SAMPLES

Numbers: I075299-I075364

Total: 66

Batch: 23, 24

Date Sent: June 25, 26, 2010

Certificate: VA10087226, VA10089855

COMMENTS

The hole was ended because it was past the targeted oxide horizon and into the MBL. The hole was lined with PVC to be used in a later downhole gravity survey.

GEOLOGY LOG

HOLE: Rau-10-85

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
0.00	3.96	3.96				OVB																					
3.96	9.14	5.18				TIL			Dark brown clay to silt with ~1 cm diameter pebbles.																		
9.14	12.69	3.55				DOL	OX		Orange-grey DOL with moderately strong ANK alteration. Trace FG-MG brassy gold Py is disseminated along the following FO, while trace dark grey-silver MG As is disseminated throughout.						ms	m				t	t						
			10.67	11.60	0.93	OX	GRT		Dark red-brown clay to grit							i											
12.69	24.38	11.69				LST	DOL		Variably DOL LST, highly oxidized and broken at top of interval, grading into more dolomitized and less oxidized LST down interval.					m		f											
			12.69	21.12	8.43	LST	OX		Light orange grey DOL LST with FO defined by orange-brown alteration seams and fracture coatings which are associated with trace SID. It is calcareous in patches, and contains trace FG-MG Py in thin stringers as well as disseminated throughout. Trace MG As is disseminated throughout. OX on fractures and pervasive through core, associated with t SID.	FO	40			f	f	ms	t										
			13.60	15.24	1.64	OX			Orange-brown to dark brown clay to rubbly oxide..							i											
			17.00	18.04	1.04	OX			Light orange brown to dark brown grit to rubbly oxide.							s											
			21.12	24.38	3.26	LST	DOL	cBX	Medium grey DOL LST with dark grey to red-brown crackle seams throughout. Some orange colouration occurs near the red-brown seams. Low angle Ca veinlets cause mBX of the unit. These veins are slightly vuggy, and rim the clasts and coat them in dark purple-brown SID alteration which fizzes strongly. mBX clasts are up to 3 cm in diameter and are subangular. Trace Py is disseminated throughout.	VN	4			ms			w			t						
24.38	28.72	4.34	24.38	26.37	1.99	DOL		cBX	White to light orange CG dolomite, with outlining medium grey seams forming a moderate cBX texture. Sparry DOL veinlets are displaced by cBX. Light orange brown alteration of seams and crystal boundaries may be ANK or OX.						t	t				t							

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			26.37	28.72	2.35	DOL			Increased OX and ANK alteration of DOL. Cavities that occur within veins and fractures are ms OX. FG MG Py mineralization is concentrated on black stringers following the FO.	FO	55				f	f											
									Very low angle DOL veinlets with offshoots at 40 degrees TCA may indicate a direction of stress.	VT	40																
28.72	47.00	18.28				LST	OX		Light grey LST with large portion of interval intensely OX. FG to MG disseminated OX Py. Some of interval is m DOL altered, w overall. Ca is MG to CG.					w		ms										
			30.20	30.48	0.28	OX			Medium brown semi-cohesive clay to grit.							i										
			31.35	31.88	0.53	OX			Medium brown to dark purple-black clay to grit.							i	m									
			33.54	33.59	0.05				Coarse crystalline Ca veinlet, 3 cm wide	VN	45																
			34.05	34.90	0.85	OX			Medium orange-brown to black grit and very corroded core.							s	ms									
			35.15	35.89	0.74	OX			Medium orange-brown to black clay to grit with small cohesive pieces.							i	ms									
			35.89	37.30	1.41	OX			Cohesive orange brown core with dark brown MG subhedral disseminated spots (OX Py).							m										
			38.50	42.97	4.47	LST	OX	cBX	Mostly cohesive light orange-brown, CG, DOL and ANK altered LST with small vugs throughout. Many of these vugs are still rimmed by Ca and appear to be the dissolution of single Ca crystals. Variably weak to moderately strong OX, with increased vugs and intervals of grit to rubble in orange brown to dark brown OX zones. Medium brown cBX seams are visible in weakly oxidized zones.					m	f	m												
			42.97	47.00	4.03	OX	LST		Dark orange-brown, fizzy, broken core with small holes in core surface associated with dark brown colouration. Lighter orange-brown spotting may be OX Py. Interval becomes increasingly black downhole.							i										
									Thin Ca veinlet set, may be following FO (too oxidized to tell).	VN	55																
47.00	54.71	7.71	47.00	49.20	2.20	OX			Non-calcareous, cohesive but easily crumbled red to medium orange-brown clay to rubble with trace talc locally.							i										
			49.20	54.71	5.51	OX			Fizzy, medium orange brown to dark brown, largely solid core with intervals of cohesive clay to grit, and incohesive clay to rubble. Rubble sections appear dark brown. Quartz fragments with within.							i										

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other				Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
54.71	58.40	3.69				LST	OX		Very DOL/ANK orange grey altered LST with CG DOL areas occurring within . Dark brown spots following possible FO may be OX Py.	FO	55			s	m	m										
			55.85	56.39	0.54	OX			Dark orange-brown rubble to grit with <10 cm long core pieces and poor recovery.																	
58.40	72.75	14.35				OX			Intensely OX dark brown to medium orange-brown incohesive to semi-cohesive clay to rubble.							i										
			58.40	61.04	2.64	OX	GRT		Orange-brown to purple-black clay to rubble, predominantly silt to grit sized, doesn't hold core shape well and is non-calcareous.							i	ms									
			61.04	63.10	2.06	OX			Medium orange-brown, semi-cohesive (holds core shape) non-calcareous clay to grit, with medium to light oreange brown bands.							i	ms									
			63.20	66.20	3.00	OX	GRT		Very dark brown to black with medium orange brown spots. Clay to rubble, mostly grit. Semi-cohesive to incohesive rubble zones. Becomes more orange-brown mottled down hole and grades into orange brown interval. Doesn't fizz.							i	ms									
			66.20	68.58	2.38	OX	GRT		Bright orange-brown non-calcareous clay to rubble (mostly grit) OX with dark purple brown spots throughout.							i	f									
			68.58	69.10	0.52	OX			Medium brown, slightly calcareous wet clay to rubble with a muddy texture. Very poor recovery.							i										
			69.10	71.63	2.53	OX	GRT		Dark brown to bright orange clay to rubble, generally gritty and incohesive.							i	m									
			71.63	72.75	1.12	OX	SLT		Dark red-brown non-calcareous semi-cohesive clay to grit, (generally silt). The lCN with marble is very sharp.																	
72.75	96.80	24.05	72.75	76.40	3.65	MBL	OX		White to light pink MG marble with intense OX intervals up to 40cm long, of dark brown calcareous clay to rubble. The last 60 cm are oxidized, strongly calcareous, cohesive material with OX Py defining FO. Most of marble is very broken and fractures are covered in dark brown OX.							ms										
			76.40	77.72	1.32	OX	CLY		Semi-cohesive bright orange-brown to dark brown non-calcareous clay to grit.							i										

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			77.72	83.38	5.66	MBL	OX		Broken, white to light pink MBL with OX intervals up to 40cm long, clay to rbl, mostly grit. Semi-cohesive to incohesive. MBL pieces found within OX zones and MBL has voids. Sharp contacts between MBL and Ox.							ms												
			83.38	86.61	3.23	OX	LST		Orange-brown to yellow-brown OX, with dark brown spots. Semi-cohesive with ~40 cm intervals of calcareous fairly oxidized orange brown OX with black stringers and zones (ANK/DOL altered LST with silty zone?) which define possible FO. OX is mainly clay to rubble in composition.	FO	55																
			86.61	90.00	3.39	MBL	SER		White-grey MBL with ~1 cm thick SER (light beige) interbeds and trace FG Py disseminated throughout Voids in core and noted by drillers.	FO	60							SER	w	t						
			90.00	90.90	0.90	OX	GRT		Medium orange-brown poorly recovered clay to gri (mostly silt) with some platy textures (possibly SER).																	
			90.90	91.52	0.62	LST	cBX		DOL/ANK altered cBX LST consisting of medium grey to light orange angular <3 cm clasts brecciated by medium grey crackle seams and yellow-white Ca. Medium grey-brown clay and silt occurs on fractured surfaces.					f	w												
			91.52	91.81	0.29	OX	CLY		Medium orange-brown to dark brown clay to grit OX holding core shape. Breccia texture remnant in clay particles as light yellow clasts with dark brown-grey matrix.																	
			91.81	96.80	4.99	MBL	SER		White to light grey MBL with irregular SER layers associated with trace vFG to FG Py. Increased SER and Py toward lower contact. ICN has irregular Ca veins and blebs, and orange altered grey stringers.									SER	f	t						
96.80	97.54	0.74				LST			Medium grey limestone with orange brown alteration on fractures and following FO in dark grey layers.	FO	55															
									97.54 m - E.O.H. The hole was ended because it was past the targeted oxide horizon and into the lower marble.																	

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

Batch: 26, 27

Date Sent: June 28, 30, 2010

Certificate: VA10089855, VA10089854

COMMENTS

The hole was ended because it was into the marble and therefore past the targeted horizon. The hole has been lined with PVC pipe for a later downhole gravity survey.

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
0.00	3.05	3.05				OVB			Overburden - no recovery																		
3.05	6.10	3.05				LST	CLY		Rubbly sub-angular limestone fragments within very soft clay rich gouge-like matrix. Occasional 10 cm portions of competent grey limestone occur scattered throughout. The lCN has a 10 cm interval of white anhedral quartz.																		
6.10	24.68	18.58				OX	GRT		Brown to dark brown, red-yellowish to orange-rusty coloured oxide unit with minor interfingerings of hydrothermally dolomitized limestone. The oxide varies from as coherent as moist soil to moderately-strong. The darker material is generally silt to medium-sand sized particles of minor-silt and limonite-siderite-quartz, and may crumble when pinched or may be coherent as solid-vesicular siderite masses. The more red-orange-rusty oxide tends to be more competent with good recovery of vesicular siderite-limonite +/- hematite. The more competent portions tend to grade gradually into the dolomitized limestone interfingerings, especially towards the lower contact. The yellow portion is associated with a higher quartz content subsequently stained with yellow oxide. The dolomitized limestone occurs interfingering closer to the lower contact, it comprises coarse-grained anhedral hydrothermal white to buff coloured dolomite. Where original limestone is visible it is extensively brecciated by fluids with cryptic limestone clasts and calcite filling the breccia matrix. The limestone however, has mostly been overprinted by hydrothermal dolomite. Most limestone has also undergone extensive cBx and along core axis brittle anastamosing fractures associated with Ca and Fe-Ox staining with minor oxidized fine-grained pyrite.					w			i			t							
			22.86						Sharp CN between CG intense SID and MG hydrothermal DOL with OX on CN . SID has rectangular vugs within it.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
24.68	28.30	3.62				LST	DOL	Bx	Highly-fluid brecciated dolomitized limestone with late fracturing and subsequent oxidation. The dolomitized limestone is grey to light grey in colour with fine-grained subangular and fractured clasts, infilled with a white calcite. A fine cBx texture is pervasive throughout the unit with black infilling seams. Late brittle Fe-Ca fractures propagate through the unit and are filled with a brown-rusty coloured oxide material. Oxidation in LST is associated with OX-fracture density.							m				t							
									Fe-OX Vn - brittle fracture-fills up to 2 mm wide and is dextrally offset by Vns at 70 TCA (reverse motion).	VN	45		80													
									Fe-Ox Vn 2 mm wide, cuts veins at 45 TCA	VN	10		2													
									Fe-OX Vn 1-4 mm wide, cuts the 10 TCA veins.	VN	70		50													
28.30	41.15	12.85				OX	GRT		Red-brown to dark-brown to yellow-rusty highly oxidized unit with abundant limonite-siderite interfingered with LST Bx at the lower contact.										t							
			28.30	34.00	5.70	OX	GRT		Red-brown coloured competent oxide, gritty to siderite dominated. Quartz pebbles occur throughout the grit. Overall clay levels are very low.																	
			32.00	33.00	1.00	DOL	OX		Medium to coarse-grained intensely dolomitized unit with cryptic fluid and timing relations. Minor pyrite occurs as fine-grained oxidized crystals, associated with oxide veins.							i										
			34.00	41.14	7.14	OX	CLY		Generally much softer oxide resembling silty gouge rock. Still rusty-brown coloured and gritty with some yellow portions that are very mica and sericite-rich. Interfingerings of oxide and LST-DOL occur closer to the lower contact. The LST-DOL is highly brecciated with grey fine-grained angular limestone clasts with white anhedral calcite breccia infilling.																	
									The lower contact is sharp below dirty, brown-yellow oxide, gritty and vesicular siderite/limonite.	ICN																
									Ca-OX, 1-3 mm calcite rich dark red to rusty coloured oxide within the fractures.	VN	40		80													
									Ca-OX cuts Vns 40 TCA, 1-5 mm wide filled with calcite and red-brown rusty oxide material.	VN	10		2													

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
41.15	54.39	13.24				LST	DOL		Highly fluid brecciated dolomitized and silicified limestone with minor dolomite veining. Limestone is generally grey, fine-grained, with sub-angular cm-scale clasts within a calcite dominant matrix from breccia fluids. Portions of this unit are more hydrothermally dolomitized than other portions making protoliths cryptic. The lower contact LST material appears to have undergone some shear with tight folds and sinuous foliations.					m						t							
							SIL																				
									Coarse-grained creamy white DOL vein 3-10 mm, crosscuts buff vein.	VN	30		1														
									Coarse-grained buff-white DOL vein 3-20 mm	VN	55		2														
54.39	58.13	3.74				OX	SID		Brown to dark brown to pale-yellow siderite dominated oxide unit. Unit is mostly very competent dark brown vugged siderite which often has a metallic lustre on fresh surfaces (hematite?). Trace unoxidized Py, FG disseminated. Light orange seams less than 1 cm wide locally (Sm ?).											t							
58.13	60.30	2.17				MBL			Medium to light grey marble with no original features recognizable. The marble is grey to light-grey and contains many dissolution seams. It becomes greyer and less marblized towards the lower contact. Relict veins are very sinuous and folded showing a strong sense of shear.																		
									1.5 cm calcite vein.	VN	10																
60.30	63.58	3.28				LST	DOL	RBL	Dolomitized highly brecciated limestone that has been broken into rubble, mostly cobble to small boulder sized blocks. Visible limestone is not marblized but highly brecciated with calcite fluid matrix, all of the unit is overprint by brittle oxide veining. Towards bottom contact one 20 cm interval has been marbleized and is white-grey and crystalline. Also at lower contact the unit is very strained on account of sinuous foliations and elongated wisps that are very cryptic.																		
									Thin 1 mm Ca-OX veins in brittle fractures.	VN	40		50														

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
0.00	4.36	4.36				OVB			Overburden - no recovery.																		
4.36	105.84	101.48				LST	FOS		Dark to medium grey, FG, fossiliferous, variably strained, variably BX LST with trace MBL alteration. Breccia textures are often obscured by strain. Fossils, dominated by large favocites coral fragments with lesser amounts of crinoid stem fragments and stem corals make up 1-3% of rock. Strain gives rock a wavy, blebby texture where strongest. Trace oxidation occurs on fracture faces.							t											
									Foliation is strong, defined by strain fabric oriented at 30-40 degrees TCA, but locally 0 degrees TCA where strongest.	FO	30																
			13.35						Strained, 1.2 cm wide curvilinear veinlet with toothy, brown Ca crystals.	VN	35	0															
									Narrow Ca veinlets, planar, 40 degrees TCA, usually around 1 mm wide, crosscutting wavy, deformed Ca veinlets.	VN	40	140															
									1-3 mm wide, wavy, weakly strained calcareous veinlets. Crosscut by veinlets mentioned above.	VN	20	10															
			4.36	64.26	59.90	LST	FOS		Dark to light grey, FOS, FG-CG, variably strained LST. Fossils are dominated by crinoid stems, but trace coarse tabulate coral (favositid) and chain (halysitid) are present. Most fossiliferous intervals are "packstone" to near "grainstone" with > 50% crinoid stem fragments. Strain is variable throughout, locally appearing parallel to subparallel to core axis with wavy fabric locally deforming relict bedding and fossil textures. Where strain is strongest, calcareous "augens" (coral fragments?) appear rounded, up to 1.3 cm in size, with pinch-swell fabric of FG limestone around clast. Strain generally increases with depth deforming tabulate coral fragments.																	x
									Foliation is 40 degrees TCA where relict bedding is still present, but is generally shallower, at times 0 degrees TCA where strain fabric obscures/deforms bedding textures. FO is 25-30 degrees TCA throughout.	FO	25															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			64.26	79.77	15.51	LST		BX	Dark to medium grey, variably brecciated and strained, weakly marblized LST. Strain deforms BX texture. Dark, FG (lime mudstone?) interbeds exhibi strain more readily than BX clasts. BX clasts are oriented/extended parallel to strain fabric orientation. Few, narrow, sinuous 1-2 mm wide Ca stringers throughout, generally following foliation exhibit strain. Interval is weakly fossiliferous, with trace tabulate coral (favocitid) fragments which can exhibi or be obscured by strain. BX matrix appears to be more like a dissolution texture with depth, becoming near stylolitic in texture. Trace Py is hosted in dark, FG LST as FG disseminations and is also present as bright, yellow subcrystalline blebs hosted in strained brecciated areas.									MBL	s	t							x
									Foliation is defined by strain fabric, generally 30 tc 50 degrees TCA in interval.	FO	40															
									Narrow, sinuous Ca veinlets, crosscutting foliation and strained/deformed Ca veinlets @ 77.39 m, 25 degrees TCA, 270 degrees to FO.	VN	25	270														x
			79.77	80.34	0.57	LST	MBL	MO	Dark grey, mottled LST with light grey "camo" patches, exhibiting fuzzy, sucrosic MBL texture. Trace Py disseminations in dark "matrix" minerals.									MBL	s								
									Foliation is defined by mottled "clast" orientation, 40 degrees TCA.	FO	40															
									Foliation changes orientation, 180 degrees to above FO, and 50 degrees TCA, from 80.05 m to 80.28 m. Foliation is defined by strain fabric and relict bedding(?). Possible fold?	FO	50															
			80.34	91.68	11.34	LST	MBL	BX	Light to dark grey, variably brecciated, strained, strongly marblized LST exhibiting sucrosic, marblization throughout. Rock appearing banded but generally exhibits BX textures. Strain deforming light coloured BX clasts and banding (FG lime mudstone interbeds?)									MBL	s								
									FO is 50 to 55 degrees, defined by strain fabric and banding in rock.	FO	50															
			91.68	100.29	8.61	LST	FOS	FG	Dark grey, FG, FOS limestone with trace Py mineralization. Fossil content is generally weak, but locally 15-20% crinoid stems in FG dark LST with trace tabular honeycomb corals (favositid). Py present as trace disseminations in black, strained/deformed layers in dark grey LST to sinuous, narrow bands rimming clasts along upper contact.											t							x

