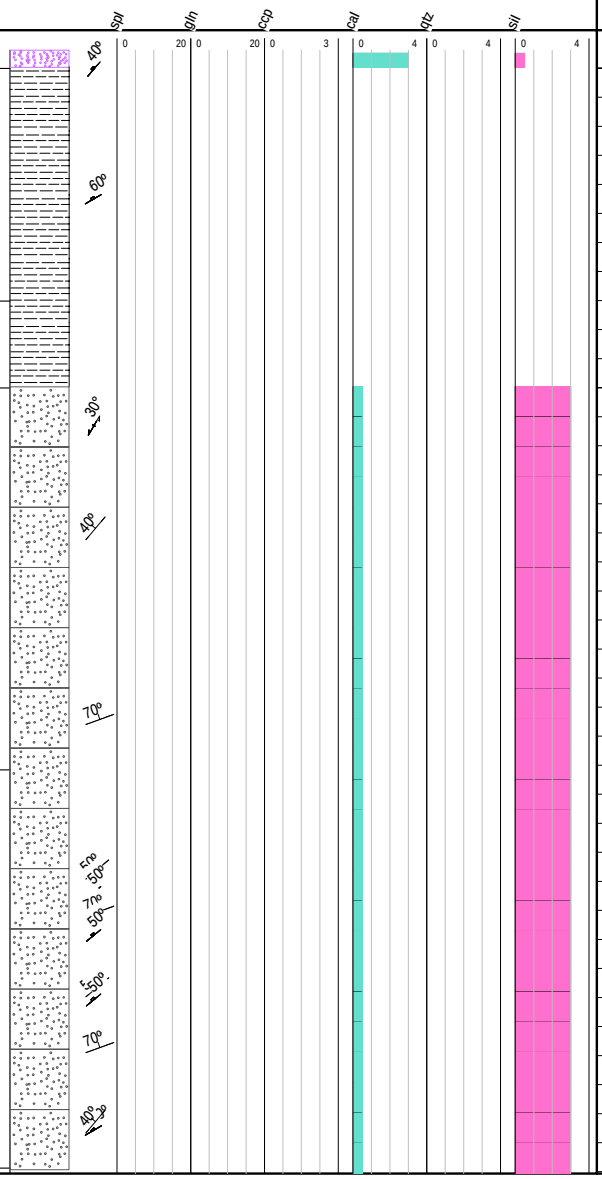
**Sandstone**

Highly silicified, medium grey, massive sandstone with 5-10% 1mm to 1cm quartz/calcite veinlets throughout. There are loalized sections of highly silicified, fine to medium grained sandstone clasts 2mm to 4cm in size which are within a black mud matrix. This breccia is clast-supported, with 70% clasts to 30% matrix. The entire unit is competent with localized sections of faulting.



The upper 5.5m of the unit is coarse-grained with subrounded clasts up to 4mm in diameter. There is a minor amount of blue opalescent quartz grains in this section. There s 10% clasts which are being weathered away to a light whitish powder.

The rest of the unit is fine to medium grained, medium grey sandstone with minor 1-50cm interbeds of finely laminated grey +/- green mudstone. The sections containing mudstone are moderately sheared. Throughout this bottom section of the unit, there is minor beds up to 50cm of dark grey to brown, non-silicifed, fine-grained sandstone, which is moderately bedded and contains sheared clasts of mudstone up to 5mm in size. Trace amounts of very fine-grained pyrite occur in masses up to 4mm, within the dark grey, unsilicified sandstone.

Faulted contact with overlying black mudstone

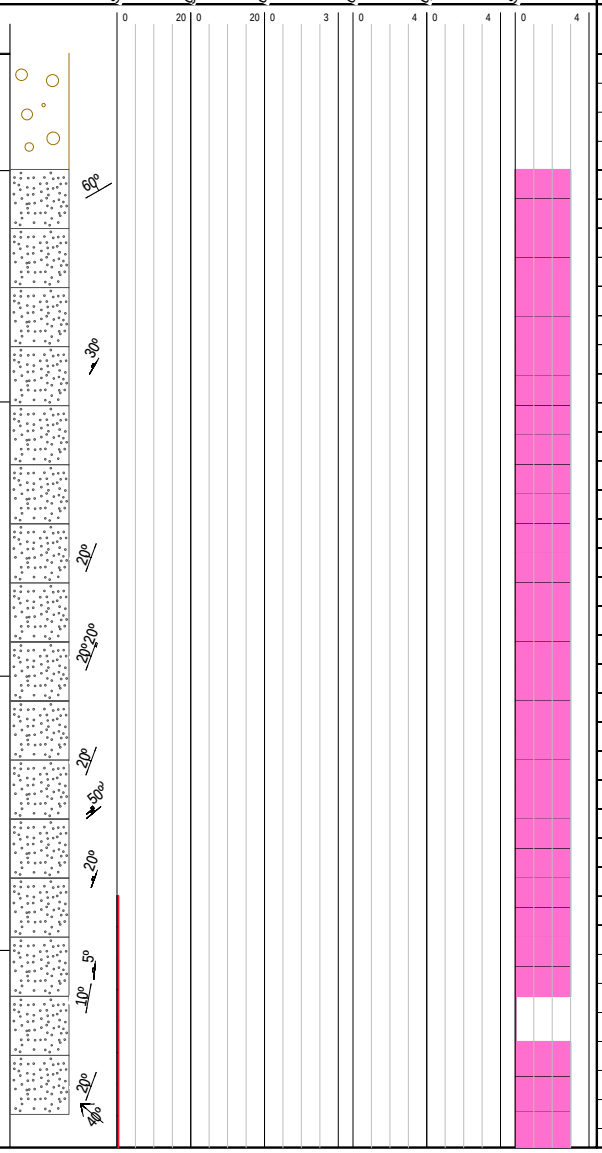
# DRILL LOG

| | | | |
|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1170.0 m |
| **Hole:** | AD08-004 | **Azimuth:** | 62.8° |
| **Proposed:** | propAD-F | **Dip:** | -49.4° |
| **Location:** | 643047 m East 6977711 m North | **Length:** | 176.78 m |
| **Area:** | Adrian_zone | **Date started:** | **Date completed:** |
| **Claim:** | AMB10 | 2008/08/05 | 2008/08/08 |
| **Logged by:** | J.Norris | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Hole AD08-004 is being drilled to further test the zinc soil anomaly known as the Adrian Zone. Three holes have been previously drilled in the area and have returned weak sphalerite mineralization. It is hoped that AD08-004 will add to the understanding of the mineralization in the area.

**SUMMARY LOG:**



0m to 0.76m - Overburden
0.76m to 64.30m - Sandstone with 2% sphalerite from 14m to 38m.
64.30m to 96.98m - Grey Mudstone
96.98m to 176.78m - Sandstone with minor sphalerite from 112.58m to 122.50m.
176.78m - End of Hole

| | | **Overburden** |
| 0.76 | 64.30 | Sst |
| | | **Sandstone** |
| | | **Strongly silicifed, medium to light grey, fine to medium-grained, weakly bedded sandstone with 5% quartz/calcite veins from 1mm to 3cm in size. The majority of the sandstone is light grey, highly silicified with blotchy sections of dark grey, less altered, original sandstone. There are minor sections throughout, of dark grey to brown, fine-grained, non-silicifed sandstone with minor 5mm to 1cm dark grey mudstone interbeds. These sections of unsilicifed sandstone occur up to 2m long. There is also minor dark grey mudstone interbeds up to 2cm thick throughout the silicified sandstone. There are minor localized sections within the silicified sandstone which are weakly altered to a light tan colour. There are localized sections up to 1m thick throughout the unit where there is 10% subrounded quartz clasts, 2-3mm in size. Trace pyrite nodules up to 1cm in size in the silicifed sandstone, as well as trace very-fine grained pyrite within the unsilicified sandstone.** |
| | | **The upper 12m of the core is highly silicifed sandstone which has been oxidied and has a tan-brown rusty alteration overprint throughout. There is also oxidized and leached quartz/calcite veins with vugs up to 5mm in size.** |
| | | **There is 0.5% sphalerite from ~14m to ~38m as reddish-orange to yellow blebs and masses associated with quartz/calcite veining. The mineralization typically occurs within 1-4cm quartz/veins, and to a lesser extent is found as small 1-2mm blebs within the sandstone and mudstone. Trace galena was observed in one vein, associated with sphalerite mineralization. The highest concentration of mineralization occurs as 3% spahlerite from 25.83m to 34.60m.** |

| | | Sandstone |
| | | Highly silicifed, light to medium grey, fine to medium grained, massive to moderately bedded sandstone. There is 5% quartz/calcite veining throughout, up to 4cm thick. There are localized sections of weakly silicifed fine to medium grained greenish grey to brownish grey sandstone throughout, up to 1.5m thick. There are also localized sections of siltstone/grey mustone interbeds throughout the highly silicified sandstone from 5mm to 75cm thick. The dark grey mudstone is finely laminated and contains minor fine grained pyrite beds. The highly silicifed sandstone shows blotches and veinlets of dark grey sandstone, these are portions of the original sandstone which have experienced less silicification and still retain trace lithic fragments. The unit is weakly folded and contains minor sections of hydrothermal breccia, where sandstone and mudstone clasts up to 5mm are seen within quartz/calcite veins. The unit is |

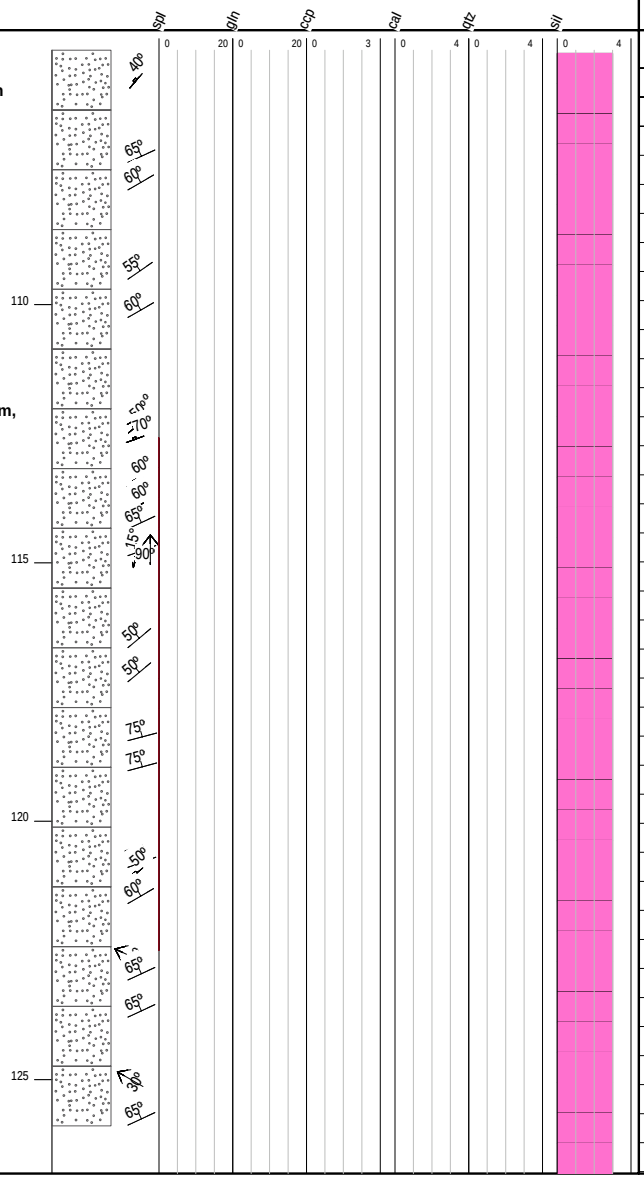
| From | To | Rocktype & Description |
|---|---|---|

very competent with few localized faults, mostly contained within mudstone interbeds. Trace pyrite thoughout, as 1-2mm blebs and subhedral crystals within the sandstone and as fine-grained pyrite within the mudstone.

There are a few localized sections up to 50cm thick within the silicified sandstone which are very coarse-grained, with clasts up to 4mm in size, with a trace amount being blue opalescent quartz.

There is minor sphalerite mineralization associated with quartz/calcite veining. The sphalerite occurs as reddish-orange blobs up to 1.5cm in size. There is also 1-2mm dark red sphalerite blebs which are located within the silicified sandstone, possibly replacing some of the clasts. The sphalerite mineralization is concentrated from ~112m to ~122.50m. From ~104.50m to ~108m, the quartz calcite veins appear weakly leached and vuggy with a minor rusty colour stain.



Sheared contact with overlying grey mudstone.

| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Hole AD08-005 is being drilled at an azimuth of 65 degrees and at a dip of -50 degrees to test the zinc soil anomaly known as the Adrian Zone. Four holes have previously been drilled on this zone and have encountered weak sphalerite mineralization. The objective of AD08-005 is to further test the mineralization encountered on this zone.

| | | SANDSTONE: medium to coarse grained sandstone. Low recovery of core. Rock fragments range in size from 1cm-wide to 15cm wide. Fragments are angular to subangular. Upper contact is gradational over approximately 50cm with overlying overburden and lower contact is sharp with underlying mudstone unit. |

| | | Veining: weak quartz veining throughout unit « qtz 1.00*» |
| 14.71 | 40.84 | Sst |
| | | SANDSTONE: unit is light grey, fine to medium grained with intense silica alteration throughout the majority of the unit. Sandstone is fairly competent with some faulted zones detailed below. Unit is interbedded with mudstone on scales of 2-40cm scattered throughout sandstone. Unit is mineralized with trace sphalerite, galena, and pyrite. Upper contact is fairly sharp over 2cm over with the overlying mudstone unit. Lower contact is gradational over 25cm with the underlying fault breccia. |
| | | Structure: Some faulted sections within unit detailed below: |
| | | -From 15.34-15.53m is a fault zone with 100% mudstone. Zone is 100% angular rock fragments ranging in size from <1cm-4cm. |
| | | -From 21.87-22.62m is a faulted/fractured zone with 5% gouge and 95% angular rock fragments. Fragments range in size from ~1cm-12cm. |
| | | -From 25.95-26.08m is a fault zone with 80% gouge and 20% rock fragments. |
| | | -From 35.28-36.16m is a faulted brecciated zone with 30% gouge cemented with 70% angular rock fragments. |

**SUMMARY LOG:**

| | |
|---|---|
| 0.00 - 3.40 m: | Overburden |
| 3.40 - 20.94 m: | Green mudstone |
| 20.94 - 35.92 m: | Grey mudstone |
| 35.92 - 77.19 m: | Sandstone |
| 77.19 - 79.05 m: | Fault brecciation of sandstone |
| 79.05 - 80.15 m: | Sandstone. Small load casts at 79.20m indicate that the unit is overturned at this point. |
| 80.15 - 82.67 m: | Calcareous sandstone |
| 82.67 - 83.35 m: | Green mudstone |
| 83.35 - 104.73 m: | Red/maroon mudstone (locally highly fault brecciated +/- gouged) |
| 104.73 - 111.25 m: | Green mudstone |
| 111.25 - 112.50 m: | Grey mudstone |
| 112.50 - 113.40 m: | Limestone |
| 113.40 - 114.30 m: | Black mudstone |
| 114.30 - 146.20 m: | Mineralized zone, exhibiting stockwork veining of spl-cal veins. Sphalerite occurs as patches and blebs from trace amounts up to sections 3 m wide of 30% spl. Overall this mineralized zone hosts roughly 5% sphalerite. |
| 146.20 - 147.18 m: | Sandstone |
| 147.18 - 151.70 m: | Felsic porphyry (quartz feldspar porphyry) |
| 151.70 - 154.31 m: | Mineralized zone, as sphalerite hosted stockwork calcite veins. Overall roughly 1% spahlerite. |
| 154.31 - 164.00 m: | Sandstone, containing trace sphalerite |
| 164.00 - 166.20 m: | Mineralized zone. Stockwork calcite veins hosting sphalerite, with roughly 7% sphalerite overall. |
| 166.20 - 170.20 m: | Sandstone |
| 170.20 - 178.42 m: | Grey mudstone |

| | | Sandstone. Fairly sharp contact with overlying sedimentary brecciated grey mudstone. Sandstone is medium grained, medium grey in colour, fairly massive with about 10-15% 1-5mm calcite veinlets throughout at varying orientations, roughly 50 degrees TCA. Interbedded with the sandstone are laminations of dark grey mudstone as well as greenish grey mudstone, plus fine-grained greenish-grey sandstone beds. The mudstone bands are typically 1-10cm thick , comprising about 15% of the unit. Bedding is well defined in the mudstone, marking shallow folds. Few rip-up clasts of mudstone within the sandstone occur. Very minor, trace pyrite blebs occur throughout the sandstone. |

| | | Stockwork sphalerite veins throughout fine to medium grained grey sandstone unit and grey to black mudstone. Sphalerite occurs as reddish-orange patches and blebs to dense masses within calcite veins. Calcite veins generally range from 1mm up to 5cm thick, but few occur as 10-60cm thick veins. Sphalerite sometimes appears to replace clasts of sandstone and grey to black mudstone which have been brecciated by calcite veins. It seems that there are at least 2 generations of calcite veins, the later set hosting the mineralization. Trace chalcopyrite is rarely associated with sphalerite, and trace galena seen is |

| From | To | Rocktype & Description |
|---|---|---|
| 146.20 | 147.18 | Sst |
| | | Sanstone. Medium grained, medium grey in colour. Fairly massve with abundant (35%) 3-5mm calcite veinlets throughout. Weak mudstones present, however there are dark grey to black mudstone veinlets/brecciated beds. No bedding is visible. Fairly sharp (yet rubbelized/faulted) contact with upper sphalerite veined unit. Competent rock with faulted contact with lower Fpo unit, which appears to be gradationally interbedded (identified by rock fragments). No orientations on contact. Unit contains no mineralization. |
| 147.18 | 151.70 | Fpo |
| | | Quartz feldspar porphyry. 70% Qtz, 30% plagioclase feldspar. Qtz is anhedral in shape and acts as the groundmass surrounding the 1-2mm feldspar crystals. The feldspar crystals are generally subhedral to anhedral in shape, but there are some euhedral crystals present. The density of the plagioclase feldspars varies throughout the unit from 10-50% in localized bands. There is no fabric defined by the feldspar crystals. No mafic minerals are identifiable in the unit. Near the lower contact of the unit, the felsic prophyry seems to be intercalated with sections of sandstone, appearing to be separated by calcite veinlets +/- fracture planes. There are 10-15% 1mm to 3mm calcite veinlets throughout, at varying orientations, with localized calcite veins up to 2cm thick. Trace minor quartz veinlets (1-3mm) are also seen. No sphaelerite seen in unit. |
| | | « 150.22- 150.25 gln 10.00% 8.00cm» Galena seen as a blebby patch of 1-2mm crystals in an 8cm calcite vein. |
| 151.70 | 154.31 | Vspl |
| | | Stockwork sphalerite veins within sandstone unit. Sandstone is a medium grained, medium grey unit, with few thin to medium interbeds of grey to black mudstone. 15-20% 1mm to 1cm calcite veins throughout at varying oreintations. Not every calcite vein hosts sphalerite. Sphalerite occurs as reddish-orange blebby patches, associated with thicker (0.5cm to 1cm) calcite veins. |
| | | Fault brecciated from 152.10m to 152.25m. 80% rock fragments to 20% gouge. |
| | | Fault brecciated from 152.67m to 152.77m. 85% rock fragments to 15% gouge. |

|---|---|---|
| | | with the green mudstone that lies above it in the hole. |
| | | This interval is composed of grey and green mudstone, fine to coarse grey |
| | | sandstone and some light grey limestone, with a stockwork of quartz-calcite |
| | | veins running through the rock containing sphalerite and galena as well as |
| | | trace chalcopyrite. |
| | | « 134.33- 135.33 spl 3.00%» |
| | | « 134.33- 135.27 gln 4.00%» |
| | | Between 134.33 and 135.27m the galena is concentrated into coarse-grained clots |
| | | that are located within veins. The sphalerite is fine-grained, red-brown and |
| | | more thinly spread throughout the length of the veins. In places where the rock |
| | | is especially brecciated, the sphalerite can appear as the matrix between |
| | | clasts. |
| | | Between 138.0 and 139.4m there is an interval of grey mudstone that has been |
| | | highly veined but contains no mineralisation to the eye. |
| | | After 139.4 the mineralisation is evident again throughout the veins. |
| | | « 139.40- 139.50 gln 3.00%» |
| | | « 139.40- 140.35 spl 5.00%» |

| | | Between 157.6 and 180.25m, the lithology that the vein stockwork intrudes is the calcareous sandstone. It gradesfrom reacting strongly with dilute HCL to reacting weakly with apparently no lithological change. The calcareous sandstone unit appears to be the same unit as the sandstone, but with a calcareous matrix, possibly that has been altered by the amount of carbonate veining that has taken place. |

| | | The contact with the next section downhole of mineralised veining is not sharp, but rather gradual where the veining gets more intense and then the mineralisation is re-introduced. |
| 195.68 | 208.40 | Vglnspl |
| | | Stockwork of mineralised calcite-quartz veins that crosscut black mudstone and grey sandstone. This section is heavily faulted and fractured. The veins seen in this interval are between 1mm and 2.5m in size, so there is a large range. The larger veins display euhedral calcite crystals and contain fragments of wall rock. |
| | | As regards mineralisation, both sphalerite and galena are present in the vein sets. The sphalerite is red-brown, and fine to medium-grained with a resinous lustre. Galena is concentrated into coarse-grained clots up to 4cm in diameter, and form euhedral cubic crystals. |
| | | Where there are fragments of wall rock encorporated into the veins, it is possible to distinguish silicified rims around the rock fragments, while the main vein itself is composed almost entirely of calcite. A later generation of quartz veining appears to cut the calcite veining. The background lithology to the interval between 203.8 and 208.4m is mostly light to dark grey medium-grained sandstone. |

| | | A fault breccia zone with 95% rock fragments and 5% gouge. The matrix of the breccia is very fine black mud, and it is a clast supported breccia. Some of the rock fragments display veining of quartz, calcite or quartz-calcite veins, showing that veining occurred prior to brecciation. Rock fragments are mostly sandstone, with some mudstone and vein pieces. Fragments are sub-angular to sub-rounded, and between 2mm and 5cm in size. It is difficult to make out a definate orientation of the faulting so no measurement was taken. |
| 209.83 | 216.35 | Sst |
| | | Light grey, generally medium-grained sandstone. The sandstone has been strongly to intensely silicified. Calcite veins appear to cut the sandstone and previous quartz veining, fracturing and brecciating the rock into angular, 1 to 10cm size clasts in places, and just cross-cutting the rock in other places. There is also black and grey mudstone that is interbedded and deformed with the sandstone. |

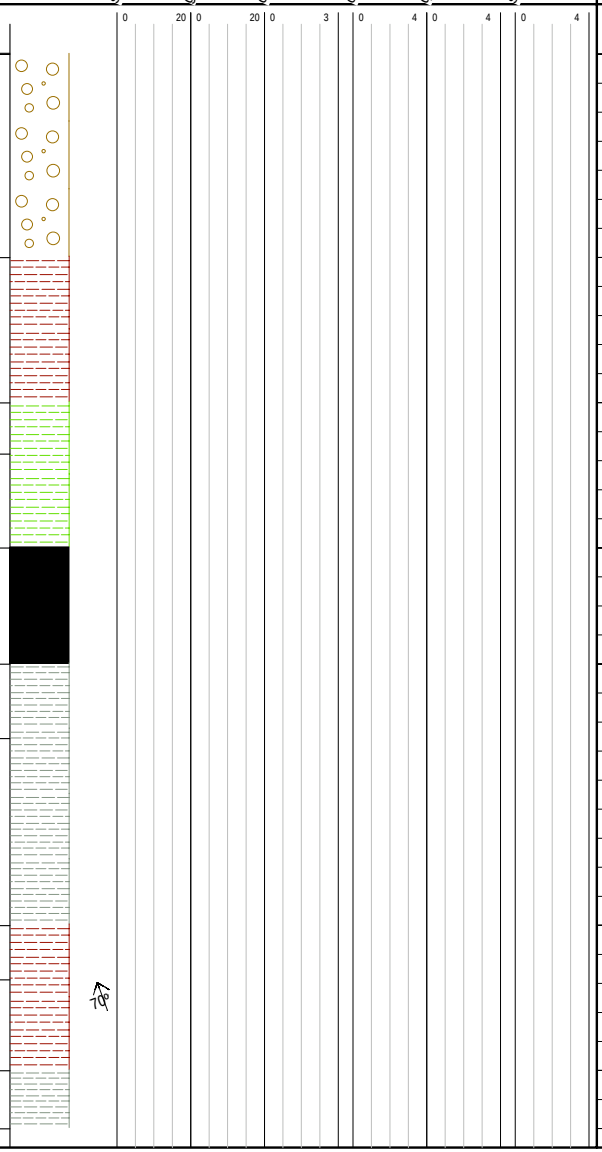
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Hole AN08-036 was drilled to test for mineralization along section 641800 at approximately 105m below surface. The hole bisects two previous drillholes, 02-019 (10.5m at 6.48% Zn, 4.6m at 2.78% Zn) and 02-020.

**SUMMARY LOG:**



2.74-4.48 - Red mudstone
4.48-5.92 - Green mudstone
5.92-8.57 - Faulted green mudstone
8.57-18.45 - Interbedded red and grey mudstone
18.45-48.52 - Black mudstone
48.52-49.82 - Faulted black mudstone
49.82-93.54 - Sandstone with interbedded black mudstone
93.54-94.24 - Calcareous sandstone
94.24-98.06 - Sandstone
98.06-125.39 - Interbedded red and green mudstone
125.39-143.23 - Quartz-Carbonate-Sphalerite stockwork (up to 2% chalcopyrite over 2.2m, and 15% sphalerite over 2.1m)
143.23-147.50 - Barren carbonate vein
147.50-149.40 - Galena and sphalerite stockwork (up to 0.5% galena and 0.5% sphalerite over 1.9m)
149.40-167.60 - Silicified carbonate-sphalerite stockwork (up to 45% sphalerite over 1.5m)
167.60-172.20 - Faulted sphalerite stockwork
172.20-180.35 - Weak carbonate-sphalerite stockwork in sandstone
180.35-185.70 - Fault breccia
185.70-192.00 - Sandstone grading to mudstone

| | | Green Mudstone. Pale green to grey in colour, thinly laminated. Bedding is moderately visible, defined by thin laminations of dark grey to black mudstone. Oxidation and limonite staining occur along fracture planes over first 10m of core. Overall, rock is fairly competent with few fractured sections. Few interbeds of red/maroon mudstone occur as beds 10-75cm thick. The red/maroon mudstone beds contain <10% thin to medium interbeds of green mudstone, as beds 1-15cm thick. There are 1-2% thin 1-2mm calcite veinlets throughout at varying orientations, roughly 50 degrees TCA. Few 1-5cm sections within the green mudstone appear to be fractured/brecciated by thin veinlets/laminations of dark grey to black mudstone. These sections likely represent fracturing of the green mudstone during diagenesis, or possibly sedimentary brecciation. |

| | | Sedimentary Breccia. Dark black mudstone matrix with 1-5mm subangular clasts of light to medium grey quartz, grey to black mudstone and green mudstone. Overall 35% clasts to 65% matrix, with localized sections up to 10cm showing 75% clasts to 25% matrix. Bedding is weakly visible. Trace 1-2mm thin calcite veins at varying orientations. 1-2% fine-grained pyrite throughout the mudstone, and also occurs as 1-2mm blebs, seeming to replace some of the clasts. Overall the unit is fairly competent with some fractured and faulted sections. |

|---|---|---|

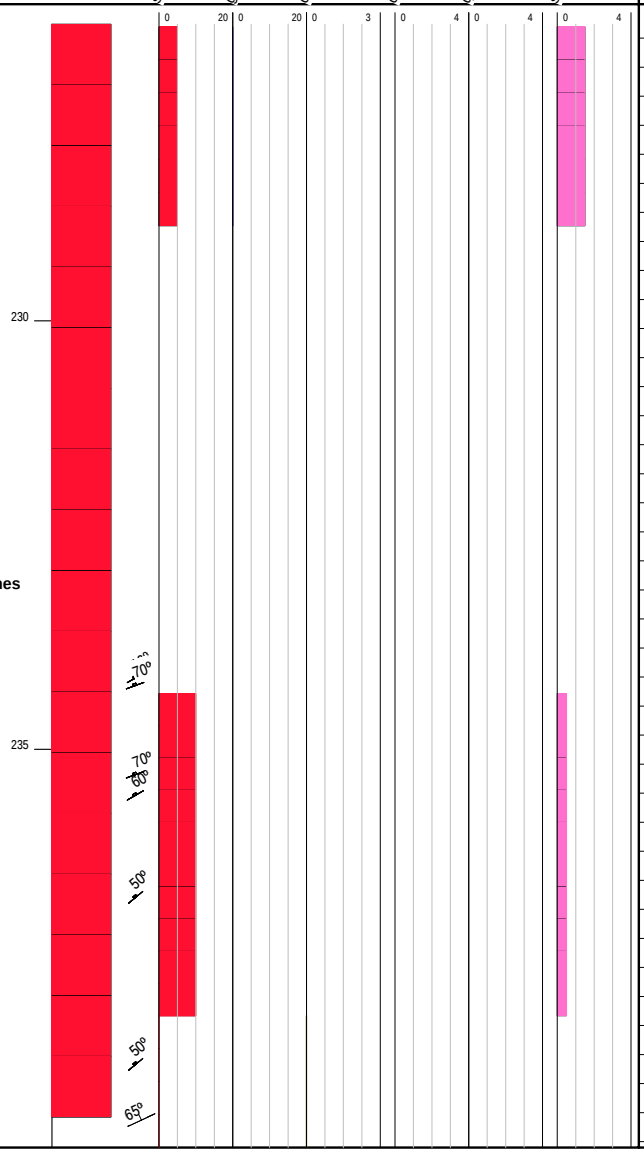
net-textured in sections of intense brecciation, surrounding the wall rock clasts, within the quartz/calcite veining. Mineralization varies in intensity across the interval, from trace to up to 30% over 35cm, but is 5% overall. Trace 1-2mm galena crystals are associated with the sphalerite.

