INTRODUCTION

The Mount Hinton property hosts an extensive system of gold- and silver- bearing quartz veins. The property lies within the Keno Hill Mining Camp of central Yukon. Rockhaven can earn a 100% interest in the property subject to an option agreement with an arms-length party.

This report describes work conducted between July 8 and August 6, 2010 by Archer, Cathro & Associates (1981) Limited on behalf of Rockhaven. The work consisted of soil geochemical sampling done by a crew of two people from three camp locations on the property. The author directed the program, and his Statement of Qualifications appears in Appendix I.

PROPERTY LOCATION AND ACCESS

The Mount Hinton property consists of 358 mineral claims located southeast of the community of Keno City in central Yukon Territory, at latitude 62°52'N and longitude 135°07'W on NTS map sheet 105M/14 (Figure 1). The claims were staked under the Yukon Quartz Mining Act and are registered in the Mayo Mining District in the name of Richard A. Ewing, who owns the claims and holds them in trust for Rockhaven until the option is completed. Claim locations are shown on Figure 2, and claim tenure information are listed below.

*Expiry dates include 2010 work which has been filed for assessment credit but not yet accepted.

Claims comprising the Mount Hinton property have only been partially surveyed, and the author has only conducted spot inspections with respect to the placement of claim posts, the position of location lines and the proper affixing of claim tags. The claim locations shown on Figure 2 are derived from government claim maps. The Mount Hinton property is not encumbered by First Nations Land Claims. Placer mining claims in upper Thunder Gulch may compromise surface

rights on the Hinton II 1 to 8 claims while placer claims in upper Duncan Creek may similarly restrict mining activity on the Lock 11-14, 16, 18, 43, 45, 47-52 and 54 claims.

Access to the property is by a 10 km dirt road from Keno City to the exploration camp in upper Duncan Creek valley. Various locations on the property are accessed by a system of four-wheel drive roads and rough bulldozer trails.

HISTORY

Exploration history of the Mount Hinton property is compiled from the Indian and Northern Affairs (now Yukon Geological Survey) Minfile database (Minfile, 2002), from a report on 1968 exploration by Zimmer (1968), and from summary reports prepared by Oullette (1985), Smith (1998), Junior Mine Services Ltd. (2003) and Carne (2003 and 2005).

Prior to 1963, numerous claims were held by individuals in the area encompassed by the present Mount Hinton property. Sporadic prospecting, both for gold and silver, was carried out with the earliest recorded work dating back to the early 1920s. The most notable effort was a 25 m adit driven in a cirque face at the head of McNeil Gulch by Charles Brefalt in 1941. No shipments of ore have been reported.

All claims within the area of the present property had lapsed by 1965, except for 14 claims on the north peak of Mount Hinton (the Erickson property). Following release of regional-scale reconnaissance stream sediment sampling results by the Geological Survey of Canada, United Keno Hill Mines (UKHM) staked 74 claims adjoining the Erickson property to the south and east. UKHM conducted prospecting and geochemical sampling program later in 1965, which identified three new veins, and enlarged the property to 276 claims in spring 1966. That summer an extensive geochemical sampling program was carried out over the entire claim group with about 12,000 soil samples collected at approximately 30 m by 100 m sample spacing. Geological mapping and prospecting were also carried out over the property and surrounding areas, identifying an additional 20 veins. Limited hand trenching was conducted on a dozen or more of these vein targets. After the field season, UKHM allowed 138 claims to lapse and optioned the Erickson property. In 1967, exploration focused on the head of McNeil Gulch where 22 new veins were discovered by detailed prospecting and hand trenching. In 1968, the McNeil Gulch area was mapped in detail with a plane table survey providing topographic control. All work was carefully tied in by triangulation and aerial photogrammetry. Prospecting identified 15 additional veins, and hand trenching or stripping was carried out on some of these new discoveries. A prospecting shaft was sunk to a depth of 8 m on the 21 Vein.

A two week bulldozer trenching program was carried out in 1971 by UKHM in the west-central part of the property in an attempt to expose strike extensions of the 5 Vein. This work was largely unsuccessful because of deep, frozen overburden.

The property lay dormant until 1980 when a short hole percussion drilling program, totaling 1780 m, was completed by UKHM on the 5 Vein. Of the 74 holes, only 24 apparently reached the intended target. In 1984, a helicopter-supported underground exploration program was

conceived by UKHM to test characteristics of the 5, 19, 21 and 24 Veins. Due to delays in funding, the work did not commence until early July and the only significant effort was directed to the 19 Vein, where a total of 98 m of drift and crosscut were completed before winter weather forced abandonment of the program. Some prospecting and limited hand trenching were also carried out in 1984, resulting in the discovery of one new vein.

Claims covering the 1 Vein area were allowed to lapse and the showing was restaked by local prospectors and optioned to Meldean Placers Ltd., which cleaned out the old hand trenches in 1981. 660250 Ontario Limited carried out soil sampling, VLF-EM geophysical surveys and further hand trenching on the 1 Vein in 1986 (Adams, 1986), and Orex Resources Limited completed two short diamond drill holes across the best area of mineralization in 1987 (Adams, 1988).

In January 1989, low silver prices and declining reserves forced the shutdown of UKHM's silver-lead-zinc mining operations in camp. The company underwent a number of changes in ownership and attempts at refinancing but none were successful. It was forced into receivership in March 2001. Alexco Resource Corp. acquired the UKHM assets in February 2006 and achieved commercial production at the Bellekeno Mine in January 2011, using a new mill located immediately west of Keno City.