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			105.84	107.57	1.73	DOL	MX	CG	White to grey coarse grained dolomite hosting CG As and FG bands to wispy strings of Py. As crystal size and frequency generally decrease with depth from 1.1 cm rhombs to FG <1 mm blebs with depth. As lustre is bright silvery white on crystal faces. Py appears to replace As where crystals occur together Py bands range in width from 1 mm to 2.7 cm, and are FG exhibiting a dull greyish-yellow colour. The dolomite contains weak concentrations of creamy yellow ankerite as well as trace milky white coarse Ca crystals. Talc-tremolite overprints or alters the dolomite to a creamy green colour, and is very soft.					i	w			TLC	t	m	s	t					
									FO is defined by Py bands, 50 degrees TCA	FO	50																
									Narrow, Qz-Po veinlet with associated talc-tremolite alteration (?). CG Po locally replaces Py at 110.36 m. The veinlet is 5 mm wide and has a sinuous	VN	60	180														
			107.57	112.46	4.89	DOL	MX	MG	White to grey, FG dolomite, trace creamy yellow (ANK) throughout. As present as trace, FG crystals disseminated among dolomite. Py is present as FG, wispy to planar bands typically between 1 mm and 1.1 cm wide, but masses up to 33 cm in width are also present. Distance between Py bands 3 mm to 16 cm, but typically between 3-15 mm.					i	w					s	t	t					
									Strong foliation is defined by Py bands, 50 degrees TCA.																		
			112.46	113.46	1.00	DOL	MX	CG	White to grey dolomite with weak levels of creamy yellow ANK hosting CG AS and FG bands of Py. As size and frequency generally increases with depth, becoming small masses of coarse, euhedral crystals exhibiting a bright, white-silver lustre. Py is seen as dull greenish-yellow, FG bands, uniform in orientation. Py bands range in thickness from 3-12 mm wide, and are 3 mm to 3.7 cm apart. Contact with unit below sharp, 60 degrees TCA (parallel with FO?)					i	w					s	ms	t					
									FO is defined by Py bands, strong foliation is 50 degrees TCA.																		
113.36	114.91	1.55				MBL			White, sucrosic marble with interfingers of VOL increasing with depth. Intense SER alteration of volcanic interfingers becoming more Bi rich with depth. Gradational contact to unit below over 27 cm.									SER	w								

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

114.91	136.37	21.46				VOL		FG	Brown to green, amygdaloidal, variably magnetic, FG VOL. SER alteration is mostly strong but also locally becoming more intense. Biotite alteration increases with depth.									SER	s									
																		BIO	m								
			114.91	117.31	2.40	VOL		BN	Olive-green to brown, FG, banded VOL with intense SER alteration. This is overprinted by BIO alteration bands ranging in width from 1 to 5 mm (generally 2 mm) and 8 mm wide BIO patches. Trace oxidation is present on fracture surfaces.							t		SER	i								
																		BIO	s								
									Foliation is defined by banding in rock, 50 degrees TCA.	FO	50																	
			117.31	120.40	3.09	VOL			Olive green, soft, intensely SER altered FG VOL hosting cubes of relict Py exhibiting exsolution textures. Trace Py cubes up to 8 mm in size have a rotted out texture. Po occurs past 118.51 m, exhibiting exsolution textures but less so than Py above. Strain fabric is shallow to core axis where Po is present.									SER	i	w		w						
									Foliation is weak to obscured but when present is oriented 50 degrees TCA. Where strain is strongest it occurs at 0 degrees.	FO	50																	
									Narrow Sp veinlet, 1 mm in width, 50 degrees TCA and parallel with FO. Only a single veinlet of this type occurs within the interval.	VN	50	0																
			120.40	122.68	2.28	VOL		AM	Olive green, fine grained, intensely SER altered VOL, appearing fractured to blocky throughout, relict textures appear strained. Dark green chloritic slickensides are present on fracture surfaces (shear zone?). A weak amygdaloidal texture occurs. An faint orangish stain occurs sporadically throughout. Weak talc alteration is identified on some fractures as a soft, greasy white powder.							f		SER	i									
																		TLC	w								
			122.68	125.01	2.33	VOL		AM	Brown to olive green moderately banded fine grained intensely SER altered VOL. This material is magnetic throughout, peppered with ~1 mm dark, magnetite grains. An amygdaloidal texture is present with depth.									SER	i	t							
																		BIO	s

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			128.97	136.37	7.40	VOL		AM	Brown, amygdaloidal, FG, intensely biotite altered VOL, becoming SER altered with depth. Amygdales are filled with calcareous, MG to CG crystals that are usually 8-11 mm in size, but are as large as 3.5 cm blebs and patches. The contact with unit below is gradational, becoming more sericitic with depth.	CN								BIO	i								
																		SER	s								
									A weak foliation is defined by amygdule alignment a 55 degrees TCA.	FO	55															
136.37	279.11	142.74				LST	DOL	BX	Light to dark grey, intensely DOL altered, variably cBX to sBX LST exhibiting FG-CG dolomite recrystalization. The cBX texture overprints the sBX texture. As the cBX texture decreases with depth, sBX textures become more obvious and dominate.					i				TLC	t	t		t					
			136.37	147.48	11.11	LST	DOL	BX	Light to dark grey, MG-CG, cBX DOL altered LST with moderate TLC alteration associated with CG Po veinlets. Bleaching occurs up to 2 m from Po veinlet. cBX textures overprint sBX, but decrease in intensity with depth, becoming finer, to near stylolitic dissolution banded texture.					i				TLC	m	t		t					
									FO is defined by dissolution bands and BX orientation, 50-60 degrees TCA.	FO	55																	
									CG, Po "stockwork" vein with smaller veinlets proximal to main vein at 144.85 m with wide, bleached vein selvages visible up to 2.35 m from vein. MG Py overprinting the Po. CG TLC alteration is intense proximal to the Po mineralization with pearly fibres up to 3-4 mm. Vein orientation is unmeasurable.	VN										50		t					
			147.48	206.57	59.09	LST	DOL	BX	Dark to light grey, variably sBX LST exhibiting variable strain through out. Dark grey breccia clasts are matrix supported in a white to light grey FG-CG breccia matrix. Trace FG Py is present as FG disseminations to small blebs to sinuous bands ~1.7 cm wide in dark, FG LST layers. Strain deforms breccia clasts, orienting them in a common plane. Where BX textures are weak to absent, dissolution bands are present, parallel to the strain fabric in the brecciated zones.					i														x
									Foliation is defined by BX clast elongation and dissolution bands, 50 degrees TCA.	FO	50																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			230.16						An unconformity (?) at 230.16 m with strongly foliated, dark, FG LST with FG blebs to wisps of Py with foliation oriented 30 degrees TCA with the layers above being massive, medium grey FG LST without foliation or Py mineralization and narrow, <1 mm carbonaceous contact. Contact is oriented 70 degrees TCA, and 180 degrees to FO of dark LST above contact.		70	180															
			242.84	253.05	10.21	VOL		BN	Green-grey, FG-vFG, strongly chloritic, weakly banded, VOL with strong Py and trace Po mineralization. Py is present as FG disseminations to bands and is a dull grey-yellow colour. Py mineralization generally increases with depth. Rock is weakly magnetic where Po is present. "Fuchsite" is present as bright green smears to blebs in rock. Rock is variable in hardness, at times harder than typical VOL (SIL alteration?) Bands of intensely altered SER VOL at times exhibit shear.									SER	s	i		t					x
																		CHL	s								
									Strong foliation defined by banding of Py and VOL layers, 45 degrees TCA.	FO	45																
									White, CG Ca veinlet, 1.8 cm wide, oriented 50 degrees TCA, 170 degrees to foliation.	VN	50	170															
			253.05	272.89	19.84	LST			Light to medium grey, deformed and bleached LST with intense, CG Qz-Po veining. CHL and TLC alteration are proximal to vein boundaries and exhib a sinuous, strained/sheared texture. Po is present as massive to fine grained crystals in veins and also as disseminations in host LST. Bright, euhedral crystals of Py overprint Po. Veins locally deform hos rock, LST exhibits strain and shear along vein boundaries. Chlorite becomes associated with Py mineralization with depth both in fractures and along Qz crystal faces. Where bleached, DOL altered LST exhibits moderate SIL alteration. Lower contact is gradational, Po mineralization becomes increasingly FG with depth over 30 cm.	CN				s				SIL	m	t	ms						x
																		TLC	f								
									FO is variable throughout, and is defined by strain fabric in banded and deformed LST. Where strain appears strongest, orientation of elongate BX clasts is 25 degrees TCA, and is 40 degrees TCA elsewhere.	FO	40																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			296.98	305.30	8.32	LST	DOL	BX	White to medium grey, FG, cBX and variably strained DOL altered LST. cBX appears to rebrecciate a pre-existing sBX texture. Trace OX alteration occurs on fracture faces. Trace Py is present as bright, whitish-yellow FG-MG crystalline disseminations. This mineralization is hosted within 45 cm of the lCN. A crinoid fossil occurs at 305.30 m. lCN is sharp over a few cm, recrystalization is gradational over 5-6 cm.	CN				i		t												x
									FO is weakly defined by BX clast orientation and strain fabric, 45 degrees TCA.	FO	45																
			305.30	307.05	1.75	DOL	MX	CG	White to medium grey, CG dolomite with strong FG Py mineralization as wisps to narrow bands. Py is grey-yellow and has a dull lustre. The DOL exhibits hydrothermal crystal texture throughout. Trace angular vugs ~1-2 mm in size are present. Weak OX alteration present on fracture faces.					i					s								x
									Defined by Py and weak DOL bands, 40-45 degrees TCA.	FO	40																
									Py veinlet is 3 mm wide, hosting 1-3 mm cubes of bright, whitish-yellow Py, oriented 10 degrees TCA, 20 degrees to FO.	VN	10	20															
			307.05	308.04	0.99	SHL	BK	FG	Black, FG shale with fair Py mineralization within veinlets to trace <1 mm disseminations with depth. uCN and lCN are sharp, 40 degrees TCA for uCN, 50 degrees TCA for lCN.	uCN	40									f						
										lCN	50																
									White-yellow, FG Py veinlet, 5 mm wide, oriented 60 degrees TCA, 0 degrees to FO.	VN	60	0	2														
									White-yellow Py veinlet, blebby in texture, 1-4 mm wide. Crosscut by veinlet below.	VN	20	0	1														
									1 mm wide, white-yellow FG Py veinlet oriented 80 degrees TCA, 180 degrees to FO. Veinlet crosscuts above veinlet oriented 20 degrees TCA.	VN	80	180	1														
			308.04	309.51	1.47	DOL	MX	CG	Medium grey to white, MG to CG, banded DOL with intense Py mineralization. Py is present as FG, white-yellow <1 mm to 2 mm sized crystals, forming small masses to bands. Qz is locally associated with Py mineralization, as the Py defines a 34 cm wide selvage of a narrow Qz veinlet. Trace angular vugs present in DOL.					i					20								
									Defined by Py and DOL bands, oriented 45 degrees TCA.	FO	45																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									Translucent-white Qz veinlet with trace creamy Ca and FG bright Py, oriented 60 degrees TCA, 320 degrees to FO. Vein selvage is intensely pyritic, up to 24 cm from veinlet boundary. Vein selvage is oriented perpendicular to Qz veinlet orientation.	VN	60	320	2														
			309.51	320.34	10.83	LST	DOL	BX	Light to dark grey, FG, intensely DOL, variably strained cBX LST with deformed shale interbeds containing Py. The cBX texture exhibits strain, as do fabrics in the FG interbeds. Strain increases with depth, cBX matrix begins to appear as near stylolitic, dissolution textures. Py occurs as FG-MG bright white-yellow, euhedral "shotgun" masses preferentially within the dark shale interbands and the dark FG LST clasts.					i		f				w							
									FO is defined by dissolution bands and BX clast orientation, 40 degrees TCA.	FO	40																	
									DOL-Py veinlets, 2-3 mm wide are oriented at 70 degrees TCA and 90 degrees to FO.	VN	70	90								i							
									Translucent, white, CG Qz veinlet ~17 cm in width with trace bright yellow 2-3 mm Py blebs are oriented parallel to FO.	VN	40	0								t							
			320.34	322.95	2.61	DOL	MX	SP	White to medium grey, MG-CG, crystalline dolomite with bands to near masses of bright yellow Py crystals, <1 mm to 3 mm in size. Trace sparry vugs occur within, and weak OX alteration is present on some fracture surfaces.					i		w				20							
									Foliation is defined by Py and DOL banding, 50 degrees TCA.	FO	50																	
									Rusty red-brown, extremely vuggy to pitted, 6 cm wide SID veinlet with grey LST clasts, oriented 50 degrees TCA and 130 degrees TFO.	VN	50	130															x
			322.95	326.09	3.14	LST	DOL	BX	Light to medium grey, FG, intensely DOL cBX LST with trace Py disseminations throughout as bright yellow, <2 mm subcrystaline blebs.					i					t							
			326.09	333.36	7.27	DOL	MX	CG	White to medium grey, MG-CG crystalline DOL with FG, greenish-yellow, dull, FG Py in bands 2 mm to 2.5 cm in width. Trace vugs are present in CG crystalline dolomite. Interval exhibits "East Zone" textures and mineralization.																		
									FO is defined by Py and dolomite banding, oriented 50 degrees TCA.	FO	50																	

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other	
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			333.36	353.83	20.47	LST		BX	Light to dark grey, FG, intensely DOL, variably BX LST hosting CG Qz veining. cBX overprints a varying sBX texture up hole with sBX texture increasing with depth. Translucent white Qz veining is CG with trace Ca and trace TLC alteration. Talc often as radiating fibers (alteration of tremolite?). Bright, crystalline white-yellow Py is associated with Qz veins and selvages, as rims around dark, FG LST breccia clasts, and trace disseminations throughout. Qz veining occurs at different orientations (25 degrees to 90 degrees TCA) and widths (6 mm to ~65 cm) but vein mineralogy and texture appear homogenous throughout.					i				TLC	t	ms			Qz	i			
									FO is defined by strain fabric/dissolution bands and BX clast orientation, ranging from 35 to 70 degrees, but generally 50 degrees TCA throughout.	FO	50															
			353.83	354.79	0.96	LST	DOL		Light to dark grey, FG to CG, intensely DOL altered, matrix supported clastic LST (debris flow-like in texture). Dark, angular to tabular, FG LST clasts supported by a light to medium grey matrix. Trace Py is present as bright yellow, FG cubes associated with a narrow, sinuous Ca stringer.					i						t							
									Foliation is defined by "bedding" of debris flow and MG to CG clast orientation, 40 degrees TCA.	FO	40															
									White, 1-2 mm wide dolomitized veinlets cross cutting "debris flow" texture at 30 degrees TCA and 270 degrees to FO.	VN	30	270	2													
			354.79	357.30	2.51	LST	DOL	BX	Medium to dark grey, FG, intensely DOL, cBX LST hosting "shotgun"-like Py mineralization. BX clasts exhibit a strain fabric. A preferential orientation/elongation is also exhibited. Py is present as white-yellow, <1 mm to 3 mm euhedral crystals forming narrow 2 mm wide bands to larger "shotgun" masses. Trace CG Qz (veinlets?) are associated with strongly pyritic rock.					i		t				ms							
									FO is defined by BX orientation and weak banding, 50 degrees TCA.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Other Type	Other Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Other Type	Other Intensity	Other Type	Other Intensity	
			357.30	359.45	2.15	LST	DOL	BX	Medium to dark grey, variably BX, variably recrystalized, intensely DOL altered LST with trace crinoid fragment fossils. Moderate-strong Py mineralization is present throughout as, FG, greenish-yellow, dull Py forming small blebs to 3.5 cm wide bands mainly occurring where dolomite is CG. Bright, white-yellow <2 mm cubes of Py is present in un-recrystalized, dark BX LST (P2 vs. P3?) Trace orange to rusty red OX alteration is present on fracture faces. (Rock appears near "East Zone" w/ variable, CG hydrothermal dolomite, interval may exhibit facies change to East Zone mineralization.)					i		t				ms							x
									Foliation is defined by Py and weak banding in dolomite, 40 to 50 degrees TCA.	FO	45																
									Oxidized, Ca veinlet, 2 mm wide and oriented 25 degrees TCA. Orientation to FO undeterminable.	VN	25	n/a															
			359.45	379.48	20.03	LST		BX	Light to dark grey, FG to CG, intensely DOL altered, variably strained, sBX LST with trace bright yellow FG to MG Py. Py mineralization forms small masses to deformed bands rimming strained FG LST clasts. BX is variable throughout, but typically see dark clasts supported in a white to light grey, CG matrix. Fine cBX is seen overprinting sBX. Strain is exhibited by deformed FG clasts/interbeds. Trace SID alteration is present on fracture faces as maroo to rusty orange-brown crystals don't fizz unless scratched. Strain decreases with depth.					i						t							
									FO is defined by strained BX, 40 to 50 degrees TCA.	FO	45																
			359.60						Narrow 2 mm wide, vuggy, maroon siderite veinlet at 359.60 m, oriented 30 degrees TCA and 270 degrees to FO.	VN	30	270															
			379.48	382.20	2.72	LST		RB	Rusty brown to medium grey, intensely SID to OX altered, faulted FG LST. Core appears blocky to rubbly, clast size down to ~1 cm. Poor recovery throughout, drillers encountered two 1 foot deep voids @ 379.48 and 380.70 m. Fractures are oriented preferentially at 50 degrees TCA.	FT				s		s	s

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			382.20	393.29	11.09	DOL		CG	Dark to light grey, variably brecciated and strained, FG to CG, variably hydrothermal dolomite with weak Py MX. A relict LST BX texture remains exhibiting partial dolomite (hydrothermal) recrystalization to complete, recrystalization intensity increases with depth. Sparry textures occur where recrystalization is most intense. Py is present as FG, greenish-yellow wisps to small masses rimming darker BX clasts. A brighter, weakly crystalline, white-yellow Py phase overprints duller FG Py as euhedral replacements ~3 mm in size. Trace TLC alteration occurs. Trace crinoid fossils are present in relict LST. Strain deforms BX clasts with depth. ICN is sharp between DOL and the lower LEP , oriented 80 degrees TCA.	ICN				i				TLC	t	w							x
									A weak FO is defined by strain fabric, 20 to 40 degrees TCA.	FO	35																
									Light grey, FG dolomite veinlets, 1.1 cm wide, crosscut BX textures.	VN	50																
393.30	408.43	15.14				LEP		MO	Brown, mottled, FG, variably strained calcareous LEP, with FG, noncalcareous interbeds intermittent throughout. Py and Po are present, Py as FG vein-like masses to narrow, Ca-Py veinlets with MG, bright yellow cubic/dodecahedral Py crystals. Po overprints FG Py masses, in Ca-Cl-Po veinlets throughout, and as FG disseminations throughout.										w		ms						x
									FO is weak, defined by strain fabric orienting BIO altered mottled texture. The angle is shallower where strain increases. Orientation is generally 30 to 50 degrees TCA, but is seen as low as 10 degrees.	FO	40															
									Ca-Po-Py-Qz-Cl veinlets sharing a common orientation are present, frequency of veinlets increase with depth. Widths range from 0.7 to 2.1 cm, but generally around 0.9 cm wide. Bright yellow, euhedral MG Py and bronzy euhedral Po are seen in veinlets.	VN	60	90	1													
									408.43 m - EOH The hole was ended because it was past targeted the targeted East Zone and into the LEP.																	

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

COMMENTS

The hole was ended because it was through the targeted oxide and into the marble.

