1.0 INTRODUCTION

1.1 General Introduction

The Cynthia property is a 4,570 ha section comprised of 218 claims situated 170km north northeast of Ross River and 60km west of the Mactung Deposit in north eastern Yukon. At 63°23.5' N latitude and 131°21'W longitude it is located on NTS map sheet 105O/06. The location can be seen on figure 2-1. A winter road extends from Canol Road west to the Plata Airstrip which is located roughly 10km south of the property. The property covers a large, >2x2km, zone of gold mineralization related to Tombstone Suite quartz monzonite intrusive bodies. The focus of the 2010 drilling program was to better define the mineralized zone, as well as to figure out the attitude and trend of mineralization.

1.2 Participating personnel

The 2010 drilling program was funded and operated by Golden Predator Canada Corp. of Vancouver British Columbia. Kluane Drilling of Whitehorse, Yukon provided the drilling services, and staged out of the Brewery Creek property. A camp was set up on the property by Golden Predator Canada Corp. Fireweed Helicopters, based in Dawson City provided Helicopter support. The helicopter pilot stayed on site in the camp provided by Golden Predator. Geological and logistical services were provided by Golden Predator Canada Corp. staff. Expediting services were provided by C.O.R.E Expediting of Whitehorse, Yukon. Alkan Air was also contracted to deliver the drill rig, groceries and other field supplies to the la Plata airstrip. All sample assay work was done by ALS/Chemex labs of Vancouver, BC.

1.3 Agreement

GPD has an option to earn 100% interest in the property, subject to a 3% NSR Royalty and the terms of the Option Agreement. This agreement was made effective on the 7th day of June, 2010 between 18526 YUKON Inc. and Golden Predator Canada Corp. and Golden Predator Corp.

2.0 PROPERTY LOCATION, CLAIM DATA AND ACCESS

2.1 Location

The Cynthia property is located in the Mayo Mining district approximately 170km north northeast of Ross River and 60km east of the Mactung deposit. At 63°23.5' N latitude and 131°21'W longitude it is located on NTS map sheet 105O/06. The location can be seen on figure 2-1.

2.3 Access

The claims are most easily accessed by helicopter, which is approximately a 70 minute flight from Mayo, and a 10 minute flight from the Plata airstrip. A winter road extending the North Canol Road to the Plata airstrip is approximately 10 km from the property as well. The claim map is located on figure 2-2 (see pocket 1).

3.0 PHYSIOGRAPHY

The property is located in rugged terrain, ranging in elevation from 1,450m to 2200m. The property is exceedingly rugged, and the only relief from this terrain lies in the cirques and broad glacial valleys in the lower regions of the property. The area was recently glaciated and is sparsely vegetated. The mountain slopes are steep and outcrop is abundant on ridge tops and, to a lesser extent, along the valley slopes which are generally scree dominated. The subarctic climate results in short, cool summers with short growing seasons for vegetation. This results in subalpine boreal forest being the dominant vegetation up to roughly 1,500m and typical tundra vegetation covering higher elevations. Mountain tops are devoid of vegetation, and small ice fields remain for the duration of the summer in some north-facing cirques.

4.0 HISTORY AND PREVIOUS WORK

4.1 Atlas Explorations Ltd.

The Cynthia property was originally staked as the ART 1-12 claims in 1967 by the Hess Project (Atlas EL, Quebec Cartier Mining Company, and Phillips Brothers (Canada) Ltd.). And in 1968, the companies performed grid soil sampling, and magnetic and electromagnetic surveys (Yukon MINFILE, 2001) (Brock, J.S 1968).

Cynthia Claims 2010

4.2 Union Carbide Canada Ltd.

In 1981, the property was restaked by Union Carbide Canada Ltd. who conducted mapping and geochemistry surveys. This included 75 rock chip samples and 116 stream sediment samples. The program located weakly pyritic to arsenopyritic quartz veins that returned values up to 3.13 g/pt Au, 775 g/pt Ag, 795 g/pt Sb and 1.7% Pb. Breccia zones returned values up to 660 ppb Au; and a black chert breccia returned 3.7% Pb and 948 g/pt Ag. By 1982 the focus of the Union Carbide exploration was to map the property at a 1:10,000 scale, to best locate potential mineralized veins and assess their economic significance (James, D.H 1982).