The Hinton Syndicate, a private group, staked claims peripheral to the main area of interest at Mount Hinton in 1998 and optioned them to Yukon Gold Corp. Ltd. in 2002. Later in 2002, UKHM claims covering the core area of interest on Mount Hinton were allowed to lapse and Yukon Gold restaked the open ground. Yukon Gold completed additional staking in August 2004.

Between August and October 2002, Yukon Gold carried out a preliminary evaluation of the Mount Hinton property with prospecting, limited hand trenching and resampling of old workings as well as minor excavator trenching and road building.

In August and September 2003, an excavator trenching program was carried out on the ridge trending north from the north peak of Mount Hinton to test for the possible westerly extensions of the McNeil Gulch veins. Excavator trenching was also performed on the 5 Vein and a total of 8 km of new road was constructed to enable vehicle access to previously inaccessible parts of the property. Orientation geochemical soil sampling was carried out along these newly constructed bulldozer trails. In addition, the Duncan Creek and Thunder Gulch access roads were upgraded four-wheel drive status.

In July and August 2004, road building and excavator trenching resumed. This work was accompanied by grid soil geochemical sampling in the Duncan creek headwaters, the floor of McNeil Gulch and the southwest flank of the south peak of Mount Hinton. A total of 890 soil samples were collected. Most of the anomalies resulting from the 2004 geochemical sampling were evaluated by prospecting.

In July and August 2006, Yukon Gold completed grid soil sampling, excavator trenching and

reverse circulation drilling. A total of 3066 soil samples were collected in the upper Duncan Creek valley and the headwaters of Lightning Creek, both significant placer gold bearing waterways. The results returned only scattered weak anomalies, possibly due to the thick overburden that covers this area. These samples were not analysed for gold. Excavator trenching was carried out to explore the apparent source areas of quartz vein float uncovered during the course of road building. The excavator was also employed to expose the 21 Vein for sampling. Two reverse circulation drill holes were attempted in 2006, but neither was complete due to a combination of operator inexperience and mechanical problems. The drill program was terminated after the first hole was abandoned at 24.4 m and the second hole at 21.3 m.

The final exploration program completed by Yukon Gold was in 2007. That program consisted of infill soil sampling, excavator trenching, diamond drilling and a helicopter-borne Versatile Time Domain Electromagnetic and Magnetic (VTEM) geophysical survey. Grid soil sampling was carried out in the headwaters area of Lightning Creek and in the 1 Vein area, to test the on-strike extensions of known veins and a large area in the west-central part of the property where a number of strong VTEM conductors were revealed by the helicopter-borne survey. As with the 2006 program, these samples were not analyzed for gold. Excavator trenching was carried out to explore the McNeil Gulch area and to expose the source of mineralised float boulders on the saddle between Granite Creek and McNeil Gulch. A total 1.39 km of trenching discovered 11 new vein showings. Three diamond drill holes were attempted in 2007. The 21 and 19 Veins were targeted by two drill holes (DDH-MH-07-01 & -02), but driller inexperience resulted in the drill rods being frozen in the ground on both holes before the target depth was reached. A final hole (DDH-MH-07-03) was collared in the floor of McNeil Gulch to test a number of the new vein structures exposed by excavator trenching earlier in the program. Two broad zones ranging between 23.2 and 36.8 m wide were discovered, which host highly elevated arsenic concentrations up to 11,500 ppm. The 1052 line kilometre VTEM survey revealed a number of east-west trending conductivity anomalies that may reflect potentially mineralized fault zones.

The Jen Claims were staked by the Hinton Syndicate in June 2008 and were explored by contour soil geochemical sampling and prospecting. The program returned multiple, coincident lead-zinc-arsenic anomalies (Smith, 2010).

In March 2010, the Hinton Syndicate optioned the Mount Hinton Project to Rockhaven Resources Ltd.

GEOMORPHOLOGY AND CLIMATE

The Mount Hinton property covers the headwaters of a number of drainages including Duncan Creek, Thunder Creek, McNeil Creek, Granite Creek and Keystone Creek. Elevations range from 900 m on the floor of the Duncan Creek valley to over 2000 m at the peak of Mount Hinton. The main area of exploration interest lies along the rugged north-facing wall of a cirque at the headwaters of McNeil Gulch. Heavy talus cover, rugged terrain and permafrost have hampered past exploration activities.

Tree line is locally about 1500 m elevation. Valley bottoms below that elevation are forested

with black spruce and willow. Above 1500 m, buck brush (arctic black birch in drier areas and willow in wet areas) predominates with scattered clumps of alpine fir. Higher elevations on the property are unvegetated. Continuous permafrost probably underlies the entire Mount Hinton area.

The lower parts of the claim block are normally explorable from late May until early October. Higher elevations are snow free from late June to late September. The climate in the area is typical of northern continental regions with long, cold winters and relatively temperate summers. Average temperatures in January are about -20°C and in July about 10°C . Total annual precipitation is approximately 90 cm, mostly occurring as rain in the summer months. Maximum snow pack averages less than 200 cm although cornices and drifts in the area of exploration interest on the north facing headwall of McNeil Gulch can have snow depths exceeding 6 or 7 metres. Although summers are temperate, arctic cold fronts often cover the area and snowfall can occur in any month on the upper slopes of Mount Hinton. Sunlight ranges from more than 20 hours per day in late June to approximately four hours per day in late December.