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	3.66	3.66				OVB			Overburden - no recovery																		
3.66	31.00	27.34				LST	MBL		White to medium grey, FG to vCG, fair to intense MBL LST. The interval is very broken with zones of orange-brown altered VOL, and a surficial orange brown coating on broken surfaces throughout the interval.																		
			3.66	6.34	2.68	LST			Medium grey, FG, foliated LST with fair MBL alteration. Ca blebs have been elongated by the strain. Light brown alteration occurs in layers and patches throughout.	FO	55																
			6.34	7.72	1.38	LST	VOL		Dark grey VOL rich LST with orange brown alteration patches. The interval is rubbly and fizzes with 10% HCl. Portions of rubble break along FO, with a sheen on broken surfaces.																			
			7.72	7.95	0.23	OX	VOL		Light orange-brown clay to rubble, incohesive, doesn't fizz. Rubble has planar shape.							m											
			7.95	9.14	1.19	LST	OX	RBL	Medium grey variably rubbly LST. The rubble ranges up to ~6 cm sized fragments, with medium brown clay to silt sized intervals throughout. Some VOL rubble is mixed within toward end of interval.							f											
			9.14	10.10	0.96	OX	VOL		Orange brown non-calcareous clay to grit, that is incohesive to semi-cohesive. Grit is more planar.							i											
			10.10	11.37	1.27	VOL	SER		Light yellow grit to rubble that is semicohesive and planar. Dark orange-brown layers of clay to silt is concentrated in the last 10 cm.							m		SER	i								
			11.11	11.25	0.14	QZ	GRT		Quartz rich interval, light grey to black rubble up to 5 cm in diameter.																		
			11.25	15.24	3.99	LST	MBL	RBL	Light grey, strongly to intensely MBL medium grained limestone. The Fo is defined by medium grey layers of stringers which appear overprinted. The interval overall is very rubble.	FO	45																
			15.24	16.26	1.02	OX	VOL		Medium orange-brown non-calcareous clay to sem cohesive core which flakes easily and has a green-grey sheen its surface.																		
			16.26	18.28	2.02	LST	OX	RBL	White to black, vCG Ca with a wispy lineated texture on core surface and <5 cm rubbly sections o orange-brown clay within the LST rubble.																			
			18.28	31.00	12.72	LST	MBL		Light to medium grey, very rubbly, moderately to intensely MBL limestone. FO is defined by dark bands. Patches of MG white/dark grey spotted Ca, elongate along FO. Orange brown clay and silt thinly covers fractured surfaces and forms intervals up to 5 cm thick.	FO	50																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			81.87	82.47	0.60	OX			Cohesive core to rubble, red to orange brown. Light orange ~0.5 cm angular patches in black matrix; remnant mBX? Metallic sheen on surface of core.							s	s										x
			83.82	83.92	0.10	QZ			Qz and MG light yellow, very reflective platy mineral (Mica) on surfaces of medium brown to black SID rich RBL.							s	i									
			86.78	91.60	4.82	OX			Light orange-brown to light yellow, clay to solid core ~50% solid core locally indenifiable as SER VOL, with pervasive OX and SID alteration. Gradational uCN.							s	s									
			91.60	96.89	5.29	OX			Very light yellow-beige, clay to grit. Predominantly clay. Holds core shape, but squishes easily. Toward end of interval, appears to have relict FO defined by dark brown bands of grit which are more competent than the surrounding yellow clay. Core preferentially fractured along FO. Planar habit of clay on broken surfaces and high Ti and K on XRF indicate VOL origin. lCN gradational, with the appearance of dark red-brown layers and spotting. uCN is sharp.	FO	35					i										
			96.89	97.54	0.65				Light orange-brown clay to rubble, predominantly clay. Light to dark red-brown spots within core.							i										
			97.54	109.57	12.03				Orange-brown and black clay to unbroken core. Clay rich zones more orange brown, while rubble and core largely black with trace grey coating. Medium green-grey colour seen on broken surfaces.							s	i									x
109.57	115.82	6.25				MBL			White, MG, with orange brown clay to grit layers ~ 4 cm thick. Medium brown to dark brown stringers and alteration patches.																	
									115.82 m - E.O.H. The hole was ended because it was through the targeted oxide unit and into marble.																	

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

COMMENTS

The hole was ended because it had past the targeted East Zone mineralized dolomite.

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other	
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	3.96	3.96				OVB			Overburden - no recovery.																		
3.96	102.74	98.78				LST		FG	Dark to medium grey, variably strained, variably BX, variably FOS, FG LST with FO angles shallow to CA, generally steepening with depth. Trace marbleization increases with depth. Py mineralization is present only at trace levels, generally as FG associations/overprints of dark, FG LST.							t		MBL	t	t							
			3.96	13.40	9.44	LST		FG	Dark to medium grey, FG, variably strained weakly FOS LST. Foliation parallel to sub parallel to CA, with a wavy, sinuous fabric throughout. Core is blocky with trace OX alteration on fractures to 13.40 m.							t											
			13.40	53.48	40.08				Dark to medium grey, FG, variably strained weakly FOS LST. Foliation parallel to sub parallel to CA, with a wavy, sinuous fabric throughout. Trace FG, dull, Py is seen rimming dark "BX" clasts. Trace amounts of fossils present, crinoids and coral fragments make up less than 1% of rock. At times, coral fragments appear deformed by stain.										t							
									FO is variable, wavy to planar in appearance, 0-30 degrees TCA, but is generally oriented 15 degrees.	FO	15															
			53.48	62.72	9.24	LST	FOS		Dark to light grey, FG to CG, FOS LST becoming crinoid wakestone in composition. Where most fossiliferous, rock is locally 30 to 50 % fossil fragments, but generally 15-20 % throughout. Strain is variable, foliation and strain fabric appear steeper to CA than in rock above. Fossils generally appear unstrained, FG interbeds most readily exhibi strain and deformation. Trace Py is present as brigh cubes <1 mm in size to darker, dull FG rims around FG LST.										t							
									FO is generally 50-60 degrees in dark, FG interbeds, but sometimes approaches 0 degrees TCA in zones exhibiting high strain.	FO	50															
			62.72	77.26	14.54	LST	BX	FG	Dark to light grey, FG, variably BX, weakly FOS LST. Strain is variable throughout, fabric becoming near stylolitic bands. Trace MBL alteration with depth. Trace deformed crinoid and tabular coral fossils present, <1% of total rock material.									MBL	t							
									FO is generally 50-55 degrees TCA, but can appear shallower where strain is apparent.	FO	50															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			77.26	82.52	5.26	LST		BN	Medium to dark grey, FG LST, moderately banded with dissolution bands and stylolites, which are generally preferentially oriented. Moderate MBL alteration is present, some rock appearing sucrosic in texture.									MBL	m								
									FO is defined by stylolites and dissolution band orientation, 45 degrees TCA.	FO	45																
			82.52	88.04	5.52	LST	MBL	BN	Light to medium grey, moderate-strong MBL altered banded LST with linear dissolutions to sinuous stylolites. Trace OX is present on fracture faces. Trace Py is present in dark, FG bands (lime mudstone interbed?) as dull, grey-yellow blebs, 1-3 mm in size.							t		MBL	ms	t							
									Strong FO defined by MBL banding, 45 to 55 degrees TCA.	FO	50																
			88.04	97.89	9.85	LST	FOS		Light to medium grey, FG, strained LST exhibiting dissolution textures throughout. FG, dark, tabular to needle-like, FG to MG crystals are present in FG, medium grey LST (andalucite?), 1-3 mm in length. Where strongly fossiliferous, rock becomes crinoid wackestone in composition. ~10% of rock is made up of coral and crinoid fragments.																		
			97.89	100.63	2.74	LST	MBL	BX	Medium to dark grey, cBX, moderately-strong MBL altered LST exhibiting sucrosic recrystalization of lighter LST BX clasts. MBL alteration increases with depth. Strain is variable, deforming BX clasts to exhibiting dissolution textures.									MBL	ms								
									FO is strong, 45-50 degrees TCA, defined by strained BX fabric and dissolution bands.	FO	45																
			100.63	102.74	2.11	LST	MBL	BN	Light to medium grey with dark bands, strongly MBL altered LST appearing sucrosic in texture. MBL increases with depth. Band frequency decreases with depth from ~1 mm apart to 2.1 cm with depth. Trace OX alteration is present on fracture faces. lCN is gradational over 15-20 cm.	lCN						t		MBL	s								
									FO is strong, defined by banding and oriented 50 degrees TCA.	FO	50																
102.74	103.30	0.56				MBL			White, "Italian" marble with trace green-grey faint bands oriented 30 degrees TCA, and 90 degrees to FO. Trace rusty orange OX alteration is present on fracture surfaces. lCN is sharp, oriented 50 degrees TCA, defined by narrow, dark Py band. Trace amounts of andalucite(?) are present in marble proximal to lCN.	lCN						t												

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other	
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
103.30	108.91	5.61				DOL	MX	CG	White to medium grey, crystalline CG DOL hosting banded Py "Tiger Zone" mineralization. Weak ANK is present as creamy yellow replacements(?) to weak bands throughout. Py is present as FG, dull greenish-yellow bands to narrow masses preferentially oriented, to bright, yellow, euhedral to subhedral blebs overprinting duller, FG Py. (P2 and P3?) The bright Py also forms bands oriented perpendicular to FO. Trace amounts of Po are present overprinting FG Py.												s		t					
									FO is defined by Py and DOL banding, 35-45 degrees TCA.	FO	40																
									Dull, greyish-yellow Py, variably exhibiting replacement by bright yellow CG Py in "veinlets" oriented 45 degrees TCA, 180 degrees to FO. Veinlets are 0.7 to 1.4 cm wide, at times veinlets feature a coarse grained white dolomite selvage up to 2.5 cm from veinlet.	VN	45	180															
108.91	117.48	8.57				VN	MX	CG	CG Po-Py-ANK-DOL vein, appearing variably vuggy in ANK-DOL crystallization and variably pitted in some zones of Po-Py mineralization. A fault is present from 111.29 to 112.30 m, with strong OX alteration, LST BX blocks, rubble and poor recovery along fault. Py is present as CG, bright yellow euhedral to subcrystalline overprints of Po. Po is present as massive veins and bands. Trace Sp is present in narrow Ca-Sp veinlets to disseminations in as coarse, red crystals with vitreous lustre. Trace Gn is associated with Sp, exhibiting a "rotten egg" smell when exposed to 10% HCl. Trace MG grey silver As disseminated. *110.05 to 110.77m, pitted Py and Po, sample number I075716	FT												s	t	i	Sp	t	Gn	t	
									Narrow, Ca-Sp veinlets oriented 50 degrees TCA, 3 8 mm wide hosting toothy Ca and CG red Sp crystals and crosscuts veining and mineralization mentioned above.	VN	50	n/a															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

117.48	127.15	9.67				VOL		AM	Brown to olive green, variably AM, intensely SER altered, variably strained VOL hosting cubic Py crystals exhibiting dissolution. Amygdules exhibit deformed, irregular shapes throughout and are infilled with CG Ca. uCN is gradational, intensely SER altered and sheared and exhibits a deformed texture throughout. lCN is gradational with sinuous, dull Py blebs and bright, CG Py forming bands to bright yellow blebs, trace Po and is strongly SER to bleached in appearance. *119.10 to 120.74 m, pitted Po and Py, sample #I075724	CN								SER	i	w		t					
									FO is defined by strain fabric and elongate amygdules, oriented 40 degrees TCA.	FO	40																
									2 CG Rhodochrosite-Ca-Py veinlets, oriented 40 degrees TCA and 0 degrees to FO, 1.9 cm and 1.2 cm wide.	VN	40	0															
									6 cm wide, orange stained band of VOL with CG, anhedral Po crystals <2.5 cm in size. Band is oriented 50 degrees TCA and 90 degrees to FO.	VN	50	90															
127.15	242.95	115.80				LST	DOL	BX	Dark to light grey, FG, intensely DOL LST, variably sBX to cBX and variably strained throughout. Trace OX alt associated with fractures. TLC alteration is associated with mineralized veins within DOL LST, at times appearing bleached.					i	t	t		TLC	t	t		t					
			127.15	148.24	21.09	LST	DOL	BX	Light to medium grey, FG, cBX LST overprinting sBX, generally bleached in appearance with trace TLC alteration from mineralized veins present in sub interval. OX alteration is fair, and increases with depth approaching a fault below. A strain fabric appears to orient the cBX texture.					i	t	f		TLC	t	f		w					
									FO is defined by dissolution bands and cBX orientation, 80 degrees TCA.	FO	80																
			134.00	134.39	0.39				CG Py-Po-Ak vein, exhibiting hydrothermal, CG crystals and vugs containing intense Py with strong Po mineralization. Vein selvages which bleach the host rock are wide and contain trace TLC alteration. Trace Cl stringers are present throughout vein selvages.	VN	50									i		s					
									Bright yellow, metallic, CG Py and trace CG Bs and Cl veinlets, 2 oriented approximately 60 degrees TCA with moderate TLC alteration of vein minerals and in vein selvages. The 2 Py veinlets are 4.1 and ~19 cm wide.	VN	60									80			Bs	t			

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			148.24	154.61	6.37	LST	DOL	RBL	Rusty brown to medium grey, FG, rubbly to competent blocks of strongly OX altered DOL LST. (Fault?) Trace CG, rusty yellow micaceous crystals are present on some fracture faces (phlogopite?) .	FT						s											
			154.61	212.38	57.77	LST	DOL	BX	Medium grey to white, FG to CG, intensely DOL altered sBX LST. Darker, FG LST clasts are supported by white, CG breccia matrix. cBX overprints sBX textures increasingly so with depth. OX alteration is strongest where rock is highly fractured. Trace FG interbeds lacking sBX texture are intermittent, and at times exhibit "camo" mottled textures.					i		m												x
									FO is defined by dissolution textures and BX clast orientations and is generally weak throughout, oriented at 70 degrees TCA.	FO	70																
			212.38	242.95	30.57	LST	DOL	BX	Dark to medium grey, strongly strained, mBX to cBX, moderately strong DOL altered FG LST. BX clasts exhibit an undulose strain fabric where strain is highest. Weak banding occurs. BX decreases with depth and rock becomes more calcareous with depth. Weak Py mineralization is present as yellow, tabular blebs within Ca filled fractures in dark, FG LST and as FG disseminations in vein selvages.					ms							w							
									FO is 60 degrees TCA, defined by strain fabric and weakly banded texture where present.	FO	60																
			234.40	242.35	7.95				Intermittent CG Qz-Py-Po veining with strong TLC alteration of veinlet minerals and within veinlet selvages. Py overprints Po where both are FG to CG. In veinlet selvages, Py is present as FG, dull greenish yellow <1mm wide bands to masses, and as bright yellow MG euhedral overprints of greenish Py. (P2 and P3?) Coarse grained vein Py appears greenish yellow, with a bright lustre. Some coarse grained DOL recrystalization (hydrothermal?) is present from 241.25 to 241.60 m.	VN	n/a	n/a									f		w					

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
242.95	248.44	5.49				VOL	SER	BN	Olive green to dark green with bronze coloured bands, FG banded, intensely SER altered VOL with strong Po and fair Py mineralization. CG Qz-Po-Py veins are present. Strain is exhibited variably throughout, some SER rich bands appear weakly sheared. Po is present as FG, wispy bands within VOL to large masses associated with Qz veins. Py is present as bright, euhedral crystals with vein selvages forming "shotgun" masses. At times Py overprints Po. VOL lacks fuchsite.										SER	i	f		s						
									Strong FO is defined by banding, oriented 35 degrees TCA.	FO	35																
									CG white Qz veinlets with Po and Py MX, locally deforming VOL along veinlet boundaries. Po is present as large masses, Py appears as overprints to "shotgun" masses in veinlet selvages. Veining in VOL appears homogeneous with veining in LST above.	VN	n/a	n/a															
									Narrow 2 mm wide Po-Py veinlet oriented 45 degrees TCA and 0 degrees to FO, coarse Py overprinting Po.	VN	45	0															
									Narrow, 3 mm wide Po-Py veinlet, oriented 50 degrees TCA and 180 degrees to FO, contains coarse Py overprinting Po.	VN	45	180															
248.44	334.04	85.60				LST	DOL	MX	Dark grey to white, variably BX, intensely DOL altered LST with intermittent and irregular horizons of mineralized hydrothermal CG dolomite. OX is fair throughout, locally strongly associated to structures in the rock. Py is present variably throughout. Where crystalline, CG dolomite exhibits a weak sparry texture.					i	t	w				w		t						
			248.44	256.40	7.96	LST	DOL	BX	Dark to light grey, variably strained, intensely DOL altered cBX LST with minor FG interbeds. Py is present as shotgun masses associated with Qz veining, as a dull, FG phase and another brighter, more coarse Py phase. Trace Po mineralization and moderate TLC alteration are associated with Qz veining. About 30% of interval is made of Qz veins.					i				TLC	m	s		t						
									A weak FO is defined by orientation of FG interbeds and cBX orientation, 70 degrees TCA.	FO	70																
									Qz-Po-Tc veining, with different orientations and widths throughout, hosting CG to FG Po blebs. Py is present as CG, bright "shotgun" masses.	VN	n/a															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			264.05	273.63	9.58	VN	MX		Massive, grey-greenish yellow, metallic Py vein with trace Qz. Py is MG, euhedral 1-3 mm crystals, and exhibits a metallic lustre on yellow crystal faces. lCN and uCN are sharp, Py vein overprints crystalline dolomite above and cBX DOL altered LST below. The cBX texture is visible below 271.99 m.	CN				m						75							
									FO is between 50 and 60 degrees TCA, defined by preferential fracturing in Py vein, and orientation of BX texture where present.	FO	55																
			273.63	274.62	0.99	LST	DOL	BX	Light to medium grey FG, intensely DOL altered cBX LST with weak Py MX. Py forms bright yellow-white blebs to <1 mm disseminations. Strain is variable, BX clasts and fabric appear undulose at times, increasingly so with depth. Trace OX alteration is present on fracture surfaces. lCN is gradational over 8 cm.	CN				i		t				w							
									Weak FO is defined by preferential fracturing and BX orientation, 50 degrees TCA.	FO	50																
			274.62	277.08	2.46	DOL	MX	CG	White to rusty yellow to medium grey, CG DOL and ANK with Py in thin bands. DOL and ANK exhibit coarse, recrystallized, weakly sparry texture (hydrothermal recrystalization?). Py in places has a pitted/vuggy texture. Py appears as dull grey-yellow, FG bands with weak to moderate bright yellow euhedral MG Py overprints. The unit is strongly oxidized with a rusty brown colouration on fracture faces and staining/overprinting dolomite and ankerite.					i	f	s				ms							
									FO is defined by banding in Py and DOL/ANK, oriented 45-50 degrees TCA.	FO	45																
			277.08	280.50	3.42	LST	DOL	BX	Dark to light grey, FG to CG, intensely DOL cBX LST, that is weakly fossiliferous with trace crinoid stem fragments. The interval becomes slightly bleached with depth. Weak Py occurs as white-yellow, euhedral to subhedral blebs to FG disseminations throughout the dark LST. Trace OX alteration is present on rusty fracture surfaces.					i		t				w							
									FO is defined by BX orientation, 50 degrees TCA.	FO	50																
			280.50	282.72	2.22	DOL	MX	FG	Light grey (bleached?) FG DOL, weakly cBX, with banded Py. The Py is FG-MG, dull grey blebs forming bands that follow fractures without a common orientation. The interval is variably OX altered, appearing rusty in colour where strongest.					i		s				s							

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

									Lack of foliation	FO	n/a																
									Narrow, <3 mm wide, rusty brown, toothy, weakly calcareous veinlets run parallel to one another and are oriented at 25 degrees TCA.	VN	25																
			282.72	283.31	0.59	LST	DOL	BX	Dark to light grey, FG, intensely DOL cBX LST with trace white-yellow Py. Py is present as subhedral disseminations, increasingly in concentration with depth.					i		w				t							
									A weak FO is defined by the crackle orientation, at 60 degrees TCA.	FO	60																
									Narrow, rusty brown, CG, calcareous veinlets, oriented 35 degrees TCA, 0 degrees to FO.	VN	35	0														
			283.31	287.90	4.59	DOL	MX	CG	White to medium grey, CG, weakly sparry DOL with strong Py MX. Py is present as FG, dull grey-yellow bands 2 mm to 1.2 cm wide throughout, to bright masses with depth. TLC alteration increases with depth.					i				TLC	w	s								
									FO is defined by Py and DOL bands, 50-60 degrees TCA.	FO	55																
			287.90	294.08	6.18	LST	DOL	BX	Light to dark grey, FG, intensely DOL altered cBX LST hosting strong Qz veining. TLC alteration is associated with Qz veins. Py is present as FG, sinuous bands to blebs weakly "East Zone" in appearance to MG, bright white yellow "shotgun" masses associated with Qz veining.					i				TLC	ms	ms		t						
			291.00	292.39	1.39				CG, white Qz-Ca vein with narrow, white, CG Qz veinlets proximal to main vein. Strong TLC alteration is present along vein selvages with Py as dull, grey-yellow MX and bright MG Py shotgun blebs. Bleaching of host rock occurs below the vein for 2.5 m. Narrow Qz veinlets are homogeneous in mineralogy and appearance to main vein.	VN	n/a																
			294.08	303.79	9.71	DOL	MX	CG	Orange grey to white, CG recrystallized, variably vuggy dolomite with mod-strong Py MX. DOL is variably stained a rusty colour. Py is present as dull grey-yellow FG blebs to bands with a weak common orientation, to trace "shotgun" textures. OX alteration is mod-strong giving fracture faces a brigh orange to red colour.					i	w	s	f			ms								
									Weak FO is defined by weakly oriented Py bands, ~50 degrees TCA.	FO	50																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			303.79	309.81	6.02	LST	DOL	BX	Dark to light grey, FG, intensely DOL, strongly OX, variably BX LST. CG translucent grey Qz and rusty orange DOL (SID? ANK?) veinlets are present. Dull, MG masses to "shotgun" blasts of Py are found on veinlet selvages. Some rusty-orange fault gouge is present at 304.39 m.					i		s				ms							
									A weak FO is defined by weak BX texture, oriented 50 degrees TCA.	FO	50																
			304.29						CG Qz-Dol veins, proximal to fault gouge. Veinlets are extremely OX (SID?) altered and share a common orientation 50 degrees TCA. Weak blebs of bright white-yellow Py are present on veinlet boundaries.	VN	50																
			304.29	306.50	2.21				CG white Qz veining of variable orientations and widths, is generally oriented 60 degrees TCA, 270 degrees to FO. Veining exhibits weak OX alteration and hosts strong grey-yellow masses of Py along vein selvages. Veining is strong below fault gouge at 304.29 m to 306.50 m.	VN	60	270															
			309.81	327.89	18.08	DOL	MX	CG	Light grey to rusty white, CG crystalline DOL, strongly OX altered with mod-strong Py mineralization. DOL is variably sparry, generally CG but exhibits MG-FG textures intermittently. Py is present as greyish yellow, dull FG blobs to sinuous masses to weak bands, at times appearing to overprint OX alteration. The Py occasionally exhibits a pitted texture. OX alteration is variable, form intense to trace. With depth, rock appears "Tiger Zone"-like, hosting banded Py and MG, euhedral As crystals forming aggregate blebs to bands <1.2 cm in width. Intense SID alteration is present at 318.00 m exhibiting a dark brown, rotted log appearance with smears of orange. A fault is present from 319.00 to 324.61 m, with associated intense OX alteration. FG dull greyish Py is disseminated throughout competent OX core with weak amounts of white Qz. As presence is below FT. Strong OX alteration persists below FT to lCN which is sharp and oriented 50 degrees TCA. Trace cBX texture is present above SID alteration and below FT appearing bleached and moderately OX altered.	FT				i		s	w			ms		t					
									FO is defined by weak banding in DOL, As and Py mineralization and cBX orientation, oriented 50-70 degrees TCA.	FO	60																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

SAMPLES

Numbers: I075977-I07026

Total: 50

Batch: 42, 43

Date Sent: July 16, 19 2010

Certificate: VA10098071, VA10098844

COMMENTS

The hole was ended because it was through the main oxide zone.