4.3 Yukon Gold Corp.

The property was restaked again in 1991 as the Hess 1-64 claims and again in 1995 as the EM 1-112. Yukon Gold Corp. focused on an intensive 10 day geochemical survey program. The helicopter supported rock-chip, silt and soil sampling, which totaled 40 chip and 29 soil samples, was located at the Twin Batholith area. The result showed several stages of hydrothermal activity evident, including spectacular miarolitic cavities containing gold, molybdenum and tungsten bearing minerals, east-west striking, north-dipping veins containing gold, molybdenum and sheelite and north-south striking, steeply-dipping fractures which sometimes contained disseminated sulphides (Lueck, 1995).

4.4 Cyprus Canada Inc.

In 1997 Cyprus Canada Inc. operated grass roots prospecting program for Alliance Pacific Gold Corp. which consisted of helicopter supported rock-chip and soil/silt sampling over a geophysical magnetic high, thought to be buried intrusions. This program indicated gold mineralization in quartz/quartz sulphide veins is localized in the margins of the intrusions and adjacent hornfels aureoles (Broughton et al 1997).

4.5 Klad Enterprises Ltd.

In 2002 Klad Enterprises Ltd. designed a program that would define the geological setting and trace zones of mineralization, which would in turn lead to diamond drilling targets (Soloviev, 2003). This design separated the work into two phases. Phase one consisted of rock, silt and limited soil sampling. Phase two was a detailed comprehensive on-site geological structural mapping interpretation, and intensive rock geochemical sampling to preliminary evaluate mineral potential and determine nature of subsequent work (Soloviev, 2003).

5.0 GEOLOGY

5.1 Geologic Setting

The Cynthia property lies at the eastern side of the Selwyn Basin. The Selwyn Basin is bound by the Tintina Fault to the South, and the Dawson Thrust fault to the north. The theory has been

proposed that the present-day Tintina Fault was the location of an ancient suture zone. The structure has undergone ~450km of transcurrent dextral slip since the end of the Mesozoic.

The Selwyn Basin rocks are that of the ancient geosynclines at the western margin of the North American plate. These rock types vary from Proterozoic basinal and platformal clastic/politic sediments to Jurassic clastic shelf sediments (Anderson and Hulstein 1998). The basin endured rifting during the Proterozoic and again in the late Devonian.

During the Mesozoic terrane accretion dominated the western edge of the North American plate. When the Intermontane super-terrane collided with the passive continental margin of North America, compressive tectonic events occurred. The result was crustal shortening, tight folding and failure along hinges resulting in large scale thrust features. The three regionally stacked thrust panels are: the Robert Service, Tombstone and Dawson thrust sheets (oldest to youngest).

Throughout the Paleozoic the Selwyn Basin was intruded by granitoids ranging from Mississippian to Eocene in age. The most dominant and extensive intrusion sequence was the mid Cretaceous Tombstone Suite. These rocks range from intermediate to felsic in composition, and are linked to known gold deposits at Brewery Creek, Dublin Gulch, Clear Creek, and Gold Dome in the Yukon, and Fort Knox, True North and Pogo in Alaska.

5.2 Property Geology

Quartzite, slate and phyllite of the Rapitan Group, as well as Road River black chert and Earn group shales and argillites comprise the majority the Selwyn Basin rocks which are observed on the property. Typical of the area, the sedimentary sequence is intruded by quartz monzonite stocks of the Tombstone suite. These stocks and plugs range in area from one square kilometer up to 20 to 30 square kilometers.