GEOLOGY

The Mount Hinton property lies along the southwest margin of Selwyn Basin, a region of deep water, off shelf sedimentation that persisted from late Precambrian to Middle Devonian time. The property is largely underlain by interbedded Mississippian phyllitic quartzite, chloritic and carbonaceous phyllite and massive to well foliated quartzite with lesser limestone of the informally named Keno Hill Quartzite or "Central Quartzite" (Roots, 1997). An underlying carbonaceous phyllite sequence, informally called the "Lower Schist", is assigned to the Middle to Late Devonian Earn Group. Triassic amphibole-chlorite metadiorite and metagabbro sills locally termed "greenstone" intrude the layered strata. The west side of the property is bounded by the Robert Service Thrust Fault, which emplaces metamorphosed clastic sedimentary rocks of the Upper Proterozoic Hyland Group (locally called "Upper Schist") over the Keno Hill Quartzite. A geological map of the property is shown on Figure 3 (Zimmer, 1986 and Murphy and Roots (1996)).

Both the Robert Service Thrust Fault and enclosing rocks are intruded by the Roop Lakes Pluton, a 100 km^2 elliptical stock that lies about 10 km east of the main area of vein mineralization on the Mount Hinton property. Igneous petrology is dominated by medium grained granodiorite with lesser quartz monzonite. A marginal phase of the stock is composed of quartz diorite to quartz gabbro. A single felsite dyke is the only granitic igneous body on the Mount Hinton property, and it may be related to the Roop Lakes Pluton.

The Mount Hinton area lies in the southeast part of the Keno Hill mining camp, which is one of several mining districts within the 550 km long Tombstone Gold Belt. Between 1913 and 1990, 6,657 tonnes (214 million ounces) of silver, 35,000 tonnes of lead and 21,000 tonnes of zinc were extracted from the extensive and numerous vein faults in the Keno Hill area. Average recovered grade was 1373 g/t (40.1 oz/ton) silver, 6.7% lead and 4.1% zinc (Cathro, 2006).

The Tombstone Gold Belt is coincident with, and genetically related to, a belt of Mid-Cretaceous

Geology after Zimmer (1968) and Murphy and Roots (1996)

plutons assigned to the Tombstone Plutonic Suite (Hart and Burke, 2002). A 92.8 ± 0.5 Ma age has been determined by isotopic dating for the quartz monzonite phase of the Roop Lake pluton. This age together with its location and petrology places the intrusion within the Tombstone Plutonic Suite.

Tombstone Gold Belt includes a wide variety of mineralization types that are generally zoned outward from the related plutons. Proximal mineralization occurs within or adjacent to the mineralizing pluton as replacements, disseminations, stockworks, skarns and discrete veins with a gold-bismuth or tungsten-copper association (Hart and Burke, 2002). Distal mineralization occurs at some distance from the pluton either as disseminations or veins that are characterized by either gold-arsenic-antimony-mercury or lead-zinc-silver association. Precious metal bearing veins on the Mount Hinton property probably belong to the distal suite.

HISTORY AND ECONOMIC POTENTIAL OF NEARBY OCCURRENCES

The geological setting and style of mineralization defined to date on the Mount Hinton property are the same as those for the vein faults that supplied silver-lead-zinc ore to a number of successful underground and surface mines in the nearby Keno Hill mining camp.

Two types of vein mineralization are represented in the district (Boyle, 1965). The earliest stage is characterized by deposition of hydrothermal silica, which precipitated as quartz lenses in dilatant zones within northeast trending faults. In addition to this constituent, considerable amounts of sulphur, arsenic, and iron with lesser antimony, lead, copper, gold and silver were introduced. This is the most common type of precious metal mineralization on the Mount Hinton property.

The second type of vein mineralization in the Keno Hill mining camp is a later stage of iron, manganese, sulphur, antimony, lead, zinc, silver and cadmium enrichment hosted by siderite rather than quartz gangue. This style of vein fault is responsible for the bulk of the historical silver-lead-zinc production from the Keno Hill area. Ore shoots typically comprise less than 2% of the vein faults but this density locally increases to 20% within productive areas. The 1 Vein and 67 Vein are the only showings of this type that have been discovered to date on the Mount Hinton property.

Boyle (1965) notes that the most favourable host rocks for vein formation are thick bedded quartzites and greenstones. The principal economic lodes are located in four structural settings:

- at the junction of two or more vein faults;
- at the junction of a vein fault and offsetting bedding plane fault;
- within or immediately below massive quartzites and greenstones; or
- where the vein faults pass into phyllite or thin bedded quartzite.

MINERALIZATION

Mineralization on the Mount Hinton property consists of fault-controlled vein and vein breccia showings. According to Ouellette (1985) there are three types of faults in the Mount Hinton area

that affect the distribution of gold and silver bearing quartz veins. Transverse faults are the main host for mineralized quartz veins on the property although some mineralization has been observed to extend into intersecting and offsetting bedding plane faults. Transverse structures strike east-northeast and dip steeply to the south. Displacement is apparently dip slip with little or no lateral movement. Zimmer (1967) observed that transverse faults are largely limited to competent units (quartzite) while the less well mineralized bedding plane faults are generally confined to intervening ductile phyllite members. In most cases transverse faults do not penetrate the thicker greenstone sills. Instead they deflect into bedding plane faults at the base of the sills. Cross faults appear to be younger than the mineralizing episode and offset the mineralized transverse or bedding plane faults in a left lateral sense.

Open space in quartzite caused by movement on the transverse/bedding plane fault systems provided corridors for incoming hydrothermal fluids and formed the locus for vein deposition. Precious metal mineralization in the veins on the Mount Hinton property typically occurs within a band of milky white vein quartz flanked by brecciated wallrock or fault gouge at the hanging wall and/or footwall. Early formed vein material is often re-brecciated or crushed by continued movement on the structure. The vein faults are often bordered (especially in quartzite) by parallel quartz stringer zones up to 5 m wide. One or both walls of the mineralized structure may be defined by an abrupt break.