GEOLOGY LOG

HOLE: Rau-10-90

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	3.51	3.51				OVB			Overburden - no recovery																		
3.51	32.92	29.41				LST	MBL		Medium to light grey, FG, LST with fair to intense MBL altered zones and some rubbly intervals. FO is evident throughout. Medium brown to orange brown clay forms layers up to 12 cm long, sometimes with angular clasts of LST ~ 1 cm in diameter. Clay also coats rubble and fractures, increasing down interval.	FO	30					f											
			3.51	15.90	12.39	LST	MBL		Medium grey, FG to MG, marbleized LST with orange-white layers following FO. Fair MBL alteration occurs with zones ~ 4 cm wide of intense orange-white MBL. Thin black stringers define some sections of the FO. Less intensely marbleized intervals contain trace fossils.									MBL	m								
			15.90	20.14	4.24	LST			Medium grey, FO, FG to MG, LST with weak MBL alteration. Small white spotting may be fossils. Light brown alteration patches and layers follow FO. Small light green patches (SER) ~ 1-3 cm wide occur throughout. Trace disseminated dark brown, subhedral, MG cubes are likely altered Py.									MBL	w	t							
			20.14	23.77	3.63	LST	OX		Medium grey, FG to MG, FO, very broken up LST. The interval contains a moderate amount of orange-brown clay with layers up to 12 cm thick layer. Rubble is slightly elongate and appears to be controlled by FO and are coated in clay. Trace disseminated and oxidized FG-MG Py follows FO.							m				t							
			23.77	27.62	3.85	LST	MBL		Light brown-grey to white, FG to MG LST. Marbleization grades from intense to weak down interval, with a corresponding increase in light orange-brown alteration which occurs as stringers, patches, breccia matrix, and pervasive alteration. Overall the interval is rubbly, with light brown clay rich zones. Trace disseminated subhedral oxidized Py.							f		MBL	f	t							
			24.83	25.00	0.17	LST	sBX		Light orange-brown matrix, with ~0.5 cm subrounded LST clasts. Matrix amount and rounding gives a sBX appearance.																		
			27.54	27.62	0.08	LST	OX		Light brown with white spots ~0.5 cm in diameter that could be remnant fossils in light brown altered LST.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			27.62	28.00	0.38	LST			Dark grey FG, FO, LST with orange-brown alteration patches for the first ~20 cm. The remainder of the interval contains rubble patches up to 5 cm that are covered in orange-brown clay.																		
			28.00	32.92	4.92	LST			Light grey, FG to CG, moderately to intensely MBL LST. FO is defined by thin dark grey overprinted seams. Most of interval is rubbly with a light brown clay coating the broken core. Some cohesive core sections are strongly clay altered with remnant LST forming cBX texture.									MBL	m							
			28.00	28.07	0.07	Ca			vCG milky white Ca; VN or MBL.																		
32.92	71.72	38.80				OX			Bright to medium orange-brown with intervals of dark red-brown, light yellow, and blue grey clay to rubble.							i										
			32.92	35.42	2.50	OX			Bright red-brown to orange-brown mottled, clay to rubble, predominantly silt. Dark red-brown SID alteration in patches.							i	m									
			35.42	37.49	2.07	OX			Increased SID content. Dark red-brown to bright orange-brown mottled clay to core pieces, predominantly grit.							i	i									
			37.49	47.50	10.01	OX			Bright orange-brown with dark brown mottled zones, clay to rubble. Increasing SID rubble and colouration down interval.							i	ms									
			47.50	48.16	0.66	OX			blue grey and orange brown interlayered clay to grit rich in Qz (~10%). Have ~10 cm light orange-brown interval which grades into blue-grey interval from bright orange oxide.																		
			48.16	52.00	3.84	OX			Bright orange-brown clay to rubble, predominantly grit. Dark brown patches with sheen (SID) most prevalent in last 20 cm.							i	m									
			52.00	53.25	1.25	OX			Gradational zone between 2 units. Light orange brown clay to grit, with light yellow clay patches and blue grey clay to grit patches.																		
			53.25	55.64	2.39	Qz	GRT		Blue-grey clay to grit, predominantly clay. Very Qz rich (30%), sand sized, RBL up to 0.5 cm. ICN is light yellow for ~25 cm. Sharp contact between light yellow and orange brown OX at 30 degrees TCA.	ICN	30																
			55.64	57.30	1.66	OX	RBL		Dark red to medium orange-brown clay to solid core predominantly rubble. Dark red-brown SID rich zones.							i	m									
			57.30	59.20	1.90	OX			Medium orange-brown clay to rubble. 5 cm zone with darker red-brown colour and QZ rubble ~ 0.5 cm in diameter, followed by slightly green-grey tinting on core surface.							i											

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			59.20	59.77	0.57				Light yellow-beige clay to solid rock, largely RBL. Relatively unaltered pieces of core are hard, mediun green-grey, botryoidal, with a cherty sheen (chert/opal).																			x
			59.77	60.35	0.58	OX			Medium orange-brown clay to grit with light orange linear patches, and dark red-brown patches.																		
			60.35	62.62	2.27	Qz			Qz rich interval with rubble up to 3 cm thick and cohesive core, medium orange to light beige.																		
			62.62	63.00	0.38	OX	Qz		Medium orange-brown to dark brown clay to rubble, with Qz rich intervals up to 20 cm long, Qz pieces up to 4 cm in diameter. Qz composes ~ 2% of interval total.							i	f											
			63.00	65.96	2.96	OX			Medium orange-brown to dark brown clay to grit, and cohesive core. Relict FO defined by light yellow lineations. Dark red-brown spots (OX Py).							i	f											x
			65.96	68.76	2.80	OX			Medium orange-brown with light yellow-orange and dark brown patches. Gradational lCN							i	i	LIM	f								
			67.22	67.97	0.75	OX			Solid core strongly OX and SID altered and fairly LIM altered. Unaltered patches are green grey, shiny, platy SER altered and in dark red-brown crystalline rock.							s	s	LIM	f								
			68.76	71.72	2.96	OX	LST		Medium grey to orange-brown, MG, calcareous cBX LST, with black to orange brown cBX seams. Altered red (HEM) patches occur within. Zones of orange-brown altered solid core to clay. Some SID rich areas. Patches of SER alteration (VOL interlayers?).							ms	s	HEM	m								
71.72	72.39	0.67				LST	DOL	cBX	Medium grey FG to MG DOL LST, becoming more DOL rich down interval. Sharp lCN with CG DOL/ANK. Black stringers form cBX.	m																	
72.39	91.59	19.20				DOL	ANK		Medium grey to yellow and pink tinted white DOL with ANK and HEM alteration. MG-vCG DOL with CG crystals having medium grey rims giving a cBX like texture due to cataclasis. OX alteration is moderate to intense. Trace disseminated MG-CG Py increasing down interval. Trace patchy Ca veinlets.						i			HEM	ms									
			72.50	73.23	0.73	DOL	mBX		Up to 5 cm diameter FG dark grey angular LST clasts, with MG DOL matrix. DOL crystals locally appear to radiate from clasts. Trace MG disseminated OX Py.																			
			74.91	76.06	1.15	OX	DOL		Intense OX alteration and MS SID altered clay to predominantly solid core. Gradational uCN and lCN.							i	ms										
									Seams of FG medium grey Ca in CG Ca..	FO	55																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

									Cross-cutting very thin orange-brown Ca veinlet; appears to form along a preferential fracture angle.	VT	35	90															
			79.70	91.59	11.89	DOL	AK		Medium grey rims around crystals of DOL/ANK have blurred, overprinted appearance, sometimes absent.						i											
			81.69	82.53	0.84	OX	DOL		Dark orange-brown OX interval, with a sharp uCN. The upper rock is weakly to moderate-strongly oxidized. The lCN is sharp, planar, has FG Py patches, an uneven corroded core surface, and fair rubble.	lCN	20					s	ms										
			83.84	84.77	0.93	DOL	OX		MG grey to yellow and red tinted white DOL. Altered red-brown, silt to core. Rims of DOL veins preferentially altered, leaving DOL crystals with striated surfaces on core face.																			
			85.00	89.00	4.00	DOL	OX		Medium grey to yellow-white FG-MG DOL with orange brown clay to rubble in zones. Dark brown MG OX with disseminated Py. Dark brown stringers likely As rich (like bellow interval), no orientation.																			
			89.00	91.59	2.59	DOL	AK		FG-CG, yellow-orange and pink tinted white, DOL and ANK. Dark grey spots and stringers weakly cBX DOL in zones. Stringers are rich in dull grey As, that is FG-MG follow possible FO at 91 m.	FO	50				i						t							
									91.59 m - E.O.H. The hole was ended because it was through the main oxide zone.

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	16.05	16.05				OVB			Overburden - no recovery																		
16.05	99.67	83.62				LST			Dark to light grey, variably strained, variably fossiliferous LST, FG to CG throughout. FO angles are shallow and increase with depth. Rock is generally weak in fossils, but can be grainstone in composition where most fossiliferous. Trace Py is present as FG, dull disseminations <1 mm in size to sinuous, FG bands in dark, FG interbeds and calcareous veins. Dissemination textures increase with depth. Stylolites are present below 69.00 m.								MBL	t	t						
			16.05	27.89	11.84	LST	FOS	CG	Light to dark grey, CG LST (crinoid fragment grainstone) with FG, whispy bands of dark minerals ~1 mm wide hosting trace vFG Py. Core is blocky at top of the hole, becoming more comptent with depth. Unit gradationally lighter in colour down interval due to weak MBL alteration. Trace OX is present on fracture surfaces. lCN is sharp and undulose, oriented 15 degrees TCA.						w		MBL	t							
									FO is defined by weak banding, generally 40 degrees TCA, but occurs at shallower angles.	FO	40																
			27.89	65.75	37.86	LST	FOS	FG	Dark to medium grey, FG, variably strained FOS LST with an undulose, shallow strain fabric throughout. Fossils make up trace to ~50% of rock, becoming crinoid packstone in composition in narrow bands where most fossiliferous. Trace Py present as vFG disseminations to forming narrow, sinuous bands with dark, FG LST. Fossils present are crinoid fragments, tabular "honeycomb" favocitid coral framents, rugose, and rare "chain" halycitid coral fragments. Strain and associated dissolution textures increase with depth. Fossils exhibit deformation where strain increases.										t						
									An undulose, generally shallow FO is present, from 0 to 35 degrees TCA, generally ~20 degrees TCA, defined by strain fabric.	FO	20																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			65.75	83.23	17.48	LST		FG	Medium to dark grey, FG LST exhibiting strong dissolution textures and strain fabric. Sinuous, narrow stylolitic dissolution bands are found throughout, becoming more regular and uniform with depth. Trace fossils present in dark, FG, deformed interbeds. Relict fossil textures are obscured to obliterated. Trace Py is present as FG, sheared bands to vFG disseminations. Trace OX alteration occurs on fracture faces.							t					t							
									FO is defined by dissolution bands with variable orientations from 35 to 55 degrees TCA.	FO	40																	
			83.23	85.31	2.08	LST	MBL		Light to medium grey, sucrosic, fairly banded, moderate-strong MBL altered LST exhibiting undulose, narrow dissolution textures to planar marble banding.									MBL	ms								
									FO is defined by dissolution and MBL banding, 50 60 degrees TCA.	FO	55																	
			85.31	90.47	5.16	LST			Light to dark grey, variably strained, variably FOS, deformed LST. Interbeds of FG, dark LST occur throughout. The strain fabric is undulose throughout oriented shallow TCA.																			
									FO is defined by the undulose strain fabric, shallow to core axis, generally 20 degrees TCA, but as low as 0 degrees.	FO	20																	
			90.47	93.40	2.93	LST	FOS	FG	Dark to medium grey, FG, FOS LST becoming crinoid packstone in the most fossiliferous layers between FG bands (relict bedding?). FG layers exhibit a sinuous stran fabric, at times fossils appear weakly strained. 15% of rock is made up of fossils, crinoid stem fragments and a lone rugose coral. Weak OX alteration is present on fracture faces.							w													
									Foliation is strong, oriented 50 degrees TCA defined by banding (bedding?).	FO	50																	
			93.40	98.31	4.91	LST		FG	Dark to light grey, FG, deformed LST with FG-MG interbeds of LST throughout. Strain is exhibited in FG layers with a sinuous fabric, occasionally becoming near dissolution in texture. Trace crinid fossils are present.																			
									Foliation is defined by banding in rock, oriented 50 degrees TCA.	FO	50																	
			98.31	99.67	1.36	LST	MBL		Light to medium grey, sucrosic MG to CG, strongly MBL altered LST with dark bands that appear near stlyolitic to planar, "fuzzy" marble bands. LCN is gradational over 25 cm.	CN						s		MBL	s								
									A strong foliation is defined by banding, oriented 60 degrees TCA.	FO	60																	

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
99.67	101.99	2.32				MBL			White to light grey, sucrosic "Italian" MBL, with trace Py and As throughout. Py and As appear as blebs within veinlets within the marble. A prefferential fracturing with fair OX alteration seen along fractures is oriented 50 degrees TCA.							f				t	t						
									Foliation occurs at 50-60 degrees TCA, defined by weak banding and a prefered orientation in the marble.	FO	55															
									2 veinlets within the marble unit appear "Tiger Zone" in appearance, with CG white to grey DOL with FG Py blebs to near bands within vein mineralization. As is associated with narrow Py sinuous blebs-bands. Trace Sp is present along veinlet selvages.	VN	60	0								ms	f		Sp	t			
101.99	109.12	7.13				DOL	MX	CG	White to medium grey, CG, weakly vuggy DOL with CG As and intense FG Py mineralization. Py is present as FG, dull, green-grey masses 12 cm wide to narrow whispy bands 1 mm wide which locally overprint As. As is present as CG, bright, silver-white euhedral crystals appearing cracked. They form weak 1.5 cm wide bands to aggregate masses a few cm in size. Fair OX alteration is pervasive along fracture faces. The ICN is sharp, defined by DOL and CG Ca vein/BX matrix mineralization.							f				i	m		Sp	t	Gn	t	
									FO is defined by banding in Py, As and DOL, oriented 50 degrees TCA.	FO	50															
									CG, white Ca vein oriented 50 degrees TCA and 0 degrees to FO appearing vuggy, 3.3 cm wide hosting MG-CG Sp and Gn along vein selvages.	VN	50	0											Sp	t	Gn	t	
109.12	110.60	1.48				VOL		BX	White CG Ca, weakly vuggy BX with clasts of intensely SER altered VOL, DOL and Py MX throughout, appearing sBX in texture. (perhaps Ca vein?) DOL and VOL clasts are mineralized with FG red Sp bands to CG crystalline black and red Sp with trace Gn. Fair OX is present along fracture faces. Interesting Ca crystal habit is noted at 109.15 m.									SER	s	t			Sp	w	Gn	t	x