228.89m to 234.35m - Minor to moderately silicified mudstones and sandstone with moderate quartz and calcite veining throughout. Few sections of mudstone are brecciated by the veining, to 1-10mm angular clasts. No sphalerite nor galena is visible. Trace very fine grained pyrite throughout the wall rock. Unit is very competent.

234.35m to 238.11m -Moderately silicified mudstones and sandstones with moderate quartz/calcite veining (1mm to 1cm thick). First 60cm is a massive quartz/calcite vein with about 15% wall rock. Sphalerite occurs as reddish-orange to brown 1-3mm blebs and patches to dense masses up to 4cm thick. Sphalerite occurs within most of the quartz/calcite veins from trace amounts up to 50% over 65cm. Overall there is about 10% sphalerite across the interval. Unit is fairly competent with few fractured/faulted sections.

238.11m to 245.14m - Weakly silicified green and black mudstones and sandstones with 3% 1-5mm quartz/calcite veinlets at varying orientations. Bedding visible within mudstones while the sandstone is fairly massive. Minor folding marked by bedding planes. Trace very faint reddish blebs of sphalerite over short intervals. Trace very fine-grained pyrite throughout the wall rock. Trace 1-2mm chalcopyite blebs. Fairly competent rock with few fractured/faulted sections.



243.71m - Cross-bedding indicates younging direction is uphole.

245.14m to 245.67m - Short interval of highly silicified sandstone with moderate 1-5mm quartz/calcite veining. Sphalerite is present as 1-4mm reddish-orange blebs and patches, about 10%.

| | | Calcite veinlets (<1 to 2 mm wide) and sparse <1 mm chlorite veinlets. |
| | | « cal 1.00*» « chl 0.50*» |
| 113.90 | 138.50 | VglnsplMINERALIZED ZONE: SPHALERITE-GALENA VEINING |
| | | Sandstone and mudstone with veining - core >30% vein material, competent with some fractured areas. Mineralization-style and intensity varies throughout interval: |
| | | 113.9 - 118.5 m: Cal-qtz-gln-spl-ccp veining (~40% of interval) with fragments of black mudstone (fragments <10 mm tend to be angular, >10 mm subangular-subrounded). Host rock is sandstone, locally silicified. Sphalerite typically interstitial to fragments and calcite, locally replacing black mudstone fragments. Galena appears to occur mainly with quartz, locally qtz-gln vein fragments within larger massive calcite veins. Trace blebby chalcopyrite. Fine black soft veinlets of chlorite cut calcite and mudstone fragments. « 113.90- 118.50 cal 4.00*» « qtz 2.00*» « sil 1.00*» « spl 1.00%» « gln 2.00%» « chl 1.00*» |
| | | 118.5 - 124.6 m: Massive coarse-grained calcite veins comprise ~60% of interval. Host rock is grey sandstone. Veins contain angular fragments of quartz but no visible mineralization. Fine black chlorite veinlets cut calcite veins and often occur at edges of calcite veins, particularly smaller veins (<10 mm) cutting sandstone. « 118.50- 124.60 cal 4.00*» « qtz 2.00*» « chl 1.00*» |
| | | 124.6 - 131.4 m: Host rock until 127.55 m is black and grey mudstone which are cut by many small calcite veins (<10 mm, many <5 mm) that are folded. Also contains fragments of calcite and mudstone and small (< 2 cm ) fault zones (gouge/slickedsides, increased clay). No sulphides seen. After 127.5 host rock is grey sandstone; decreased folding, increased brecciation. In some areas the calcite veins contain angular fragments of sandstone. Surrounding the subangular fragments is a dark grey, moderately hard, fine-grained matrix - also subangular fragments of quartz, some with sphalerite. From 129.1 to 129.85 m, breccia of calcite, quartz, sphalerite (as blebs with calcite or quartz), sandstone, and black mudstone (with earlier calcite veins, <2 mm) fragments. |

Grey mudstone that varies from dark grey to green-grey to maroon-grey. The mudstone has interbedded silt to fine sand beds, between 1-2mm and 3cm thick. Most sand or siltstone beds are finely laminated displaying cross-beds and sometimes grading, although some beds are massive, showing little or no structure. The beds have been folded and faulted, on at least two scales, and the folds range from being tight to fairly open. Most of the faulting and offsets appear to occur along veins, which are composed of different combinations of quartz, calcite and chlorite. Over some intervals quartz-chlorite veins are cut by calcite veins, wheras over other intervals the calcite veining is crosscut and offset by quartz-chlorite veins. In genreral the calcite veins are a few-mm in size, and the quartz-chlorite veining occurs together in wider veins.

| 156.40 | 171.70 | Sbx<br>Brecciated interval of rock that appears to be sedimentary in origin rather than tectonic. The breccia varies between clast supported and matrix supported. Clasts are angular to sub-rounded, and there is a large range of sizes ranging between 2mm and 25cm. ~60% of the clasts are sandstone that has been calcite veined prior to brecciation. All the sandstone clasts react vigorously with dilute HCl, and combined with the calcite veining it would suggest that the carbonatisation occurred prior to brecciation. The matrix of the breccia is black and very-fine-grained, and contains up to 1% pyrite. There are also blebs of pyrite that are up to 2cm in diameter and fine to medium-grained.<br><br>< @ 159.00 S0 20.00º > |

| | | Brecciated rock consisting of ~90% mudstone clasts and interbeds, with ~10% sandstone clasts. Clasts range between 2mm and 5cm and are angular to sub-rounded. Imbrication of clasts is displayed in some areas. Some clasts display laminations and calcite veining up to 2mm in size. Quartz veins cutting the breccia are present. |
| | | This does not appear to be a true sedimentary breccia, as it appears as though the mud layers and beds have been remobilised around clasts. |

| | | Zone of brecciation that appears very similar to the sedimentary breccia that lies uphole, but it contains more brecciated vein material that is mineralised with both galena and sphalerite. Most veins over the interval are calcite, but clasts within the breccia are moderately silicified. The sphalerite mineralisation is located entirely within brecciated vein material, and there is some associated galena with this. At the end of the interval the sphalerite |

| | | Stockwork of calcite veins up to 20cm thick that are rich in red-brown and tan sphalerite. There are euhedral calcite crystals up to 1.5cm in diameter, and the spahlerite appears to have grown around these crystals. Quartz or silica appears as a rim to the outside of the calcite veins, and the rock in between the stockwork is silicified. Quartz also appears in the centre of some of the patches of sphalerite. One possibility is that the calcite veins occurred first, followed by later quartz alteration at the same time as the sphalerite was deposited. Quartz appears as a buffer between the calcite and sphalerite in some places, but not in others. The background lithology to the stockwork veining is a mixtureof grey mudstone and light-grey medium-grained sandstone. |

sphalerite generally appears as veins between 2mm and 5cm thick. Over ~1m interval the sphalerite and galena appear as the matrix of a breccia of which the clasts are mainly vein material. The background lithology where it can be seen is mainly grey mud and carbonate sandstone. At ~235m small millimetre-size vugs appear that have been partially infilled with mixtures of quartz and calcite.

| | | Carbonate sandstone that has been moderately veined by calcite. There are intervals of the sandstone that do not react with dilute HCL, so the carbonatisation could be interpreted as secondary alteration. Some of the interval has been moderately brecciated, and almost the entire interval displays some small scale faulting. The bottom 15m of the interval consists of a very regularly bedded succession of sandstone, where repeated grading, fining-up beds, load casts, cross-beds and thin laminations indicate a possible turbiditic environment. Over this interval the younging direction consistently seems to be downhole suggesting strongly that the rock is overturned. Beds are on average between 4 and 40cm true thickness. |

| | | MINERALIZED ZONE: SPHALERITE VEINING |
| | | Dark grey sandstone and mudstone with sphalerite+/-quartz+/-calcite veining. Core competent. Several different styles of mineralization (including large barren calcite veins) so split into several intervals: |
| | | 116.25 - 117.47 m: Sphalerite occurs in hairline to 1 mm veinlets, including some that cut/follow edges of calcite veining. Host is pale green siltstone. |
| | | 117.47 - 123.5 m: Sphalerite in veins (with calcite) to massive. Grey sandstone and black mudstone host. Sphalerite veins cut by calcite veins. Fine (<1 mm cal-spl veinlets cut and minorly displace larger spl-cal-qtz veins. Chalcopyrite blebs locally occur with sphalerite veins. Several areas (including very beginning of interval) of deformed, almost sheared looking, mudstone, sandstone, cal-qtz fragments, with sphalerite occuring around fragments (sedimentary breccia?). Mineralized veins cut and displaced by calcite only veins (photo). |
| | | 123.5 - 128.08 m: Massive calcite vein; no mineralization. |
| | | 128.08 - 132.26 m: Texture similar to above calcite vein, but no massive sphalerite. Smaller qtz-cal-spl veins (2-10 mm) cut by large (next interval) calcite vein, with sphalerite at vein margins. Stylolitic boundaries to larger cal-qtz veins (1-10 cm), sphalerite typically occurs along boundaries. |

| From | To | Rocktype & Description |
|---|---|---|
| | | 132.26 - 134.11 m: Massive calcite vein, this interval barren. Upper boundary stylolitic with sphalerite along it but appears to be on the outer boundary and not intergrown (photo); also fragment of mudstone with sphalerite within vein - sphalerite previously there? However at lower margin, sphalerite vein (2 mm wide) cuts calcite vein. |
| | | 134.11 - 147.0 m: Mineralization style similar to above calcite vein, with qtz-cal-spl veining (1-8 mm) which appear slightly deformed (in some areas brecciated or displaced by later calcite veins) and several larger 3-43 cm cal-spl veins. Host is dominantly black mudstone. Cal-gln vein at end of interval (galena not seen elsewhere in interval) with galena in centre of vein, which cuts, and exploits the margin of, a cal-qtz-spl vein. Locally 2 colours of sphalerite, lighter brown at margins and along fractures into blebs of darker brown - later? In a silicified zone (146.4-.55 m) sphalerite forms net texture around quartz (photo). |

| | | MINERALIZED ZONE: SPHALERITE VEINING |
| | | Dark grey, competent to factured. Host is grey sandstone, locally grey to black mudstone. Interval dominated by both mineralized and unmineralized open-space quartz textures - sphalerite typically occurs in centre of cockscomb textured quartz. |
| | | 150.05 - 155.35 m: Qtz-spl veins, quartz commonly growing inwards from vein margins (can locally see euhedral crystals) with sphalerite filling in the middle of the vein. Also cockade quartz with quartz growing around angular mudstone clasts and sphalerite inside vuggy quartz (photo). |
| | | 155.35 - 157.7 m: Increase in cockscomb quartz+/-calcite, but decrease in sphalerite. |
| | | 157.7 - 159.8 m: Qtz veining in silicified sandstone. |
| | | 159.8 - 162.90 m: Qtz-cal-spl veins. |
| | | 162.90 - 170.71 m: Calcite veining containing fragments of quartz (veins?) in sandstone and grey-black mudstone, trace sphalerite within veins and as blebs. |
| | | 170.71 - 172.2 m: Cockscomb quartz with sphalerite in centre of quartz, minor brecciation. At end of interval vuggy quartz growing inwards (open-space) but no sphalerite in centre (no late mineralizing fluid here?). |

| | | Green mudstone with red mudstone interbeds; both are fine grained. Some fine grained disseminated pyrite seen near the contact but grades out over first 2m. Unit is very faulted with many 0.1 - 0.5m zones composed entirely of soft gouge (90%) and rock fragments (10%). Few quartz calcite veins cross-cut core with no prefered orientation. |

Grey, coarse grained calcareous sandstone interbedded with grey mudstone. Mudstone is fine grained and finely laminated. Both rock types are crosscut by quartz calcite veins (1-4mm in width) that show no prefered orientation. Small scale faulting and slip along bedding planes result in areas of broken core.

Very fine grained pyrite seen in both rock types in bands parallel to bedding, as well as along the margins of some of the veining. Few small blebs of sphalerite and galena associated with a quartz chlorite vein at 175.36m.

Crossbeds and flame structures seen throughout unit indicate youngening downhole.

**BLACK MUDSTONE**

Black mudstone interbedded with grey mudstone, core fractured to competent with small areas of rubble and gouge - several small faults within this interval. Upper 8 m is very fractured and broken. Black mudstone is thinly laminated (only seen on fresh surfaces), grey mudstone typically forms planar laminae (most 1-5 mm). Locally cross-stratified (but can't determine younging direction).

Fe-oxide on fractures, thin calcite veins (1-2 mm) cut and locally displace bedding by up to 10 mm. Chlorite occurs along some fractures/thin veinlets (<1 mm).

« Calcite 1.00*» « Iron oxide 1.00%» « Chlorite 1.00*»

< @ 9.25 Calcite vein with vugs, displaces beds Vein 20.00° 2.00mm >

< @ 11.32 Calcite vein, displaces beds Vein 65.00° 1.00mm >

< @ 14.70 Fault Gouge 50.00° 2.00cm >

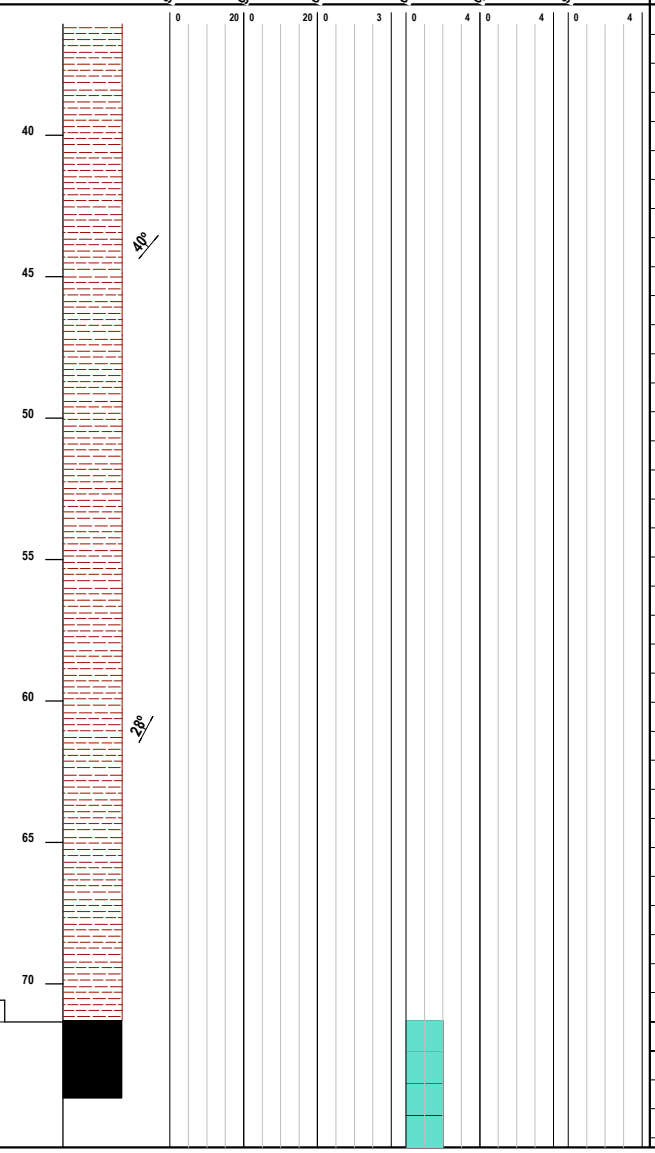
**RED MUDSTONE**

Maroon-red mudstone with interbedded green mudstone, core competent with several small areas of gouge and/or highly fractured core - small faults. Red mudstone is thinly laminated but very similar grain size and colour so bedding orientations and structures are hard to identify. Green mudstone intervals are typically 10-20 mm thick and planar stratified. Gentle folding has deformed many of the beds in mm- to cm-scale folding (axial planes often steep TCA), but locally load casts can be identified (@ 61.46 m green siltstone forming load casts into pale green mudstone - younging downhole).

Sparse calcite veinlets (<1 mm).

28.65 - 35.6 m: Green mudstone, faulted for first 1.5 m (highly fractured with slickensides on fractures and areas of gouge).

< @ 29.80 Fault Gouge 50.00° 5.00cm >



< @ 44.35 Bedding 40.00° >

< @ 61.46 load casts suggest younging downhole Bedding 28.00° >

| | | Green mudstone and siltstone (~70% mud) with interbeds of both red and grey mudstone and some sandstone. There are frequent faults throughout the interval, and the rock displays folding and quartz veining. Some cross-bedding is evident as well as thin laminations within beds. Parts of the unit are moderately to strongly silicified. Younging indicators include cross-bedding and load casts. The unit does not have an overall younging direction and displays intervals of overturned beds as well as beds that are right way up, sometimes with fold noses seen in between. To summarise, at ~22m the beds appear overturned; at ~28m the beds appear right way up; at ~35m the beds appear to be overturned; between 39-41m the beds are right-way u; and at 42.5m the beds are overturned again. |

| | | Sedimentary breccia that appears to have been deformed. Clasts range between 2mm and 40cm, and some alignment of elongated clast can be seen in conjuction with apparent shearing of the matrix. The matrix is made of grey/brown to black mud, and appears to flow around some clasts. Veining appears in the clasts as well as later veins that cross-cut the breccia. Moderate to strong faulting of the breccia has occurred, which appears to be concentrated along planes of weakness in the breccia. Chalcopyrite is present as ~5% over a 30cm interval as blebs. |

| 216.35 | 271.67 | VglnspI<br>Stockwork of sphalerite and galena-rich quartz veins that cut the rock. Contact with interval above is not faulted or sharp, the veining appears and then gradually increases in percentage of mineralisation and veining present. There are some massive suphide intervals, such as 231.34 to 232.65m, 239.4 to 241.2m and 250.68 to 252.98m. The sphalerite appears as a red-brown colour and less often as a light-tan colour, and it has a resinous lustre. The galena appears mainly as medium-grained clots either by itself or with sphalerite. The sphalerite appears in veins between 0.5cm and 1m wide and is associated nearly always only with quartz and galena, while weak calcite veining seems only to be associated with the background mudstone. In several places, notably 260.8 to 261.31m, the sphalerite and galena form the matrix of a breccia in which the clasts are angular to sub-rounded and between 2mm and 2cm in size. Clasts are sand, mud and calcite vein material.<br>At 263 to ~264m there are cross-beds and load casts that indicate the beds are younging uphole i.e. they are right way up. The background lithologies are mainly green mudstone up to 239.4m, then a mixture of sandstone and mudstone, then mainly grey mudstone at the end of the interval.<br><br>< @ 272.10 flg 30.00° ><br><br>« qtz 3.00*»<br>« cal 1.00*» |

Overburden. Composed of redrilled red mudstone interbedded with green mudstone.

Red mudstone, interbedded with layers of green mudstone 1-10cm thick. Both rock types are fine grained and finely laminated. Many small scale faults and slip along bedding planes occurs throughout unit, resulting in fairly broken core and areas of rounded rubble. Slipped surfaces are associated with weak chloritic alteration and commonly occur at the boundary between units. Bedding is fairly consistant.

Some fine grained pyrite seen at margins of quartz veins (~1mm) in green mudstone.

Areas of rounded, very rubbly core occur between 23.41 - 24.75m and between 27.8 - 28.45m; also between 34.02 - 34.90m and 45.70 - 47.0m.

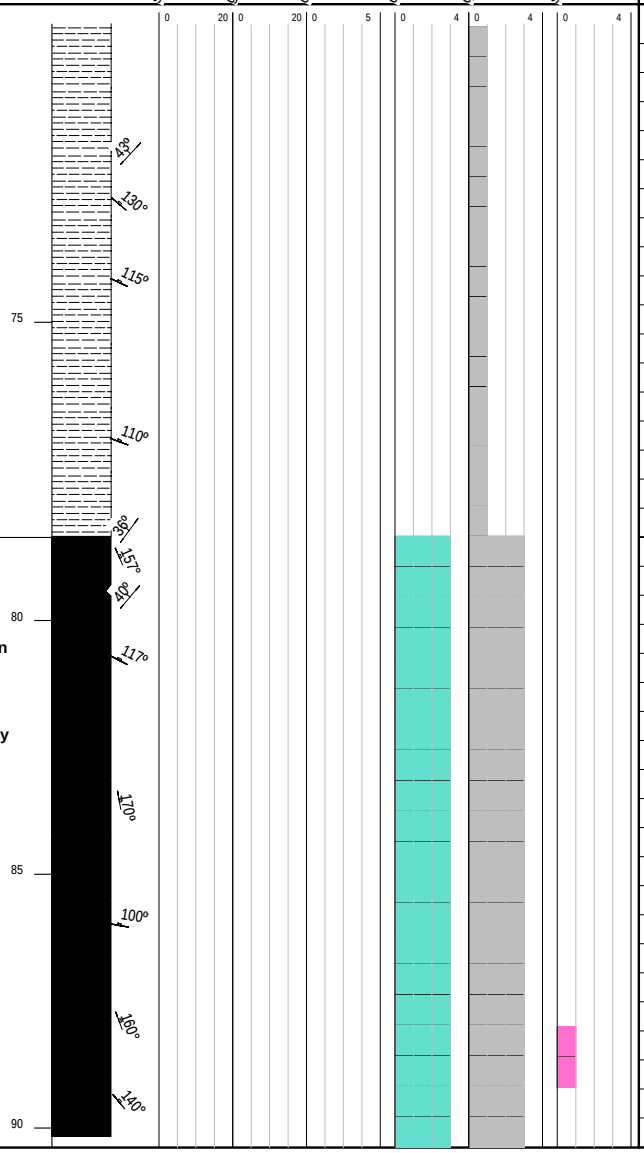
Black mudstone with interbeds of very dark grey sandstone. Mudstone is fine grained and finely laminated; sandstone is coarse grained with large, blueish quartz grains that give core a speckled appearance. Many small scale faults result in areas of broken, fractured core and fault gouge. There is very minor limonitic weathering on some of the fractured surfaces. Small quartz veinlets approximately 1-2mm in width crosscut core with no prefered orientation.

Fine to medium grained pyrite (0.5%) occurs in bands parallel to bedding.

One bleb of sphalerite at 74.52m found at the margin of a quartz vein.



Major core loss between 77.0m and 78.0m; only recovered 30cm. Possible due to faulting. Rubbly zone with some core loss between 70.1 and 72.35m.

| | | Barren stockwork veining. Host rock is brecciated calcareous sandstone interbedded with grey mudstone. It appears as if there were two veining events - the first occuring before brecciation, as veining is confined to clasts and doesn't crosscut the mudstone matrix; and the second occuring after brecciation as the veins crosscut both the mudstone matrix and the clasts. |
| | | The clasts are angular to subrounded, and range in size from 1mm to 10cm. Very fine grained to medium grained pyrite is associated with the mudstone matrix. |
| | | From 88.71m to 88.82m there is a hydrothermally brecciated area containing blebs of sphalerite and significant pyrite. Clasts are composed of mudstone, sandstone and calcite; the matrix is silicified sandstone. |

| | | Green mudstone interbedded with grey and black mudstone. Both units are fine grained and finely laminated; the green mudstone over the first 2.75m has a pinkish colour due to weak-moderate sericitic alteration. Some quartz calcite veins 1-5mm in width crosscut both units with no prefered orientation. Small scale faulting results in areas of broken, rubbly core with gouge. |
| | | Very fine grained to medium grained pyrite associated with the black mudstone, occuring as bands parallel to bedding. |

ZONE OF MINERALIZATION

Sphalerite-rich stockwork veining in a host rock of interbedded grey sandstone and black mudstone. Sandstone has been weakly silicified over the first meter from the upper contact.

Mineralization is associated with quartz calcite veins that cut the rock with no prefered orientation. Sphalerite appears both as blotches within the sandstone and following the quartz calcite veining.

| 161.01 | 222.50 | Sst_cct |

Grey, coarse grained calcareous sandstone interbedded with light grey sandstone and black mudstone. In some areas, both sandstone units have large quartz grains that give the core a speckled appearence. There is some quartz calcite veining throughout the unit, crosscutting each rock type with no prefered orientation. Small scale faulting and slipping along bedding planes results in small areas of broken core and gouge. Bedding is fairly consistent throughout unit. There is minor very fine grained pyrite in the black mudstone seen as bands parallel to bedding.

Cross beds and graded bedding at multiple locations indicate youngening is downhole.

| | | **SANDSTONE** |
| | | Grey sandstone with interbedded grey mudstone. Core competent. Sandstone is coarse- to medium-grained, and typically massive and silicified. Up to 20% rounded quartz grains (up to 2 mm, typically ~1 mm) more commonly <10% quartz. Locally graded bedding where fining direction (and inferred younging direction) can be determined. Fold axial plane at 101.1 m, ~70 TCA, with distinctive coarse-grained bed that fines away from axial plane on either side. Bedding throughout most of the interval (until ~125 m) is shallow TCA - most of this interval being drilled at a shallow angle to bedding, and folding is at a steep angle to the hole, so beds are repeated or being drilled down therefore homogeneous over a long interval(?). Sandstone is often silicified. Calcite-quartz veins cut bedding. Areas of sedimentary breccia. Locally boudanaged sandstone beds between mudstone. |

competent. Mudstone typically planar-laminated, coarser horizons locally display cross-bedding, but often displaced. Locally sedimentray breccia with clasts of sandstone and grey mudstone in black mudstone matrix. Limestone from 194.3 to 194.6 m (light grey with black clay-filled stylolites). Calcite veinlets throughout (1-2 mm) some with quartz. Many beds/laminae displaced along fine fractures

< @ 194.80 x-stratification indicates downwards younging Bedding 45.00° >« Calcite 2.00*»

196.76 223.00 Sms bk

**BLACK MUDSTONE**

Black mudstone, core competent. Thinly laminated with pyrite-rich dark grey laminae and black mudstone laminae. Gougy fault zone at start of interval Actinolite first 60 cm. Locally folded - i.e., at 201.8 m folded with hinge steep TCA, then cut and displaced along fine calcite veinlets (<1 mm). Highly fractured fault zone 204.40 to 204.95 m, chlorite on fractures.