Veins appear to pinch and swell both along the strike and dip of the fault structure. Width and continuity is largely controlled by host lithology. Where both walls of the vein fault are relatively ductile phyllite, a narrow zone of fault gouge may be the only expression of the structure. The widest and strongest quartz veins occur where one or both walls are brittle quartzite or greenstone. Veins are especially well developed and well mineralized immediately beneath large greenstone lens that underlies the north peak of Mount Hinton.

Vein mineralogy is summarized by Ouellette (1985), based primarily on work by Zimmer (1967). The Mount Hinton veins consist of fractured milky white quartz hosting, in approximate order of abundance: arsenopyrite, galena, jamesonite, pyrite, sphalerite, siderite and gold as well as the weathering products scorodite (after arsenopyrite), limonite (after pyrite) and anglesite (after galena).

- Arsenopyrite is present in all mineralized veins as well developed crystals and fracture fillings.
- Galena is also present to some degree in all veins although in poorly mineralized structures it is sparsely and erratically disturbed, occurring as irregular fracture fillings in yellowish quartz that may carry high silver values (up to 1700 g/t in pure galena) and as small disseminations in white to yellow quartz that seldom carry more than 500 g/t silver. In high grade quartz veins, galena occurs as sheeted zones that parallel overall vein attitudes.
- Jamesonite is abundant only in the southwest part of the vein system on the north face of Mount Hinton and in the 5 Vein on the south peak of Mount Hinton. In the 21 Vein, jamesonite is the primary sulphide mineral, and it occurs as finely fibrous, sheared masses that contain minor sphalerite and pyrite.

ARCHER, CATHRO & ASSOCIATES (1981) LIMITED

5 VEIN DETAIL MOUNT HINTON PROJECT

Drawn By: RCC

Project: Mount Hinton

File: 5VEIN.dwg

Date: March 2011

- Pyrite is present in nearly all veins and it is usually found as disseminated crystals as opposed to veinlets. Pyrite is particularly associated with arsenopyrite and nearly massive jamesonite in the 21 Vein.
- Sphalerite was observed in small quantities in the 5, 15, 21, 31, 35 and 52 Veins. It occurs as irregular masses without an apparent association with other metallic minerals.
- Oxidation affects most near surface sulphide mineralization. Murphy (1997) notes that oxidation can extend to depths up to 150 m in the Keno Hill area.
- In 1967 UKHM used a mortar, pestle and gold pan to visually test samples taken from gold veins as they were exposed by hand trenching. There was little correlation between the quantity of free gold particles liberated by the mortar and pestle and the assay grade, especially in samples that assayed less than 1 oz/ton (34.3 g/t) gold. Boyle (1965) suggests that metallic sulphide minerals carry the bulk of the gold in the Keno Hill mining camp as a lattice substitution, explaining the generally observed paucity of free gold. For example, a selected grab sample of massive jamesonite and scorodite collected from the 21 Vein in 2002 assayed 210.1 g/t gold and 1754 g/t silver although no visible gold was present. Zimmer (1967) noted that at Mount Hinton:
 - high gold values are always associated with metallic sulphide minerals,
 - gold has a particular association with jamesonite, and
 - gold and silver values usually parallel each other.

All creeks draining the property contain anomalous placer gold concentrations to some degree. Duncan Creek and Thunder Gulch, in particular, have supported long term placer mining operations.

As many as 72 mineralized veins, vein segments or discrete mineralized vein float trains have been discovered to date on the Mount Hinton property (Figure 3). They are identified by numbers that reflects their order of discovery (i.e. 1 vein was found first). UKHM's discoveries were typically made by prospecting to find mineralized talus or float then following up with hand trenching. Hand trenching and mucking, occasionally assisted with blasting, were employed to remove loose talus and frozen overburden from the veins. Bedrock was not penetrated unless it was highly broken. Veins judged to be low grade because of low sulphide mineral content were only exposed with randomly spaced foxholes. The more accessible, well mineralized veins were continuously trenched until they pinched out or until overburden became excessively deep. The full width of solid vein quartz plus 30 cm or so of the footwall and hanging wall were typically exposed. Channel samples were normally taken on regularly spaced intervals of 61 cm. No attempt was apparently made to expose or sample associated crushed quartz or gouge zones and adjacent weakly mineralized wallrock. Very little evidence of the UKHM trenching program remains on the steep cirque face of the McNeil Gulch headwall due to sloughing of the talus cover.

The headwall of McNeil Gulch forms an east-west trending cliff face that contains most of the important vein occurrences discovered to date on the Mount Hinton property. Gold bearing vein faults are confined to a 300 m wide, 3.4 km long belt that coincides with the arcuate trend of the cirque face. This distribution believed to be more a function of exposure than a reflection of the primary distribution of mineralized quartz veins. For example, in 2007 excavator trenching in

the till covered valley bottom north of the cirque face of McNeil Gulch exposed numerous vein swarms with locally strong mineralization.

2010 TARGET DESCRIPTIONS

The 2010 soil sampling program mainly explored for possible strike extensions of three known veins: 5 Vein, 1 Vein, and 55 Vein. The Granite Creek Basin, a relatively unexplored valley containing creeks that had yielded very high historical gold-in-silt values, was also grid soil sampled. These targets are discussed in the following paragraphs where results of the 2010 sampling are described in the Soil Geochemistry section.