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	2.79	2.79				OVB			Overburden - no recovery																		
2.79	35.97	33.18				LST	MBL	BN	Grey to light grey moderately foliated, moderately fossiliferous and intensely marbleized limestone. Unit contains strongly foliated portions up to a mylonite texture. The unit is comprised of fossiliferous intervals up to crinoid packstones as well as interbedded lime-mud and crinoid packstones. Fossils present are Rugosans, Crinoid fragments, Halysities and Favosites.												n							
									The strain is most recognizable in the marbleized portions however other portions also show strain in the form of foliation, micro-folds, clast rotation and offset veins.	FO	30															
			20.73	31.39	10.66	LST			LST becomes more fine-grained, black and silty as well as slightly carbonaceous. Often 5 mm intervals of gouge occur in core fractures. This interval is more fractured than the other portions and is also less marblized but while retaining a dominant foliation.																		
									Small portions of weak oxidation staining the core a rusty-orange colour. Millimetre scale oxide veins cu perpendicular to foliation which here exhibits some chlorite within it.	ICN																	
									Foliation is defined by strain	FO	30															
									Thin<1 mm orange veins with calcite.	VN	35	180	2														
35.97	61.61	25.64				VOL	AM		Pale green to dark-grey to slightly brown amygdaloidal volcanic. AM's occur in the middle of the unit along with extensive calcite veining, all of which occur in a prominent foliation. The upper contact has no AM yet has elongated fine disseminated Po with calcite. Larger calcite veins are euhedral and are associated with Bs or tetrahedrite. Deeper green colours are associated with calcite veining within the VOL.													t						
									Foliation is defined by an elongation of Ca fillec amygdules.	FO	35																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			53.30	61.61	8.31	VOL	AM		Pale green to pale brown-yellow coloured, fine-grained almost clastic-like in appearance (possibly strained amygdale rich volcanic). Highly foliated and sericitized and has floating clasts of rounded limestone, from 1-10 cm. Upper contact has large bulbous 0 deg TCA Qz-Ca veining with cryptic cross cutting relationships. This volcanic is also very calcareous.	uCN								SER	i							
			54.00	54.10	0.10				Carbonaceous gouge	FT																	
									Thin, mm-scale calcite veinlets with sharp contacts.	VN	40	270	4															
									Coarse-grained grey-blue calcite cuts white calcite.	VN	30	0	2															
61.61	82.00	20.39				MBL	LST	BN	Grey to light grey, highly foliated, intensely marblized LST. The foliation is defined by various forms of dissolution seams.																		
									Intensely foliated ranging from single stylolites to anastamosing stylolites to well developed stylo-mottled. Relict pre-strain calcite veins are offset by annealed cm-scale shear planes.	FO	30																
									Broken core along foliation with oxidized gouge material in fractures. Also has abundant cBx textures in MBL.	UCN																	
82.00	161.15	79.15				LST			Dark to medium grey, fine-grained fossiliferous limestone with a strong foliation defined by strain. Dark grey and white spotted veining and blebs, sometimes with vertical white Ca spots. Thin white Ca veinlets generally follow FO. Light orange-brown alteration on fracture surface, veinlets and patches following FO, increases down interval, grading into pervasively altered zones. Trace FG disseminated Po is oxidized down interval following the FO and rimming veinlets.												t						
			94.81	98.62	3.81	LST		cBX	Increased dark grey-white spotted irregular veinlets and blebs form a cBX of the FG medium grey LST. FG dark grey stringers, slightly orange brown altered, cut spotted veinlets and follow FO. Blurred ICN.	FO	30																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			112.49	134.27	21.78	LST	VOL		Dark grey LST with increased orange-brown fg alteration with patches following FO. Alteration increases down interval, with strongest pervasive alteration of core at centre of interval. Orange-brown disseminated spots likely altered Po. Small zones break in platy manor, and SID alteration on fracture surfaces that is more common in platy zones. Very gradational uCN and lCN.	lCN																
			122.02	122.09	0.07				Approximately 7 cm thick Ca vein. Dark grey and white spotted layers and white Ca layers, with green-grey FG stringers . Vugs with round Ca precipitates, and SID alteration occurs in patches.								w									x
			134.27	139.96	5.69	LST	VOL		Dark grey FG LST with orange-brown seams of VOL following FO are very closely spaced (~ 0.5 cm apart). Very broken core, with fractures showing platy grey surfaces. Dark to light grey, MG, spotted layers are thinner than above and tend to follow the FO. Orange-brown alteration is pervasive in zones, increasing toward the lCN. Ca spots could be broken up fossils.	FO	65															
			139.96	142.95	2.99	LST			Orange-brown to medium grey, FO, VOL rich LST. Very broken and altered clay to rubble.																		
			142.95	154.78	11.83	LST			Medium grey, MG LST, with FG, medium to dark grey LST zones. Orange-brown and brown alteration layers are more prevalent in FG zones. Ca and Ca/Qz veinlets up to 3 cm wide occur throughout. Crinoids occur in trace quantities, while other white spots may be fossil fragments. Overall the interval is very broken.																	
			142.95	143.57	0.62	LST		cBX	FG to MG, overprinted cBX with thin dark grey stringers as matrix.																		
			144.21	145.90	1.69	LST			Light to medium grey overprinted coral fossil.																		
			154.78	161.04	6.26	LST	MBL		Light grey, MG , moderately MBL LST, with light orange brown altered patches and zones. Qz/Ca veins up to 2 cm thick cut at various angles TCA. Ca patches and intensely MBL zones ~ 4cm long generally occur near intense orange-brown alteration with thin black stylolites and FG disseminated mineral . Interval is very broken overall.	VN			2					MBL	m							x
			161.04	161.15	0.11				Medium grey clay to grit with subrounded LST rubble up to 1 cm. Possible Fault surface that forms the contact between the surrounding units.	FT	55																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

161.15	215.34	54.19				VOL			FG dark to medium grey or medium green-grey variably magnetic and calcareous, foliated VOL. Ca VT cut at various orientations. Overall the unit is very rubbly, with fractures occurring parallel to the foliation with minor gouge on their surfaces.																			
			161.15	162.31	1.16	VOL	Mg		Dark grey, magnetic, FG VOL with FG white Ca spots. First 15 cm has irregular Ca VT cut off along FO. Gradational lCN.	FO	45																
			162.31	167.28	4.97	VOL	Mg		Green grey, FG VOL with a gradational uCN and lCN. The units is very magnetic and has trace Py disseminated throughout. A Ca vein cuts at 70 deg to CA. The interval overall is quite broken, with <4 cm clay intervals.											t			Mg	ms			
									Ca VT set ~ 0.5 cm wide	VN	70	180														
			167.28	169.13	1.85				Dark grey, non-magnetic VOL with a gradational uCN. White Ca veins are concentrated in top 55 cm and generally follow the FO. The edges of the Ca veinlets are altered a light grey.																		
			174.34	183.65	9.31	VOL			Pale green to grey fine-grained volcaniclastic, with elongated clasts in a highly foliated-sheared magnetic matrix. uCN has 10 cm of coarse-rubble to gouge material.	uCN															Mg	f	
									Strain induced foliation.	FO	60															
									Calcite veins, 1 mm-1 cm with oxide staining, as well as many micro folds and annealed shear planes.	VN	60	0	3			w										
			183.65	187.50	3.85	CGL	Mg		Moderate to weakly magnetic grey to pale greer pebble conglomerate, with elongated 2 cm rounded clasts. Magnetite occurs disseminated in clasts as well as fine-grained cryptic matrix material. The interval is highly strained.																Mg	m	
			195.20	200.20	5.00	VOL	OX		Moderately oxidized version of the green volcaniclastic unit with more sericite alteration and overprinting orange rusty colour. Higher amounts of sericite cause higher fissility and rubbly nature of core. Gougy contacts.							ms		SER	w							
									Strong foliation induced by strain	FO	65															
									Thin 1 mm to cm scale calcite veins with Ox staining.	VN	30	90	1			f										
			204.20	215.34	11.14	VOL	OX		Oxidized and sericitized pale yellow-cream to rusty orange volcaniclastic that is quite rubbly and fissile. The oxide begins in moderately competent sericite altered volcaniclastic and proceeds to softer, gougy and more gritty material. Sericite and strain induced foliations are visible however any smaller features are cryptic at best.							i		SER	i							

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
215.34	221.07	5.73				MBL		cBx	Grey to pale orange marblized unit with extensive cBx and a weak oxide overprint. This unit has no foliation, and has disseminated fine to medium-grained euhedral pyrite, abundant broken core and small oxidized gouge material occur locally. The lower contact becomes more marblized and whiter, less cBx and slightly foliated.							w				w							
									Thin calcite veinlet.	VN	40		1														
221.07	243.20	22.13				MBL			Light grey to white strongly banded fine-grained marble. The foliation is formed by strained single and folded-sinuous grey lines, they appear to be relict stylolites. This unit varies in competency from 40 cm sticks to rubbly core, about 50% of each, often broken core is associated with thin clay-oxide gouge material. The highly foliated marble grades into white non-foliated marble around 235.00 m in sharp interfingerings. This later portion of white marble is much more broken up and rubbly, with abundant oxide gouge.																			
243.20	269.43	26.23				OX			Dark brown to brown soft and silty yet competent enough to remain in core shape oxidized unit. This unit contains small sections of harder rock-like vesicular siderite-limonite portions as well as quartz pebble rubble zones and 40-50 cm LST sticks.							i											
			243.20	249.02	5.82	OX			Very dark brown gritty oxide, minor silty concentrations, no clay, minor quartz rubble in a 5 cm portion.							i											
			249.02	251.30	2.28	Qz	RBL		White bull quartz, very rubbly up to 4 cm cobbles, with minor Ox staining in quartz fractures, poor recovery.																		
			251.30	252.37	1.07	OX			Very dark brown gritty oxide, low silt, no clay, soft.																		
			252.37	254.00	1.63	Qz	RBL		Bull quartz, very rubbly, very poor recovery																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			254.00	262.78	8.78	OX			Pale yellow to yellow-brown to deep red soft oxide with minor quartz rubble occasionally within oxide core. The lighter yellow-brown oxide has very faint and cryptic sericite wisps now heavily oxidized, it also has high muscovite-clear mica contents and is very brittle with poor recovery, maybe a small interbed of volcaniclastic. Grain sizes are mostly fine-silt sized with no clay.																		
			262.78	263.25	0.47	LST	DOL		Intensely cBx dolostone, grey in colour and cBx has a weak preferred orientation at 30 TCA with occasional Ca and OX stain infill at the mm-scale.	cBX				i													
			263.25	265.90	2.65	OX			Reddish brown fine-silt sized oxide unit, soft yet core holds shape. Upper contact is grey as it grades into LST units. Lower contact is darker brown OX to black siderite material which grades into LST-DOL.																		
			265.90	266.80	0.90	LST	DOL		Grey to pale rusty cream coloured and soft oxide holds core shape. LST-DOL has a strong cBx, primary features are distorted and cryptic, fractures and broken core have siderite-OX and brown crumbly grit.	cBX				i													
									Ca and Ox in thin veins	VN	70		2													
			266.80	267.33	0.53	OX			Brown soft yet competent.																	
			267.33	268.00	0.67	LST	DOL		Grey to pale cream coloured dolomitized limestone with a strong cBx. Along various fractures up to 2 mm Ca and OX veining occur, Primary features do not exist.	cBX				i													
			268.00	269.43	1.43	OX			Brown to deep brown to pale yellow competent soft oxide, mostly fine silt sized grains.																	
269.43	299.62	30.19				LST	DOL		Grey to light grey cream coloured extensively cBx dolostone with portions of oxide. Soft rubbly to silty pale yellow brown oxide occurs in upper portions and interfingers with dolostone. Minor veining occurs, cBx has no regular orientation, cBx matrix appears similar to that of dissolution seam organic fill. Minor portions up to 5 cm of matrix dominant breccias occur with the black organic infill and sub-rounded clasts. Most core fractures have oxide staining on the faces. Trace disseminated euhedral medium-grained pyrite occurs.	cBX						w				t						
									Ca and Ox staining in 1-4 mm veins, slightly undulating to irregular contours.	VN	40		1													

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			271.00	274.00	3.00	OX			Silty to soft to sandy light-brown yellow oxide with no siderite. Portions show alteration from Bx-dolostone to oxide as a gradational change.																		
									Dolostone displays more sBx masked by a 'fuzzy' looking slight marbleization. The dolostone fragments are grey and sub-angular and the matrix appears to be dolomitized calcite. One small red-spec of sphalerite occurs with quartz in a vug infill overprinted by the marble.	ICN														Sp	t	
									299.62 m: EOH - The hole was ended because it was through the main oxide horizon.

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
0.00	3.30	3.30				OVB			Overburden - no recovery																		
3.30	218.96	215.66				LST			Dark to light grey, variably strained, FG to CG, variably interbedded, variably FOS LST. Weak amounts of MBL alteration are present throughout. FO is variable throughout, shallow to moderate angles, with a general steepening trend with depth.							t		MBL	w								
			3.30	10.51	7.21	LST		BN	Dark to light grey, fairly OX, CG LST (crinoid fragment packstone?) with FG, soft, brown, BIO (?) altered VOL. The VOL bands become increasingly SER altered with depth. OX alteration is present on fracture faces and occasionally is pervasive into the core from fractures. VOL interbeds host trace, FG disseminated blebs of Po and very trace FG Py. VOL bands are generally parallel to each other (relic bedding?) OX alteration decreases with depth.							f		BIO	m	t		t					
																				SER	f						
									FO is strong, defined by banded VOL layers, oriented 35 degrees TCA.	FO	35																	
									CG white DOL and rusty orange ANK vein with trace, subhedral MG yellow Py, oriented 25 degrees TCA, 45 degrees to FO, at 110.27 m. Trace Ca minerals within veinlet.	VN	25	45															
			10.51	14.22	3.71	LST		CG	Medium to light grey, CG, fairly MBL altered LST with SER altered VOL interbeds throughout. VOL interbeds decrease in thickness and frequency with depth. MBL alteration obscures relict fossil textures. Trace OX is present on fractures.							t		MBL	f								
																				SER	f						
									A strong FO is defined by VOL bands, oriented 35 degrees TCA.	FO	35																	
									CG white Ca and orange, translucent Qz veinlet, 5.5 cm wide, oriented 50 degrees TCA and 50 degrees to FO.	VN	50	50															
			14.22	17.42	3.20	LST	MBL		Light to dark grey, FG to CG, interbedded, strongly MBL altered LST. Soft, dull, medium grey interbeds (VOL?) with FG, mottled LST 16.25 to 16.76 m. MBL strength increases with depth. Trace OX is present on fracture faces.									MBL	s								
									Defined by banding in MBL and LST interbeds, 30 degrees TCA.	FO	30																	

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									Narrow, white, <3 mm wide Ca stringers throughout, roughly oriented parallel to each other, 30 degrees TCA, 90 degrees to FO.	VN	30	90															
									Grey, translucent, CG Qz veinlet, oriented 60 degrees TCA, 90 degrees to FO.	VN	60	90															
			17.42	53.00	35.58	LST	FOS		Dark to light grey, variably strained, FG to CG, FOS LST. Strain fabric is most strongly exhibited in FG, undulose to sinuous interlayers, sometimes hosting carbonaceous, CG augens with pinch-swell fabric surrounding them. At times fossils exhibit strain. Generally crinoid fossil content is ~30% of rock, but locally as high as 50 to 60% where most fossiliferous, becoming crinoid wakestone in composition. Trace "honeycomb" favocitid tabular corals occur.									MBL	w								
									Foliation is strong, varying in angle throughout, defined by a undulose strain fabric ranging from 0 to 40 degrees TCA and is on average 15-20 degrees.	FO	20															
			53.00	58.02	5.02	LST		BN	Dark to medium grey, FG, variably mottled, variably strained FOS LST. Bands of dark, FG material exhibit a wavy strain fabric, and range from 3 mm to 2.7 cm thick. Fossil content is ~20% of rock.																		
									A steep, strong FO is defined by banding, ranging from 40 to 85 degrees TCA.	FO	70																
			58.02	61.04	3.02	LST		BX	Dark to medium grey, weakly FOS, variably BX, variably strained, LST. An undulose strain fabric is exhibited by deformed mBX textures, with dark LST clasts in a CG, white calcareous matrix. Trace "honeycomb" favocitid and crinoid stem fossil fragments are present.																		
									A steep foliation is defined by strain in BX fabric, oriented 70 degrees TCA.	FO	70																
			61.04	94.63	33.59	LST	FOS		Medium to dark grey, FG-CG, variably strained, weakly FOS LST. A shallow, undulose strain fabric is pervasive throughout, dark, FG bands and some fossils exhibit elongation with orientation of strain, noted by deformed "honeycomb" favocitid corals and crinoid fragments.																		
									A shallow, undulose FO is defined by a strain fabric throughout and is generally oriented 15 degrees TCA but ranges from 0 to 30 degrees TCA.	FO	15															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			94.63	130.28	35.65	LST	MBL		Medium to dark grey, CG, sucrosic, strongly MBL LST. Rock appears weakly cBX in texture where MBL alteration is weakest, and exhibits dissolution where MBL ALT is strongest. MBL textures overprint cBX where both overlap. An undulose strain fabric is pervasive throughout, shallow TCA. Trace crinoid and "honeycomb" favocitid coral textures are obscured to obliterated by MBL alteration. Where strain is strongest, rock lacks BX textures but maintains MBL banding.								MBL	s									
									A strong FO is defined by banding and BX orientation and is oriented 20-40 degrees TCA.	FO	30																
			130.28	165.39	35.11	LST		BN	Dark to light grey, FG-MG, variably banded, variably strained, weakly FOS, weakly MBL altered LST. The banded texture is defined by narrow (interbeds?), weakly undulose to sinuous bands roughly parallel TCA; steepening with depth with respect to the CA. Where strain is strongest, calcareous augens with pinch-swell textures are present (relict fossils?) Trace crinoid fragment fossils supported in a FG, dark LST matrix. At times these layers are deformed and fossil textures become obscured to obliterated. Py is present within dark, FG, deformed LST bands as bright yellow, FG blebs (diagenic?).								MBL	w	t								x
									FO is generally shallow, ranging from 0 to 30 degrees TCA, generally 10-15 degrees.	FO	15																
			165.39	190.31	24.92	LST	MBL		Dark to light grey, MG-CG, sucrosic, strongly MBL altered, FOS LST with variable strain throughout. Weak BX to BN in texture, with BX exhibiting elongation with strain fabric. Trace Py is present in FG, deformed, dark bands and BX matrix material. Fossils present are deformed "honeycomb" favocitid corals to deformed beds of crinoid fragments in dark FG narrow "beds".								MBL	s	t								x
									FO is defined by banding textures, oriented 30-50 degrees TCA.	FO	40																
			190.31	208.11	17.80	LST		BN	Dark to light grey, FG-CG, variably strained, FOS LST, weakly BN in texture. Strain is exhibited most readily by FG, dark variably fossiliferous, sinuous LST bands. Crinoid content increases with depth, along with deformed chain, honeycomb and rugose coral fossils. Overall, fossil content is less than 10%.								MBL	w									