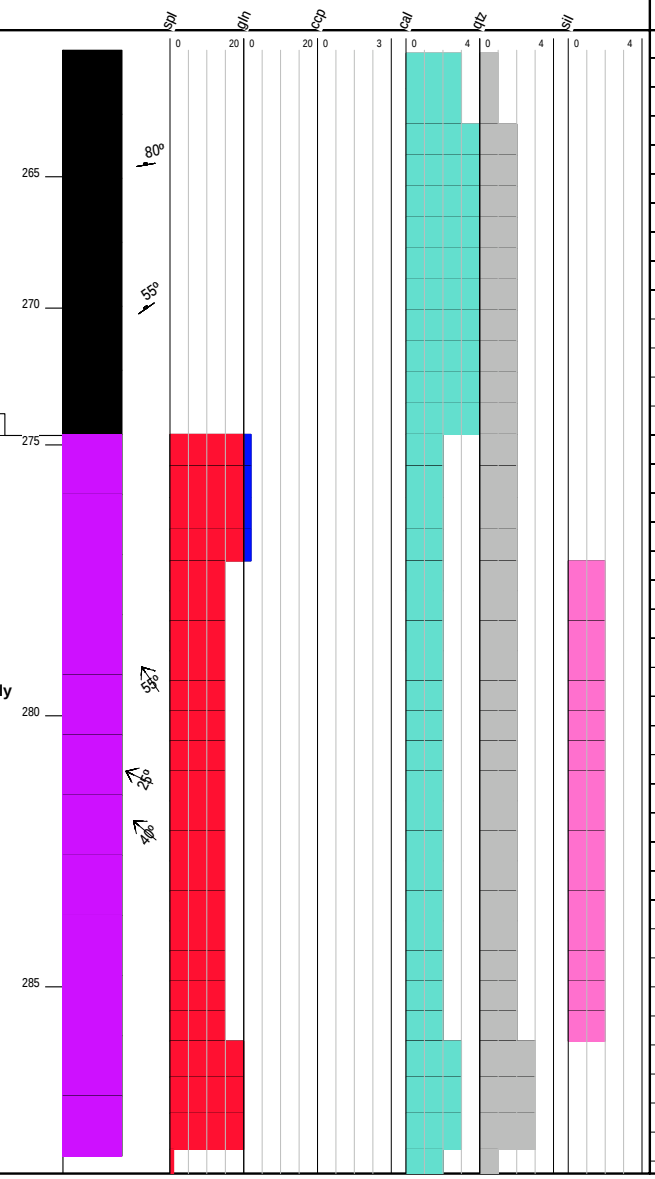
**CLASTIC SANDSTONE-MUDSTONE (SEDIMENTERY BRECCIA)**

Black to dark grey clastic sandstone to mudstone, core competent. Poorly sorted 1-3 mm subangular (smaller can be subrounded) fragments of dominantly grey

| From | To | Width | Sample | Zn ppm | Pb ppm | Ag ppm | Ge ppm | Au ppm |
|---|---|---|---|---|---|---|---|---|

**Project:** Andrew **Hole Number:** AN08-047



| From | To | Rocktype & Description |
|---|---|---|
| | | mudstone in a sand- to mud-sized matrix. Lithics up to 70% of bed. Also black mudstone and pyrite-rich fragments. Interbedded with black mudstone - abundance of clastic beds increases down interval. Beds typically steep TCA and up to 2 cm thick; fragments are often aligned along their long axis parallel to bedding. Where graded bedding is locally seen, appears to fine in both directions within a few cm of core so inconclusive for younging direction. Fine calcite veining.<br><br>< @ 223.35 S0 60.00° > < @ 238.40 S0 70.00° > < @ 244.80 S0 55.00° > « cal 1.00*» |

|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1330.0 m |
| **Hole:** | AN08-048 | **Azimuth:** | 175.8° |
| **Proposed:** | prop1000 | **Dip:** | -59.6° |
| **Location:** | 641451 m East 6978401 m North | **Length:** | 284.90 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW7 | 2008/05/08 | 2008/05/10 |
| **Logged by:** | J.MacDonald | **Objective:** | |
| **Drilled by:** | Kluane | Drill Hole AN08-048 (Prop 1000) will be drilled on section 641450 to a target depth of 300 m. Intersection of the mineralized "Andrew zone" is expected at a depth of 263 m and the zone is expected to end at 264 m. The hole will be drilled at an angle of - 60 degrees and is designed to test the "Andrew zone" between drill hole's AN02-016 and AN01-015 which were drilled on the same section (641450). | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |

**BLACK MUDSTONE**

Fine-grained, black mudstone with interbeds of finely bedded grey sandstone, and massive grey sandstone. Laminations in the mudstone and bedding in the sandstone are typically parallel with slip surfaces (fault planes), most of which are planar, smooth, and in places talcose (such as @ 36.8 m). From 38.3 - 39.0 m finely bedded sandstone interbeds in the mudstone are long and drawn out (strongly strained).

**BLACK MUDSTONE**

Fine-grained, laminated black mudstone. Fairly compitent core through the interval, with local quartz veining occuring over various angles. Disseminated trace - 1% pyrite associated with coarser-grained beds in the mudstone. Grey sandstone interbeds are very rare in this unit compared to previous units; silty laminations in mudstone are more common.

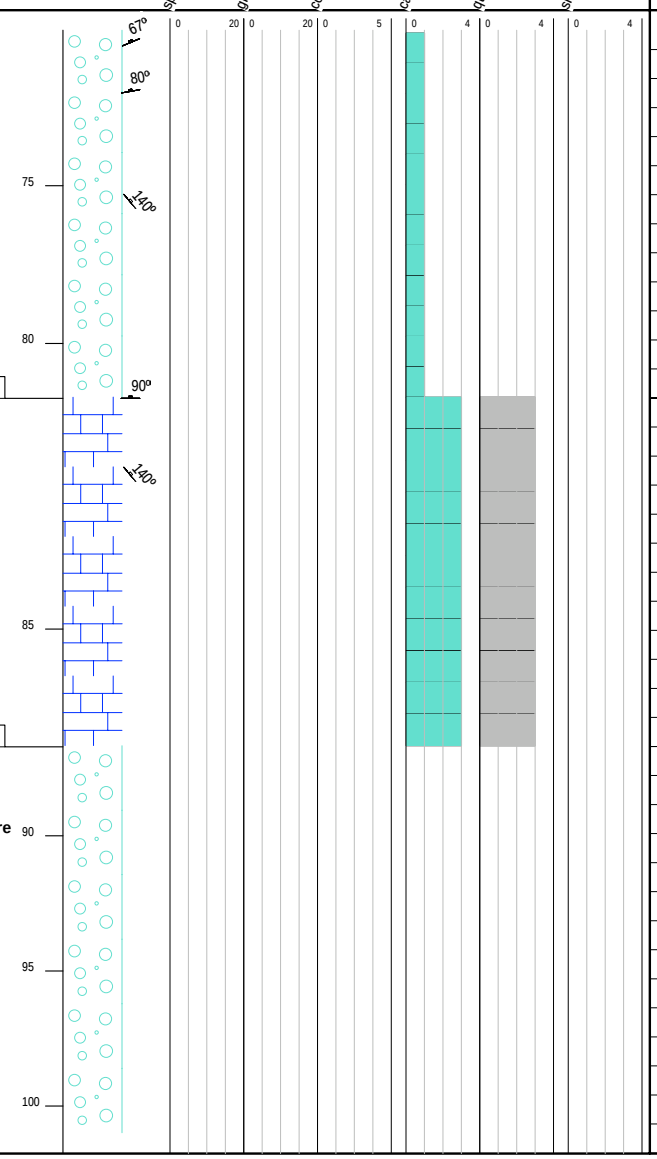
**81.70 86.66 Sls**

Light grey, crystalline limestone with many black styolites crossing the rock with no prefered orientation. There is significant quartz calcite veins 1-10mm in width cross cutting the limestone in every direction. The bottom contact is gradational into sedimentary breccia and is broken up as clasts in a black mudstone matrix.

< @ 81.70 Fault 90.00° >
< @ 82.80 Fault 140.00° >



« Calcite 3.00*»
« Quartz 3.00*»

**86.66 108.16 Sbx**

Sedimentary breccia, with a grey to black mudstone matrix. Clasts are mudstone, sandstone, and limestone, and range in size from 1mm-10cm. The clasts are poorly sorted, and have an angular to semi-rounded shape. There are few quartz calcite veins 1-5cm in width crosscutting the core with no preferred orientation.

Very fine grained pyrite (0.5%) occurs in thin bands in the mudstone matrix; fine to coarse grained pyrite forms clasts approximately 3cm in width as part of the sedimentary breccia.

|---|---|---|
| 108.16 | 131.06 | Sms gy |

Grey mudstone, interbedded with red mudstone at the start of the unit. The mudstone is fine grained and finely laminated, with a fairly consistent bedding angle. There are a few large (1-5cm in width) quartz calcite veins crosscutting the core with no preferred orientation that contain chlorite blebs; many small quartz calcite veinlets also occur at no preferred orientation. There are areas of fractured, rubbly core that have angular to semi-rounded fragments due to faulting and slip along the bedding planes.

Vuggy, medium to coarse grained pyrite is associated with the larger quartz calcite veins. The pyrite occurs down the centre of the veins with minor chloritic alteration along the margins.

Crossbeds at 117.11m indicate younging is in the downhole direction.

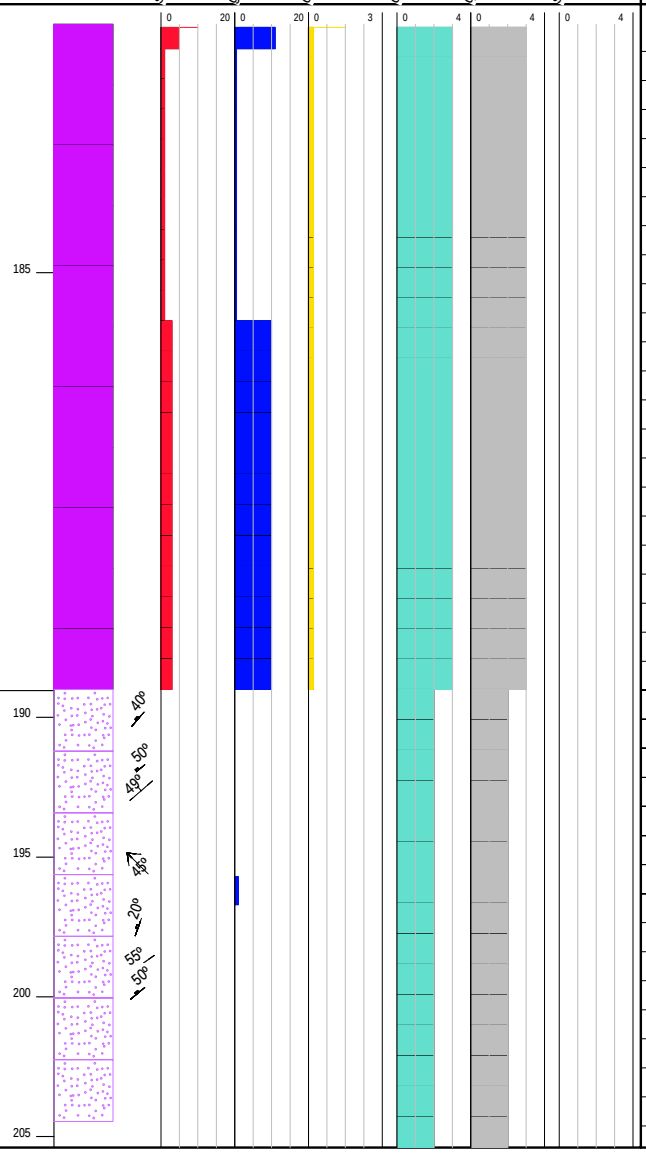
ZONE OF MINERALIZATION

Galena and sphalerite rich stockwork veining. The host rock from 177.85 to 182.85m is sandstone interbedded with black mudstone; the host rock from 182.85 to 189.00m is fault breccia composed of black mudstone and sandstone. Within the fault breccia, the rock is very broken and rubbly with the more competent pieces containing mineralization.

Mineralization is associated with major quartz calcite veining that cross cut both host rock types; veins are 1-10cm in width and have no preferred orientation. Over the interval, there is approximately 9% galena and 3% sphalerite.

Galena occurs as massive to semi-massive veins 5-40cm in width; it also occurs as scattered blebs within a large quartz calcite vein at 185.7m.



Spahlerite occurs as large blotches and smaller blebs with and without the

# DRILL LOG

| | | | |
|---|---|---|---|
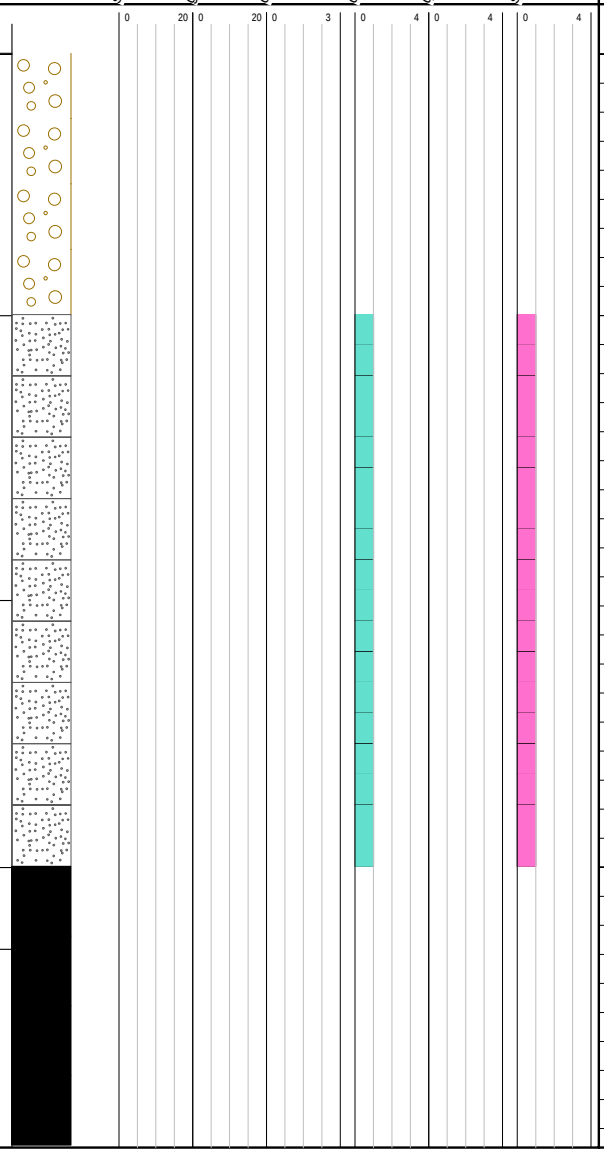
| **Project:** | Andrew | **Collar elevation:** | 1274.0 m |
| **Hole:** | AN08-053 | **Azimuth:** | 171.4° |
| **Proposed:** | prop1022 | **Dip:** | -60.0° |
| **Location:** | 641699 m East 6978504 m North | **Length:** | 352.04 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW8 | 2008/05/11 | 2008/05/16 |
| **Logged by:** | H.Jaggard | **Objective:** | |
| **Drilled by:** | Kluane | To intersect mineralization at 260-310 meters along section line 641700E. | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**SUMMARY LOG:**



0.45-9.5m: sandstone
9.5-11.6m: fault breccia
11.6-22.4m: sandstone
22.4-39.62: green/grey mudstone
39.62-59.3m: red mudstone with green mudstone interbeds: 52.0-59.0m 0.1-0.5% pyrite
59.3-76.3m: sandstone
76.3-81.4m: grey mudstone
81.4-185m: sandstone
185-227m: black mudstone
227-248m: sedimentary breccia: 248.3-248.75m= 0.5% gln, 1% spl
248-256m: stockwork breccia with no mineralization
256-286.5m: mixed galena and sphalerite stockwork veining: 259.75-262.13m= 3-5% spl, 3% gln.
264.12-268.22m= 40-60% spl, 2-3% gln. 268.6-270.0m= 8-30% spl, 10% gln
277.3-280.4m= 1% spl, 1% gln
286.5-297m: grey mudstone
297-300.2m: stockwork sandstone with mineralization: 296.76- 300.2m= 5-15% spl
300.2-316m: sandstone
316-332m: grey mudstone with mineralized veining: 316.2-318.1m= 1-3% spl. 326.7-327.1m= 2% gln, 2% spl
332-340m: green mudstone
340-352.04m: sandstone with veining: 339.85-344.42m= 0.5-1% spl, 344.6-345m= 2% spl, 2% gln.
349.9m= 0.5% spl
352.04m: E.O.H.

Maroon mudstone with few interbeds of green mudstone: green mudstone shows some deformation, some interbeds appear to be sheared. Green mudstone interbeds typically between 0.03-2cm thick. Few green mudstone interbeds up to 50cm. Fractures typically ~45 degrees TCA.

|---|---|---|
| | | on the marker blocks. The problem is thought to be linked to using the EZY-Mark tool to orient the hole as the tool was only used on some runs and not on others, however the tool extension was left on, therefore the mistake in footage seems to have been accumulated over many runs. This is only a potential cause for the problem. To fix the issue the marker block lableled 302.5ft was changed to 322.5ft and each marker block was changed accordingly measuring away from 322.5ft up and down hole. The depths above 62.50m were not corrected: i.e. the corrected depths start at 62.50m and continue to EOH. The original as well as corrected marker blocks remain in the core boxes. NOTE: START of corrected meters to EOH |

**Black to light grey mudstone and minor intercalated fine grained sandstone protolith with intense stockwork veining of claclite, quartz, galena and sphalerite.**

**Mineralization:**
**Sphalerite occurs as disseminated to clotty to thick veined and is associated primarily with calcite veins and occupies space between breccia clasts/fragments. Galena occurs as veins up to 20 mm thick and as blebs and clots. Sphalerite and galena occur together in veins and are semi-massive to massive sulphide in localized areas.**

| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Resource drill hole AN08-058 was proposed to hit mineralization from 95-148m along section 1500; actual mineralization occured from 134.63-159.75m and was predominantly galena-rich.

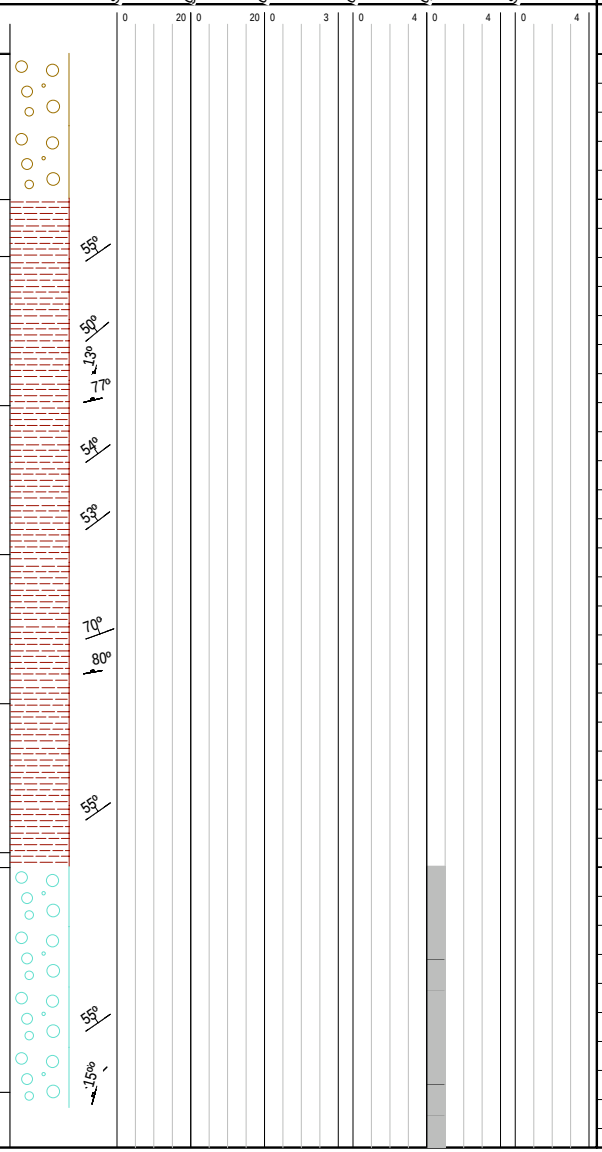
**SUMMARY LOG:**

0.0-3.05 Overburden
3.05-25.46 Red Mudstone
25.46-41.21 Sedimentary Breccia
41.21-45.13 Sandstone
45.13-49.24 Sedimentary Breccia
49.24-63.03 Limestone
63.03-68.46 Shear Zone
68.46-78.88 Sedimentary Breccia
78.88-115.00 Red Mudstone
115.00-127.35 Black Mudstone
127.35-128.68 Fault Breccia
128.68-134.63 Green Mudstone

134.63-142.63 Mineralized Fault Breccia
134.63-137.16: 1% sphalerite, trace galena
139.50-141.75: 10% galena, 3% sphalerite

142.63-156.28 Sphalerite- and galena-rich stockwork veining
7% galena, 5% sphalerite

156.28-159.75 Sphalerite-rich stockwork veining
1% sphalerite



159.75-173.74 Calcareous sandstone

| | | Overburden, composed of rubbly and broken red mudstone. |
| 3.05 | 25.46 | Sms_rd |
| | | Red mudstone with green mudstone interbeds; both rock types are fine grained and finely laminated with a consistent bedding angle of 55 degress to core axis. The core is broken and rubbly in places due to small scale faulting; zones from 5-30cm are fragmented and have poor core recovery. There is weak limonitic weathering on most of the fractured surfaces. Very few, small quartz veins come in at the end of the unit. Moderate chloritic alteration in the green mudstone layers. |

| 128.68 | 134.12 | Sms_gn |
| | | Green mudstone interbedded with black mudstone and grey sandstone. Mudstone is fine grained and finely laminated; the sandstone is coarse grained. Both rock types have significant quartz calcite veining with one set that seems to be relatively parallel to bedding, and another set with no preferred orientation. Towards the bottom of the unit, the rock becomes very faulted and broken with little to no competence; the last 1.5m has no pieces longer than 5cm. |

| | | ZONE OF MINERALIZATION |
| | | Mineralized fault zone, with a host rock of black mudstone and sandstone. Entire unit is rubbly and broken with very poor core recovery; the fragments are angular to semi-rounded and range in size from gouge and sand up to 5cm wide. The mineralization occurs in two zones of intense quartz calcite stockwork veining separated by black gouge. |
| | | From 134.63 to 137.16m there is 1% sphalerite and trace galena occuring as veins and blotches in the stockwork veining. The veining has brecciated the host rock and the sphalerite occurs as clasts in the quartz calcite matrix. |
| | | From 137.16 to 139.50m there is trace galena and trace sphalerite in a black mudstone gouge. |
| | | From 139.50 to 141.73m there is 10% galena and 3% sphalerite occuring as semi-massive veins and blotches within the quartz calcite veining. Zone is |

| 141.70 | 156.28 | VglnsplZONE OF MINERALIZATION<br><br>Sphalerite- and galena-rich stockwork veining in a mudstone and sandstone host rock. Unit is very broken and faulted with areas of gouge and rock fragments separating the more competent mineralized zones. The mineralization occurs as two zones: semi-massive galena (8%) with minor sphalerite (1%), and major sphalerite (5%) with minor galena veinlets (2%). The two zones are separated by faulted, broken sandstone with trace mineralization.<br><br>There is approximately 7% galena mineralization over the entire interval, with semi-massive galena veins 5-30cm in width . The mineralized veins are hosted in the quartz calcite stockwork veining. There is much more galena at the start of the mineralized zone than at the end; the galena becomes spotty and occurs as sparse veinlets 0.5-2cm in width downhole.<br><br>The sphalerite grades approximately 5% over the entire interval; most of the sphalerite occurs in one zone from 155.20 - 156.28m which grades up to 7%. The mineralization occurs as veins hosted within the quartz calcite stockwork. |

| From | To | Rocktype & Description |
|---|---|---|
| | | clasts mainly at end of interval. Sandstone and limestone often have uneven boundaries (some brecciated along stylolites?) and can be up to 5 cm diameter. Mudstone fragments typically subangular with planar boundaries and < 1 cm. |
| | | Quartz veining, often disturbed by folding and locally fault brecciation. |
| | | Sphalerite+/-quartz veining. 49.83 - 50.23 m: semi-massive sphalerite, with interstitial to net textured orangey brown sphalerite surrounding grains/fragments of quartz and subangular mudstone fragments. This is cut by dark brown sphalerite veining. In this zone subangular galena clots up to 10 mm diameter. Semi-massive galena for 15 cm from 53.26 m. Fe-oxides and Fe-carbonates on some fractures. |
| | | Several small (<3 cm) gougy fault zone, typically with >60& gouge. Some areas of sedimentary breccia re-brecciated/sheared by later faulting? |

| | | QUARTZITE |
| | | Pale grey quartzite with interbeds of sandstone and grey mudstone. Core competent with areas of gouge. Medium grained quartzite comprised of ~30% subrounded quartz grains (up to 2 mm) and a few % feldspar grains in a silica cement. Orange Fe-oxide and Fe-carbonate along fractures and replacing feldspars. Areas of mudstone typically strongly foliated or gougy - taking up the deformation between the harder quartzite. No mineralization. Coarse-grained calcite veins. |

| | | ZONE OF MINERALIZATION: SPHALERITE & GALENA<br><br>Blobby to massive sphalerite mineralization associated with wide interval of coarse-grained, massive calcite, and calcite stockwork. Minor galena associated with the sphalerite. The massive, coarse-grained calcite occurs from 42.60 - 52.45 m, and from 52.65 - 54.88 m, and the remaining intervals are more stockwork with smaller sections of massive calcite. |

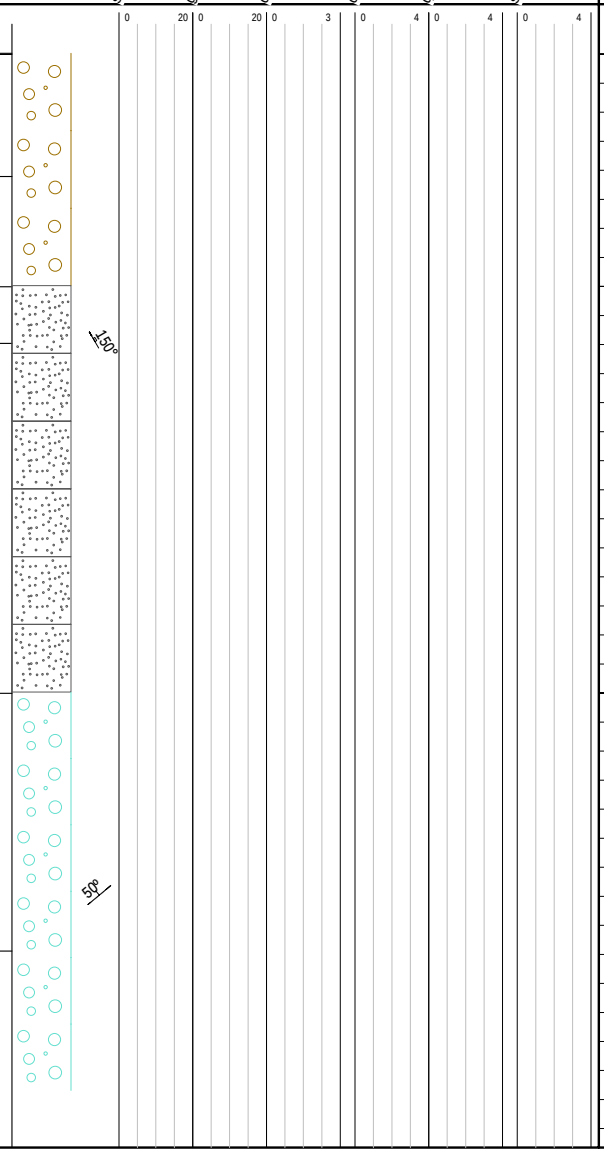
# DRILL LOG

| | | | |
|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1325.3 m |
| **Hole:** | AN08-065 | **Azimuth:** | 176.0° |
| **Proposed:** | prop1055 | **Dip:** | -53.8° |
| **Location:** | 641478 m East 6978251 m North | **Length:** | 79.25 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW7 | 2008/05/21 | 2008/05/24 |
| **Logged by:** | K. Dodge/LM | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Drill hole AN08-65 was drilled along transect 641475mE. It is southern most drill hole to date along the proposed line.
This hole will determine the local depth and extent of mineralization. The hole intersected 14.9m mineralization, galena and sphalerite were both present.
The drill depth reached 79.25m.