The Cynthia property is situated between two mid-sized (5 by 3km and 3 by 2km) exposures of quartz monzonite belonging to the aforementioned Tombstone Suite (Soloviev 2003). These are likely exposures of the same pluton, with the southern exposure being coarse grained equigranular and the northern exposure is potassium feldspar porphyritic, suggesting a closer to surface emplacement as opposed to the southern. Quartz and quartz-feldspar dykes can be found throughout structural corridors on the property as well, and these structural corridors are key to hosting much of the gold mineralization.

Structural Geology

This discussion (structural geology) is largely taken from a personal communication of Bruce Otto, Golden Predator's structural geologist.

Folds

Stratigraphy on the Cynthia property contains a variety of structural fabrics from disharmonic concentric to similar style folds, thrust faults and two orientations of normal or transpressional strike-slip faults. Silicified beds of black cherty argillite display folding which is concentrated along the western end of a major high-angle northwest-striking fault. The amplitude of the fold increases the closer to the fault one gets. It is then likely to assume that the folds and adjacent fault resulted from the same compressional stress.

Faults

The property hosts two prominent sets of faults striking northwest and northeast. Small-scale shear zones are abundant and take on the same general orientation as the faults. North-east striking features terminate against northwesterners.

Two northeast striking faults cut strata units of cherty argillite and strike approximately 30 degrees azimuth, and dip steeply to the southeast. Both faults terminate against the major northwest-trending fault. Slickenlines plunging from 45 degrees southeast to vertical suggest oblique to vertical movement along this fault.

The northwest-striking fault which is exposed in the cirque mapped by Bruce Otto strikes approximately 345 degrees, and dips near vertically. The fault emplaces the black cherty argillite units in the west against metamorphosed siltstone units to the east. The offset between units suggests that the fault is a major, through-going fault with displacement of up to hundreds of meters or more. As mentioned before, quartz porphyry dikes utilize the structural corridor, and intrude the fault zone. These dikes have been altered, mineralized and brecciated by recurrent fault movement.

6.0 MINERALIZATION

Proximal to the intrusion, metasedimentary rocks have undergone intense hornfelsing and contain pyrite and pyrrhotite. The resulting gossan is visible for hundreds of meters away from the intrusive contact. In addition, multiple episodes of hydrothermal activity have resulted in quartz-dominated mineral assemblage formations. Pervasive replacement-style and fracture controlled silicification, chalcedony quartz formation in open spaces and fractures and druzy to cockscomb quartz have all formed as a result of these episodes (Soloviev 2003).

Auriferous mineralization is dominant within the three broad fault zones (Ted, Gary and Intersection). Intensity and unique mineral assemblages depend on local structural setting, host lithology and the specific type of hydrothermal alteration.

The Ted Zone, which hosts a limestone horizon, has had all three silicification events take place within the limestone unit, at the central portion of the property. This strongly silicified limestone is host to the NNE-striking, steeply east-dipping chalcedony veins previously described, and in addition this limestone layer also hosts quartz stockwork.

The Gary zone hosts a most intense stockwork, which may indicate mineral formation occurring as fracture-filling veins. These stockworks have a WNW orientation, host thick veins along with minor chalcedony veins. The central part of the Gary zone hosts abundant dyke swarms, and resulting veinlets within the stockwork varies from 5 to 10 veinlets per meter. The stockwork is superimposed on the dykes, indicating post-intrusive formation.

The Intersection Zone is an area of intersection of the Gary and Ted zones, each of which had an impact on the formation of this zone. Most pronounced in the Intersection zone is the greater abundance of mineralized veins, dikes and greater density of quartz stockworks in comparison to the Ted and Gary zones. The greater abundance of quartz stockwork is likely due to the intersection of district-scale faults. The Intersection zone was the focus of the 2010 exploration season, and a map of the area can be seen in figure 6-1 (Pocket 3).