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

									FO is defined by banding textures, oriented 30-45 degrees TCA.	FO	40																
			208.11	212.16	4.05	LST	MBL	BX	Light to dark grey, sucrosic, strongly MBL altered LST. MBL textures overprint BX textures. Strain and MBL alteration increase in strength with depth, exhibiting a marble banding texture down hole. Trace, FG, brownish (VOL?) interbeds are occasional throughout. Deformed "honeycomb" favocitid and rugose coral fragments are present, with fossil textures obscured by strain and MBL alteration.									MBL	s								
									FO is defined by banding and strain, oriented 55-60 degrees TCA.	FO	55																
			212.16	215.97	3.81	LST		BX	Medium to dark grey, FG, cBX non-fossiliferous LST that is variably strained throughout. Fine, crackled BX texture is pervasive throughout, and exhibits a uniform orientation.																		
									A strong FO is defined by BX orientation, 60 degrees TCA.	FO	60																
			215.97	218.96	2.99	LST	MBL	BX	Light to dark grey, sucrosic, strongly MBL LST, with MBL textures overprinting relict BX textures throughout. Rock is variably strained, relict BX clasts (and relict coral fossils?) exhibit a preferential strain orientation. MBL alteration increases with depth, becoming banded in texture.										MBL	s								
									A strong FO is defined by strain fabric and banding, oriented 60 degrees TCA.	FO	60																
218.96	219.13	0.17				MBL			Light grey, sucrosic MBL with a uniform colour throughout. uCn is gradational over several cm. Trace, disseminated, medium grey spots occur throughout. Trace, faint, narrow bands are occur throughout.	uCN																	
									FO is defined by faint bands in unit, oriented 60 degrees TCA.	FO	60																
219.13	219.49	0.36				DOL	MX	CG	White to medium grey, CG, DOL with banded Py and As. Py occurs as FG, dull, greenish yellow bands and as trace, bright, euhedral overprints. As occurs as CG, euhedral crystals. Po overprints the FG, greenish Py and is overprinted by the bright, FG euhedral Py. The entire interval fizzes weakly with HCl.						s								ms	m	f				
									FO is defined by Py banding, oriented 60 to 65 degrees TCA.	FO	60																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									Defined by orientation of amygdules, a weak FO is oriented 50 to 60 degrees TCA.	FO	60																
									Qz-Ca veinlet, oriented 60 degrees TCA, 0 degrees to FO, undulose, with trace CHL alteration along veinlet boundaries, 0.8 to 3.5 cm wide.	VN	60	0														
			233.45	238.65	5.20	VOL	SER	AM	Brown to olive grey, strongly BIO and SER altered, FG VOL, becoming moderately SIL with depth. Amygdules become larger and more irregular with depth, appearing as deformed, large amorphous blobs generally 3 cm in size, to sinuous, near BX matrix in texture approaching ICN. BIO alteration overprints SER, rimming and replacing large masses of sericitic VOL between large, soft grey amygdules. Trace Py is present forming small, bright yellow, FG masses that are rare throughout.	CN								BIO	s	t						
																			SER	s							
																			SIL	m							
									FO is defined by amygdule orientation and perhaps a weak strain fabric deforming larger amygdaloidal masses, 50 to 60 degrees TCA.	FO	50															
			236.09	236.15	0.06				FG-MG chlorite veinlet, with grey, soft, clay altered veinlet selvages, 5.5 cm wide @ 236.09 m.	VN	65	0														
									Ca "BX" veinlet. The brecciated texture consists of VOL clasts within a white, Ca BX matrix with later soft, white TLC alteration of Ca.	VN	60	0														
238.65	351.90	113.25				LST	DOL	BX	Medium grey to white, intensely DOL altered, variably BX LST. Generally sBX in texture, occasionally cBX or both with cBX overprinting sBX. Weak ANK and OX alteration throughout. Trace Py present, but only locally as small masses. Strain appears to increase with depth.					i	w	w				t							
			246.44	253.25	6.81	LST	DOL	BX	Medium grey to creamy yellow, strongly ANK altered, intensely DOL altered sBX LST. CG creamy yellow sBX matrix supports coarse, subangular DOL LST BX clasts. Where rock does not exhibit brecciation, CG ankerite veinlets are present. Py occurs as dull, FG nebulous bands oriented 30 degrees TCA where rock is most strongly ANK altered.					i	s				t							
									Rock lacks a uniform fabric throughout, FO not apparent.	FO	n/a															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			323.52	342.14	18.62	LST	DOL		Dark to medium grey, FG to CG, variably strained, weakly BX, intensely DOL altered LST appearing "debris flow"-like throughout with trace favocitid "honeycomb" coral fragments. Trace Py is present forming sinuous, narrow bands to FG disseminations. Py content generally increases with depth. Strain fabric is consistent throughout, orienting BX, debris flow and dissolution textures.					i						t							
									FO is defined by strain fabric oriented debris flow and breccia textures, 55 degrees TCA.	FO	55																
									CG, white, toothy DOL veinlets, weakly brecciating and fragmenting host rock forming clusters appearing to weakly brecciate host rock. Py is present as FG to MG subhedral bands along veinlet boundaries and selvages of a veinlet cluster. Py crystals exhibit a growth banding texture. Veinlets are weakly oriented along a FO. Veinlet frequency increases with depth, forming 5 cm wide clusters of 4 to 6 mm wide veinlets.	VN	60	0																
									White CG Ca and grey MG-FG grey Py veinlet with weak Cl along veinlet walls, oriented parallel to FO. Veinlet is 5.0 cm wide and is found at 343.14 m.	VN	60	0																
									CG Qz-Ca veinlet, 3 mm wide, oriented 30 degrees TCA and 50 degrees to FO. Veinlet cross cuts FO structures at 343.04 m.	VN	35	50																
			343.90	351.90	8.00	LST	DOL	BX	Medium to dark grey, intensely DOL altered, variably BX, FG to MG LST appearing variably clastic in texture. FG to MG medium grey matrix supports coarser, dark clasts. Rock exhibits variable BX textures throughout with CG white BX matrix minerals as above, and also cBX textures with broad, angular clasts brecciated by fine, dark breccia matrix minerals. Strain is variable, generally increasing and deforming breccia textures with depth, exhibiting an undulose fabric where strain is highest. Weak Py MX is visible and forms bright yellow euhedral to subhedral crystals, strongly associated with dark, FG bands and deformed masses of LST, to forming cloud-like masses of disseminations. lCN is interbedded with VOL over 18 cm.	ICN				i						w							
									FO is defined by strain fabric, and is oriented 50 to 60 degrees TCA.	FO	55																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									Qz-Ca veinlet, cross cutting white, CG BX-type veinlet, 50 degrees TCA, 350 degrees to FO. BX veinlet is oriented at 35 degrees TCA, 0 degrees to FO.	VN	50	350															
351.90	369.16	17.26				VOL			Dark grey to black with white bands, FG, moderately SIL altered, VOL with intense Qz-MX veining throughout. Hardness is greater than typical VOL (SIL alteration), and weakly calcareous. Where calcareous, VOL hosts bands of bright yellow MG Py. Qz is white, CG, and veining hosts Po as sinuous stringers to small MG masses throughout. Trace bands of Po are also hosted in the VOL rock. Trace amounts of Py is seen replacing Po near vein boundaries, and as masses along Qz VN contacts. Qz VN makes up about 45% of total unit. TLC alteration is present within veining (relict Ca?) and in vein selvages.	VN								SIL	m	s		m					x
																		SER	w								
																		TLC	t								
									FO is defined by banding in VOL, oriented 50 to 55 degrees TCA.	FO	50																
369.16	387.57	18.41				DOL	MX	BX	Light to medium grey, intensely DOL altered, variably recrystallized, weakly BX, Py mineralized DOL and cBX LST. Rock exhibits weak East Zone appearance, with intervals stronger in East Zone textures and mineralization above and below. Py is present as bright, euhedral yellow metallic MG crystals exhibiting weak banding to "shotgun" masses. Py MX is weak throughout, but is locally stronger in zones exhibiting East Zone appearance.					i		w		TLC	w	w		t					
			369.16	374.31	5.15	DOL	MX	SP	White to medium grey, CG DOL with moderate, creamy yellow ANK alteration increasing with depth. uCN is gradational, from Po, CHL and TLC alteration to CG crystalline dolomite over 45 to 50 cm. Py is present as MG, yellow euhedral to subhedral crystals forming weak bands to narrow masses. Creamy green TLC alteration of DOL exhibits CG, radiating fibres throughout. A weak sparry texture is noted throughout.	CN				i		m		TLC	f	m		w					
									FO is weak, defined by Py bands, oriented 70 to 80 degrees TCA.	FO	75																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

SAMPLES

Numbers: I076027-I076087

Total: 61

Batch: 43, 44, 45

Date Sent: July 19, 2010

Certificate: VA10098844, VA10098846

COMMENTS

The hole was ended because it was through the main oxide mineralization. The hole was then lined wih PVC for a later downhole gravity survey. All samples were sent for MET sampling.

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	3.20	3.20				OVB			Overburden - no recovery																		
3.20	12.02	8.82				LST	OX	RBL	Light to dark grey, altered light brown, rubbly, LST.					w		w											
			3.20	6.50	3.30	LST	DOL	RBL	Light to dark grey, FG, rubbly LST with weak to moderate DOL alteration. DOL spots ~ 1 cm thick with irregular and angular thin black styolites that form enclosed areas . Other zones have FG to MG white Ca spotting. Very poor recovery. Notably unoxidizeded.					f													
			6.50	12.02	5.52	LST	OX		Medium grey altered light brown, rubbly LST with Ca and Qz/Ca veins forming local cBX textures. CG Ca is preferentially cut by dark brown stringers along crystallographic surfaces. Alteration is clay to grit, mostly silt, which covers broken surfaces and pervasively alters core.							ms											x
12.02	89.31	77.29				OX			Medium orange-brown clay to solid core, predominantly grit. SID rich patches and zones occur with intervals of blue to green-grey Qz rich clay rubble, and other Qz rich zones.							i	ms										
			12.02	14.00	1.98	OX			Dark orange-brown oxide with dark red brown patches and a texture ranging from clay to solid core pieces. Unaltered sections of CG DOL also occur and are seen with cross cutting Ca veins. The texture of the interval is predominantly grit.							i	ms										
			14.00	16.22	2.22	Qz			Dark green-grey clay to rubble, predominantly gritty oxide with a milky white and light orange Qz rich interval (~15%). Quartz occurs as FG sand to pebbles ~ 2 cm in diameter, with a single Qz core piece ~ 6 cm long. Some sand to pebble sized rounded LST clasts occur. The lower contact is very gradational.	ICN																	
			16.22	17.68	1.46	OX			Dark green-grey to dark orange-brown oxide with a smeared outer surface, and sideritic black shiny inside. It is clay to rubble in texture with zones that hold core shape but easily crumble, predominantly grit. Trace Qz grit occurs within.							i	i										
			17.68	18.14	0.46	OX	Qz		Medium brown clay to rubble fragments up to 4 cm in long. Qz rubble represents approximately 20% of the interval and occurs in fragments up to 2 cm in diameter.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			18.14	18.54	0.40	OX	Qz		Oxide with a dark brown outer surface and a blue grey inside. The overall texture is clay to grit with minor rubble scattered throughout.																			
			18.54	29.31	10.77	OX			Medium orange-brown clay to solid core oxide (predominantly in intensely SID altered zones). Zones with bright orange-brown colour and dark brown SID patches occur throughout but still have a medium orange-brown smear on the cored surface.							i	s										
			25.60	25.90	0.30	OX	Qz		An interval that is up to ~35% Qz, with Qz fragments up to 1 cm in diameter.							i	s										
			26.82	27.30	0.48	OX	Qz		Light to medium orange-brown clay to grit oxide with Qz rubble up to 1.5 cm diameter representing approximately 5% of the interval.							i											
			28.86	29.01	0.15	OX	Qz		Medium orange oxide with black SID alteration. Qz represents approximately 90% of interval as broken but in-place pieces.							i											
			29.01	30.29	1.28	OX			Light yellow-orange-brown oxide with dark red brown patches. The texture is clay to SID rich rubble. Qz rich fragments up to 3 cm represent approximately 10% of the interval.							i	s										
			30.29	31.00	0.71	OX			Medium brown clay to rubble oxide (predominantly clay) light grey up to 1.5cm in diameter occur scattered throughout. Overall the core is non-cohesive.							s											
			31.00	36.35	5.35	OX			Oxide with a medium brown to orange-brown surface and orange-brown and dark brown to black patches inside. Clay to SID rubble in composition. Qz rich patches and layers <5 cm thick occur scattered throughout.							i	i										
			32.75						Blue grey clay to grit inside core.																		
			36.35	38.05	1.70	OX			Orange brown oxide surface, with increased SID on broken surfaces. It has a clay to RBL but predominantly grit texture. A small Qz zone ~ 4 cm thick occurs at 36.96 m.							i	i										
			38.05	45.86	7.81	OX			Medium brown to orange-brown clay to solid core oxide with Qz rich zones throughout and including pieces up to 5 cm in diameter. Light yellow or grey patches is commonly associated with a platy light yellow reflective mineral (Mica or SER). The lCN is particularly Qz rich. The oxide begins to fizz weakly at 42.06 m.							i	i										
			43.54	43.74	0.20	OX	QZ		Medium brown clay rich oxide with Qz fragments up to 1 cm in diameter. A platy white mineral (mica?) occurs scattered throughout.							i											

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			45.86	48.28	2.42	OX			Orange-brown to medium brown clay to rubbly oxide, predominantly grit. Orange-brown and dark brown patches occur with trace Qz scattered throughout. The entire interval fizzes weakly with acid.							i	i										
			48.28	48.59	0.31	OX	LST		Dark red-grey FG to MG (LST?) crystals, with Qz veins and dark red to black oxide. The unit fizzes strongly with acid.							s	s										
			48.59	51.65	3.06	OX			Medium brown to orange-brown clay to rubble oxide predominantly grit. Orange-brown and dark brown patches occur with rubbly to cohesive core texture.							i	i										
			49.58	49.88	0.30				Qz rich zone containing 25% up to 1 cm fragments of quartz.																		
			51.65	52.98	1.33	LST	DOL	RBL	Light orange and light pink-grey, relatively unoxidized , intensely DOL/ANK altered LST. Overall the texture is core to rubble, with veins and blebs of Quartz throughout. Strongly oxidized mineralization (Py?) occurs as stringers and disseminated throughout.	FO	35			l	ms	s	s	HEM	ms								
									Irregular Qz VN that narrows to 0.5 cm and thickens to over 15 cm.	VN	50	340														
			52.98	53.76	0.78	OX			Medium orange-brown clay to rubble oxide that is, predominantly grit. The centre of the core is dark brown with orange-brown patches.							i	i										
			53.76	54.62	0.86	LST	OX		Medium grey to orange brown, MG, moderately oxidized LST. The competency ranges from core fragments to clay, and is predominantly rubble. Qz rubble up to 3 cm in diameter occurs scattered throughout. The interval fizzes intensely with acid.							ms	m										
			54.62	56.32	1.70	OX			orange-brown with dark brown patches and zones. Clay to rubble, predominantly grit. Cohesive core SID altered.							i	i										
			56.32	56.95	0.63	LST	OX		Grey-brown clay to core oxide that is, predominantly rubble. Fizzes strongly with acid, and contains remnant cBX texture. ICN is gradational.	ICN						m											
			56.95	59.74	2.79	OX			Medium brown to orange-brown, clay to rubble oxide that is, predominantly grit. Fizzes moderately with HCl. Light yellow, medium orange, and dark brown to black patches occur throughout.							i	i										

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			59.74	61.96	2.22	OX	LST		Medium brown, with light grey and white coloured strongly oxidized LST with white, and pink relatively unaltered patches throughout. The interval fizzes fairly with acid and contains patches and zones of orange brown and black alteration throughout. A gradational zone occurs between intensely and weakly OX intervals.					ms		s	s										
			61.96	64.12	2.16	LST	DOL		Medium grey, FG LST, with medium brown alteration patches along veinlets and on fractures. The entire interval fizzes fairly with acid. MG Ca as forms local mosaic brecciation. Trace As is visible along with oxidized spots that were likely original As grains.							f				t							
			64.12	65.33	1.21	OX			Orange-brown weakly calcareous clay to rubble oxide.							i	f									
			65.33	65.85	0.52	LST	OX		Green grey, clay to solid core oxide with white Ca veinlet that cut at irregular orientations. The interval fizzes strongly with acid.							m										
			65.85	66.45	0.60	OX			Orange brown oxide with black sheen on inside of core. Clay to core competency, but predominantly rubble. Non-calcareous.							s	i									
			66.45	68.59	2.14	OX	LST		Medium brown-grey altered weakly DOL altered LST. Competency is mainly core that is easily broken into rubble. SID coats broken surfaces. Unaltered surfaces show irregular Ca veining.					f		s	w									
			68.59	74.07	5.48	OX			Medium brown to medium orange-brown, clay to solid core oxide that is predominantly silt. Non-calcareous with some Qz rubble <1 cm scattered throughout. SID alteration occurs locally, near solid core pieces and in patches.							i	f									
			74.07	80.16	6.09	OX	SID		Bright orange-brown core surface with dark brown to black core centres. It is intensely SID altered and ranges from clay to solid core, but predominantly rubbly texture. Subangular Qz rubble up to 5 cm in diameter occur throughout. Rubble and core have large vacancies, and a corroded appearance.							s	i									
			80.16	80.42	0.26				Blue-grey clay to rubble oxide that is predominantly silt. Subrounded rubble up to 3 cm is common. Trace Qz occurs, but not as much as usually associated with blue grey colour. The lCN is gradational.																	
			80.44	86.66	6.22	OX			Oxide with a bright orange-brown core surface and red brown to black core centres. Competence ranges from clay to rubble, predominantly rubble and core which is easily broken to rubble.							i	i									