**SUMMARY LOG:**



0.00-9.43 Overburden
9.43-13.44 Sandstone
13.44-16.24 Sedimentary Breccia
16.24-22.24 Sandstone
22.24-24.00 Sedimentary Breccia
24.00-25.22 Shear Zone
25.22-29.67 Sedimentary Breccia
29.67-47.25 Red Mudstone
47.25-56.00 Fault Breccia
56.00-70.90 Mineralized Zone showing sphalerite and galena in stockwork veins. Galena is semi-massive in patches. Sphalerite occurs as blobs aswell. On average zone hosts 3% sphalerite. One area hosts 25% galena.
70.90-76.81 Mudstone
76.81-79.25 Limestone

**LIMESTONE/CALCAREOUS SANDSTONE INTERBEDS**

Light to mottled grey limestone with interbeds of calcareous sandstone. Both units have significant quartz calcite veining - part of the stockwork? The unit is very broken and faulted with rusty orange limonitic weathering on the fractured surfaces. Styolites in the limestone are oriented at 50-60 degrees to the core axis. There is very minor pyrite along some of the styolites.

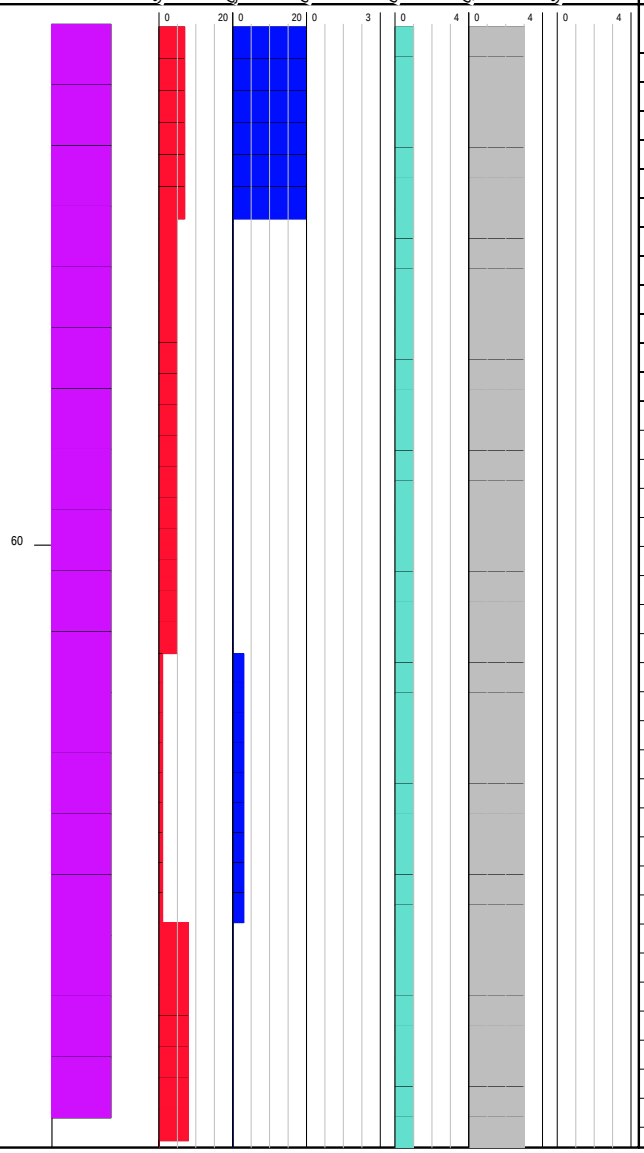
**ZONE OF MINERALIZATION**

Sphalerite and galena rich stockwork veining in a green mudstone host rock. There is a noticeable lack of calcite associated with the stockwork veining - there is almost no reaction to HCl anywhere in this interval. Small scale faulting throughout the unit resulted in zones of rubble and broken core; from 60.36 to 62.50m there is significant core loss.

56.00 - 57.50m: Semi-massive galena (25%) , patchwork sphalerite (7%) and trace chalcopyrite in quartz stockwork veining. The galena occurs as two veins, 30cm and 40cm in width. The sphalerite occurs along with the galena as blotches and veinlets.

57.50-60.83m: Trace galena and sphalerite (5%) in a faulted mudstone and sandstone host rock. The sphalerite occurs as veins and blotches within the quartz stockwork veining; the host rock appears brecciated with sphalerite as the matrix. The galena occurs as veinlets and blebs in the quartz veining.

60.83-62.89m: Semi-massive galena (3%) and sphalerite (1%) in a faulted sandstone host rock. The galena occurs as two veins 6 and 10cm in width; the sphalerite occurs parallel to the quartz stockwork veining.

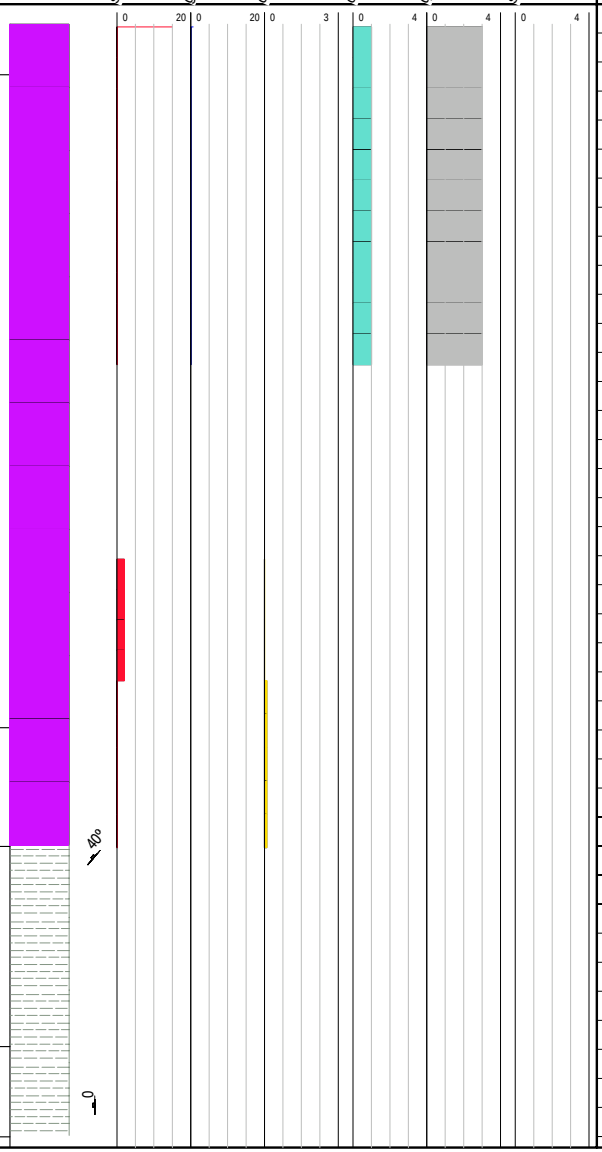


62.89-64.57m: Trace galena and sphalerite (8%) in a sandstone host rock. The sandstone appears brecciated with the quartz stockwork and sphalerite as the matrix. The galena occurs as small blebs scattered throughout the sphalerite.

64.57-67.22m: Trace galena and trace sphalerite, both occuring as small blebs in the quartz stockwork.

67.22-68.71m:Sedimentary breccia barren

68.71-69.64m: 2% vein sphalerite and trace chalcopyrite in sedimentary breccia. Quartz veins throughout



69.64-70.95m: 0.1% chalcopyrite 1%sphlalerite occuring in sedinentary breccia. Both occuring in veins and veinlets.

| | | BARREN CALCITE VEIN BRECCIA |
| | | Massive calcite vein breccia with some sandstone intervals. Some sphalerite is present however the sphalerite appears to be wallrock fragments transported into the calcite stockwork breccia. These sphalerite clasts are cross cut by tiny calcite stringers as are many other wall rock clasts. Furthermore the massive calcite vein nature, lacking in silica does not reflect what was seen in the strong mineralized zones above, and as a result this zone is believed to be a barren calcite vein breccia. |
| | | Wallrock appears to be silicified clasts, of probably both sandstone and mudstone. The clasts are also cross cut by tiny calcite stringers. |

**SPHALERITE AND GALENA MINERALIZATION**

Sphalerite is in much less of a stockwork than above. Instead it occurs as irregular veins or bands. Galena is found as disseminated blebs or as bands

Sphalerite also appears to be replacing wall rock fragments in silica rich zones.

The rock itself is dominantly sandstone and some quartz vein breccia.

| **Project:** | Andrew | **Collar elevation:** | 1315 m |
| **Hole:** | AN08-069 | **Azimuth:** | 181.2° |
| **Proposed:** | PROP1063 | **Dip:** | -69.9° |
| **Location:** | 641577 m East 6978355 m North | **Length:** | 225.55 m |
| **Area:** | Andrew | **Date started:** | 2008/05/23 |
| | | **Date completed:** | 2008/05/27 |
| **Claim:** | ANDREW7 | | |
| **Logged by:** | C. Zwarich | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Relfex_MS | | |

**Objective:**

This is a geotech/resource hole oriented with the EZY-Mark tool. The objective is to obtain structural data as well as see if the hole intersects the mineralized zone from 175-270m.

**SUMMARY LOG:**

0-70.70 Maroon mudstone
70.70-96.77 Grey mudstone
96.77-123.02 Black mudstone
123.02-138.49 Limestone
138.49-158.11 Sandstone
158.11-167.07 Sphalerite and galena mineralized zone: 3%spl, 2%gln
167.07-173.74 Grey mudstone
173.74-220.76 Sphalerite and galena mineralized zone: 2%spl, 1%gln
220.76-225.55 Black mudstone
225.55=EOH

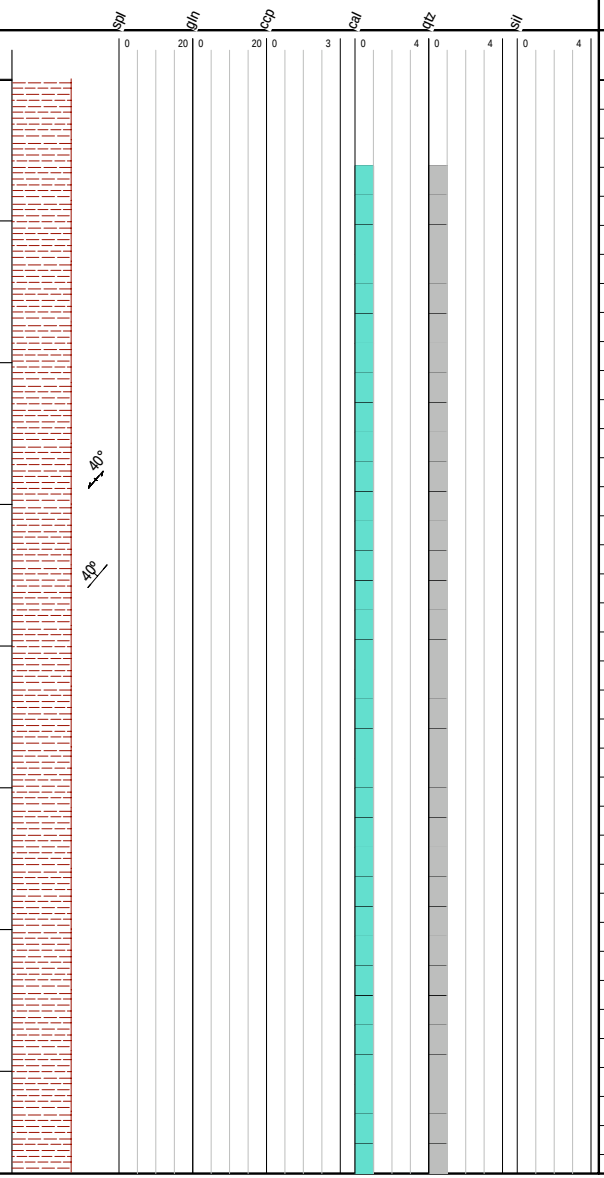
**MAROON MUDSTONE**

**Maroon mudstone with green mudstone interbeds. Fairly competant core. Most green mudstone interbeds near parallel to core axis and typically 0.5-5cm thick., few more than 10cm. Slightly weathered, weak iron oxides.**
**Few quartz and quartz-calcite veinlets, mm-1cm scale, no preferred orientation. Cleavage is visible at an angle to bedding and to core axis. Locally crenulated seen best in the green mudstone interbeds on fracture surfaces.Mudstone is locally finely laminated (mm-scale laminations).**
**« lim 1.00*»**
**« V qtz 1.00*»**
**« V cal 1.00*»**

**< @ 13.64 Fr 50.00° >**

**< @ 14.07 cleavage S1 40.00° > This angle of cleavage is fairly consistant and fractures/breaks are typically along cleavage planes.**



**< @ 17.93 S0 40.00° >**
**< @ 17.93 Lc 70.00 ° >**

**Interval from 36.33-45.72 is blocky green and red interbedded mudstone. Fairly crumbly but still competant core.**

**< @ 45.79 Fr 60.00-300.00° >**
**< @ 52.12 cleavage S1 40.00° >**

**57.91-60.16: Fault zone, very broken core, with 30cm interval of semi-competant breccia ( clasts of mudstone in gougey matrix)**

**< @ 63.71 S0 45.00° >**

| **Hole:** | AN08-070 | **Azimuth:** | 178.5° |
| **Proposed:** | prop1054 | **Dip:** | -69.4° |
| **Location:** | 641478 m East 6978252 m North | **Length:** | 127.10 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW7 | 2008/05/24 | 2008/05/26 |
| **Logged by:** | L.McClenaghan | **Objective:** | |
| **Drilled by:** | Kluane | AN08-070 was drilled to undercut AN08-065 in an attempt to intersect the mineralization zone down dip. It will delineate the width of the mineralized intersection at this site. Extensive massive galena and slightly lesser sphalerite mineralization was found. A small amount of sphalerite mineralization was found very shallow in the hole. The final hole depth was 127.10m. | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

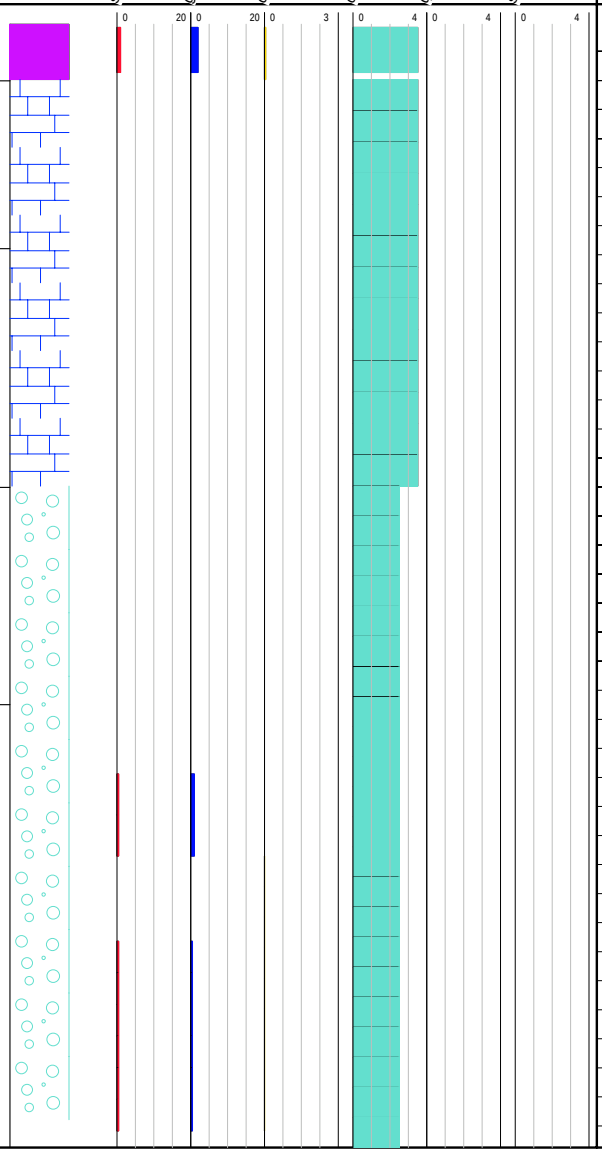
LIMESTONE: strongly calcefied sediment with intense calcite veining. Interbeds of green to grey mudstone and grey sandstone. Reaction to HCL throughout unit with veins reacting slightly stronger than sediment matrix.

Structure:
From 115.82- 115.95m there is a faulted zone with 90% rock fragments and 10% gouge.
No observable faulting between limestone and above mineralized unit.

Mineralization: no mineralization

Veining: « 3.5* cal » strong to intense calcite veining

| From | To | Rocktype & Description |
|---|---|---|
| 117.95 | 124.49 | Sbx |



SEDIMENTARY BRECCIA: Tectonically controlled brecciation. Clasts are angular to subangular, range in size from mm-scale to 7cm in diameter, and is composed of grey mudstone to laminated sandstone.

Structure:
From 117.95- 118.15m is a faulted area with 40% rock fragments and 60% gouge.

From 119.97- 120.2m there is a faulted (??) area of 100% clay. Suspicious of fault theory because could be result of drilling activity.
No bedding measurements preserved.

Mineralization:
« 120.65- 121.42 0.5% spl »« gln 1%»
« 121.42- 124.00 0.01% ccp »« 0.01% pyr »
« 122.22- 124.00 0.5% spl »« 0.5% gln »

Veining:
« 117.95- 124.49 2.5* cal » moderate to strong calcite veining

| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-072 was drilled to undercut AN08-070 and AN08-065. Sphalerite and galena mineralization was intersected in a fault zone from 122.97m to 138.29m. The last 2 readings of the downhole survey extended beyond the EOH. These last 2 readings were removed from the lagger database; however the other readings were not adjusted and left as is, as it is not possible to speculate where the readings were taken.

| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

AN08-073 was drilled on section 1675 at a dip of -60 and an azimuth of 180. The hole was expected to hit mineralization from 32m to 53m depth. The hole did not intersect any significant mineralization. The majority of mineralization was found within faults at low concentrations. The hole was however heavily faulted.

| | | FAULT ZONE WITH SOME MINERALIZATION |
| | | The unit is strongly faulted, showing very broken core, gouge, and graphitic coatings on fracture faces. |
| | | The mineralization is trace over the entire unit, but is concentrated near the top. The galena is in small blebs while the sphalerite is in both blebs and bands of stringers. The unit also contains trace pyrite and chalcopyrite |
| | | The rock type is fault brecciated black mudstone and grey mudstone. The unit has moderate calcite veining |

| | | FINELY LAMINATED GREEN MUDSTONE WITH SOME INTERBEDDED GREY MUDSTONE |
| | | The green mudstone unit has moderate calcite veining and several faults. Calcite veining has no preffered orientation except for larger veins which are generally at around 30-35 deg. |
| | | From 58.99 to 59.19 the green mudstone is brecciated by calcite veins just above the bottom of the unit. |

# DRILL LOG

| | | | |
|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1307.5 m |
| **Hole:** | AN08-075 | **Azimuth:** | 188.4° |
| **Proposed:** | prop1066 | **Dip:** | -69.5° |
| **Location:** | 641581 m East 6978251 m North | **Length:** | 117.35 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW7 | 2008/05/27 | 2008/05/28 |
| **Logged by:** | W.Carter | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-075 was drilled as an undercut of AN08-074 on section line 1575. AN08-074 intersected approximately 20 metres of Zn-Pb mineralization.

| **Location:** | 641672 m East 6978267 m North | **Length:** | 131.06 m |
| **Area:** | Andrew | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW7 | 2008/05/28 | 2008/05/30 |
| **Logged by:** | M.Eckfeldt | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-076 was drilled on section 1675 to a total depth of 131.06m. The hole was expected to intersect mineralization at 66m. The actual depth depth of intersection was 78.45m. The mineralization was dominantly galena associated with quartz veins. Sphalerite was much less common, but was also associated with quartz veins.

**SUMMARY LOG:**

**GREEN MUDSTONE**

The green mudstone unit is semi massive with some deformed bedding. There is also some interbedded red mudstone as well as chloritized sandstone laminations.

Some chlorite on fracture faces. The unit also shows a strong cleavage. There is a fault at 27.90 with gouge but no orientation may be determined

| From | To | Rocktype & Description |
|---|---|---|
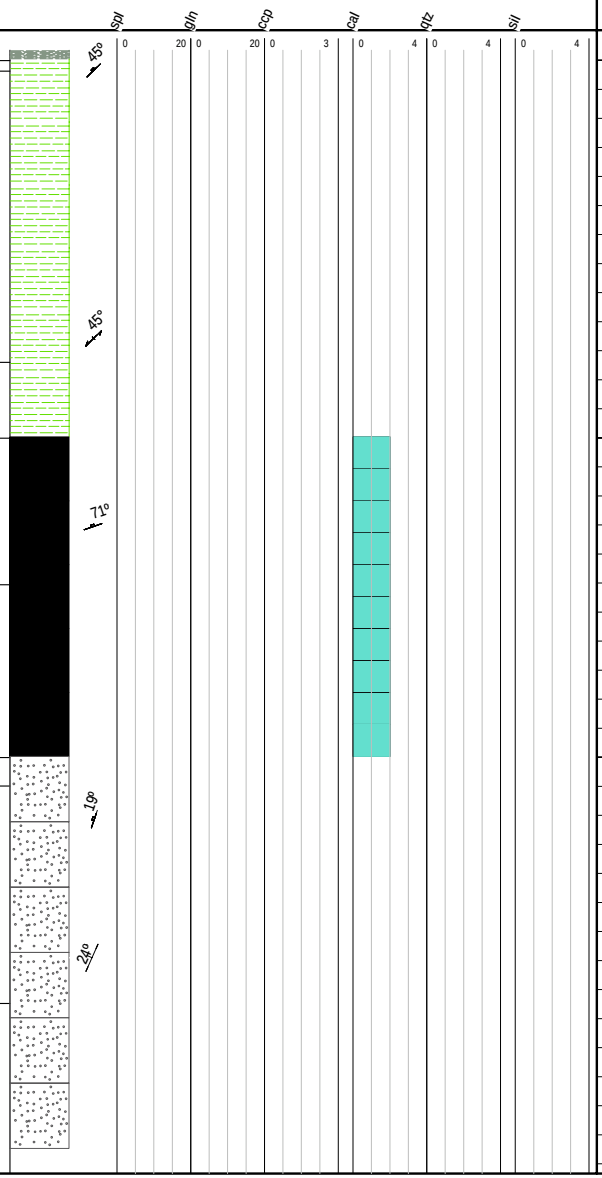
| 39.32 | 51.34 | Sst |



**SANDSTONE WITH SOME FAULTS**

The unit is massive to well bedded sandstone with some mudstone laminations.

From 39.92m to 41.06m the sandstone appears to have coarse grained feldspars and finer quartz. At first this was considered to possibly be a feldspar porphyry, but sections with much larger grains of all types indicates a sandstone.

Some dark blackish alteration generally runs in bands at 23 deg. to core axis.

| | | Fine grained limestone shows finely laminated bedding. |
| | | < @ 59.80 S0 60.00° > |
| 59.86 | 78.45 | Sst |
| | | SANDSTONE WITH INTERBEDDED MUDSTONE AND SOME QUARTZITE |
| | | The sandstone shows faint bedding in the upper part of the unit and becomes more semi massive near the bottom. Grain size tends to transition back and forth from medium to coarse. Some intervals appear to be a quartzite or silicified sandstone such as from 71.42 to 73.15. Occasional mudstone is interbedded. Rare 4cm band of limestone also present in upper part of unit. |
| | | Some smaller faults throughout the unit. |

MAROON MUDSTONE

Maroon mudstone with few green mudstone interbeds. Few quartz and quartz-calcite veinlets, mm-scale, no preferred orientation. Locally green mudstone interbeds show soft-sediment deformation and shearing. Locally cleavage occurs at an angle to primary bedding and to core axis. Chlorite occurs locally.

| | | Sedimentary breccia consisting mainly of grey-black mudstone, but also contains light-grey limestone, medium-grained dirty sandstone and vein material. There are compentent intervals of unbrecciated rock up to 30cm, but in general the rock is brecciated. Clasts range between 2mm and 6cm, and are generally angular to sub-rounded. The matrix is dark mud, and the breccia is clast supported. There is minor disseminated diagenetic pyrite within mudstone sections. Some vein material (mainly calcite) appears as clast within the breccia, but there are also veins that cross-cut the unit. Some weak silicification has occurred over small intervals. The breccia, although sedimentary, appears to have been tectonised, and some clasts contain veining showing that veining must have occurred prior to brecciation. This could suggest that some of the breccia is a healed fault breccia rather than sedimentary in origin. |

|---|---|---|
| | | fractured and brecciated by the veining. The interval of core itself is very competent. |
| | | The sphalerite is red-brown to orange-tan-brown in colour and fine-grained. It occurs as veins by itself between 1 to 3cm wide, and also as part of quartz and quartz-calcite veins. The calcite veins can be up to 50cm wide with the sphalerite occurring within them as blebs and clots up to 3cm wide. The sphalerite can also occur as the matrix to a breccia with country rock forming the clasts. Thin calcite veins appear to form a later generation of veins that cross-cut the other veining. |

| 136.05 | 207.26 | VglnsplSphalerite and galena-rich quartz and calcite vein stockwork. The country rock is mainly grey mudstone and fine-grained sandstone. There is a sequence of beds that grade from fine calcareous sand to mud. The beds repeatedly fine downhole suggesting that they may be overturned. Coarse sandstone is also present and many intervals of rock are brecciated. The sphalerite is much the same as further uphole and occurs in both quartz and calcite veins. The galena forms medium-grained clots up to 8cm in size, and is generally intergrown with the sphalerite. Quartz appears to be cut by calcite veins in places. The mineralisation , although it continues for quite some time, is mainly low grade with higher-grade intervals. |

| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

Hole AN08-080 was a resource hole drilled on section 1675. The expected mineralized zone was from 103m to 146m depth. The hole was strongly faulted and the mineralization was weak and intermittent from 95m to 167m.