7.0 2010 EXPLORATION

7.1 Exploration

The 2010 exploration season focused on the intersection zone. Prior to the 2010 drilling, the property was visited by Bruce Otto, Golden Predator's senior structural geologist. The purpose of this 10 day camp (Bruce Otto, Max Ryan field assistant) was to establish a structural setting and basis of which to base the 2010 drilling program on. Mapping concentrated on the breccias and the structural controls of the alteration patterns as well as the temporal sequencing of alteration. Following the July preliminary camp, Fredy Marino, Sr. Project Geologist and Cynthia project manager spent a few helicopter supported days mapping in order to verify findings of Mr. Otto and also to present a more focused drill plan.

7.2 2010 Drilling

Seven diamond drill holes were drilled from 3 different drill pads in 2010. The focus of these holes was on the area mapped by Bruce Otto in July 2010. This cirque area is part of the Intersection zone, which was the focus of the 2010 exploration. A table of the collar locations can be found below (table 7-1), and a map of the collar locations can be found on figure 7-1.

Holes DD-CY10-001, 002 and 003 were done at the same location with azimuths 85, 110 and 75 degrees respectfully. The purpose of drilling at this location was to test the large quartz-porphyry cored quartz vein exposed in the bottom of the cirque. DD-CY10-004, which was drilled along on its own pad, was designed to test a strongly altered and mineralized quartz porphyry dike exposed on the ridge immediately south of the cirque. DD-CY10-005, 006 and 007 were also done on the same pad.

7.3 Collar Locations

Collar locations were surveyed using a handheld Garmin GPS with accuracy of approximately $\pm$ 3 meters. Table 7-1 presents the collar file for the 2010 program.

7.4 Sampling Methodology

All core from the 2010 drill program was sealed and transported to the la Plata airstrip by helicopter. From there, they were shipped to Mayo by Alkan Air and then transported by a Golden Predator employee to the Brewery Creek complex via truck. This kept the chain of custody intact. An electric rock saw was used to split the core once logged and sample intervals were laid out. One half of the core was sent for sampling, and the other is kept on site for future analysis. Drill core samples were transported to Whitehorse by C.O.R.E expediting, and then samples were sent to ALS Mineral's prep lab in Whitehorse, and then forwarded to one of their ISO 9001 certified preparation facility in Terrace or Vancouver. The pulps were analyzed at ALS Mineral's ISO 9001 certified laboratory in Vancouver. Approximately 5% of the pulps are sent for secondary check assays at Stewart Group's Eco Tech laboratory in Kamloops, B.C. Blanks, commercial standards and duplicate samples were included in each batch. To determine Au levels at the ppb level detection limit of 5-10,000 ppb (5-1000 ppb at Stewart Group) 30 g samples are fire assayed then digested in aqua regia solution and analyzed by atomic absorption. At Eco Tech, values over 1,000 ppb are re-assayed by fire assay, digested with aqua regia and then re-analyzed by an atomic absorption instrument (detection limit 0.03 g/t). At ALS Minerals, values over 10 g/t Au are re-assayed by fire assay followed by a gravimetric finish (50 ppb lower detection limit). Additional check-analyses are being carried out by the lab which did not receive the original sample.

Other elements, including silver, were analyzed by a 35 elements package (ME-ICP41) in which the sample is dissolved in an aqua regia acid solution and then analyzed by ICP-AES (Inductively Coupled Plasma - Atomic Emission Spectrometry). Ag values over 100 g/t are re-assayed by method Ag-OG46 which involves digestion in Hydrobromic, Nitric and Hydrochloric acids followed by analysis by ICP-AES. Ag values over 1,500 g/t are re-assayed by method Ag-GRA21, a 30 g fire assay with gravimetric finish (5 g/t lower detection limit).

7.5 Results

Drilling at Cynthia's Intersection zone resulted in multiple encouraging intersections, 4 of which produced results of 1 g/t Au over 1.5m. The following table (7-2) displays the highlights of the program. The program was designed to test mineralized zones hosted by structural corridors previously discussed.