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other						Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
			86.66	87.58	0.92	OX			Medium brown clay to rubble with whole core up to 2 cm long. Rubble up to 4 cm in diameter including Qz rubble and LST rubble, from reaming rods occurs. The lCN is gradational with increased pink hue SID alteration, and trace fizz over last 10 cm.							i	t										
			87.58	89.31	1.73	OX			Pink-brown to light yellow, mainly core with commonly planar rubble. Clay occurs in small intervals ~3 cm long, as well as coating surfaces. Dark brown/black SID alteration occurs on fractures. The entire interval fizzes weakly with acid.							i	t										
89.31	91.59	2.28	89.31	91.59	2.28	OX	DOL		Orange-brown to buff, core to rubble oxidizec dolomite with SID alteration of FX. Dark brown seams locally occur, up to very high density, forming cBX texture.							i	s										
									91.59 m - E.O.H. The hole was ended because there was high torque on the rods, and was also past the main oxide zone.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
0.00	3.20	3.20				OVB			Overburden - no recovery																		
3.20	218.52	215.32				LST	FOS		Dark to medium grey, FG to CG, variably MBL altered, variably FOS LST. Strain is variable throughout. VOL inerbeds are found at the top of the interval and gradually disappear with depth. BX textures are trace throughout, but increase with depth. MBL and FOS is generally strong throughout. In layers where rock is most fossiliferous, composition appears to be crinoid grainstone.							t		MBL	m			t					
			3.20	17.12	13.92	LST	FOS	BN	Dark to light grey, MG to CG, moderately MBL altered, FOS LST with brown to grey VOL interbeds. VOL units give rock a banded appearance. Bands decrease in width and frequency with depth. Fair OX alteration is present on fracture surfaces and slightly pervasive into LST, weakly staining rock. FOS content increases with depth, large crinoid fragments are present. Where most fossiliferous crinoid fragment grainstone occurs. Trace Po is seen with VOL layers, as either narrow, FG bands or as FG disseminations in VOL. Strain is most readily seen in VOL, exhibiting an undulose fabric with depth.							f		MBL	m			t					x
									FO is defined by VOL "banding", oriented 50 to 60 degrees TCA.	FO	55																
			17.12	45.98	28.86	LST	MBL	CG	Dark to light grey, strongly MBL altered, strongly strained, strongly FOS LST. Interbeds of coarse, fossil rich beds with deformed, undulose, FG LST occur throughout. Strain is exhibited by FG interbeds, appearing undulose to sinuous with variable angles from shallow to moderate relative TCA. Fossil textures generally lack strain. Fossils make up roughly 35 to 40% of material present, and is crinoid wakestone/grainstone in appearance where most fossiliferous. Trace Py is present proximal to Ca veinlets as MG, yellow blebs.							t		MBL	s	t							
									FO is oriented 20 to 50 degrees TCA, but is generally 45 degrees TCA throughout. FO is defined by FG interbed "banding" textures.	FO	45																
			21.25	21.27	0.02				2 CG, white Ca veinlets, 1.7 and 1.3 cm wide with proximal yellow blebs of Py .	VN																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			45.98	54.02	8.04	LST	FOS	CG	Dark to medium grey, FG to CG, interbedded/layered FOS LST exhibiting variable strain throughout. FG beds exhibit strain most readily, with pinch/swell textures are present around crinoid fragment fossils, and generally exhibit an undulose foliation. Crinoid stem fragments up to 1.5 cm in size are present. Where most fossiliferous, rock appears wakestone in composition. Overall amount of fossils in unit is roughly 30%. Trace, FG, soft, weakly SER altered VOL interbeds are present with depth. Weak MBL alteration throughout, decreasing to trace down interval. uCN is gradational.	CN								MBL	w									
									FO is defined by banded texture from interbeds, oriented 40 to 60 degrees, but generally 45 to 50 degrees TCA.	FO	45																
			54.02	58.36	4.34	LST	FOS	BX	Dark to light grey, FG to CG, weakly FOS, moderately mBX LST. Intermittent zones of mBX are present throughout, angular to tabular breccia clasts are supported by a white, CG, calcareous matrix. Moderate crinoid fragments (5%) and trace large fragments of favocitid "honeycomb" corals are present.																			x
									A weak FO is defined by BX orientation, 50 to 60 degrees TCA.	FO	55																
			58.36	62.20	3.84	LST	FOS	BX	Dark to medium grey, FG to MG, strongly FOS, variably strained, cBX LST. Fossil content increases with depth, with rounded, tabular fossils increasingly common with depth. Fossils make up 20-25% of material, with rock appearing as grainstone where most strongly fossiliferous. lCN is gradational over 10 cm, becoming deformed, foliated and weakly MBL altered with depth.	CN																		
									FO is defined by BX orientation, 70 degrees TCA.	FO	70																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			62.20	118.30	56.10	LST	MBL	BX	Dark to light grey, strongly MBL altered, sucrosic, variably strained, weakly FOS LST. MBL textures overprint relict, deformed BX textures throughout. Where fossils are present, they appear deformed, extended with strain fabric orientation, even where silicified. Strain fabric is undulose, orienting foliation shallow TCA. lCN is gradational, becoming strongly banded/foliated and increasingly finer grained with depth. Rock becomes less FOS and BX also with depth. Where strain is most strongly exhibited, the fabric of the rock is undulose, oriented shallow to near-parallel with CA. Deformed rugosa "horn" and favocitid "honeycomb" coral appear variably deformed, crinoid stem fragments are present in dark, FG, undulose bands.								MBL	s								
									FO is variable, oriented 0 to 20 degrees TCA where strain appears strongest, and is oriented up to 40 to 45 degrees elsewhere, generally 30 degrees TCA throughout.	FO	30															
			118.30	146.52	28.22	LST	MBL	BX	Dark grey, FG, strongly strained, weakly MBL altered LST, exhibiting an undulose to sinuous fabric throughout. Trace dull yellow Py blebs are associated with dark, deformed narrow mud layers/bands. Trace white, CG calcareous augens (relict fossils) are present, 1.3 cm in size on average, with FG lime muds around exhibiting pinch/swell textures oriented with strain fabric.										t							
									FO is strong, defined by shallow, banded texture, variably oriented from 0 to 25 degrees TCA, generally 15.	FO	15															
			146.52	152.78	6.26	LST	MBL	BX	Light to medium grey, strongly MBL altered LST, exhibiting deformed cBX textures. Rock exhibits strain textures throughout, variably undulose when seen in a few muddy LST bands that are present. Trace Py is present with dark, cBX matrix minerals as dull, FG disseminations.										t							
									FO is oriented 0 to 20 degrees, defined by banding and strain fabric throughout. Typically, FO is oriented 15 degrees TCA.	FO	15															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			152.78	170.16	17.38	LST		FG	Dark grey, FG. Strongly foliated and banded LST with weak amounts of crinoid fragment fossils. Crinoid fragments exhibit strain in narrow, fossil rich bands, with occasional competent fossils and pinch-swell textures wrapping around them. Trace deformed calcareous bands are present throughout, appearing sinuous to amoeboid (relict fossil fragments?)																	
									FO is strong, variably oriented 0 to 30 degrees TCA, but FO is typically shallow throughout, oriented 15 degrees TCA.	FO	15																
			170.16	187.04	16.88	LST	MBL	BX	Light to dark grey, sucrosic, strongly MBL altered LST. MBL and strain overprint a relict BX fabric, large clasts appear deformed and elongated. MBL alteration increases with depth, marble banding present where MBL ALT is strongest. LST appears MO with depth with dark, patches present from 186.02 to 187.10 m. A few large ferocities "honeycomb" coral fragments are present, exhibiting strain that obscure the obvious fossil textures. Trace Py is found as <1 mm blebs appearing in undulose, dark muddy layers present up hole.									MBL	s	t							
									A strong FO is defined by BX elongation orientation. FG muddy bands and marble banding occurs, oriented 20 to 55 degrees TCA, but generally is oriented 40 degrees TCA.	FO	40															
									White, CG, calcareous, 17 cm wide vein oriented 40 degrees TCA, 270 degrees to FO crosscutting BX at 174.85 m.	VN	40	270														
			187.04	191.15	4.11	LST	SIL	FG	Dark grey, FG, moderately SIL altered, strained LST, weakly MO in appearance. Patches of strongly SIL altered LST up to a few cm in size are present throughout, sometimes exhibiting a cryptic, deformed "honeycomb" texture (relict corals?). Crinoids are present with depth near lCN, with visible deformation and appear ovular to bleb-like in shape. Trace Py is present as FG yellow, metallic blebs.									SIL	m	t							
									FO is defined by weak mottled texture oriented 45 degrees TCA.	FO	45															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			191.15	201.45	10.30	LST	MBL		Dark to light grey, sucrosic to FG, variably strained, strongly MBL altered LST. Strain and MBL overprint relict BX textures. cBX clasts appear elongate, matrix sometimes appear near stylolitic. The texture becomes more deformed and rounded with depth. Where fine grained, rock appears weakly mottled. Trace white-yellow euhedral <1.5 mm Py crystals are present with dark bands of BX matrix minerals.								MBL	s	t						
									FO is oriented 50 to 70 degrees TCA, generally at 55 degrees but increasing with depth. FO is defined by banding and BX strain orientation.	FO	55															
									Narrow, white, CG Ca veinlet, oriented 25 degrees TCA, 170 to FO and is 3 mm wide with 2 mm wide selvages of calcareous, light grey, MG alteration of dark, FG LST host.	VT	25	170															
			201.45	206.69	5.24	LST		FG	Dark grey, strained, variably FOS, FG to MG, weakly MO LST with patches of weak SIL alteration. Trace crinoid fossils occur exhibiting strain becoming oval in shape in muddy interbeds with dark, tabular black mineral <1 mm in size and trace, bright yellow Py. A weak banded fabric is present in muddy layers.								SIL	w	t						
									FO is defined by banding and elongation in the mottled fabric, oriented 40 to 55 degrees TCA, generally 45 degrees.	FO	45															
			206.69	212.59	5.90	LST	MBL	BN	Light to dark grey, strongly MBL altered, sucrosic LST with strained interbeds of FG dark LST. Dark, muddy interbeds appear deformed, exhibiting an undulose to sinuous fabric. Strain and MBL alteration overprint a relict large, widely spaced BX texture. Trace crinoid and coral fossils are present; fossil textures are cryptic to obliterated. Trace FG Py is present as disseminations in FG, muddy bands.								MBL	s	t						
									FO is defined by banding and strain orientation, 50 to 55 degrees TCA.	FO	50															
			212.59	218.52	5.93	LST	MBL	BX	Light to medium grey, variably BX, strongly MBL altered LST. cBX texture cuts the LST with thin dark grey crackle seams. A deformed, coarser BX texture that is strongly MBL altered appears in between cBX layers. Layers and bands are evident, wide bands exhibit clear, sharp contacts oriented with FO. ICN is gradational, MBL alteration increases with depth over 12 cm.	CN							MBL	s							x

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									A strong FO is defined by BX orientation and banding oriented 60 to 70 degrees TCA. FO is steeper where appearing cBX occurs.	FO	70															
									MBL altered, calcareous veinlet crosscutting cBX texture at 215.15 m, appearing undulose, 4 mm wide, 20 degrees TCA and 180 degrees to FO.	VN	20	180														
218.52	218.77	0.25				MBL			Light grey, sucrosic, MBL, uCN and lCN contacts are gradational; lCN increasingly DOL altered with depth.	CN																
218.77	219.15	0.38				DOL	MX	CG	White to medium grey, CG, hydrothermal crystalline DOL with Py and Po MX. Po is present as bands to blebs, at times being replaced by bright yellow Py which is also seen in narrow bands to wisps. lCN is sharp, defined by a Py band/marble boundary oriented 70 degrees TCA.	lCN	70									w		m				
									FO is defined by DOL and Py banding, 70 degrees TCA.	FO	70															
219.15	219.77	0.62				MBL			White to medium grey, sucrosic MBL, becoming grey with depth. lCN is gradational over 7 cm, becoming increasingly coarser and more dolomitic with depth.	CN																
219.77	221.45	1.68				DOL	MX	CG	White to medium grey, CG, crystalline DOL with Py and As MX, exhibiting a weak sparry texture. Py is present as narrow bands commonly oriented to small masses of FG yellow Py. Weak As present as CG, euhedral crystals forming a weak band at 220.19 m and as MG euhedral crystals up hole near uCN. lCN is sharp defined by a Py band, oriented 60 degrees TCA.	CN									ms	w					
									FO is defined by Py and DOL banding, generally oriented 50 degrees TCA, but varies from 45 to 60 degrees.	FO	50															
221.45	222.94	1.49				MBL			White to light grey sucrosic MBL, weakly banded with faint dark bands. The lCN is gradational with narrow, deformed, VOL interbeds.	CN																
									FO is defined by faint banding textures, oriented 45 degrees TCA.	FO	45															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

222.94	240.01	17.07				VOL		AM	Dark green, FG to MG, variably AM and magnetic, strongly CHL and BIO altered VOL. A banded texture is variable throughout. uCN is gradational, with moderate SER alteration below marble becoming dark green and strongly chloritic over 50 cm.									CHL	s									
																		BIO	s								
			223.74	227.42	3.68	VOL	CHL	AM	Dark green, FG to MG, variably amygdaloidal and magnetic VOL. Rock is magnetic from 223.74 to 226.48 m, and Am from 225.33 o 227.42 m. Amygdules are <1.2 cm in size and filled with CG calcite. lCN is gradational, becoming brown with depth.									CHL	i									
									FO is defined by AM orientation at 60 to 70 degrees TCA.	FO	65																	
									Creamy, FG, 6 mm wide Ca veinlet with 2.3 cm SER altered veinlet selvages, oriented parallel with FO.	VT	60	0																
			227.42	230.72	3.30	VOL	BIO	AM	Brown, FG to CG, strongly BIO altered, variably AM VOL with Py and Po MX. Py appears as CG subhedral to cubic replacements in amygdules to narrow bands throughout. Po increases with depth and is associated with bands of chloritic alteration at 229.00 m.									BIO	s	t		w						
									FO is defined by banding and amygdule orientation, 45-60 degrees TCA.	FO	55																	
			230.72	240.01	9.29	VOL		AM	Brown to light grey, FG to MG, strongly BIO altered, variably AM, strained VOL with Py and Po MX. VOL is brown with a buff-tan with soft clay alteration around grey, calcite filled amygdules. The amygdules become larger and more irregular in shape with depth. Sinuous margins of tan SER altered VOL exhibit shear. Fair Py is present as dull blebs to wispy bands to small masses and replacements of amygdules. Po is present as narrow veinlets or fracture fills. Weak Ca crack seal veinlets are present with depth. lCN is gradational, becoming FG, light grey with minor LST DOL interbeds with depth.									BIO	s	f		t						
									FO is defined by a banded texture and preferential fracturing of core, oriented 50 to 70 degrees TCA.	FO	60																	
									White, Ca crack-seal veinlets, parallel with FO and generally less than <1 mm wide increasingly present with depth.	VN	60	0

SAMPLES

Numbers: I076104-I076157

Total: 54

Batch: 45, 46, 47

Date Sent: July 19, 21 2010

Certificate: VA10098846, VA10089879, VA10098845

COMMENTS

The hole was ended because it was through the oxide an into the lower marble. The hole was lined with PVC pipe for use in a later downhole gravity survey.

HOLE: Rau-10-96

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	4.42	4.42				OVB			Overburden - no recovery																		
4.42	6.15	1.73				LST	RBL		Medium grey, FG, locally FO, locally cBX, LST. cBX matrix is Ca veined, very broken, with medium brown clay to grit in intervals up to 15 cm long. Gradational lCN.																		
6.15	14.09	7.94				OX			Medium orange and dark red-brown clay to rubble, with light yellow and blue grey intersections. Small unaltered core sections and rubble fizz with acid very weakly at top of interval, (i DOL altered LST grading into DOL?).							i	i									
			10.50	11.50	1.00				Light yellow to light blue-grey clay to small rubble, predominantly clay. Sharp transition to SID OX rubble at uCN and lCN. Very poor recovery.																	
			13.72	14.02	0.30				Blue grey clay to grit with light orange DOL rubble and core which breaks easily.																	
14.09	28.00	13.91				DOL	MX		Variably OX and MX, FG to CG DOL. Py is FG, brassy, defining FO and massive. As is grey, MG, locally disseminated. DOL has cataclastic texture, with thin seams rimming crystals.											s	ms					
			14.02	15.52	1.50	DOL	MX		Light yellow-white MG to CG DOL, intense FG Py MX that is brassy and both disseminated and defining FO. The last 15 cm have MG to CG strong As disseminated, with light green FG mineral associated in trace amounts (actinolite?). Intensely OX zones ~ 2 cm wide probably altered VT.	FO	45					w				i	f					
									Mineralization is cBX by thin Qz/DOL VT, altered dark brown (SID), at 2 orientations; with FO and as noted.	VT	30	160														
			15.52	16.17	0.65	DOL			Medium grey, CG DOL, cBX by thin grey seams. Intensely OX layers with CG DOL crystals on FX faces are ~ 3 cm wide, may be altered VT. No noticeable MX. Very hard.							m		SIL	f							
			16.17	19.00	2.83	DOL	MX		Light yellow to white MG to CG DOL, with OX zones up to 10 cm wide. Brassy, FG Py found along rims of DOL crystals, disseminated, defining FO to massive. Dull grey MG to CG As found locally in fair amount, trace overall.	FO	60					w				i	t					
			18.33	19.00	0.67	MX	DOL		Massive FG brassy Py with DOL VT.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			19.00	20.30	1.30	DOL	cBX		Medium grey FG to MG DOL with dark grey stringers cross cutting white DOL VT. Very broken and altered DOL ranging to orange brown rubble and medium brown clay. Trace Py stringers.							f				t							
			20.30	23.82	3.52	DOL	MX		MG to CG light yellow DOL locally pink-red stained (HEM), and greenish around rims. Pink stain around dark brown SID altered fractures and VT. Intensely mineralized by FG green-brassy Py, disseminated, defining FO to massive. As, MG to CG, dull grey to silver on fresh surfaces. Py appears to cross-cut As. Increasingly As rich down interval.	FO	55							HEM	w	i	i						
										VT	20	225															
			23.82	25.53	1.71	DOL			FG to MG, light yellow to white DOL with FO defined by fine grained grey layers. The interval is very hard and less well MX than surrounding intervals. Py is FG, brassy and follows FO with trace MG dull grey disseminated As.	FO	55							SIL	f	f	t						x
									Qz/DOL VT cross-cutting MX, with Qz preferentially at sections where MX trend crosses VT.	VT	25	180															
			23.82	24.38	0.56				Highly OX along FX planes, possibly altered VT. Unoxidized portions of interval display quartz eyes and small Qz VT.									SIL	s								
			25.53	27.21	1.68	DOL	MX		Light orange, yellow, and white FG to CG DOL, with grain size variety defining FO along with FG brassy Py and MG grey disseminated As. Light orange DOL appears to be Fe-staining from Py bands.											s	f						
			27.21	28.00	0.79	LST	OX		Orange brown OX, with unoxidized zones white to dark grey, intensely dolomitized LST with SID coating fractured and broken core.					i		s	f								
28.00	39.66	11.66				OX			Orange brown non-calcareous clay to core. SID rubble is common.							i	i										
			28.00	30.90	2.90	OX	SID		Orange brown to dark red-brown clay to core, predominantly SID altered core.							s	i										
			30.90	39.66	8.76	OX			Orange-brown clay to rubble with dark red brown colour common below smeared surface of the core. Predominantly silt with small rubble zones.							i	i										

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
39.66	50.81	11.15				DOL	MX		Light yellow to light pink MG to CG DOL, locally cBX and containing a cataclastic texture. Mineralization consists of FG to MG Py, defining FO and disseminated to massive in a brassy to light gold colour. As is MG to CG, dull grey, euhedral to anhedral in shape and disseminated throughout.											m	w						
			39.66	40.74	1.08	DOL	MX		Medium pink, MG DOL (HEM altered) with orange DOL as rims around Py patches. Py is FG, brassy silver, disseminated, forming bands at various orientations. As is trace, MG, subhedral, found in Py planes. Core surface corroded, with Py planes particularly OX. Last 20 cm very corroded and altered dark red-brown.							t	w	HEM	s	ms	t						
			40.74	42.34	1.60	DOL	MX		Light pink to yellow-white, MG to CG, cBX DOL/ANK with zones of dark grey, FG, intensely DOL altered LST with white spotting. The unit has sharp contacts with DOL. Py is FG to MG, disseminated, and doesn't form planar structures. As is MG to CG, anhedral and disseminated to patchy. OX coats fractures near Py.						f	t		HEM	f	s	w						
			40.74	40.98	0.24	DOL	mBX		DOL matrix with <1 cm diameter clasts of FG dark grey LST. Trace seams of dark grey mineral with sheen and flat surfaces (graphite?).														Gr	w			
			42.34	43.56	1.22	DOL	MX		Light to medium pink and light orange, MG, DOL/ANK with HEM alteration. Py is FG to MG, brassy, defining FO in thin stringers and massive up to 10 cm thick. As is MG to CG, anhedral and appears to be replaced by Py						w			HEM	f	s	w						
			43.56	45.37	1.81	DOL	MX		MG to CG, light yellow with medium pink patches, DOL/ANK (HEM altered). Py is FG to MG, defines FO and is brassy. As is MG, dull grey and disseminated. Bismuthinite (very soft, dark grey) is found in trace amounts.	FO	60				w			HEM	s	m	t		Bs	t			
			45.37	45.88	0.51	DOL	MX		Light orange DOL/ANK, FG to MG, cBX by thin dark grey seams, locally very concentrated. DOL VT ~ 0.5 cm thick, with vugs from corrosion, occur en echelon, coinciding with zone of elongation of grey stringers and DOL (Strain zone?). Py/As is trace and disseminated.						ms					t	t						x
			45.88	48.55	2.67	DOL	MX		MG to CG light orange to pink white, DOL/ANK with FG Py defining FO and MG to CG As disseminated near Py. OX is weak around Py and on FX.	FO	60				m	t				ms	w						
									Ca VT with offshoots at low angle TCA. Irregular.	VT	30	80															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

0.00	2.60	2.60				OVB			Overburden - no recovery																		
2.60	28.20	25.60				LST			Grey to light-grey medium to fine-grained partially marbleized and fossiliferous limestone.																		
			2.60	12.80	10.20	LST			Light grey to grey limestone unit that interfingers between slightly marbleized crinoidal wackestones and mudstones with a weak foliation. Unit terminates in broken core along foliation with abundant carbonaceous material.																		
									Foliation is defined by the shear fabric	FO	40																
			12.80	17.37	4.57	MBL	LST		Grey highly foliated and strained marbleized limestone. Primary clastic lithology is cryptic and not visible due to the marbleization and the ductile nature of the fabric. The sinuous foliation becomes anastomosing in some portions. Lower contact becomes broken along foliation with carbonaceous material.																		
									Foliation is define by a ductile fabric	FO	30																
			17.37	28.20	10.83	LST			Dark to medium grey interbedded clastic crinoidal wackestones to mudstones and floatstones. Floatstone fragments are mostly favosites with tightly packed tabulae from shear, with minor Rugosan corals. Favosites may occur as one unit for 1 m. Lower contact is slightly yellow along oxidized fractures surfaces along foliation.	FO	50															
									Coarse grained angular Quartz-calcite veins that is 1 cm thick and occurs along a strained foliation.	VN	50	0	1														
28.20	50.06	21.86				VOL			Pale green to dark grey fine to medium-grained foliated and strained volcanic. This unit is non-magnetic and has abundant calcite veining and fair biotite alteration. The unit is fairly fractured and has gouge material throughout fractures. Unit interfingers with a cobble conglomerate. Upper contact has rubbly oxide volcanic, the lower contact has more gougy oxide.							w		BIO	f								
			28.20	36.40	8.20	VOL			Pale dark green foliated volcanic. Pre-shear irregular calcite veins are common and appear strained along foliation. Biotite occurs as fine-grained dark-brown networks within the volcanic.																		
									The foliation is strain induced	FO	30																
									Coarse, euhedral calcite vein that is 3 mm to 1 cm thick.	VN	45	270	3														