**SUMMARY LOG:**

| **Claim:** | ANDREW7 | 2008/05/31 | 2008/05/31 |
| **Logged by:** | L.McClenaghan | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

AN08-081 was drilled as the first hole along line 1525. This hole attempted to intersect the ore body down dip from its projected outcrop along the south facing slope of the mountain. The hole was drilled to a depth of 114m. It intersected a short mineralized zone between 81.60- 91.19m. A zone of 80cm section contained 20% galena and 10% sphalerite, smithsonite mineralization was found in vugs within well mineralized galena.

**SUMMARY LOG:**

0-8.21 Overburden
8.21-19.96 Black Mudstone
19.96-24.23 Sandstone

| | | MAROON MUDSTONE |
| | | Maroon mudstone with green mudstone interbeds. Interbeds typically 1-5cm thick and ~40-60 degrees to core axis. Few quartz and quartz-calcite veinlets, mm-scale, no preferred orientation. Chlorite occurs locally. Limonite and possible other iron oxides occur locally on fractured surfaces. Cleavage occurs at an angle near perpendicular to core axis. |

| | | Fault gouge zone that contains red-maroon coloured gouge and rock fragments. Consists of ~60% gouge and 40% rock fragments. There is only 70cm of recovery for this interval. No orientations on the faulting are available. |
| 129.40 | 142.12 | Sst |
| | | Light to dark-grey fine to coarse-grained sandstone. The rock has been moderately faulted and there is weak to moderate calcite and quartz veining. Several of the sandstone beds grade from coarse to fine possibly indicating that the beds are right-way up, but there are other conflicting younging direction indicators such as load casts. Overall there is no conclusive younging indicators. Some intervals of the unit have been silicified moderately. |

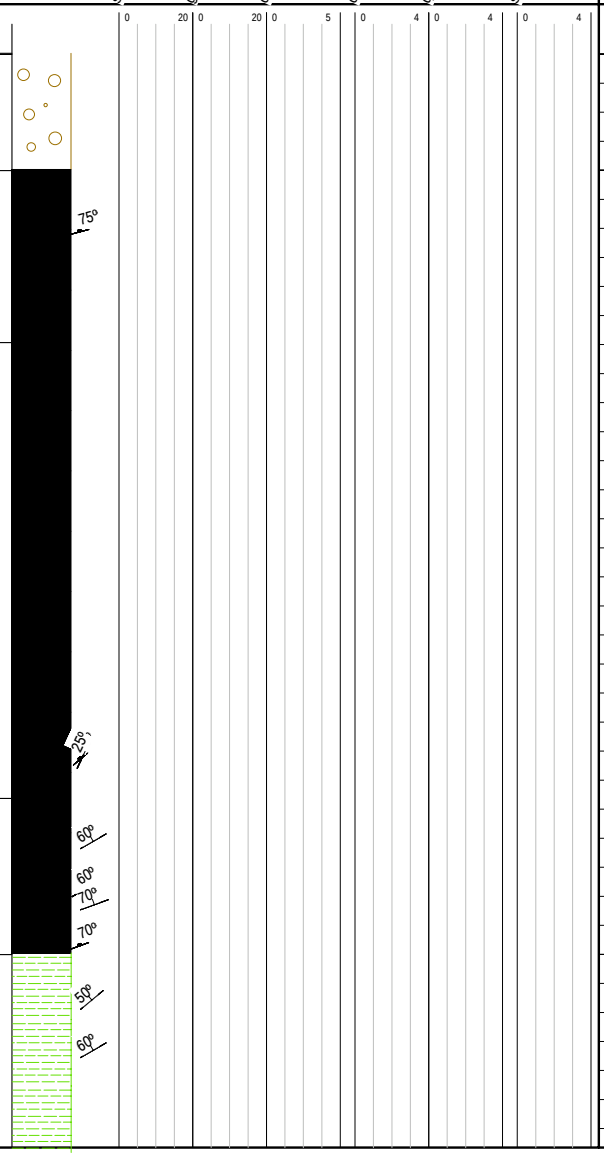
# DRILL LOG

| | | | |
|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1308.0 m |
| **Hole:** | AN08-084 | **Azimuth:** | 180.0° |
| **Proposed:** | prop1061 | **Dip:** | -70.0° |
| **Location:** | 641525 m East 6978244 m North | **Length:** | 143.87 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW7 | 2008/06/01 | 2008/06/02 |
| **Logged by:** | J.Norris | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

Drill Hole AN08-084 will be drilled to test the mineralization at depth from what was encountered in hole AN08-081. The hole will be drilled at an inclination of -70 and at an azimuth of 180 degrees. It is expected that mineraliztion will be encountered at 47m.

**SUMMARY LOG:**



0m to 3.10m - Overburden
3.10m to 11.70m - Fault breccia
11.70m to 15.76m - Green Mudstone
15.76m to 18.25m - Fault breccia
18.25m to 22.08m - Sandstone
22.08m to 22.85m - Calcareous Sandstone
22.85m to 24.59m - Sandstone
24.59m to 32.83m - Calcareous Sandstone
32.83m to 34.02m - Green Mudstone
34.02m to 44.75m - Maroon Mudstone
44.75m to 46.45m - Sandstone
46.45m to 49.91m - Maroon Mudstone
49.91m to 53.34m - Sandstone
53.34m to 54.56m - Maroon Mudstone
54.56m to 71.18m - Grey Mudstone
71.18m to 71.94m - Calcareous Sandstone
71.94m to 99.22m - Green Mudstone with 6cm massive galena band at 80.77m.
99.22m to 101.86m - Stockwork veining/brecciation (barren)
101.86m to 109.73m - Stockwork veining with Galena and Sphalerite mineralization. Overall 5% sphalerite and 0.5% galena.
109.73m to 116.95m - Stockwork veining with Sphalerite mineralization. Overall 1% sphalerite.
116.95m to 117.96m - Fault Gouge
117.96m to 122.19m - Fault breccia with trace sphalerite and galena
122.19m to 124.06m - Fault Gouge
124.06m to 126.30m - Fault breccia
126.30m to 129.74m - Sandstone
129.74m to 141.85m - Calcareous Sandstone
141.85m to 143.87m - Grey Mudstone. End of Hole.

| | | Fault brecciation of sandstone and mudstones. Overall 85% rock fragments to 15% gouge. Few competent beds of grey, fine to medium grained sandstone showing 5% 1-2mm calcite veinlets at varying orientations. Minor bedding seen in sandstones. Rock is fairly oxidized, showing rusty alteration staining throughout. Mudstone fragments are reddish brown to greenish grey in colour and are finely laminated. Few visible 1-2cm beds are much more reddish-brown in colour showing oxidization. Some of these beds appear leached and vuggy. Mudstones do not show calcite veinlets. Few slightly competent sections of mudstones appear to show tight folding. Slickenlines are visible on some fracture surfaces. |

Mineralization

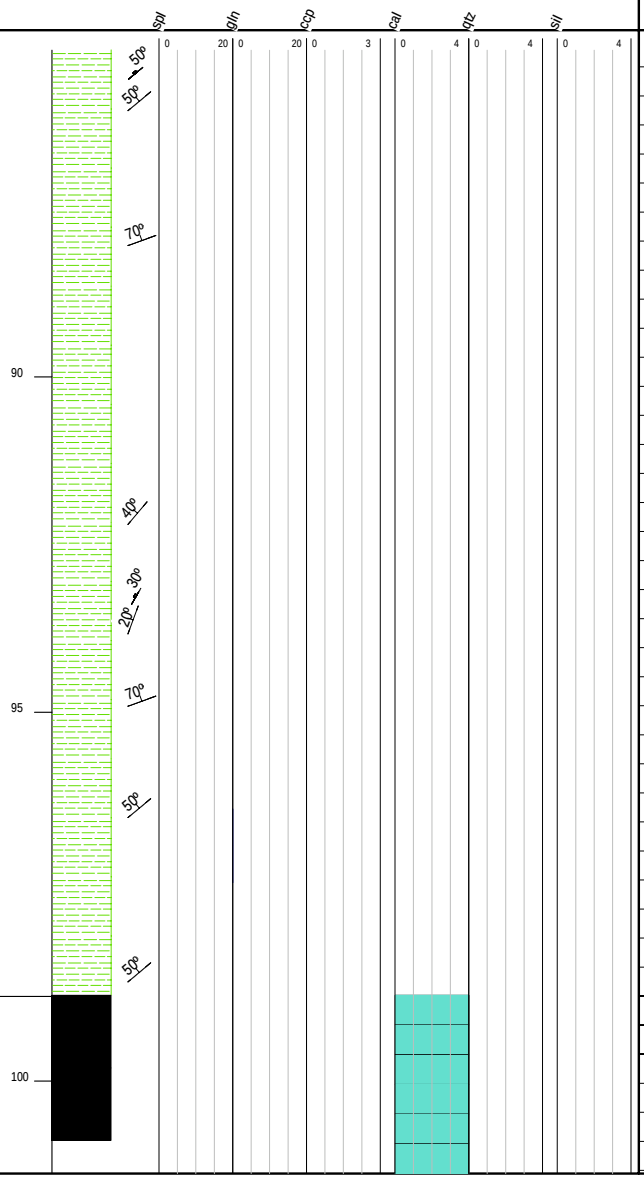
« 78.77- 79.77 gln 0.02% 2.00mm» Galena as 1mm crystals within 1-2mm calcite, quartz veinlets.

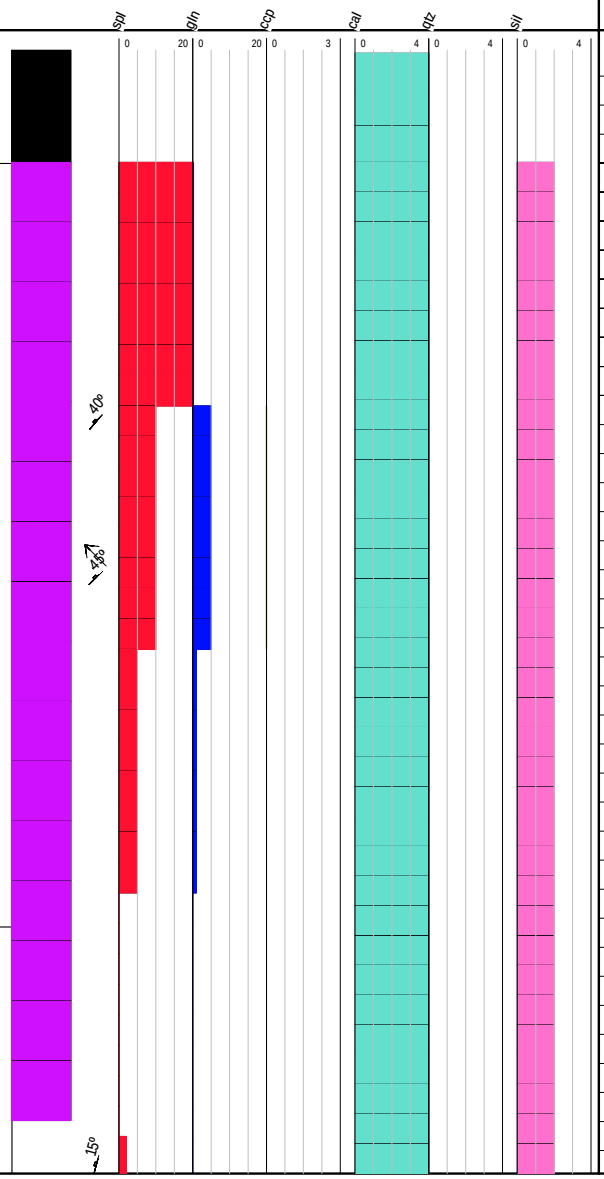


« 80.77- 81.47 gln 10.00% 60.00mm» Galena as 1-2mm crystals in a 6cm mass, associated with calcite, quartz veining.

« 96.44- 97.54 gln 0.02% 2.00mm» Trace galena as 1-2mm crystals as small patches up to 3mm across. Associated with calcite, quartz veining.

« 97.54- 98.20 pyr 0.01% 660.00mm» Trace very fine grained pyrite within green mudstone, up to 1mm blebs.

99.22 101.86 Zbxv



Stockwork veining/brecciation (Barren).
Fairly massive calcite and quartz vein, with minor amounts of green mudstone within, up to 15cm thick. Vein is quite competent. No orientation on the vein is visible. No mineralization seen within or associated with the veining. Can see calcite rhombs on fracture surfaces. Minor limonite staining on fracture surfaces.

| | | Stockwork Veining with Galena and Sphalerite. |
| | | Massive calcite, quartz stockwork veining containing patches and masses of reddish brown to tan sphalerite and lenses and veinlets of galena. Veining is moderately siliceous. Sphalerite occurs as patches throughout, up to 60cm long, of up to 40% mineralization. Galena occurs as small masses and large blebs of 1-2mm crystals, up to 3cm wide of up to 15% mineralization. Galena also occurs as isolated dendritic veinlets up to 2cm wide within the calcite, quartz veining. Trace chalcopyrite blebs up to 2mm associated with the mineralization. |
| | | 101.86m to 105.86m - Minor amounts of greenish grey mudstone brecciated by the stockwork veining. |
| | | 105.86m to 109.73m - Calcite, quartz veining is reduced to 40%, brecciating tan to dark grey sandstone with minor interbeds of green to grey and black mudstone. No bedding visible. Veins are 1mm to 2cm in size, at varying orientations. Some veins show a quartz-rich core with a 1-2mm calcite outer rind, others show a calcite-rich core and a 1-2mm outer rind of quartz. |

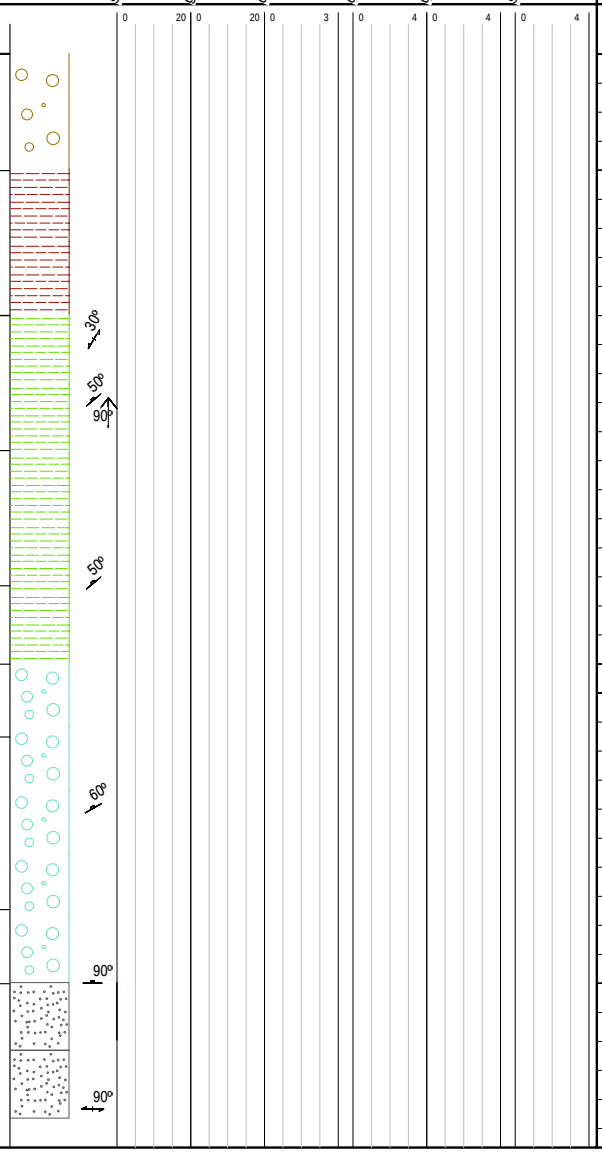
**Objective:**

This hole was drilled in order to undercut AN08-081 and AN08-084. It was meant to intersect mineralization downdip from previous holes to delineate its depth, extent and structural relationships. Mineralization zone was seen between 121.68m-128.58 m with both galena and sphalerite within a heavy calcite stockworked zone. The zone is faulted at upper and lower contacts. The azimuth value is off from ideal, due to unstable drill pad and possibly migrated due to slumping.

**SUMMARY LOG:**



0-2.09m Overburden
2.09-4.97m Red Mudstone

|---|---|---|

unmineralized sections of green to grey mudstone up to 1.5m thick. These mudstone sections show 5% 2mm to 1cm quartz/calcite veinlets at varying orientations. Trace very fine-grained pyrite alone some bedding planes within the mudstones.

Sharp lower contact with barren stockwork veining at 70 degres TCA.

Mineralization occurs as a net texture of orangey-brown sphalerite up to 15% over 25cm. The sphalerite mineralization occurs where the quartz/calcite veinlets have highly brecciated the sandstone and mudstone units, occuring up to 50% veining. The sphalerite is located within the quartz/calcite veining; interstitial to the sandstone and mudstone clasts. There are some 2mm quartz/calcite veinlets cutting through the sphalerite patches. Overall there is 1% sphalerite across the unit. Trace 1-2mm crystals of galena occur as 3-4mm patches, associated with the sphalerite mineralization.

| From | To | Rocktype & Description |
|---|---|---|

The sphalerite occurs within the veining and along foliation (?) planes. Roughly trace to 0.25% sphalerite over the unit. Trace galena as 1-2mm crystals in 2-3mm blebs along foliation planes, either isolated or associated with sphalerite. Trace 1-2mm blebs of chalcopyrite, associated with the quartz/calcite veins.

Structure

135.08m - Upper contact between Zbx and the massive quartz/caclite vein in the Vspl is sharp, at 40 degrees TCA.

135.54m - Foliation plane in massive vein, filled by sphalerite and galena is at 25 degrees TCA.

135.71m - Plane of mineralization of a collection of 1-2mm sphalerite blebs is at 40 degrees TCA.

137.08m - Sharp contact at base of massive quartz/calcite vein is at 70 degrees TCA.

< @ 138.18 S0 30.00° >

< @ 138.35 V 70.00° > V Unmineralized 5mm quartz/calcite veinlet

139.36m - Sharp contact into 40cm massive quartz/calcite vein at 40 degrees TCA.

139.76m - Faulted contact at bottom of quartz/calcite unit at 40 degrees TCA.

< @ 139.76 Ft 40.00° 30.00mm > Fault gouge.

< @ 139.93 V 70.00° 35.00 > Calcite vein, with few chalcopyrite blebs on margins.

Barren Stockwork Veining/Brecciation.
Dark grey medium grained sandstone and grey to black mudstone brecciated by barren quartz/calcite veining. Overall, moderately siliceous rock, with 10-50% quartz/calcite veins and localized sections of massive quartz/caclite veins up to 1.5m long. Some sections show 2mm to 2cm angular clasts of sandstone and mudstones. Bedding is weakly visible, mostly in areas of mudstone. Quite competent rock. Localized sections up to 5cm thick show up to 1% chalcopyrite as 2-3mm blotches, associated with the quartz/calcite veining/brecciation.

145

Structure
149.15m - Foliation plane in massive quartz/calcite vein is at 40 degrees TCA.

< @ 149.50 V 40.00° 12.00 > V Quartz/calcite vein within sandstone.
152.30m - Foliation plane in massive quartz/calcite vein is at 15 degrees TCA.

**Objective:**

AN08-087 was drilled to determine depth and character of the mineralized zone in section 641625 at approximately 65 m up-dip from the previous drillhole, AN0111. Mineralization was expected to be encountered between 32 and 61 m depth.

**GREEN MUDSTONE**

Green mudstone grading in colour to medium grey. Trace pyrite. Bedding slightly deformed. Non-planar quartz veins cut through bedding, and are filled in places by later calcareous material.

< @ 74.50 Bedding 55.00° >

« quartz veins 1.00*»
« calcareous veins 1.00*»

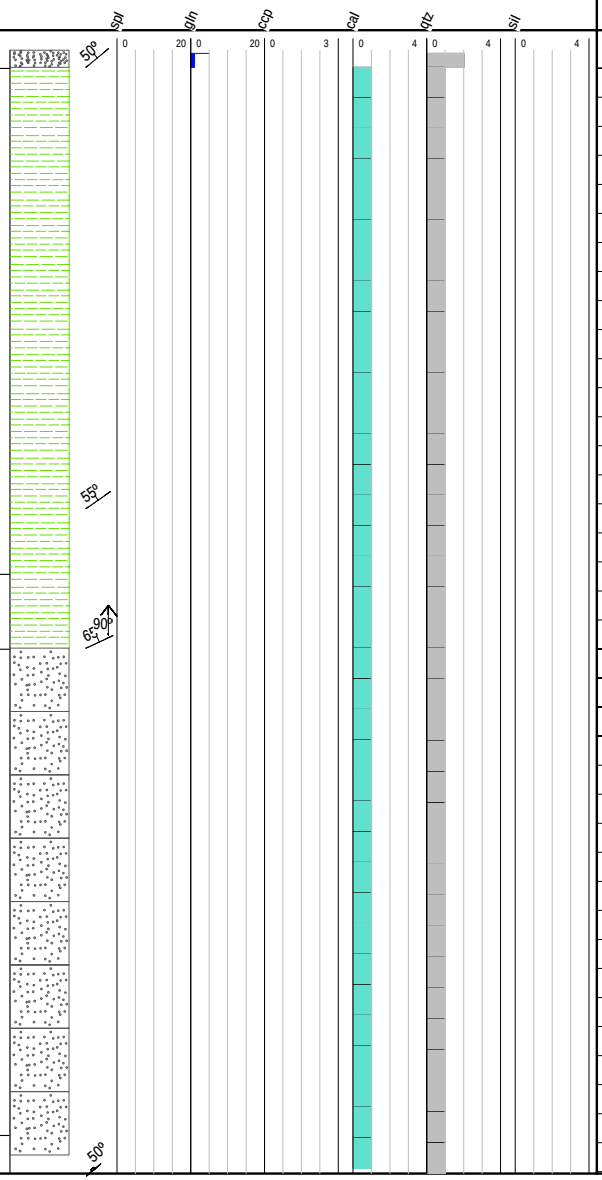
Fining within beds, cross-stratification and load deformation at 75.46 m suggest that this unit youngs up-hole. (90% confidence as some fining is inconclusive, appearing to suggest down-hole younging.)

< @ 75.46 younging direction, upright S 90° >

< @ 75.56 Contact 65° >

| From | To | Rocktype & Description |
|---|---|---|
| 75.56 | 81.91 | Sst |

**SANDSTONE**



Pale green/blue greyish coarse-grained sandstone with occasional mudstone inclusions. 15 cm zone of 15% mineralization at 80.42 m in light siliceous stockwork. Layer is broken and brecciated below this to the contact with the underlying grey shales, suggesting a fault contact. Calcareous veins intrude and intersect siliceous veining, though calcareous material is not found in or below the mineralized zone in this unit.

« 80.42- 80.57 Galena 15%»

**Objective:**

This hole was drilled as the second hole at this site. It is the undercut to hole AN08-085, and was an attempt to locate the ore zone and discover any structural relationships. The hole reached a depth of 206.65m It intersected galena mineralization 50m above the main sphalerite zone at ~150m. The azimuth value is off from ideal, due to unstable drill pad and possibly migrated due to slumping.

| | | Sphalerite-rich calcite and quartz stockwork veining. Over this interval it appears that the sphalerite and quartz are a later stage of veining that cross-cut previous generations of calcite and quartz veining. The sphalerite is medium reddish-brown in colour and has a resinous lustre. Between 88.40 and 88.95m there is an ooidal limestone unit. The ooids show concentric patterning and are 3mm diameter on average. The matrix is dark grey and fine-grained. The limestone is ooid-supported and the ooids are well sorted. |

| **Proposed:** | prop1069 | **Dip:** | -70.0° |
| **Location:** | 641626 m East 6978307 m North | **Length:** | 201.17 m |
| **Area:** | Andrew _deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW7 | 2008/06/05 | 2008/06/07 |
| **Logged by:** | S.Berdahl | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

The objective of hole AN08-090 is to test the mineralization encountered in hole AN08-086 at depth. Mineralization is expected to be encountered at a depth of 140m, roughly 25m down dip from the mineralization in AN08-086. This hole will be drilled at -70 degrees inclination and at an azimuth of 180 degrees.

| | | **OVERBURDEN** |
| | | Orange-tan weathering red and green mudstones, parting along bedding planes. |
| 2.20 | 25.50 | Sms_rd |
| | | **RED MUDSTONE** |
| | | Red mudstone interbedded with coarser-grained green mudstones and siltstones, with one heavily deformed 40 cm grey mudstone bed starting at 19.71 m. Deformed stratification is usually visible in green beds, and provides hints for an overall upwards younging direction. The unit is tightly folded, however, so this may not be an accurate interpretation of younging overall. Quartz and calcite veining are apparent in some green beds deeper in the unit. |

| | | GREY MUDSTONE |
| | | Mainly medium grey mudstone, with regions of deformed and quartz-veined dark grey mudstone as well as regions of green mudstone and red mudstone with green beds. Though juxtaposed by fault contacts on both sides, the unit is likely related to the overlying and underlying red shales, and may simply be a variation of the same sequence. Calcite veining only occurs at the very top of the unit, and appears to have occured after the quartz veining. |

| | | « Quartz 1.00*» |
| 69.19 | 92.35 | Sms_gy |
| | | **GREY MUDSTONE** |
| | | Dark grey mudstone with thick green mudstone interbeds above 79.25 m. Regions of deformation are present, but for the most part planar (cleavage) features seem relatively intact. Bedding stratification is not usually visible in the green beds, and cleavage fractures are common, so the unit has probably been sheared. Quartz veining is present throughout the unit, getting slightly more intense in darker mudstone beds near the lower contact with the underlying sandstone. Trace pyrite present in the lower dark beds. |
| | | 69.19 - 72.60: Dark, lightly quartz stockworked grey mudstone with green interbeds, irregularly deformed. |
| | | 72.60 - 79.97: Sheared, fairly constant dark grey and green mudstones. |

| | | SANDSTONE |
| | | Dark, medium-coarse grained grey/blue sandstone with small grey mudstone interbeds. Units seem to be deformed syn and post-depositionally, so bedding angles and younging direction are difficult to determine. Tensional-fracture calcite veins are present, particularly in the more brittle sandstone sections. Underlying limestone contact seems parallel to bedding, but it is fractured into blocks by fine-grained mudstone. |

| | | consistent with bedding direction, and grey mudstone layers at the top of the unit. Two regular beds of limestone in mudstone in the upper part of the unit suggest that the limestone represents an original deposition, though the large lower portion is heavily tilted, forming a fold nose, and it contacts the underlying mudstone discordantly. This is likely a result of the faulting associated with the underlying breccia zone.<br><br>< @ 100.10 S0 25.00° ><br>< @ 99.80 Contact S0 65 ><br><br>« Veins mostly around 10 deg cal 2.00* 15.00mm» |

| | | SPHALERITE-RICH STOCKWORK |
| | | Quartz-calcite stockwork through a very coarse-grain (up to 5 mm diameter) sandstone with grey and black mudstone interbeds. Heavy sphalerite mineralization occurs in the region from 146.0 to 151.1 m depth, while heavy galena mineralization occurs farther down-hole from 159.4 to 160.3 m depth. Sphalerite mineralization seems largely associated with quartz veining, though there are exceptions to this. Crosscutting and vein characteristics between quartz, calcite, sphalerite and galena give evidence for multiple fluid generations, including contemporaneous formation of some quartz and calcite features, though quartz veins are often cut by later calcite veins. Galena seems to have formed later than the sphalerite. Low in the unit is a relatively unmineralized 3m sandstone bed starting at 167m, and below that, the qtz-cal stockwork cuts through black and green mudstones. |

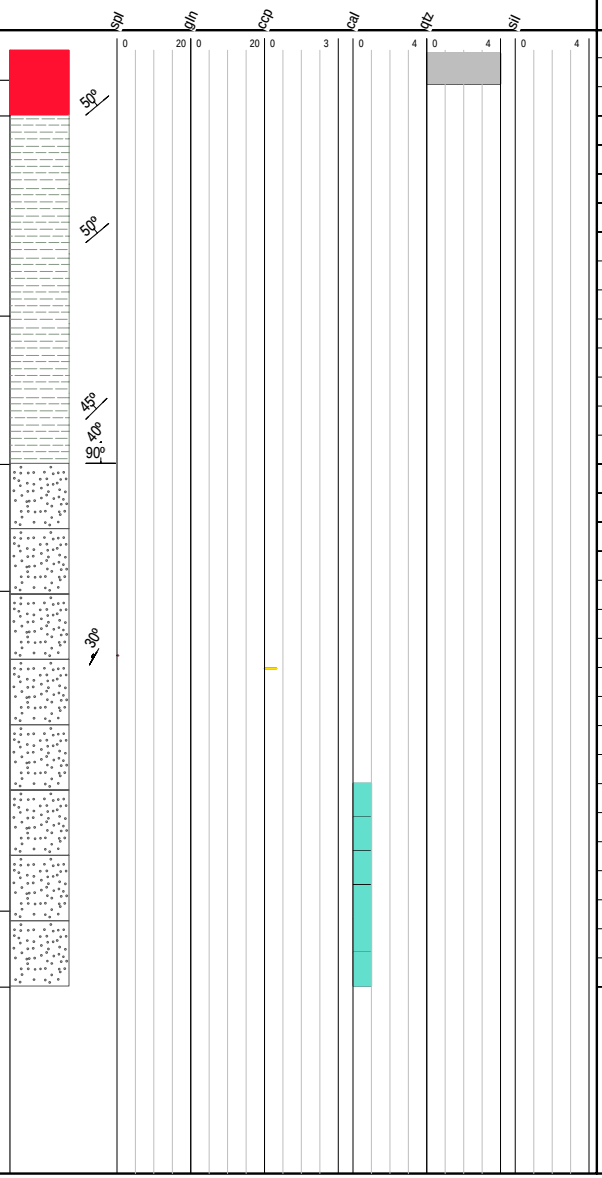
SANDSTONE



Heterogeneous sandstone with regions of medium greyish blue, coarse-grained sandstones, grey mudstone beds, breccias and a dark-groundmass sandstone with large (mm) rouded quartz clasts. Calcite veining is present in the last 3 metres of the hole, and trace mineralization (sphalerite and chalcopyrite) can be seen.

| **Claim:** | ANDREW7 | 2008/06/06 | 2008/06/10 |
| **Logged by:** | L.McClenaghan | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

This hole was drilled as the most northerly target on the 1525 section line. It has the steeper dip of the two holes being drilled at this site (-70degrees). It will reveal the characteristics of the mineralized zone at depth, as it is the deepest drill hole along this section.