Hole DD-CY10-003 was drilled to intersect the quartz-porphyry cored quartz vein mentioned previously positioned in the cirque bottom. At 168.50m the hole intersected foliation bound disseminated pyrite and a massive quartz vein just prior to the auriferous zone. This 1.5 meter section returned a result of 1.675 g/t of gold. The samples taken both above and below this sample, 167-168.50m and 170-172m also returned gold grades of over or very nearly 1 g/t Au. This underscores the importance of the fluid in the system, as some of the highest gold grades are located enveloping a quartz vein.

Hole DD-CY10-002 intersected 1.365 g/t Au over a 1.5m intersection starting at 120.50m. A 10 meter lithological unit of undifferentiated hornfels comprises the rocks of 110 to 122.60m. This zone also shows brecciation throughout. Although the zone did not display any visible mineralization, the entire 12 meter section shows zones of brecciation, as well as hairline quartz veins bound by foliation. The other results displayed from DD-CY10-002 are also located within a zone of abundant veining and localized brecciation.

Hole DD-CY10-001 had one intersect over 1 g/t Au, and multiple hits around .5 g/t Au. 130 to 131.5m displays a grade of 1.305 g/t Au through a zone of patchy pyrite dissemination hosted in undifferentiated sedimentary rocks.

7.6 Demobilization

All drill pad timber was collected and left on the final drill pad, and all camp timber was broken down and left in the camp location. This allows ease of access to timber for next field season. The corresponding photographs of the final demobilized camp and drill pad timber can be seen in appendix 6.

8.0 CONCLUSIONS AND RECCOMENDATIONS

Seven drill holes totaling 1099.8m were drilled at the Cynthia property to test the mineralized (1.5 by 1.5 km) Intersection Zone mineralized structure, and two occurrences of clay altered quartz porphyry rocks.

Logging and core samples show three significant features: (1) high chalcedonic vein density which appears to associate with a sedex mineralizing event; (2) very narrow strong clay altered porphyry dykes with very low grade gold mineralization, which is restricted to a high-angle vein emplaced along the northwest-trending fault system; and (3) dark graphitic breccias in a strong cataclastic zone adjacent to that main NW-trending structural system.

We conclude that the auriferous hydrothermal system and the host porphyry dykes formed in a strike-slip environment subsequent to, or perhaps during intrusion of the nearby tombstone plutons, at a depth inconsistent with epithermal mineralization.

Further detailed mapping, rock and soil sampling would be recommended.

Analytical Methods and Detection Limits

Geochemical Procedure - ME-ICP41
Trace Level Methods Using Conventional ICP-AES Analysis

Sample Decomposition: Nitric Aqua Regia Digestion (GEO-AR01)
Analytical Method: Inductively Coupled Plasma - Atomic
Emission Spectroscopy (ICP - AES)

A prepared sample is digested with aqua regia in a graphite heating block. After cooling, the resulting solution is diluted to 12.5 mL with deionized water, mixed and analyzed by inductively coupled plasma-atomic emission spectrometry. The analytical results are corrected for inter-element spectral interferences.

NOTE: In the majority of geological matrices, data reported from an aqua regia leach should be considered as representing only the leachable portion of the particular analyte.

Fire Assay Procedure – Au-AA23 & Au-AA24
Fire Assay Fusion, AAS Finish

Sample Decomposition: Fire Assay Fusion (FA-FUS01 & FA-FUS02)

Analytical Method: Atomic Absorption Spectroscopy (AAS)

A prepared sample is fused with a mixture of lead oxide, sodium carbonate, borax, silica and other reagents as required, inquarted with 6 mg of gold-free silver and then cupelled to yield a precious metal bead.

The bead is digested in 0.5 mL dilute nitric acid in the microwave oven, 0.5 mL concentrated hydrochloric acid is then added and the bead is further digested in the microwave at a lower power setting. The digested solution is cooled, diluted to a total volume of 4 mL with de-mineralized water, and analyzed by atomic absorption spectroscopy against matrix-matched standards.