5 Vein:

The 5 Vein is located in the south-central part of the property and is the strongest structure found to date in the Mount Hinton area. UKHM traced the structure through a combination of prospecting, hand trenching, bulldozer trenching, and percussion drilling for a distance of about 1300 m. It strikes east-west with a dip that varies from 40 to 80° south. Where exposed to date, the 5 Vein is hosted within a graphitic phyllite unit. Widths of vein material and enclosing fault gouge or breccia range up to 20 m. Grab samples have assayed up to 11.3 g/t gold, but most returned values less than 5 g/t gold. Excavator and bulldozer trenching in 2003 tested the 5 Vein at 25 to 40 m intervals over a 170 m distance down the west flank of the south peak of Mount Hinton. The best results from this work were a chip sample across a 4.5 m wide quartz vein exposed in Trench 03-05, which graded 0.47 gold and 183.0 g/t silver; and, a chip sample across a 4.2 m interval of vein quartz in Trench 03-06, 33 m to the west, which graded 1.04 g/t gold and 92.5 g/t silver. A compilation of historical work at the 5 Vein is shown on Figure 4.

1 Vein:

The 1 Vein is located in the eastern part of the property about 4 km northeast of the 5 Vein. Historical work consisted of closely spaced soil geochemical surveys, hand trenching, VLF-EM geophysical surveys and two diamond drill holes. A compilation of historical work at the 1 Vein is shown on Figure 5.

Character assays of relatively abundant galena float boulders that comprise the original discovery returned extremely high silver values, including 30,822 g/t (899 oz/ton) silver with 72% lead and 14,400 g/t (424 oz/ton) silver with 75% lead.

The 1966 hand trenching outlined a 120 m long, southeasterly trending, bedding plane vein fault mineralized with scorodite and short discontinuous veinlets of galena. The vein fault typically varies in width from 20 cm to 60 cm but it widens to greater than 1.8 m at a transverse fault that terminates the northerly end of the structure. The southeast limit of the mineralization was not determined due to deep overburden. Channel sampling results were disappointing with typical assays of 206 to 274 g/t silver over 1.5 m (gold assays were less than 10 g/t although they were considered at the time to be unreliable). The best assay of 645 g/t silver over 1.5 m was at the north end of the structure, adjacent to the transverse fault.

1 VEIN DETAIL
 MOUNT HINTON PROPERTY

UTM Zone 8, NAD83, NTS sheet 105M14

FILE: .../2010/Mount_Hinton/Figures

DATE: MARCH 2011

Results of close-spaced soil geochemical sampling carried out in 1967 reveal that a very strong lead anomaly extends east-northeast along the trend of the postulated transverse fault for a distance of about 200 m where it is open to extension beyond the limit of sampling. Work done in 1986 and 1987 did not have the benefit of this information because it was reported in assessment reports that were still confidential at that time. Thus, that exploration continued to focus on the southeasterly trending bedding plane vein fault, which produced results comparable to the earlier UHKM hand trenches. The source of the very high grade galena float is probably the untrenched east-northeast trending transverse fault, which parallels the strongest lead soil geochemical anomaly. This trend also coincides with a VLF-EM geophysical anomaly. This target has not been adequately tested by any of the physical work carried out to date.

55 Vein:

The 55 Vein was discovered in 2006 by excavator trenching (Carne 2006). Vein material was incompletely exposed through frozen overburden in a recessive linear, and the full width and character of the vein fault are not yet known. Two chip/channel samples were taken across the structure 3.5 m apart. A hanging wall grey fault gouge zone with about 10% admixed milky white quartz fragments returned values of 1.00 g/t gold and 16.7 g/t silver over 125 cm in the western trench and 1.75 g/t gold and 6.4 g/t silver over 2.20 m in the eastern trench. The hanging wall contact of the mineralized zone was not exposed. A zone of rusty fault gouge in the footwall of the grey gouge assayed 0.59 g/t gold and 5.6 g/t silver over 175 cm in the western trench and 0.32 g/t gold with 4.0 g/t silver over 200 cm in the eastern trench. The footwall to the rusty gouge in the western trench is a 75 cm zone of grey gouge with 35% quartz fragments, which assayed 1.22 g/t gold and 27.9 g/t silver. The full width of this zone was not exposed due to permafrost and the source of the strong gold-silver geochemical anomaly was not fully evaluated.

Granite Creek Basin:

The Granite Creek Basin target is situated in a valley immediately northeast of the #5 Vein. This target was originally identified in 1965 when silt samples taken from the valley during a district-wide geochemistry program conducted by the Geological Survey of Canada returned the strongest gold-in-silt anomalies within the Keno Hill mining camp. Despite these very encouraging results, no systematic exploration had been conducted at this target.

SOIL GEOCHEMISTRY

Historical soil geochemical sampling on the Mount Hinton Property was carried out by UKHM (1965, 1966 and 1968), 660250 Ontario Limited (1986), Yukon Gold Corp. (2003, 2004, 2006 and 2007) and the Hinton Syndicate (2009). Details of these and the 2010 survey are discussed in the following paragraphs. Sample handling and analytical procedures are found in Appendix II while Certificates of Analysis appear in Appendix III.

In 2010, a total of 1598 soil samples were collected by Rockhaven from four main areas on the property. Sample locations from the 2010 program are shown on Figure 6. Results of the 2010 program and historical UHKM soil sampling surveys as well as Yukon Gold 2003, 2004, 2006,

and 2007 geochemical surveys for gold, silver, lead, zinc, arsenic and antimony are summarized as thematic maps on Figures 7 to 12. Geochemical anomalies for various metals are compiled on Figure 13 and are described below.