**SUMMARY LOG:**

Calcite veining event brecciated mudstone and shalerite appears to be replacing it. Towards end of this unit angular brecciated sphalerite can be seen 2mm-0.1mm with brecciated mudstone clasts and quartz veining. Contact at base of unit 30 degrees. |

|---|---|---|
| | | mudstone consisit of a fault at 190.77m then a vein breccia zone, and green mud bedding begins at 190.9m wtih an angle of 45 degrees. Green mudstone contains brecciated zones. Large stockwork structure between 194.38m-195.68m brecciated chunk of sphalerite contained within. Stockwork faulted at the base. Sphalerite is honey brown as well as a darker beer bottle brown. Usually occurs associated with veining and brecciation of country rock. Galena appears much more massive and pristine in comparison. Zones of high concentration of mineralization are associated with higher stockworking. |

| | | Red mudstone with green mud and siltstone interbeds. Same as above. Some of t |
| | | beds of green siltstone appear to be fragmental. This may be a primary |
| | | breccitaion during deposition. Along siltstone beds there is a reduction rim |
| | | usually several millimetres wide that changes the red mudstone to a pale green |
| | | colour, and this happens as a rim around the fragmental beds as well, not |
| | | around individual fragments. Between 53.34 and 55.7 there is clay and sand, but |
| | | it does not appear to be a fault, simply the result of a worn out drill bit. |

Mainly grey mudstone interval, that grades from the red mudstone into grey and then into pale green about 3m before the end. It has also been highly colour altered ~1m before the end (at ~97.6m) to a bright tan-brown colour just before a fault zone. The rock has been moderately faulted and is moderately quartz and calcite veined over certain stretches. Between 90.3 and 91.6 the grey mudstone is moderately brecciated and more faulted than the rest of the rock.

| | | Galena and sphalerite-rich vein stockwork. The veins are mainly calcite with some quartz. The country rock is green mudstone up to 135.35m depth, then massive calcite veins until 141m, and then sandstone and breccia for the remainder of the interval. There are intervals of calcite for up to 3m, notably between 135.7 and 137.55m, and 137.8 and 140.98m. There is sphalerite veining along the edges of these large calcite veins, and in general the sphalerite contact with the calcite is sharp and then grades away from it over 3 to 4cm. This may be a replacement texture. The sphalerite is a red-brown colour and fine-grained. The galena is medium-grained and in places appears to have later brecciated the sphalerite and calcite/quartz veins. The mineralisation is quite low-grade over the interval. |

| | | Sedimentary breccia that has been tectonised, probably related to the veining and faulting seen uphole. Clasts range in size between 3mm and 10cm in diameter and are angular to sub-rounded. Clasts are mainly sandy or muddy, and some contain calcite veining. For most of the section the matrix is fine-grained and black, but for several small intervals, for example between 168.8 and 169.16m, the matrix is a light-grey silicious fine-grained matrix. Trace galena and sphalerite are present over very small intervals. |

| | | Sphalerite and galena-rich veins up to 2cm wide. There is moderate to strong quartz veining and moderate calcite veining. The country rock is grey mudstone up to 202m and then it changes to medium-coarse grained sandstone. The sphalerite varies in colour between dark red-brown to light tan. The galena appears to form clots adjacent to sphalerite veins. chalcopyrite is present over the interval as trace blebs. |

| | | SPHALERITE VEINING |
| | | Host rock is a massive grey/green mudstone. Calcite, quartz stockwork has increased and brecciated country rock in places. |
| | | Sphalerite is generally found in the central portion of veins Black minerals are also found within veins (black quartz?). Several episodes of veining is evident due to crosscutting relaitonships. « 147.71- 149.72 spl 2.00%» |
| | | 149.72-151.71 barren |

| | | ZONE OF MINERALIZATION |
| | | Host rock goes from green/grey mudstone into black mudstone then into a sandstone and towards the end of the zone it grades back into black mudstone. |
| | | Sphalerite is localized to inner portion of veins while galena is not confined in this way. Many of the veins are folded. Core fractures easily along graphitic surfaces. Galena appears to cross cut sphalertie when found in the same vein. |

|---|---|---|
| 0.00 | 1.20 | Ogv<br>**OVERBURDEN** |
| 1.20 | 11.75 | Sst<br>**SANDSTONE**<br>Medium to fine-grained light blue-grey sandstone with interbeds of green siltstone and grey mudstone. The unit appears to be heavily deformed, especially along the mudstone beds, with folds apparent and bedding angles ranging from 0 to 90 degrees. The contact with the underlying grey mudstone may be faulted, but similarites in the grey mudstone beds with the mudstone unit beneath suggest the two units may be related. Light quartz veining occurs along the sandstone beds. |
| 11.75 | 16.30 | Sms_gy<br>**GREY MUDSTONE**<br>Short unit of dark grey mudstone with a large proportion of green siltstone interbeds. The unit is folded, and faulted along small-offset fractures, with bedding angles between 0 and 90 degrees. Though the lower contact is defined along a fault, a gradual transition between the darker grey mudstone beds and the red mudstone beds of the underlying unit suggest that these two units are a part of the same sedimentary sequence. A few light calcite veins are present within the unit. |
| 16.30 | 63.54 | Sms_rd<br>**RED MUDSTONE**<br>Maroon-red mudstone, likely of the Narchilla Formation. Two types of green interbeds are present: depositional, coarser grained silt and mudstones in which bedding stratification is apparent, and reduced regions of green mudstones around quartz veins that follow bedding. The depositional green beds occur mostly high in the unit, and then again at the bottom of the unit below a small region of dark grey sandstone, green mudstone and fault gouge that runs from 54.86 m to 56.74 m depth. The contact with the underlying dark grey mudstone is gradual and appears conformable. |

| | | STOCKWORK VEINING/BRECCIATION (BARREN) |
| | | Intense quartz and calcite stockwork through grey mustone host rock with a few large fragments of sandstone. Multiple fluid events have occured, and the major stockwork veins (which are a late feature) appear to have crystalized calcite and quartz simultaneously, though quartz looks to be largely responsible for the major stockwork structures. Stockwork becomes less intense below 104.92 m, after which the rest of the unit is lightly stockworked dark grey mudstone. The unit is heavily fractured throughout. The underlying contact with Vspl is uneven and along a large siliceous vein. |

| | | Sphalerite-rich vein stockwork of mainly quartz with some calcite. The quartz appears as many thin veins that crosscut each other randomly. The sphalerite is a light brown to a red-brown colour and appears as veins up to 52m, and then changes texture so that it appears as the matrix to a breccia with sub-rounded silicious clasts. In the breccia section, the sphalerite appears to be associated with calcite whereas in the veined section sphalerite is associated with quartz which cut an earlier quartz phase. Background lithology is extremely brecciated sandstone and mudstone. |

| | | Intensely stockwork veined grey mudstone with galena-rich veins. Veins are composed of quartz and calcite. The calcite veins are up to 5cm wide in places. Quartz can be seen as a rim to calcite veins, and in places quartz veins fragments are inside the calcite vein that is being rimmed by quartz. This would indicate that the quartz came first and the calcite exploited earlier quartz veins. The galena is medium grained and is associted mainly with calcite but also with quartz. Chalcopyrite appears as trace over the interval. |

| | | Matrix supported sedimentary breccia that has been tectonised. Clasts are angular to sub-angular and range in size between 1mm and 40cm in diameter. The matrix is fine-grained and black, reminiscent of the Earn Group clastics. The clasts include fine sand, mudstone fragments, veined clasts and vein fragments. No definate chert is found. Some mudstone clasts are green mudstone that resemble the Narchilla Formation, which would imply that this unit is younger than the Highland Group, making it either Road River or Earn. The is a fabric that runs through the interval at ~40 degrees. Galena, sphalerite and chalcopyrite appear as trace. The interval becomes very broken and weathered at the end. |

| | | Very coarse-grained sandstone to granule conglomerate that contains ~10% rounded feldspar grains and at least 40% of rounded quartz grains, both up to 5mm in diameter. The rock is clast supported and the matrix is granular. Overall the unit is moderately to strongly silicified and contains moderate to strong quartz veining in places. Calcite veins are seen later cutting quartz veins, and in several areas quartz veins are folded and then cut by later apparently undeformed calcite veins. Faulting is present, generally occurring on the contacts of grey-black mudstone interbeds, 3 to 8cm wide on average. Trace malachite can bee seen. This may be a coarse clastic from the Highland Group, as opalescent quartz grains are seen throughout. |

| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

AN08-097 was the first of two holes drilled in a fan on the 1475 section. There were two small mineralized zones: 1.81 m zone from 196.14 - 197.95 m of 3% sphalerite and 4% galena and 4.25 m containing semi-masive to massive sphalerite and galena truncated by a large graphitic fault at the base from 203.00- 204.95 m. Minor sulphides, from trace to 2%, were located within a stockwork zone below the fault.

| From | To | Rocktype & Description |
|---|---|---|

Largely calcareous stockwork through dark grey mudstone. Trace sphalerite (hosted in quartz) and galena (hosted in calcite) are present, as well as trace chalcopyrite. Towards the bottom of the unit, the rock becomes less competent, with regions of heavily fractured rock, and the bottom contact fades into a sedimentary breccia.

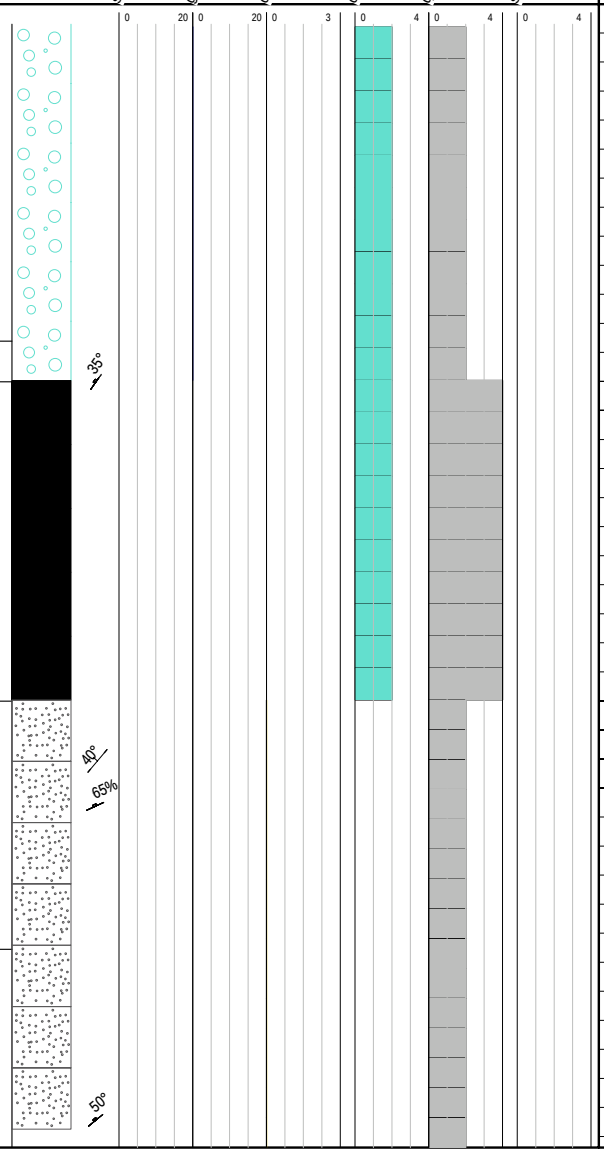
**SEDIMENTARY BRECCIA**

Clasts of quartz sandstone in a dark mudstone matrix, matrix-supported, crosscut with later quartz and calcite veins; minor galena present. Post-mineralization faulting may have intensified the breccia. Downhole, the unit becomes a more lightly brecciated sandstone, supported by clasts. The coarse-grained sandstone appears similar to the sandstone unit at 82.41m, though they are seperated by two large faults and a region of intense veining.



< @ 77.14 Small gouge zone Ft 40° 4mm > - Follows general fracture (possible horizon at deposition) direction.

**Objective:**

This hole was a geotechnical hole drilled trending 315 degrees. Its purpose was to test anisotropies in the bed rock at an orientation differing from the majority of drilling to facillitate design of the proposed pit. This hole was not anticipated to hit mineralization. Orientating of the core was sporadic starting at approximately 45 m depth.

| | | < @ 16.25 Contact - conformable S0 60° > - Some shearing along contact. |
| | | 9.74 - 10.38: Fractured zone. |
| 16.25 | 20.50 | Ssl |
| | | **SILTSTONE** |
| | | Stratified green siltstone, similar to what is seen in certain green beds within the overlying red mudstone. The unit has interbeds of grey mudstone which may simply represent a variation in colour of the Narchillan red mudstone beds. Stratification appears to have been deformed syn-depositionally, and possiby post-depositionally as well. Cross-stratification indicates that the unit youngs down-hole and is thus overturned, but a strata-overturning fold at 19.30 m might mean that this is only local. Bottom contact is heavily fractured along a sedimentary breccia, and appears to have been faulted. |

| | | STOCKWORK VEINING/BRECCIATION (BARREN) |
| | | Quartz-calcite stockwork through siliceous sandstone, green and grey mudstones, and sedimentary breccia. Minor sphalerite mineralization in quartz veins. The upper 40 cm of the unit are a sedimentary breccia (containing a large limestone clast), and the lower contact is defined at the end of a large fault zone of fractured rock and gouge. Calcite appears to intrude through quartz veins, suggesting that calcite formed after an intial silica-rich fluid stage. |

| | | SPHALERITE-RICH STOCKWORK |
| | | Quartz-caclite stockwork through a largely sandstone host rock, grading into grey mudstone and what once may have been sedimentary breccias farther down the unit. Minor to semi-massive sphalerite seems to be associated with both quartz and calcite veins: in some areas is is hosted entirely within quartz veins while in others it looks to have formed contemporaneously with the calcite, particularly at 105.16m, where euhedral calcite crystals can be seen enclosed within the spahlerite. Galena forms in large veins in only a few localized areas. Throughout the unit, calcite veins cut across and through quartz veins. The unit is separated from the underlying barren stockwork by a fault. |

though the lower contact occurs at 30 degrees--but given the heavy fault brecciation of the underlying barren stockwork, the 30 degree contact may be due to a large rotated segment between the fault zones.

« Fragments in breccia spl 1%»

**133.91 144.40 Zbxv**

**STOCKWORK VEINING/BRECCIATION (BARREN)**

Largely calcareous stockwork through grey mudstone, with heavy fault brecciation above 140.21m. The upper 1m of the unit is a qtz-cal stockwork through a sandstone host with trace sphalerite. Below this the grey mudstone is heavily fractured with some gouge present. No mineralization is seen past the upper sandstone region. The bottom contact with the underlying grey mudstone is marked where the calcareous brecciation fades in intensity, and thus it is a conformable contact.

« 133.91- 135.00 Trace spl 0.01%»

135.00 - 140.21m: Heavy fault brecciation, though only minor amounts of gouge.

| From | To | Rocktype & Description |
|---|---|---|
| | | Strong sphalerite-rich veining with intervals of sandstone and dark-grey mudstone as the country rock. Moderate faulting is seen. The sphalerite is a tan-red-brown colour and appears in veins 1 to 3cm wide with quartz and calcite. The veins are infrequent over the interval amounting to only 1%.sphalerite. Trace chalcopyrite is also present. |

| | | Galena-rich stockwork-veining through grey mudstone with an interval of sandstone between 77.8 and 78.6m. The galena is medium-grained and is associated with calcite veins that have a ~3mm thick quartz rim. Some veins contain trace sphalerite and chalcopyrite. The veins are up to 6cm wide, and are infrequent over the interval so that galena only amounts to 2% overall. |

|---|---|---|
| 0.00 | 4.03 | Ogv |
| | | **OVERBURDEN** |
| | | Broken up fragmented core. Poorly sorted sub-angular fragments.« lim 1.00*». |
| 4.03 | 8.12 | Sst |
| | | **SANDSTONE** |
| | | Fine-grained grey sandstone, any surfaces are orange due to oxidation. Calcareous nodules present. Black deformed mudstone interbedded. Unit is fairly broken up,appear faulted although angles are difficult to measure. Contact towards base of unit with black mudstone at 45º, just before faulted unit begins. |
| | | « lim 3.00*» < @ 4.26 gouge Ft 70.00º 80.00mm |
| 8.12 | 15.42 | Zfzg |
| | | **FAULT ZONE** |
| | | Soft gouge. Competent pieces of black mudstone containing pyrite make up middle of the zone and is punctuated by sections of rubble. Last 2m of unit is semi-consolidated gouge, large range in clast size. Fractured clasts are suspended within a fine clay-like matrix, with a wavy banded texture. |
| | | « lim 2.00*» « pyr 0.10%»< @ 13.02 Ft 25.00º 2400.00mm > |
| 15.42 | 26.22 | Sbx |
| | | **SEDIMENTARY BRECCIA** |
| | | Core is soft. Fine black mud matrix, showing debris flow textures. Clasts range in size from 7cm to 2mm, subrounded to subangular. Flow textures include aligmened clasts with elongation direction of mud beds. This texture is not present throughout. Clasts are more rare from 15.82-17.98m. Pyrite globules are seen in muddy matrix. Anatomosing microfractures contain soft beige mineral. « pyr 0.10%» Faulted contact with unit above, calcite along fault surface showing slikenlines/linear crystallization. Calcite veins through sandstone clasts. |

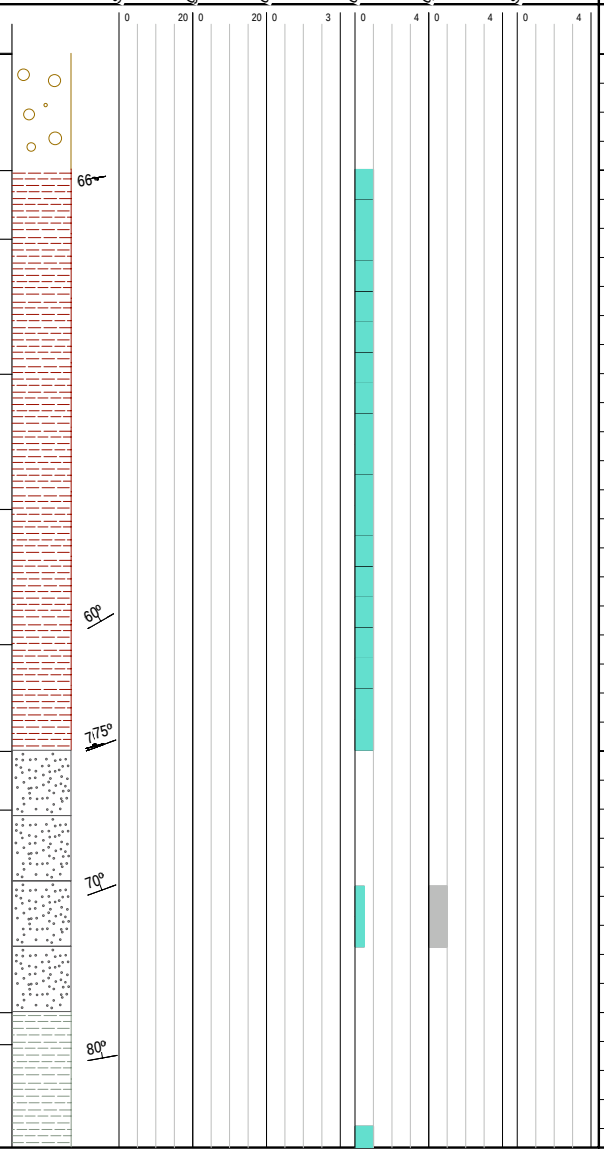
# DRILL LOG

| | | | |
|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1260.0 m |
| **Hole:** | AN08-103 | **Azimuth:** | 181.1° |
| **Proposed:** | prop1081 | **Dip:** | -59.5° |
| **Location:** | 641774 m East 6978314 m North | **Length:** | 152.40 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW6 | 2008/06/16 | 2008/06/18 |
| **Logged by:** | E.Alesi | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-103 was drilled as an infill hole on the 1775 section of the Andrew deposit. It intersected sphalerite and galena mineralization from 83.59 - 95.40 m, 95.40 - 99.75 m, 112.72 - 115.10 m and 121.22 - 124.78 m within quartz-calcite stockwork veins hosted in sandstone.

**SUMMARY LOG:**



| | |
|---|---|
| 0.00 - 2.42 m | Overburden |
| 2.42 - 23.90 m | Red Mudstone (Narchilla Fm) |

Sedimentary breccia that consists of well-bedded intervals of dark grey and light grey-brown mudstone, with intervals in between of highly disturbed bedding with angular clasts, some of which display bedding, possibly representing rip-up clasts. The brecciated intervals may or may not indicate local debris flows. The matrix of the breccia is fine to medium-grained medium-grey sand, and clasts are angular to sub-anguar and are composed mainly of mud. The bedding has since been faulted with offsets that can be seen up to 4cm. The interval appears possibly folded, but on a very gentle scale. The beds start off dipping ~30 degrees, then over >10 m they become parallel to core

| | | Limestone with mudstone, siltstone and fine-grained sandstone interbedded. Truncated cross-beds and load casts indicate that the rocks are right-way up for the most part, but just at the end of the interval two fold axes, an antiform and synform occur, and the rocks appear overturned downhole adjacent to them, but the beds are cut off by faulting, so they may simply be folded beside the faulting. The limestone is moderately pure, but contains very thin interbeds of grey granular material. Limestone beds are up to 1m wide (not true thickness). |

| | | Green mudstone with moderate faulting and veining.<br><br>< @ 122.50 Gouge Ft 45.00º ><br><br>« qtz 2.00*»<br>« cal 2.00*» |
| 123.00 | 129.62 | Zbxv |
| | | Intensely vein stockworked sandstone that has been strongly faulted and contains limonite weathering. Trace sphalerite is present over the interval in with quartz veins. The country rock which is sandstone grades between medium and coarse-grained and is mainly light grey.<br><br>< @ 124.42 Gouge Ft 30.00º 10.00mm ><br>< @ 126.25 Gouge Ft 60.00º 40.00mm ><br>< @ 128.40 Calcite V 35.00º 8.00 ><br>< @ 129.05 Calcite-quartz V 30.00º 10.00 ><br><br>« qtz 4.00*»<br>« cal 4.00*»<br><br>« spl 0.05%» |
| 129.62 | 150.27 | Vspl |
| | | Sphalerite-rich stockwork veining. The veins appear random, and there are at least two generations of veins. In general, calcite seems to have come before quartz and sphalerite, which mainly appear together and crosscut the calcite. However in places, calcite cuts quartz, and quartz is seen rimming calcite veins.<br>The sphalerite is a red-brown colour with a resinous lustre that appears as blebs within the veins and also as veins itself up to 10cm, but on average several cm.<br>The country rock is sandstone up to 150m, then grey mudstone to 150.27. Much of the rock is highly brecciated from veining and faulting. The calcite forms veins up to 2m-wide for example between 138.45 and 140.5 m (not true thickness). Between 135 and 146 m the calcite is stained yellow-orange, probably limonite staining possibly from preculating groundwater.<br>There is up to 1% galena over shorter intervals and trace chalcopyrite.<br><br>< @ 131.77 Calcite contact. V 30.00º 400.00 ><br>< @ 131.55 Quartz vein cutting calcite. V 30.00º 10.00 > |

# DRILL LOG

| | | | |
|---|---|---|---|
| **Project:** | Andrew | **Collar elevation:** | 1262.0 m |
| **Hole:** | AN08-105 | **Azimuth:** | 176.0° |
| **Proposed:** | prop1079 | **Dip:** | -73.2° |
| **Location:** | 641770 m East 6978330 m North | **Length:** | 195.07 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW6 | 2008/06/18 | 2008/06/21 |
| **Logged by:** | S.Berdahl | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_M | | |

**Objective:**

AN08-105 will be drilled to test mineralization in section 1775 between that observed 30m up-dip in AN08-100 and that observed 100m down-dip in AN07-28. A dip of -73 degrees will be used, as opposed to the original -70 degrees, so that the section will have more uniform coverage. Mineralization is expected between 120m and 168m depth.

**SUMMARY LOG:**

0.00 - 3.05m: Overburden

3.05 - 15.97m: Sandstone
15.97 - 21.75m: Grey mudstone
21.75 - 24.93m: Fault breccia

**SANDSTONE**

Coarse-grained quartz sandstone, medium grey to blue-grey, with iterstitial rusting, concentrated towards the top of the unit. The upper 75cm of the unit are a relithified fault gouge, and there are a few more smaller breccia zones throughout the unit. Calcite veining cuts through an earlier generation of quartz veining, and both generation are affected by small deformations.

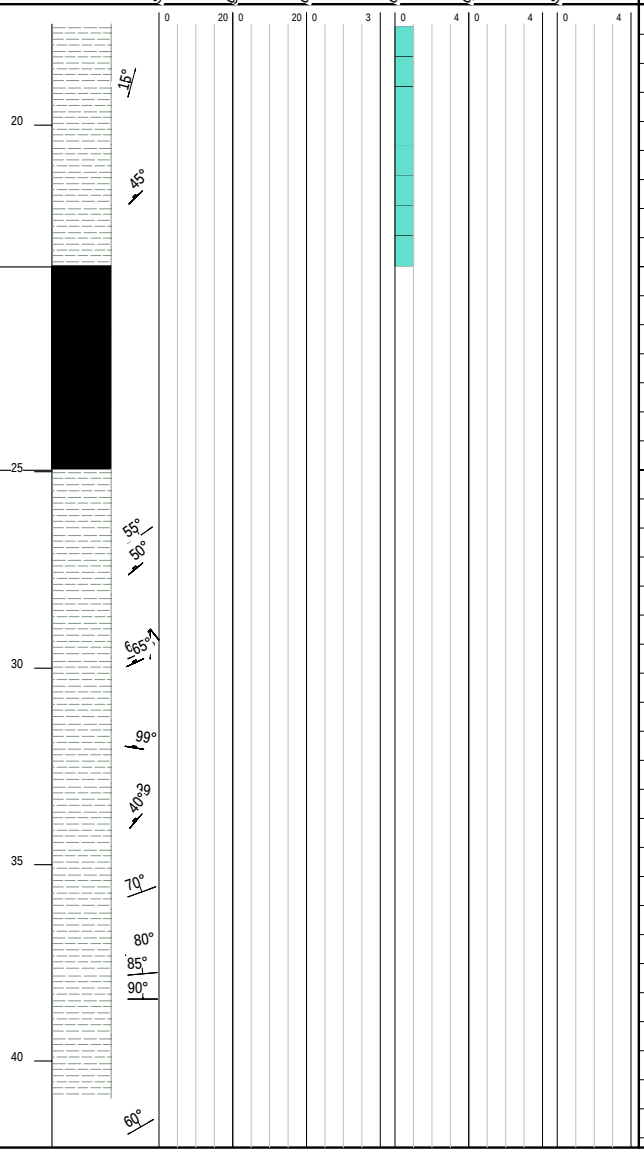
**GREY MUDSTONE**



Dark grey mudstone with large interbeds of green and dark grey siltstone. The unit is has been deformed ductily as well as faulted and fractured, and bedding angles are near that of the core axis. Light calcite veiing along older quartz veins. The unit becomes heavily brecciated near the bottom contact with the fault zone.

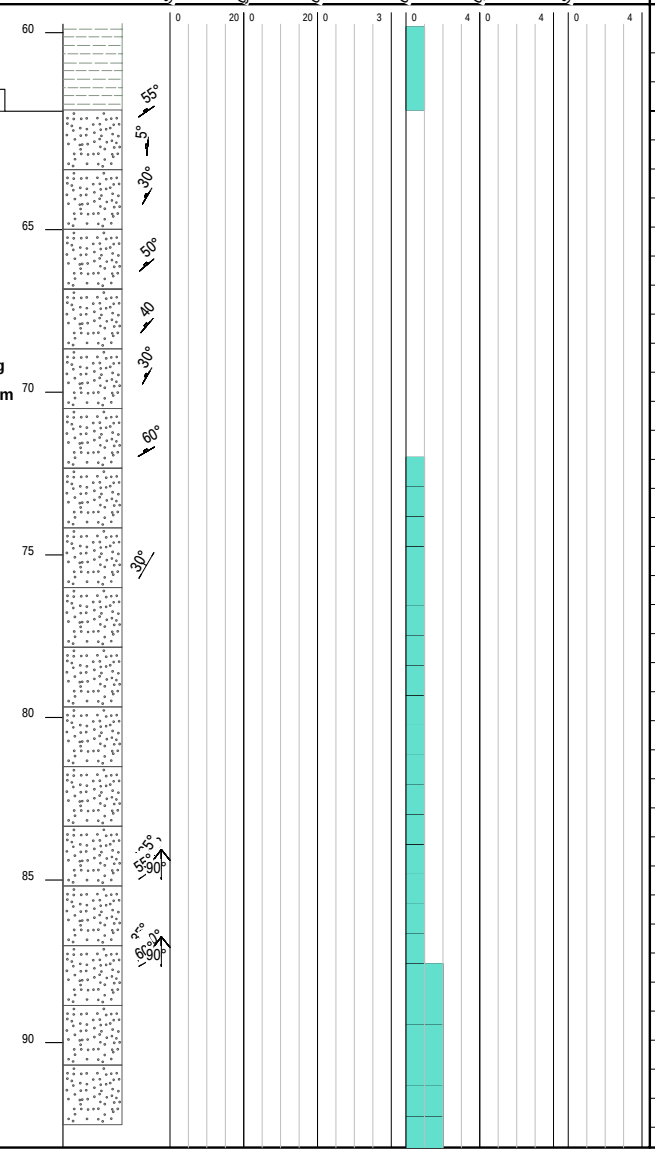
« cal 1*»

61.32 94.36 Sst



**SANDSTONE**

Coarse-grained medium blue-grey quartz sandstone with interbeds of dark mudstone. Some mudstone beds are stratified, while others are breccias containing sandstone clasts with calcite veins that are cut off at the matrix. Light calcitic veining begins at around 69.5m depth and gradually increases in intensity to a light stockwork at the bottom of the unit. Heavy fracturing occurs around faults in the top few meters of the unit. Cross-stratification in mudstone interbeds near the bottom of the unit suggest an upright younging direction, however, the underlying limestone bed and Narchilla mudstones seem to suggest an overturned stratigraphy.

| 118.69 | 120.85 | Sms_gn |
| | | GREEN MUDSTONE |
| | | Green mudstone with regions of dark grey, likely a continuation of the overlying red mudstone. A few calcite veins are present along tensile fractures, and others appear to have been folded and sheared. The bottom contact with the underlying sphalerite-rich stockwork does not appear to be conformable, though there is no obvious faulted contact or gouge. |
| | | < @ 119.25 Sheared mudstone Sz 45° > |
| 120.85 | 177.38 | Vspl |
| | | SPHALERITE-RICH STOCKWORK |
| | | Large stockwork zone of sphalerite mineralization, mainly calcareous veins cutting through coarse-grained medium grey sandstone (up to 6mm diameter grain size) and dark grey mudstone (lower in the unit). Sphalerite seems to be hosted mainly in quartz, with later calcite veining cutting through and remobilizing some sphalerite. Several large, unmineralized caclitic bucky veins cut through the unit. Along the edges of one such vein (135.50m), as well as at the top of the unit, chalcopryite is intergrown with sphalerite. The largest bucky vein, intersecting from 160.93 to 165.74m, is immediately above the richest zone of sphalerite mineralization. The bottom of the stockwork consists of sphalerite in quartz veins through a quartz sandstone, which contacts a grey mudstone with trace sphalerite mineralization at the bottom of the unit along a region of faulting. Very little galena is present in the stockwork. |

| | | Sphalerite-rich vein stockwork. Country rock is grey-black mudstone up to 129.8 m depth and sandstone from then until the end. The vein stockwork is composed of both quartz and calcite, and the sphalerite is mainly associated with the quartz, with calcite veinlets cross-cutting them both. There is moderate faulting throughout the interval, but in general the core is competent compared to the fault zone uphole. Much of the rock has been silicified. |

| | | SANDSTONE: unit ranges from green to grey, fine to coarse grained sandstone. Minor mineralization throughout. Upper contact is gradual out of the stockwork veining of the overlying mineralized unit and bottom contact is gradational into the underlying brecciated unit. From 172.21-172.9m is a limestone bed. Visually, there is no distinction between the limestone and surrounding sandstone other than it reacts violently to HCL. |
| | | Structure: some laminations present throughout the sandstone. |
| | | < @ 170.53 S0 46° > |

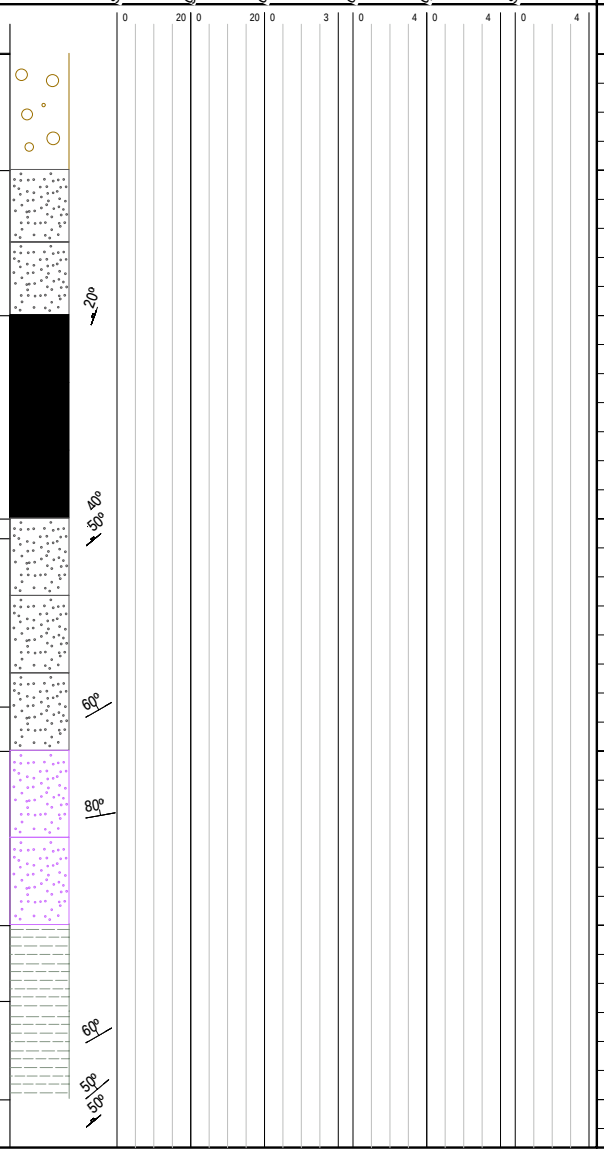
| **Project:** | Andrew | **Collar elevation:** | 1339.0 m |
| **Hole:** | AN08-110 | **Azimuth:** | 178.9° |
| **Proposed:** | EBA-9 | **Dip:** | -50.2° |
| **Location:** | 641407 m East 6978448 m North | **Length:** | 300.23 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW9 | 2008/06/22 | 2008/06/27 |
| **Logged by:** | M.Eckfeldt | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-110 was drilled as a geotechnical hole at 180 degrees, to gain information regarding pit-wall design. The planned depth was extended beyond the original 230m to test the location of any major fault structures.

**SUMMARY LOG:**



| | |
|---|---|

| | | CALCAREOUS SANDSTONE |
| | | The unit is a well bedded calcareous sandstone. Interbeds of black and grey mudstone are frequent. The black mudstone often contains small rounded quartz grains 2mm to less than 1mm in size. |
| | | Pyrite is commonly found within the mudstone interbeds and occasionally as primary or possibly replacement of some of the small quartz grains in the mudstones. |
| | | The core is fairly competant however some broken intervals exist such as from 287.88 to 288.12 and from 288.8 to 289.60. |
| | | Chlorite and calcite is occasionally on fracture faces. |

Veining: weak calcite veins « cal 1.00*»

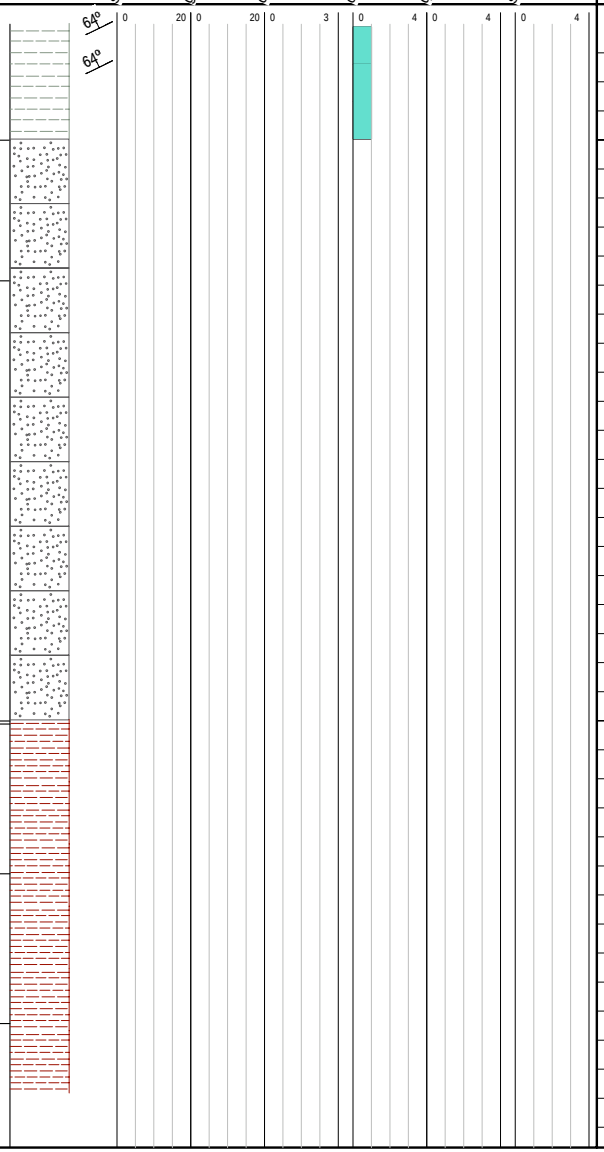
48.43 54.86 Sst

SANDSTONE: sandstone unit is fine to medium grained and is light to medium grey in colour. The unit has interbeds of grey mudstone and minor sections of limestone and breccia.

Limestone section is from 53.0-53.2m and is interbedded with some brecciated clasts.

Brecciated section is from 52.45-54.86m and alternates between sandstone matrix and mudstone clasts to mudstone matrix and sandstone clasts. Clasts range from mm-scale to 13cm in diameter.

Structure: Some minor fault and fracture sections detailed below:
-From 50.1-50.3m is a fractured zone with 100% rock fragments ranging in size from 1-4cm in width.
-From 52.45-52.52m is a fault zone with 50% gouge and 50% rock fragments.
-From 53.4-53.47m is a faulted zone which has been fairly cemented but looks to be 70% gouge and 30% rock fragments.



No mineralization and no veining within this unit.

54.86 69.40 Sms_rd

RED MUDSTONE: massive, red/maroon mudstone with minor interbeds of green mudstone. The green mudstone interbeds do not show preferential lamination directions as they occur sporadically throughout the red mudstone. Upper contact is faulted with the overlying sandstone unit and the lower unit is gradational into the underlying grey mudstone unit.

Structure: little bedding measurements but primary fracture plane meaurement taken:

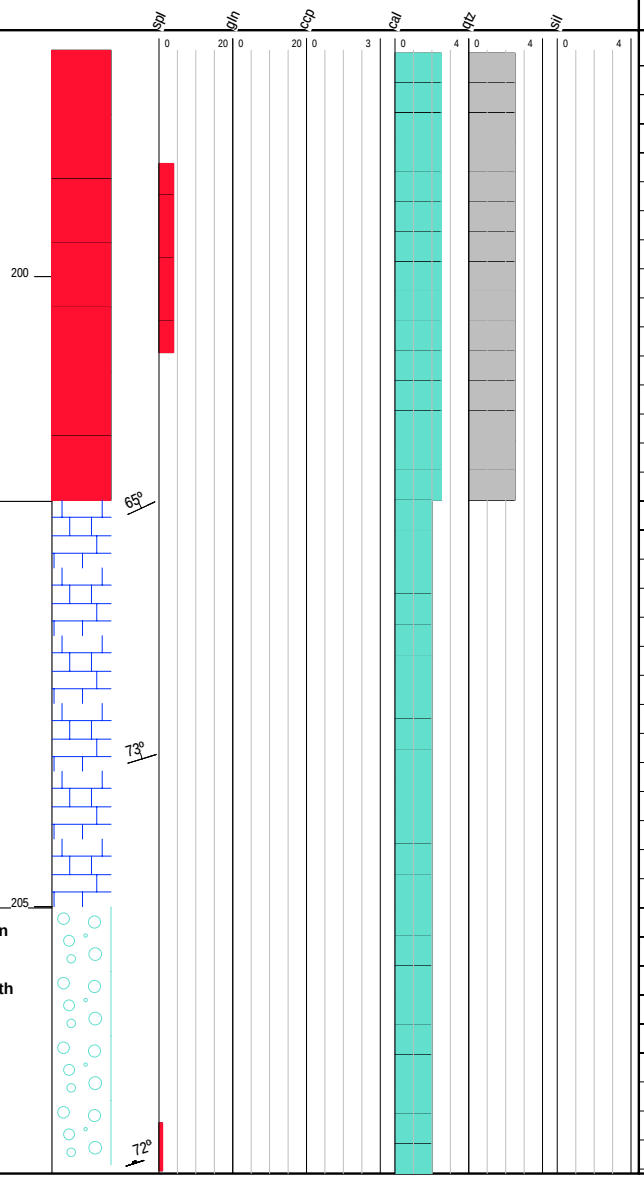
« qtz 2.50*» moderate to strong

**204.15 205.00 Sls**

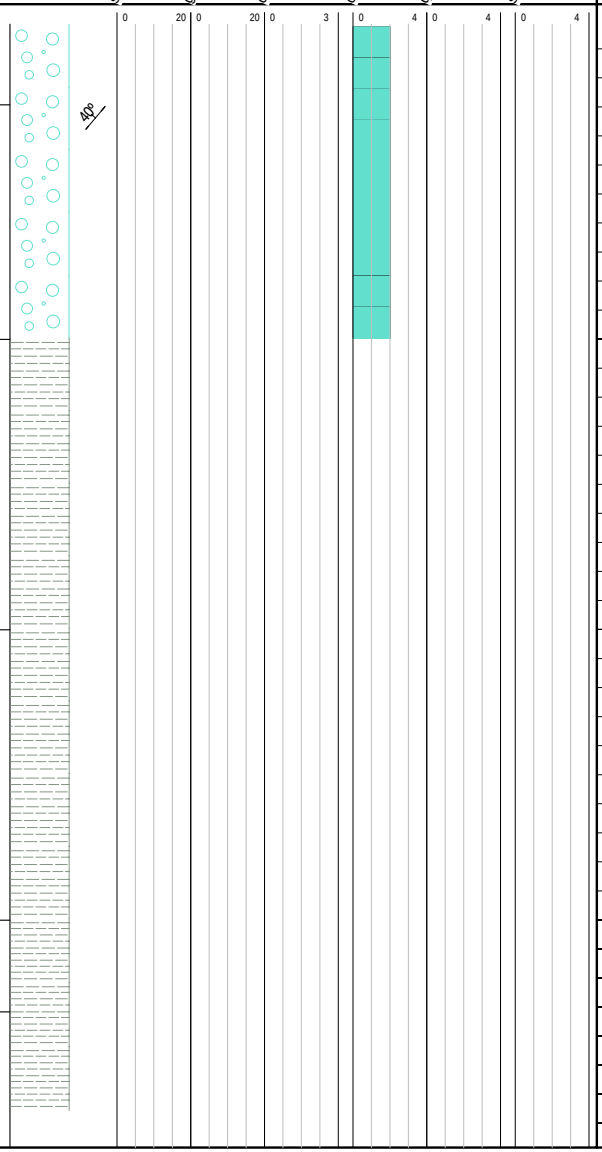


LIMESTONE: white to dark grey limestone ranging from fine to medium grained. Bed sets from white limestone sharply contacted with grey mudstone are seen throughout this unit. Bed sets range in width from 1-5cm.

Structure:
< @ 204.18 S0 65.00° >
< @ 204.70 S0 73.00° >
Preferred fracture plane: < @ 204.30 Fr 72.00° >

Veining: moderate calcite veining « cal 2.00*»

**205.00 213.36 Sbx**



BRECCIA: breccia ranges from clast to matrix supported throughout the duration of the unit. Matrix ranges from coarse grained, grey sandstone to grey mudstone. Clasts are subangular to subrounded and are primarily sandstone with a varying amount of calcite veining within them. Some clasts are 100% calcite suggesting remobilization of veins. Clasts range in size from mm-scale to 5cm in diameter. Sections of brecciated unit are grey mudstone with no clasts. These mudstone interbeds range in size from 5cm-70cm. Weak sphalerite mineralization found within this unit.

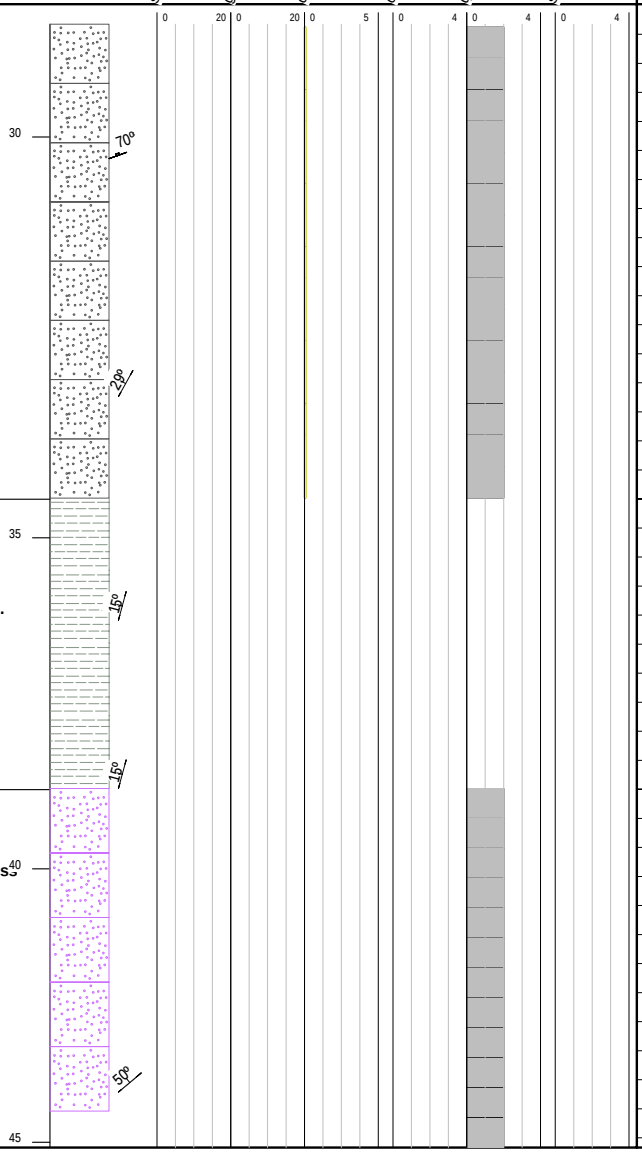
**34.44 38.53 Sms_gy**

**GREY MUDSTONE**

The grey mudstone unit is well bedded with alternating laminations of light and medium grey mudstone. Some short intervals are a dark grey to black mudstone. Some fine silty laminations also exist, as well as parallel bands of disseminated pyrite parallel to bedding.

< @ 36.16 Bedding 15.00° >

**38.53 49.15 Sst_cct**

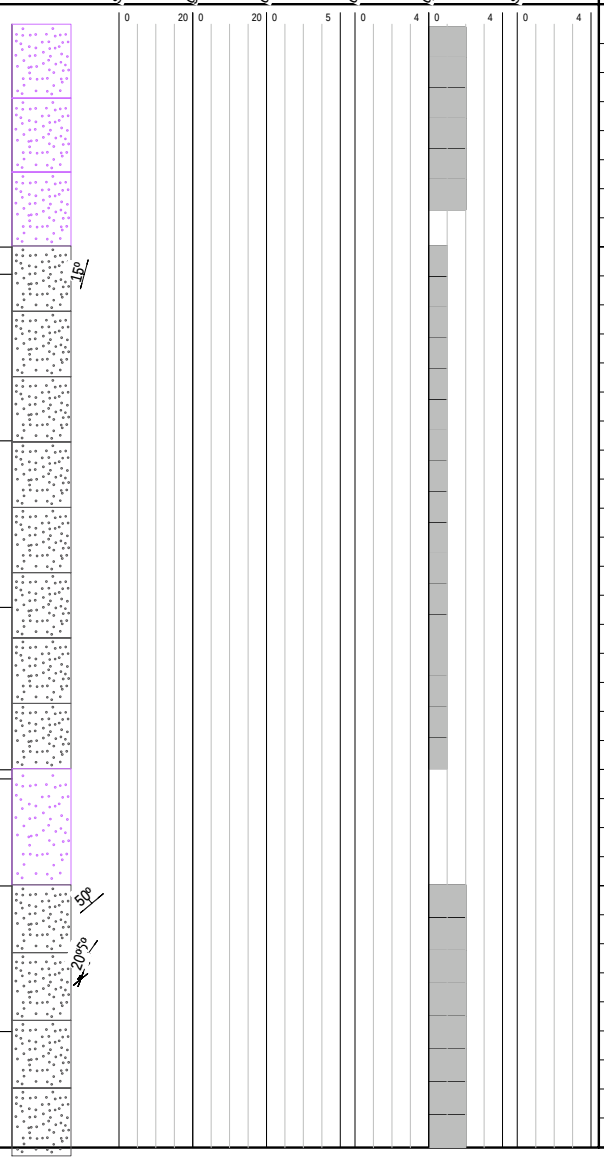


**CALCAREOUS SANDSTONE**

The calcareous sandstone shows faint bedding and moderate quartz veining cross cutting the bedding.

Some interbeds of dark grey mudstone exist.

From 45.00 to 48.49 the unit appears to be more of a calcareous sedimentary breccia with calcareous grains fine to coarse sand sized, within a black mudstone matrix.