Anomaly A:

This large continuous anomaly reflects downslope dispersion from numerous veins on the steep headwall slopes of McNeil Gulch. Most soil samples returned 25 to 100 ppm lead with isolated peak values greater than 250 ppm. The widespread lead response was replicated by results of the 2005 survey. Anomalous arsenic values from the modern survey support the high lead response. Gold anomalies are much more restricted in extent and they probably result from downslope or down ice dispersion from specific vein targets. In particular, anomalous gold results reflect an apparent easterly strike extension of the 19 Vein into a region of thick talus cover and downslope dispersion from mineralization in the 26 and 32 Veins.

Anomaly B:

A moderate strength anomaly (25 to 200 ppm lead) from the 1966 - 1968 exploration program lies downslope of vein float discovered in a recessive zone along a ridge. This vein was named the 60 Vein and returned 29.5 g/t gold and 20.5 g/t silver from a grab sample. There is a multi-element soil geochemical anomaly from 2004-2006 work downslope of this vein.

Anomaly C:

Moderate to strong lead results (25 to 356 ppm) occur along a 1400 m long, northeast linear trend that crosses the divide between McNeil and Erickson Creeks. There are no known vein occurrences that correspond to this feature, but Costin and Zimmer (1966) note that old hand trenches with vein quartz float are associated with the strongest part of the anomaly. Grid soil geochemical sampling in 2004 did not extend as far east as Anomaly C, however soil samples taken at the extreme northeast edge of the grid, on strike with the UKHM lead anomaly, returned moderately anomalous values of gold and lead.

Anomaly D:

Moderate to strong lead geochemical values occur at the head of the east fork of Granite Creek along the easterly strike extension of the main vein trend. The 7 Vein is the only known showing in this area and it lies at the downslope edge of the east end of the anomaly.

Anomaly E:

Weak to moderate lead geochemical response has been identified on the south facing slope of the northeast branch of the west fork of Granite Creek. The 41 Vein occurs at the northeast end of this anomaly but a larger area of mineralization is probably present.

Anomaly F:

A moderate strength, northerly trending lead geochemical anomaly lies about 200 m north of the 1 Vein. Costin and Zimmer (1966) suggest that this anomaly could represent a mineralized bedding plane fault. Spot highs to the west and uphill of Anomaly F indicate

that one or more parallel structures could be present.

Anomaly G:

Results of soil sampling conducted by UKHM in 1966 to confirm limits of the 1 Vein as outlined by hand trenching (Costin and Zimmer, 1966), but the source of very high grade silver bearing galena float found the previous year was not located. Detailed soil sampling carried out in 1968 extended the strongest part of the lead anomaly to the northeast, well beyond the apparent limits of the 1 Vein and at right angles to its southeast strike. The location of the 1968 soil geochemical anomaly, coupled with the discrepancy between assays of the argentiferous galena float and relatively low silver values of galena exposed by follow-up hand trenching, suggest that the weakly mineralized structure trenched in 1966 and drilled in 1987 is a bedding plane fault that intersects a potentially well mineralized, northeast trending transverse vein system (Zimmer, 1968). 2010 sample taken 600 m to the east along the projected surface trace of the showing returned a strongly anomalous value of 93.2 ppm silver and 1185 ppm lead.

Anomaly H:

Anomaly H lies about 1 km southeast of the property boundary. Isolated spot lead highs outline one or possibly two northeast trending exploration targets. No mineralized vein occurrences have been located here, but Costin and Zimmer (1966) note that an unmineralized transverse fault was mapped in the area. There has been no modern evaluation of Anomaly H.

Anomaly I:

The 2010 soil geochemical survey along strike to the southwest of the #5 Vein outlined a well-defined multi-element anomaly that extends 1100 m south from the vein exposure. This anomaly is 50 to 100 m wide and features elevated gold (10 to 171 ppb), arsenic (31 to 681 ppm), silver (0.2 to 4.1 ppm), and antimony (4 to 61 ppm) values. Geological mapping and prospecting indicate that this anomaly is associated with brittle rock units, which are particularly favourable for vein development. Overburden depths here are likely to be considerable so that even a subtle geochemical anomaly can be significant.

Anomaly J:

Reconnaissance sampling along a new bulldozer road in 2003 returned anomalous values for gold and pathfinder elements. This discovery was followed up in 2004 with a small soil geochemical grid located uphill to evaluate possible source areas for the anomaly. That grid was sampled at 50 by 50 m spacing and outlined an east-west trending soil geochemical anomaly with individual samples 1855 ppb gold, 13.4 ppm silver, >10,000 arsenic, 1535 ppm lead and 571 ppm antimony. This anomaly follows a broad recessive linear (55 Vein) that runs straight up the slope to the ridge crest then down a cliff on the east side of the ridge towards the Granite Creek valley floor. Neither the area of the 2004 anomaly nor the easterly strike extension of the linear recessive zone into the Granite Creek basin was sampled by UKHM. However, follow up prospecting in 2004 discovered minor quartz vein material in the recessive linear. The best assay of eight samples was a grab sample of rusty quartz-quartzite breccia with arsenopyrite seams that carried 0.46 g/t gold and <0.2 g/t silver.

Lead values were very low (<34 ppm) and it is most likely that the vein material responsible for the very strong soil geochemical response is buried beneath the recessive linear.