Some orangy and yellowy orange iron oxidation exists on fracture faces. Core is

| | | FAULT BRECCIA WITH WEAK SPHALERITE AND GALENA MINERALIZATION |
| | | Minor sphalerite and galena in and amoungst broken sandstone grains. Some sphalerite mineralization is on the periphery of sandstone clasts floating in a black mudstone matrix, or is within the black mudstone matrix. The sandstone clasts are either very fine grained or possibly even broken quartz veins within a mudstone matrix. The sphalerite is fine to medium grained and is generally a light brown to an occasional medium brown. |
| | | Sphalerite appears to follow a general 38 degree to core axis trend. It would appear that mineralization is ground up within a fault zone. |

| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-116 was drilled at -60 and 180 degrees on section 1400. The purpose of the hole was to gather more information on the orebody. The hole was expected to intersect mineralization at 55m depth. No significant mineralization was intersected within the 150.88m hole.

| | | FAULT ZONE |
| | | Broken and crumbly sandstone and mudstone. Gouge filled as well as loose sand. Orientations difficult. |
| 118.16 | 134.50 | Sst |
| | | SANDSTONE |
| | | The sandstone unit has short intervals of calcareous sand and frequent mudstone interbeds. The sandstone varies from medium to coarse grained and shows variation in quartz feldspar and lithics content. Black mudstone interbeds commonly have pyritic laminations. The mudstone layers frequently show some strain. Moderate quartz veining and weak calcite veining. Quartz veins rarely contain trace pyrrhotite. Chloritic vein margins are common. |

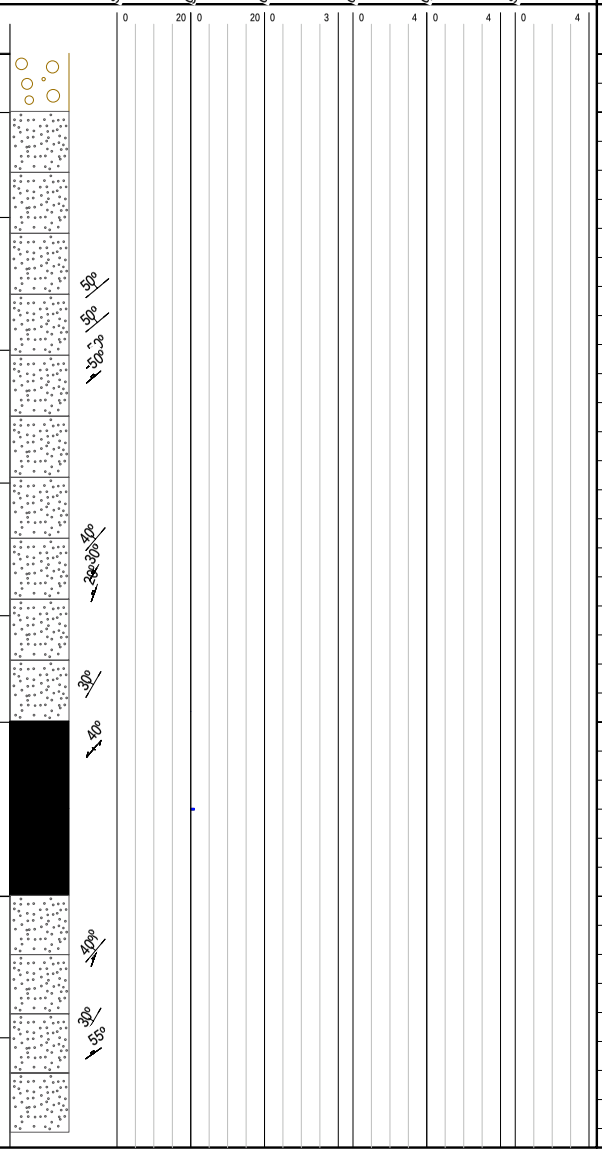
| **Location:** | 641702 m East 6978567 m North | **Length:** | 411.48 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW8 | 2008/07/04 | 2008/07/13 |
| **Logged by:** | J.Norris | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Hole AN08-117 is being drilled to test the down-dip mineralization encountered in holes AN08-47 and AN08-53. The hole is being drilled at an azimuth of 180 and at a dip of -70. It is expected that mineralization will be encountered from approximately 370m to 425m. The hole is planned to go to a depth of 470m.

NOTE: CORE WAS REDUCED TO BTW AT 274.02m.

**SUMMARY LOG:**



0m to 1m - Overburden
1m to 23.97m - Sandstone
23.97m to 24.97m - Fault Breccia with minor galena in carbonate vein.
24.97m to 79.36m - Sandstone with2% sphalerite in shear zone over 1m.
79.36m to 81.77m- Fault Breccia
81.77m to 89.48m - Grey Mudstone
89.48m to 118.18m - Sandstone
118.18m to 143.15m - Grey Mudstone
143.15m to 143.95m- Fault Breccia
143.95m to 189.41m- Grey Mudstone
189.41m to 224.68m - Sandstone
224.68m to 227.46m - Fault Breccia
227.46m to 273.45m - Sedimentary Breccia
273.45m to 279.86m - Fault Breccia
279.86m to 304.50m - Black Mudstone
304.50m to 310.59m - Fault Breccia
310.59m to 328.21m - Black Mudstone

Sandstone

Medium to dark grey, medium grained sandstone. Localized zones of greyish green sandstone. Massive, with thin 1-2mm interbeds of dark grey to black mudstone throughout. Interbeds of finely laminated grey and black mudstone up to 1m thick. Overall there is <5% thin 1-5mm quartz/calcite +/- chlorite veins at varying orientations. Fairly competent rock with few localized sections of faulting. Trace 1mm blue opalescent quartz grains. Trace amounts of fine grained pyrite occur in small blebs and lenses within the mudstone interbeds and 1mm pyrite blebs associated with quartz veins within the sandstone. Localized zones 1 to 5cm thick of tectonically brecciated mudstone and sandstone.

Faulted upper contact with overlying grey mudstone No orientation on fault.

200.97m to 201.17m - Light to medium grey Limestone unit with 1-2mm black laminations, strongly reactive to acid. Faulted upper contact.

202.46m to 202.60m - Light grey Limetstone unit with 1-2mm black laminations, moderate to strong reaction to acid. Faulted upper contact.

202.60m to 205.39m - 10% quartz/calcite veining at varying orientations, within sandstone beds.

Sedimentary Breccia.
Dark black muddy matrix with 50% clasts of grey and black mudstone as well as some grey chert. Clasts average 2-5mm in size, and can occur up to 1cm. Clasts are sub-angular in morphology. There is about 2-5% of 1-5mm quartz/calcite veinlets at varying orientations. Bedding is weakly visible in some sections. Rock is quite competent. Trace amount to 1% of very fine-grained to 1-2mm blebs of pyrite, occurs throughout and also replaces mudstone clasts in localized sections.

The presence of chert clasts indicates this unit is of the Earn Group.
Faulted contact with overlying fault breccia at 70 degrees TCA.

256.10m - Starting to see bands of black mudstone and grey mudstone from 1cm to 50cm thick.

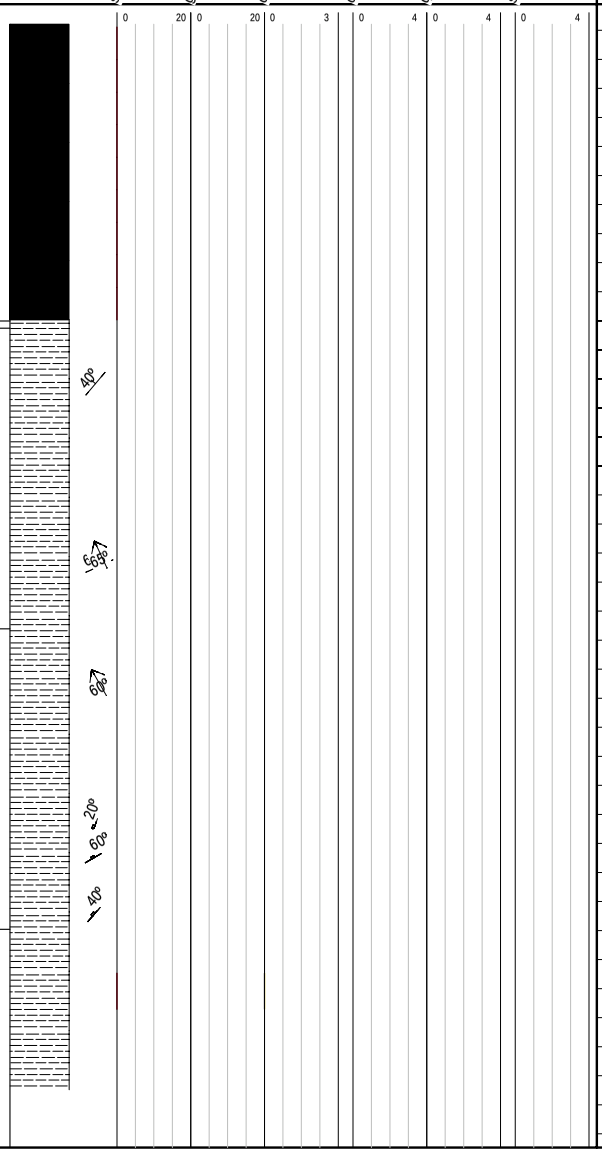
Black Mudstone.



Massive black mudstone with 40% interbeds of sedimentary breccia from 2cm to 1m thick. The black mudstone is weakly bedded and contains 2-5%, 1-5 mm quartz/calcite veins at varying orientations. The black mudstone contains minor amounts of very fine grained pyrite along bedding planes.

The beds of sedimentary breccia contain 1mm to 2cm (average 3-5mm) clasts of grey mudstone, black mudstone and chert. The clasts (60-90%) are angular and lie within a dark black matrix (10-40%). Bedding is rarely preserved within the sedimentary breccia. Fine grained pyrite sometimes replaces some clasts and is often found within the black mud matrix.

The package of black mudstone and sedimentary breccia appears to be gently folded. The rock is fairly competent with sections of fracturing and faulting. Trace to minor amounts of sphalerite occur as reddish-orange, 1-4m blebs within quartz/calcite veins and in sections of black mudstone. Trace amounts of pyrrhotite occur in a small section along with sphalerite and trace chalcopyrite.

Fault Breccia.

HIghly fractured and faulted black mudstone and sedimentary breccia. 20% competent rock, 5% fault gouge and 75% rock fragments. Few competent pieces preserve bedding, which appears to be weakly folded throughout. Some sections show silicified grey mudstone (possibly chert) which is brecciated by thin 1-2mm grey to black veinlets (tectonic breccia?). Overall the black mudstone is highly graphitic, especially on fracture and fault surfaces. There is <2% 1-4mm quartz veinlets in this zone of brecciation. Trace fine grained pyrite is seen along bedding planes in the black mudstone. Trace sphalerite as reddish-orange blebs to masses occurs over a short 15cm interval.

| | | Sandstone. |
| | | Medium-grained, medium grey sandstone and light grey to greyish green fine grained sandstone with 2cm to 1m interbeds of finely laminated greenish grey and grey mudstone. Bedding is weakly preserved in the sandstone yet readily visible in the mudstone interbeds. Overall there is 2-5% 1mm to 1cm quartz/calcite veinlets throughout, predominantly occurring in the sandstone beds. The unit is quite competent with few localized areas of faulting and shear. |
| | | Trace amounts of galena and pyrite occur as 1-2mm blebs within medium grey sandstone over the top 25cm of the unit, associated with quartz/caclite veining. One 1cm dark reddish-brown sphalerite vein occurs at 409.80m |

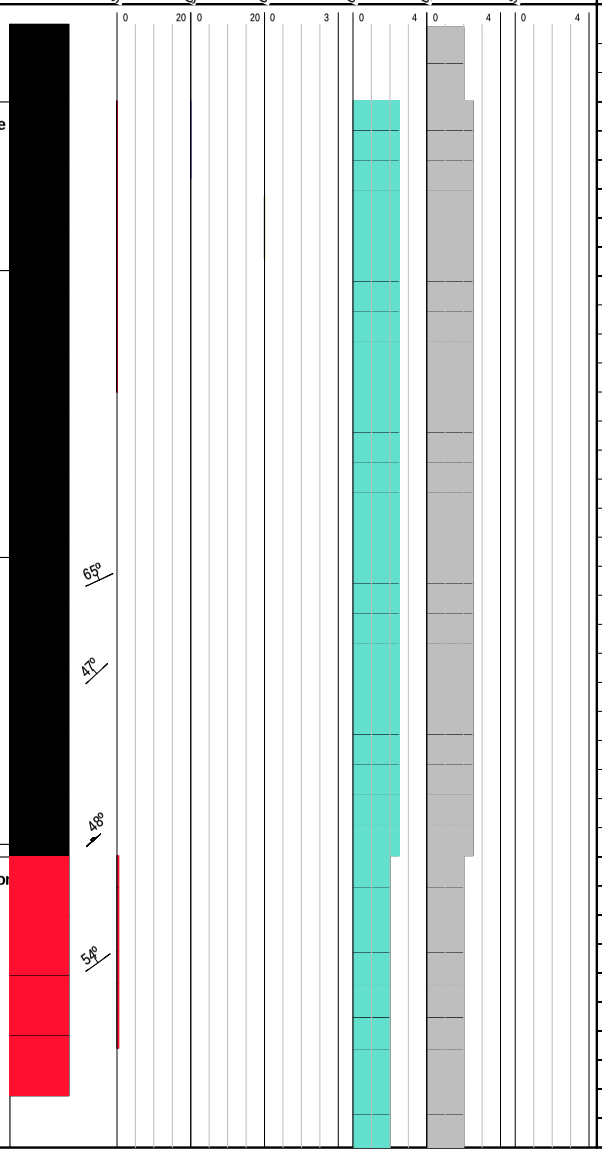
BARREN STOCKWORKED VEINED BRECCIA: Primarily barren breccia, however, there some trace amounts of sphalerite and galena throughout unit.
Lithology ranges from breccia to sandstone to mudstone throughout with breccia dominating. Breccia ranges from sandstone to mudstone matrix and clasts range from sandstone to mudstone as well. Veining ranges from moderate to strong throughout unit. Unit is moderately to strongly fractured and there are some faulted sections detailed below.

Structure: minor bedding measurements obtained:
< @ 55.50 S0 65.00° >
< @ 57.20 S0 47.00° >
< @ 59.90 Ft 48.00° >
Some faulted sections throughout barren breccia detailed below:
-From 47.34-48.77m is a fault section with 10% gouge and 90% rock fragments.
-From 51.82-53.45m is a fault zone with 100% rock fragments



Mineralization: trace to moderate amounts of sphalerite and galena.
« 47.04- 52.12 spl 0.1%» trace to minor amounts

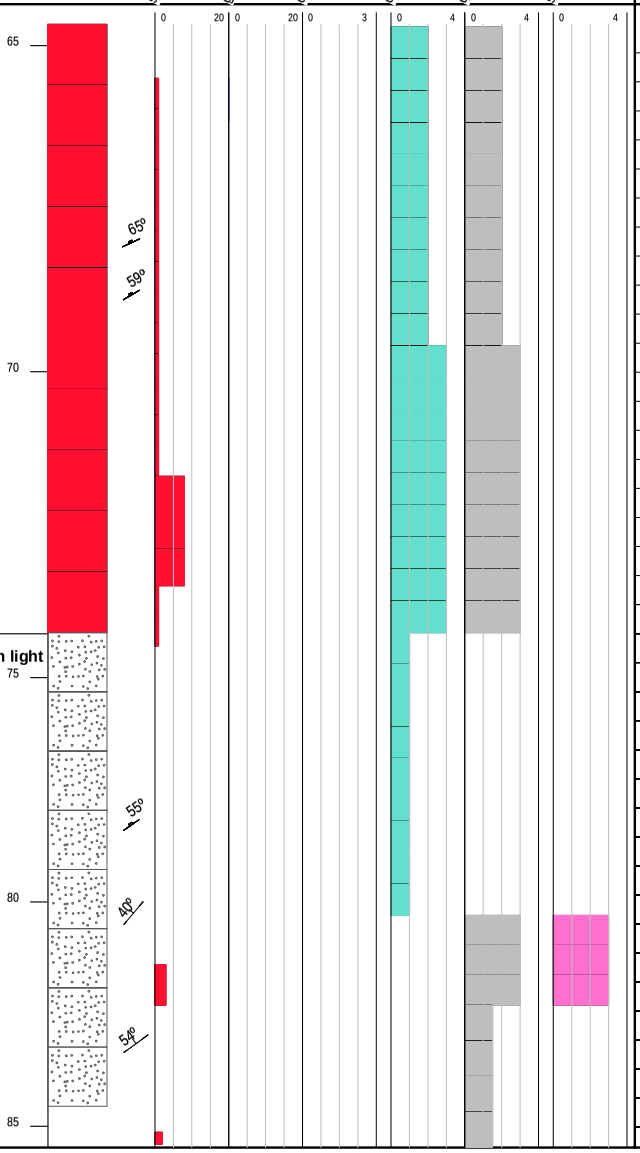
STOCKWORK VEINED SPHALERITE MINERALIZATION: lithology ranges from sandstor breccia. Unit is fairly fractured and faulted. Breccia is primarily sandstone matrix with mudstone and sandstone clasts. Veining is moderate to intense throughout overprinting most structural measurements. Primarily sphalerite mineralization with trace galena over a short interval.



Structure: Faulted sections found throughout unit. Details below:
-From 60.96-61.65m is a fault zone with 5% gouge and 95% angular rock fragments.
-From 65.5-65.65m is a faulted section with 30% sand and 70% subrounded to

| **Hole:** | AN08-119 | **Azimuth:** | 187.5° |
| **Proposed:** | prop1087 | **Dip:** | -70.3° |
| **Location:** | 641823 m East 6978280 m North | **Length:** | 169.77 m |
| **Area:** | Andrew_deposit | **Date started:** | 2008/07/07 |
| **Claim:** | ANDREW6 | **Date completed:** | 2008/07/10 |
| **Logged by:** | M.Eckfeldt | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-119 was drilled on section 1825 to test the location and size of the orebody on its eastern end. The hole intersected mineralization from approximately 65m to 97m depth. The mineralized zone was abruptly truncated at its base by a gouge filled fault.

| | | SANDSTONE |
| | | The sandstone unit is variable from coarse grained poorly sorted quartz rich sandstone, to a medium to fine grained sandstone with approximately 3% lithics, 92% quartz and 5% feldspars. The unit is semi-massive showing faint bedding with occasional mudstone interbeds. Some disseminated pyrite throughout the unit. Fractures are a rusty orange and occasionally filled with gouge. The level of faulting is unclear due to the proximity to surface. |
| | | The nature of the bottom contact with the mudstone is also unclear. The contact is broken with some evidence of shearing, however it is not known if the two units are conformable. |
| | | Faulting appears to be generally at 45 deg. or more. |

BARREN QUARTZ AND CALCITE VEIN BRECCIA

Quartz and minor calcite stockwork have brecciated dominantly sandstone and some mudstone. The quartz veining appears to have been introduced in 3 to 4 seperate phases. Some intervals are dominantly vein material carrying wallrock fragments. Intervals of mudstone appear more sheared. Fracture faces often show oxidized coatings.

Trace sphalerite located in a short shear zone. The sphalerite appears to be

| **Proposed:** | prop1040 | **Dip:** | -60.2° |
| **Location:** | 641846 m East 6978290 m North | **Length:** | 134.11 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW6 | 2008/07/10 | 2008/07/13 |
| **Logged by:** | M.Eckfeldt | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

AN08-120 was drilled on section 1850 to test the location of the orebody near its eastern edge. The hole was initially planned for 85m, but was lengthened to 130m when comparisons with neighbouring sections indicated a deeper and possibly thicker intersection.

| **Proposed:** | prop1098 | **Dip:** | -61.2° |
| **Location:** | 641301 m East 6978359 m North | **Length:** | 258.78 m |
| **Area:** | Andrew_deposit | **Date started:** | **Date completed:** |
| **Claim:** | ANDREW9 | 2008/07/14 | 2008/07/19 |
| **Logged by:** | J.Norris | | |
| **Drilled by:** | Kluane | | |
| **Assayed by:** | ALS_Chemex | | |
| **Core size:** | NTW | | |
| **Dip tests by:** | Reflex_MS | | |

**Objective:**

Hole AN08-121 is drilled at an azimuth of 180 degrees and at a dip of -60. The purpose of this hole is to drll EBA-5.2 for getotechnical information. This hole is also being drilled to test "Phil's Fault" in the area. Mineralization is expected to be encountered at a depth of 235m. The hole is planned to finish at 260m down-hole.
NOTE: The first downhole survey measurement was taken at 8.23m and was a bad reading.

**SUMMARY LOG:**

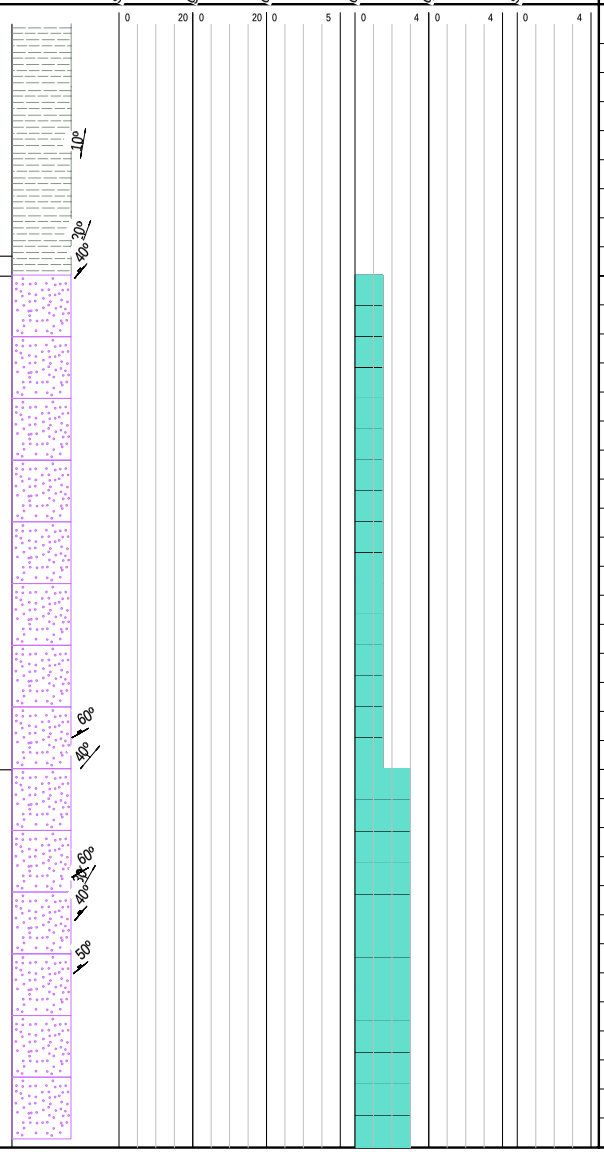
Grey Mudstone.



Finely bedded grey mudstone with a 20cm bed of fine grained, finely laminated light tan sandstone. Unit is gently folded about the core axis. 2-5% thin, 1-4mm quartz/calcite veinlets at varying orientations. Unit is sub-competent with moderate faulting througout, often too disrupted to get orientation on faults.

|---|---|---|

Finely bedded, grey to greyish green mudstone with minor dark grey, medium grained sandstone beds up to 25cm thick. The grey mudstone shows <2% thin 1-3mm quartz/calcite veinlets. The rock is gently folded throughout, as evidenced by bedding. Sandstone beds are massive and contain up to 5% 1mm to 1cm quartz/calcite veinlets at varying orientations. Fine-grained disseminated pyrite is seen throughout the mudstone and also occurs as 1-5mm subhedral blebs within the sandstone and the quartz/caclite veinlets. Rock is competent with few faulted sections.

Sharp contact with overlying sandstone.

Grey Mudstone.

Finely laminated dark greenish grey to black mudstone with few thin 1-5cm interbeds of greenish grey siltsone/ fine-grained sandstone. <2% thin 1-4mm quartz/calcite veinlets. Competent rock. Minor amounts of fine-grained pyrite along bedding planes throughout the sandstone. Few beds show cross bedding indiating bedding is normal way up. Bedding is consistent thoughout the unit. One small 3mm bleb of sphalerite occurs within a 5mm silicified mudstone/siltstone bed.

Sharp, conformable contact with overlying sandstone at 20 degrees TCA.

|---|---|---|

calcite-rich middle, bounded by 1-2mm of quartz, then with another 1mm quartz veinlet running near the center of the vein. Few localized sections of weak to moderate calcareous sandstone occur from 1cm to 30cm thick. The contacts into the calcareous sandstone are usually gradational. There are few green and grey to black mudstone interbeds from 2-10cm thick, which are finely laminated.

Trace amount of sphalerite occurs as reddish-orange 1-5mm blebs within quartz/calcite veinlets or within the sandstone. At 219.93m there is a 1cm long by 5mm high lens of sphalerite within a section of sandstone which interfingers with an interbed of green mudstone. The sphalerite appears to be a rind on some of the quartz grains. There is trace amounts of fine-grained pyrite throughout the sandstone. There are trace amounts of pyrrhotite as 1mm stringers and up to 2mm blebs associated with quartz/calcite veining.

Sharp, conformable contact with overlying grey mudstone at 30 degrees TCA.

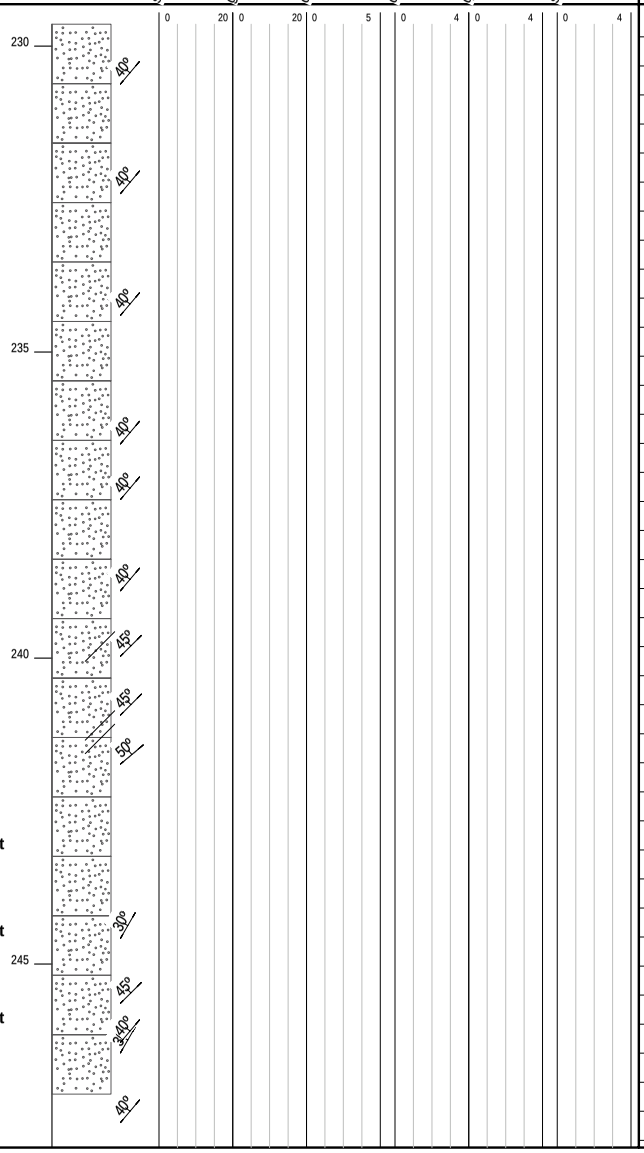
Sandstone.



Medium to dark grey to greyish brown, fine to medium grained, moderately bedded sandstone. There are minor to moderate amounts of grey, green and black mudstone interbeds 5mm to 20cm thick, which are finely laminated. There is 2-5% quartz/calcite +/- chlorite veins 1-4mm thick, at varying orientations. Bedding within the sandstone is fairly consistent, with some gentle folding seen. There are a few localized sections of sandstone which are weakly reactive to acid. Rock is quite competent. There are trace to minor amounts of fine grained to 2mm blebs of pyrite within the sandstone as subhedral blebs and crystals, usually associated with quartz/calcite veining and along bedding

planes.

Trace amounts of sphalerite occur as deep red to marroon 1-2mm blotches associated with quartz/calcite/chlorite veins, appearing to be caught up in shear zones. Trace pyrrhotite occurs as 1-2mm blebs and stringers, associated with quartz/calcite veining.

Sharp contact with overlying calcareous sandstone at 40 degrees TCA.

| | | Grey Mudstone. |
| | | Moderately laminated, greenish grey mudstone is highly fractured and faulted over the first 4m of core. The rest of the unit is competent. There is a moderate amount of oxidation along fracture surfaces throughout. Trace amounts of 1-2mm quartz/calcite/carbonate veins within the mudstone. Bedding is consistent throughout, with gentle folding about the core axis, as evidenced by few fold noses. |

Grey mudstone.

Fine to very fine grained grey mudstone with interbeds of sandstone throughout. Sandstone interbeds range in width from mm-scale to 2cm in width. Excellent bedding measurements taken on mudstone/sandstone contacts. Little to no veining observed within this unit. Upper contact is faulted with the overlying sandstone unit and the lower contact is gradational into the underlying zbxv (stockwork veined breccia) unit.

Stockwork veined breccia (barren).

Hydrothermally brecciated sediments ranging from grey mudstone to fine sandstone. Host rock is primarily grey mudstone with minor sections of sandstone found throughout. Sandstone sections range in width from 5-30cm.