Excavator trenching was attempted on this target in 2006 but it was frustrated by frozen overburden. A reconnaissance soil sample traverse along the base of a cliff face east of Anomaly J suggests that the 55 vein continues into the Granite Creek valley.

The 2010 detailed grid does not appear to have adequately tested the inferred trace of the 55 Vein. Strongly anomalous gold values were returned from two samples, both collected north of the detailed grid, and these samples may mark the trace of the structure.

Anomaly K:

A string of nine soil samples collected at 50 m intervals along a newly constructed road in 2003 returned weak to moderate gold (26 to 77 ppb), arsenic (up to 215 ppm), antimony (6 to 15 ppm) and lead (26 to 122 ppm) response. The area was tested by grid soil sampling in 2004 and a relatively narrow northeast trending multi-element anomaly was outlined for an 800 m distance. Maximum values (up to 485 ppb gold, 13.2 ppm silver, 788 ppm arsenic, 1165 ppm lead and 59 ppm antimony from one soil sample) occur in a coarse talus field. Excavator trenching was attempted in 2004 but a combination of deep, wet and unstable talus and permafrost prevented adequate evaluation of this anomaly. This may be a westerly strike extension of the 52 Vein.

Anomaly L:

Grid soil sampling in 2004 returned moderate to strong gold-arsenic-lead values downslope of the reported trace of the 38 Vein. No follow up has been carried out.

Anomaly M:

Grid soil sampling in 2004 outlined a north-northwest trending, moderate strength arsenic-antimony-silver anomaly with zinc and lead support. This anomaly is open to the northeast in to an unsampled area in the headwaters of Thunder Creek, an important placer gold producer.

Anomaly N:

Grid soil sampling in 2007 outlined a large area (300 x 500 m) hosting a moderate strength lead-zinc-arsenic-antimony-silver anomaly that coincides with strong VTEM conductors. This anomaly is located near a prominent hill and drains into Thunder Creek.

Anomaly O:

The Granite Creek Basin target is situated in a valley immediately west of the #5 Vein. This target was originally identified when samples taken by the Geological Survey of Canada returned the strongest gold-in-silt anomalies within the Keno Hill mining camp. Auger soil sampling conducted by Rockhaven in 2010 discovered a 600 m by 500 m soil geochemical anomaly within which 40% of the samples yielded strongly anomalous values between 50 and 3310 ppb gold. This sampling else where in the Granite Creek Basin also returned anomalous results along the northeasterly trend of the 13 Vein. Stockwork mineralization was noted at the 13 vein by previous operators and the extension of this structure may be the source of the

anomalous gold values in the southeastern part of the Basin.

DISCUSSION AND CONCLUSIONS

Despite its relatively long exploration history, the Mount Hinton property has received only minor physical work to fully evaluate the numerous prospecting discoveries and soil geochemical anomalies. The bulk of the exploration occurred in the 1960s and it was carried out under difficult conditions, requiring numerous fly camp set ups in order to keep crews close to their work sites. Trenching was all by hand, and mostly completed without the aid of explosives. Most of the more than fifty prospecting discoveries received only partially successful follow up because of coarse unstable talus, permafrost and steep terrain. Four wheel drive vehicle and heavy equipment access has recently been extended to the north, west and central parts of the property, enabling more efficient exploration.

The Mount Hinton veins are hosted within fault or shear zones. It is apparent from records of historical work that transverse normal faults in brittle quartzite units are the preferred host, and this is the same setting found at many of the most productive silver veins in Keno Hill mining camp. Transverse faults are offset or linked by less well mineralized bedding plane shears that are localized within relatively incompetent phyllite interbeds. In this manner, the “en echelon” vein distribution that is apparent in plan view may actually represent laterally and vertically continuous vein systems that are dismembered by the bedding plane shears.

As many as 72 mineralized veins, vein segments or discrete mineralized float trains have been found on the property to date.

The best developed vein fault on the Mount Hinton property is the 5 Vein. Historical work by UKHM and trenching completed by Yukon Gold in 2004 confirmed the strength of the structure but only low grade silver mineralization has been reported. Many of the trenched exposures of the vein are within graphitic phyllite, a poor host for gold-silver mineralization elsewhere in the Keno Hill mining camp. Grid soil sampling by Rockhaven in 2010 outlined coincident moderate to strong gold, silver, lead, arsenic, and antimony anomalies that appear to define a 1100 m southwest strike extension of the previously explored vein system. The anomalous area is swampy and heavily vegetated, but the presence of numerous large boulders of quartzite in the overburden suggests that favourable wallrocks may be present.

Soil sampling and hand trenching conducted by UKHM in 1966 appeared to delineate limits of the 1 Vein but it did not find the source of very high grade, silver-rich galena float boulders (30,822 g/t and 14,400 g/t or 899 oz/ton and 424 oz/ton). Detailed soil sampling subsequently extended the strongest part of the lead anomaly to the northeast, well beyond the apparent limits of the 1 Vein and at right angles to its apparent southeast strike. This work suggested that the weakly mineralized structure exposed by trenching is actually a bedding plane fault that intersects a potentially well mineralized but unexplored northeast trending transverse vein system. The 2010 soil sampling confirmed and better defined the northeast trending anomaly. The type of high grade mineralization observed in float at the 1 Vein has been profitably exploited by small-scale open pit mining as direct shipping ore at a number of locations within

the Keno Hill mining camp.

Historical reports document swarms of narrow quartz veins or zones of quartz-flooded breccia in wallrocks adjacent to well mineralized quartz veins on the Mount Hinton property. The 13 Vein is described as a "wide fractured quartz system" sporadically mineralized with arsenopyrite, stibnite and galena. Previous operators did not routinely sample this type of lower grade mineralization so the bulk tonnage potential has not been systematically evaluated. The 13 Vein trends into the lower Granite Creek Basin where strongly elevated gold values were returned from the 2010 program. Similar type mineralization was noted in the 5 Vein, which coincidentally trends into the upper Granite Creek Basin where highly elevated gold soil geochemistry was also discovered.

APPENDIX I
STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

I, Matthew Turner, geologist, with business addresses in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in Vancouver, British Columbia, hereby certify that:

1. I graduated from the University of British Columbia in 2002 with a B.Sc. majoring in Earth and Ocean Sciences.
2. From 1997 to present, I have been actively engaged as a geologist in mineral exploration in British Columbia, Yukon Territory and Northwest Territories
3. I have personally participated in or supervised the field work reported herein and have interpreted all data resulting from this work.

Matthew Turner, B.Sc.

APPENDIX II

SAMPLE HANDLING AND ANALYTICAL PROCEDURES

UKHM carried out systematic grid soil sampling over parts of the current Mount Hinton property in 1965, 1966 and 1968. B or C Horizon samples were generally taken at 30 m intervals on lines spaced 91 m apart. Colourmetric (dithizone) determinations of an aqua regia-hydrochloric acid extraction of a one gram sample were carried out for lead and zinc at the company's Elsa Mine assay office. Lead, with its relative insolubility in surficial environments has been traditionally used as a discriminator for Keno Hill area silver-lead veins and UKHM used a 24 ppm lead anomaly threshold.

Yukon Gold carried out grid and contour soil geochemical sampling in 2003, 2004, 2006 and 2007 (Carne, 2007). B or C Horizon samples were generally taken at 50 m intervals on lines spaced 100 m apart.. Analyses were carried out at the ALS Chemex laboratory in North Vancouver B.C. on an aqua regia digestion of a 50 gram, minus 180 micron sieved split using a Fire Assay-Atomic Absorption Spectroscopy procedure for gold and an ICP-AES procedure for 34 additional elements.

Yukon Gold completed additional soil geochemical sampling during the 2006 and 2007 field seasons. In 2006, the upper Duncan Creek valley underlying the Lock claims was explored by soil sampling at 50 by 100 m intervals. Samples were analyzed for 34 elements on an aqua regia digestion of a 50 gram, minus 180 micron sieved split. The results returned only slight anomalies sporadically across the grid possibly due to the thick overburden that exists over this area.

CERTIFICATE VA10100829

Project: Mount Hinton

P.O. No.:

This report is for 180 Soil samples submitted to our lab in Vancouver, BC, Canada on 26-JUL-2010.

The following have access to data associated with this certificate:

JOAN MARIACHER

BILL WENGZYNOWSKI

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-ICP21	Au 30g FA ICP-AES Finish	ICP-AES
ME-ICP41	35 Element Aqua Regia ICP-AES	ICP-AES

Project: Mount Hinton

P.O. No.:

This report is for 179 Soil samples submitted to our lab in Vancouver, BC, Canada on 26-JUL-2010.

The following have access to data associated with this certificate:

JOAN MARIACHER

BILL WENGZYNOWSKI

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-ICP21	Au 30g FA ICP-AES Finish	ICP-AES
ME-ICP41	35 Element Aqua Regia ICP-AES	ICP-AES

CERTIFICATE VA10106645

Project: Mt. Hinton

P.O. No.:

This report is for 232 Soil samples submitted to our lab in Vancouver, BC, Canada on 3- AUG- 2010.

The following have access to data associated with this certificate:

JOAN MARIACHER

BILL WENGZYNOWSKI

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI- 21	Received Sample Weight
LOG- 22	Sample login - Rcd w/o BarCode
SCR- 41	Screen to - 180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au- ICP21	Au 30g FA ICP- AES Finish	ICP- AES
ME- ICP41	35 Element Aqua Regia ICP- AES	ICP- AES

CERTIFICATE VA10106646

Project: Mt. Hinton

P.O. No.:

This report is for 162 Soil samples submitted to our lab in Vancouver, BC, Canada on 3- AUG- 2010.

The following have access to data associated with this certificate:

JOAN MARIACHER

BILL WENGZYNOWSKI

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI- 21	Received Sample Weight
LOG- 22	Sample login - Rcd w/o BarCode
SCR- 41	Screen to - 180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT

CERTIFICATE VA10109949

Project: Mt. Hinton

P.O. No.:

This report is for 188 Soil samples submitted to our lab in Vancouver, BC, Canada on 9- AUG- 2010.

The following have access to data associated with this certificate:

JOAN MARIACHER

BILL WENGZYNOWSKI

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI- 21	Received Sample Weight
LOG- 22	Sample login - Rcd w/o BarCode
SCR- 41	Screen to - 180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au- ICP21	Au 30g FA ICP- AES Finish	ICP- AES
ME- ICP41	35 Element Aqua Regia ICP- AES	ICP- AES

CERTIFICATE VA10109960

Project: Mt. Hinton

P.O. No.:

This report is for 187 Soil samples submitted to our lab in Vancouver, BC, Canada on 9- AUG- 2010.

The following have access to data associated with this certificate:

JOAN MARIACHER

BILL WENGZYNOWSKI

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI- 21	Received Sample Weight
LOG- 22	Sample login - Rcd w/o BarCode
SCR- 41	Screen to - 180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au- ICP21	Au 30g FA ICP- AES Finish	ICP- AES
ME- ICP41	35 Element Aqua Regia ICP- AES	ICP- AES