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			36.40	39.95	3.55	VOL	CGL		Pale green foliated conglomerate with rounded elongated clasts following the foliation. Clasts are darker green-grey and have irregular white clastic fragments in them.							t											
									Foliation is defined by elongated clasts and sheared foliation with minor mm scale oxide staining.	FO	35					t											
									Medium-grained euhedral calcite vein	VN	35	195	1														
			39.95	42.60	2.65	VOL			Brown fine-grained biotite rich volcanic with abundant calcite spotted texture as well as pre-shea irregular calcite veins. This unit has many brittle faults, now annealed, offsetting many features of veining and strain.																			
									A strained fabric defined the foliation	FO	30																
									1 mm wide white calcite veinlet.	VN	50	270	2														
			42.60	46.00	3.40	VOL	CGL		Deep and pale green conglomerate with clasts up to 5 cm long elongated with foliation, the matrix is a mottled green-black colour and clasts are pale green and subrounded with some weak biotite alteration. The unit is non magnetic.									BIO	w									
									The foliation is defined by elongated clasts and strained fabric.	FO	35																
									1.2 cm calcite vein.	VN	30	260	1														
			46.00	50.06	4.06	VOL			Dark grey to pale green fine-grained to very fine-grained slightly calcareous volcaniclastic. The calcareous portions appear muddy like deep marine silts with broken core and gouge in the fractures.																			x
									Weak foliation.	FO	50																
									1 cm calcite veining with oxide staining.	VN	49	195	1														
50.06	157.36	107.30				LST			Grey to light grey fine-grained limestone with some muddy interbeds. Oxidized and marbleized portions occur throughout. The upper contact shows light-grey cBx textures.					t		t				w		w					
			50.06	93.00	42.94	LST			Grey, fine-grained LST. Upper contact has very broken core along the foliation with minor oxidation and gouge material. The less broken core tends to be marbleized and is lighter grey. Weak pyrite and pyrrhotite occur along the foliation as anhedral elongated masses and are also associated with intruding calcite. The sulphides are associated with a grey stylo-mottled texture and often bound fossils.					t		t				w		w					
									Foliation is defined by a strained fabric with minor oxide stain.	FO	45																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									Grey calcite vein that is undulating from 45 to 0 TCA.	VN	45																
			93.00	110.70	17.70	LST			Grey to dark grey fine-grained limestone with minor oxide staining associated with broken core along a foliation. No sulphide mineralization in this unit aside from possibly oxidized reddish pyrite grains. Coarse white calcite occurs pre-strain and is cut by a grey calcite. Along the foliation there are interfingerings of slightly sericitized and oxidized volcaniclastic material (?) and gougy material.							w		SER	w							
									Moderately defined foliation along the strained fabric.	FO	62																
									The lCN gradationally interfingers with sericite and oxidized wispy units resembling slightly oxidized silty gouge. A small pre-strain quartz vein also occurs at the lower contact.	lCN																
			110.70	120.00	9.30	LST	OX		Moderately strong oxidation of limestone with interbedded sericitized wisps of pale yellow volcaniclastic (?).							ms										
									Moderate to strong foliation defined by strained fabric.	FO	35																
			120.00	131.49	11.49	LST			Light to medium grey FO banded LST. Light grey bands are FG, spotted white and black texture (MBL alteration?). Dark grey layers are vFG with homogenous grey colour. White Ca VT and MG white and black spotted VT follow FO. Trace Qz VT occur at irregular orientations throughout the interval. Orange brown FG alteration coats FX and following FO. Overall the interval is very broken up.							t		MBL	f							
									The foliation is locally irregular and often undulatory.	FO	40																
			131.49	155.09	23.60	LST			Medium grey, very broken, FG LST with orange brown to dark red brown FG alteration on FX, following FO, and pervasive through core sections up to 5 cm wide. Zones of light grey FG white and black spotted Ca occur throughout (MBL alteration?). White and black spotted MG Ca VT and white FG Ca VT generally follow FO. Rubble zones up to 50 cm long occur intermittently throughout.	FO	40						m		MBL	m							
			146.91	149.96	3.05	LST	SHL		Very rubbly LST rich in dark red brown to grey platy shaley layers following FO. The shaley material is the matrix to rounded LST clasts. The unit fizzes weakly therefore is likely dolomitized.	FO	40			m														

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			150.90	151.49	0.59	LST			Medium grey with weak orange brown alteration patches pervasive in core. VOL rich LST?																		
			155.09	157.36	2.27	LST	MBL		Light grey intensely MBL LST that is very broken with orange-brown to medium brown alteration in clay zones associated with medium grey seams and pervasive throughout some sections of the core.									MBL	i								
157.36	196.62	39.26				VOL			Medium green-grey to dark grey, FG, FO VOL. The unit starts off magnetic and becomes less so with depth. The unit contains thin Ca VT throughout. A zone of moderately strong OX iteration occurs within.	FO	60																
			157.36	166.73	9.37	VOL	Mg		Medium green-grey, FG VOL with FG white Ca spots elongated along the FO. White Ca VT generally following the FO occur throughout. The interval contains weak concentrations of black very fine grained magnetite patches.	FO	60														Mg	w		
			166.12	166.73	0.61	VOL	Mg		Dark grey VOL, with increased magnetite content and Ca veining at irregular orientations. The lCN is gradational.	VT			10											Mg	m		
			166.73	168.31	1.58	VOL	OX	CGL	Light orange, yellow and green grey, FG VOL CGL with intense SER alteration and moderate strong OX alteration. Alteration variations highlight light yellow elongate clasts in green-grey matrix. This interval is non-magnetic and non-calcareous. Fractures are generally aligned along the FO and have a yellow sheen on their surfaces. Both the upper and lower contacts are gradational.	FO	60					ms		SER	I							
			168.31	172.64	4.33	VOL			Dark grey, FG VOL with buff SER altered sections. Weak fine grained disseminated magnetite occurs in the groundmass. Ca veinlets and patches occur throughout, but become slightly oxidized after 17.5 m. The conglomerate clasts do not occur throughout, rather they occur in zones and can reach up to 4 cm in diameter.															Mg	w		
			172.00	172.52	0.52	VOL	RBL		Very broken, FG dark grey weakly calcareous VOL that is weakly magnetic. Possible FLT.	FLT																	
			172.64	189.32	16.68	VOL	CGL		Gradational uCN into medium green-grey FG non magnetic VOL with <2 cm diameter Ca spots and clasts of varying colour (white, buff, orange) elongate with the FO. These spots do not appear to be amygdules. Trace irregular Qz is associated with bright orange Ca.	FO	60																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			174.00	189.32	15.32	VOL			Interval containing intense Ca veining. The veinlets generally follow the foliation at 60 deg TCA.	VT			10														
			174.00	189.32	15.32	VOL			Green to deep pale green, fine to medium-grainec foliated volcaniclastic. 1 mm scale and elongated Ca clasts are overprinted by a rusty coloured oxide stair generally rimming the calcite. The lower contact becomes more heavily fractured and oxidized especially in the gouge that often forms in the fractures.																		
									Foliation is defined by elongation of clasts and a pervasive strong strain fabric.	FO	60																
									Ca Vns occur throughout and undulate with the strain fabric.	VN	60	0	3														
189.32	196.62	7.30				VOL	OX		Highly oxidized and sericitized orange to rusty coloured and foliated volcanic unit. This unit has abundant broken core with rusty orange gouge along the fractures.							i		ser	i							
196.62	237.60	40.98				MBL			White to light grey banded and highly strained MBL. Foliation is grey and sinuous to folded bands, cryptic, likely old foliation structure before marbleization. The uCN is sharp with the oxidized volcaniclastic. Overall the core is very broken and often has 1-4 cm intervals of rusty OX gouge along fractures. The there is a gradational increase in gouge content deeper in the unit.							m				t							
									Strong foliation occurs in the MBL	FO	40																
237.60	243.23	5.63				OX			Rusty orange to deep brown competent and silty oxide unit. Some darker brown portions are more gritty and don't hold the shape of the core well.																	
243.23	248.72	5.49				MBL	OX		White to rusty coloured rubbly marble with rusty staining. Sections of broken core are associated with intense rusty colour and grittier material.							w										

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
248.72	263.96	15.24				OX			Deep red to brown to grey soft and silty yet competent oxide. The deeper brown the rock is the more rubbly to gritty it becomes. Minor sections of rubbly weathered quartz occur. Portions of more competent rock within the oxide appear to be the leopard unit, highly calcareous and foliated with biotite and calcite. Deep red and deep green foliations are present on the leopard unit. The leopard rock fractures easily.																			
									Foliation is defined by green to red tabular clasts.	FO	45																
263.96	269.14	5.18				LEP			Grey to light grey foliated leopard unit with moderate foliation. The unit has broken core which is accompanied by gouge and gritty oxide material.							m										
									There is a weak to moderate foliation present in the unit. Occasional oxide stain occurs along the FO.	FO	55																
									269.14 m - E.O.H. The hole was ended because the hole was past the targeted oxide horizon.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

COMMENTS

The hole was ended because it was past the targeted East Zone. The hole appears to skirt the edge of the mineralization present in other holes with only intermittant zones of hydrothermal DOL.

GEOLOGY LOG

HOLE: Rau-10-98

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
0.00	2.97	2.97				OVB			Overburden - no recovery																		
2.97	215.68	212.71				LST												MBL	f								
			2.97	9.09	6.12	LST	SHL		Medium grey, MG, FOS LST with brown, FG SHL interbeds throughout. SHL bands decrease in width and frequency with depth, are reddy-brown in colour and do not fizz with HCl. LST is medium grained, hosting weak amounts of crinoid stem fragments. Weak OX alteration is present on fracture faces.																		
									FO is defined by shale interbed orientations, 45 degrees TCA.	FO	45																
			9.09	52.60	43.51	LST	MBL		Light to dark grey, FG to CG, variably strained, variably FOS, strongly MBL LST. A banded appearance is exhibited by light to medium grey, strongly MBL altered zones with darker, FG, FOS, less MBL altered muddy limestone interbeds throughout. The unit is weakly FOS, with crinoid and coral favocities "honeycomb" and halycites "chain coral") fragments present in dark, FG, muddy LST beds. FOS content increases while MBL alteration decreases with depth.									MBL	s							
									FO is defined by a banded texture in strongly marblized rock and "bedding"(?) in FG muddy LST, oriented 40 degrees TCA.	FO	40																
			52.50	57.95	5.45	LST		BX	Dark to light grey, FG to CG, variably BX LST. A weak mBX texture is exhibited intermittently, locally appearing sBX with clasts supported by a white, CG, calcareous matrix. Weak fossils are present, including deformed crinoid stem fragments throughout.																		
									FO is defined by BX orientation, 50 degrees TCA.	FO	50																
			57.95	75.69	17.74	LST	FOS	MO	Dark to medium grey, FG, strongly strained, mottled, fossiliferous LST. A mottled texture is oriented with strain fabric. Strain is also exhibited by deformed fossils including cryptic honeycomb favocities and rugose corals.																		
									FO is undulose, defined by strain fabric, oriented 10 to 30 degrees, generally 25 to 30 degrees throughout.	FO	30																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			75.69	118.14	42.45	LST	MBL	BN	Medium to dark grey, sucrosic, weakly FOS, strongly MBL altered, strained LST. Strain is exhibited by a variably undulose, shallow fabric throughout. Coral and crinoid fossils are present, often deformed to obliterated by strain and marbleization. White and dark bands define strain fabric (MBL dissolution?)									MBL	s								
									FO is undulose throughout, variably oriented from 0 to 30 degrees TCA, typically around 10 degrees. FO is defined by banded fabric throughout.	FO	10															
			118.14	127.42	9.28	LST		BX	Dark grey, FG, finely laminated to BX LST hosting Qz-Ca veining. Where not laminated, rock appears cBX with FG black BX matrix appearing deformed with localized Qz-Ca veining. Qz-Ca veining occurs between 122.00 m and 126.99 m with CG white Ca and translucent Qz																		
									Where laminated, FO is oriented 40 degrees TCA, but can be shallower.	FO	40																
			122.00	126.99	4.99				Qz-Ca white "stockwork" veining, locally deforming and brecciating LST. At times veinlets have soft, non-calcareous (DOL?) selvages with trace epidote. Veining lack a common orientation, but narrow veinlets 2 to 9 mm wide are generally oriented 70 degrees TCA. Veins are up to 25 cm wide and make up nearly 10% of interval.	VN	70																
			127.42	146.03	18.61	LST	MBL		Light to dark grey, sucrosic, weakly FOS, strongly MBL altered, strained LST. Strain is exhibited by undulose, shallow laminated fabric. Trace coral fossils are present, but their textures appear deformed to obliterated.																		
									An undulose FO is defined by banded fabric oriented from 0 to 30 degrees TCA, generally at 15 degrees.	FO	15																
									CG white Ca and translucent Qz veinlet 8.5 cm wide, oriented 45 degrees TCA and 270 degrees to FO. Mineralogy and habit is similar to Qz-Ca veining above.	VT	40	270														
			147.45	147.47	0.02				White Ca-Qz-DOL VN, locally "brecciating" host rock with coarse, vuggy core with rhombs of grey dolomite at the centre of the veinlet. VN selvages are soft, grey, non-calcareous (DOL?). VN is oriented 10 degrees TCA, 270 degrees to FO and is 2.1 cm wide.	VT	10	270														

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									Qz-Ca-DOL veinlets lacking uniform orientation, often near 180 degrees to FO, between 10 and 80 degrees TCA throughout.	VT		180															
			146.03	149.60	3.57	LST		BX	Dark grey, FG, weakly BX LST hosting Ca-Qz-DOL veining which at times locally brecciated host LST appearing sBX in texture. Generally rock exhibits a BX texture throughout, at times BX matrix appears near stylolitic. BX clasts at times appear mottled (dissolution?).																	
									FO is defined by BX orientation, 50 degrees TCA.	FO	50																
			149.60	185.23	35.63	LST	MBL		Light to dark grey, sucrosic to FG, strongly MBL altered, strained LST. Trace coral fossils are present, textures are often deformed to obliterated. An undulose fabric persists throughout. Where MBL and strain are less evident, relict BX/debris flow textures are less obscured. Crinoid, rugose and favocities corals present.																	
									FO is defined by banded fabric and is variable throughout, oriented from 0 to 50 degrees. Foliation steepens with depth generally oriented 35 to 40 degrees TCA.	FO	40																
									Dark grey, FG, variably BX and strained LST hosting Ca-Qz veinlets. Ca-Qz veining locally brecciated host rock, supporting dark LST clasts in a white, CG veinlet matrix. The LST also have a variable mottled to cBX texture throughout.																	
									FO is defined by a weak undulose strain fabric oriented at 50 degrees TCA.	FO	50																
									CG, white Ca-Qz veinlets locally sBX LST with variable thicknesses 4 mm to 3.5 cm that are generally oriented parallel to FO but where narrower appear shallow TCA and up to 90 degrees to FO.	VN	50	0

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			186.89	209.01	22.12	LST	FOS		Dark to medium grey, strongly FOS, variably MBL altered, weakly SIL altered, variably strained LST. Crinoids and rugose and favocities corals dominate, rock appearing locally wakestone to packstone where most fossiliferous, usually as narrow beds between soft, FG lime muds, giving a banded texture to rock. Where strained, beds appear convoluted and deformed (soft sediment deformation?) MBL appears where strain is highest, sucrosic MBL textures obscure fossils. Trace patches of cherty SIL alteration of nodules 2 to 3 cm in size. A clast with bedding textures is present at 196.50 m (speliothem?)								MBL	w							X
									FO is defined by banding/bedding, oriented 50 degrees TCA, increasing with depth.	FO	50							SIL	w							
			209.01	215.68	6.67	LST		BX	Medium to light grey, variably BX, FG LST with trace vuggy textures. Generally a cBX texture is exhibited with weak sBX throughout. lCN is gradational, lightening in colour before a sharp CN with a FG Py band.	CN																
									Narrow, white, 2 mm wide fracture filling Ca veinlets are present throughout, with a weakly common orientation shared at 30 degrees TCA.	VN	30															
215.68	219.46	3.78				DOL	MX	SP	White to medium grey, intensely DOL altered, CG, sparry crystalline DOL with banded Py MX. Weak ANK alteration is present where core is most sparry occurring as creamy yellow coarse crystal rhombs. Py MX appears as FG, dull, metallic yellow bands, 1 mm to 1.2 cm wide. Trace bright euhedral MG, pitted Py overprints FG dull PY at 219.27 m. A narrow FG, light grey, dolomitic MBL interlayer from 216.59 to 216.92 m occurs. Trace Po is present as CG overprints of Py at 218.80 m, trace As is present near uCN as MG, euhedral crystals. uCN is gradational, increasingly DOL with depth over 15 cm, becoming coarser, and hosting sulphide MX.	CN				i	w					ms	t	t					
									FO is defined by Py banding, oriented 60 to 70 degrees TCA, most commonly 60 degrees.	FO	60															
			216.59	216.92	0.33	MBL			DOL altered MBL, light grey, fizzes when scratched. CNs are sharp, defined by MG bands of Py oriented 60 to 70 degrees TCA.					i				MBL	i							

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
219.46	220.75	1.29				MBL			White, sucrosic, "Italian" MBL with faint bands throughout. uCN is sharp, defined by a Py band oriented at 70 degrees TCA. lCN is defined by convoluted beds between MBL and VOL unit.	CN																	
									FO is defined by faint bands in MBL, oriented 70 degrees TCA.	FO	70																
220.75	235.93	15.18				VOL		AM	Dark green to brown, variably AM, variably magnetic, FG to MG VOL. Unit is green where intensely CHL altered, becoming brown, intensely BIO altered with depth. AM textures are variably present in both green and brown VOL. Rock appears bleached and SER altered at CN's, much more so at the lCN. SER alteration is also associated with narrow Ca veinlets.									CHL	s								
																			BIO	s							
			220.75	226.24	5.49	VOL	CHL	AM	Dark green, variably magnetic, variably AM, intensely CHL altered VOL. Magnetism is exhibited strongest from 221.30 to 224.50 m. Trace SER is associated with Ca veinlets. AM textures become apparent with depth. Amygdules range in size from 2 mm to 1.4 cm across, and are infilled with CG calcite. lCN is gradational, changing from green to brown over 60 cm.									CHL	i								
																			SER	t							
									FO is defined by AM orientation and weakly banded textures intermittent throughout, oriented 45 to 55 degrees TCA.	FO	50																
									Narrow Ca stringers oriented 0 degrees to FO, 2 to 4 mm wide throughout, 30 to 50 degrees TCA and appear as angular, fracture fills. Occasional SER alteration over 7 mm is seen with widest Ca stringers.	VT	40	0														
			226.24	231.46	5.22	VOL	BIO	AM	Brown, variably AM, variably magnetic, intensely BIO altered, FG VOL becoming calcareous with depth. Amygdules range in size from 2 mm to 1.4 cm across, infilled with CG calcite. Py is present as cubic crystals <4 mm forming bands and variably exhibiting exsolution textures. FG wisps of Py are also present. Trace Po present in a narrow VT.									BIO	i	f		t					
									FO is defined by a weak banding fabric, oriented 45 to 50 degrees TCA.	FO	45																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									Ca-Po VT with trace CHL alteration, 2 to 3 mm wide oriented 40 degrees TCA, 90 degrees to FO.	VT	40	90															
			231.46	235.93	4.47	VOL	SER	FG	Grey-yellow to dirty olive green, FG to CG variably SER altered VOL with strong Py MX. Rock becomes more grey with depth with fine, delicate wisps of SER. SER alteration up hole is stronger, more pervasive forming soft masses of altered VOL. Strong Py MX is present as dull FG masses to octahedral crystals 6 mm in size, and as bright, FG disseminations. Py abundance increases with depth. lCN is gradational, becoming less calcareous and grey in colour and having a more pronounced BX texture over the last 20 cm of unit. (Harry Cook identified pumice texture, delicate wisps of SER alteration in FG, irregular grains)								SER	s	s						
235.93	346.71	110.78				LST	DOL	BX	Dark to light grey, FG to CG, variably BX, intensely DOL altered LST. Trace dissolution textures are seen throughout. Trace fossils are seen with depth. Generally, unit is sBX in texture, but "camo" mottling and crackle breccia textures are also evident.					i												
			235.93	315.10	79.17	LST	DOL	BX	Dark to light grey, FG to CG, variably BX, intensely DOL altered LST. Generally, rock is sBX with a white, CG, sparry matrix throughout, but at times exhibits cBX textures.					i												
									A lack of pervasive orientation of grains or clasts prevents a FO measurement.	FO	n/a																
									CG, DOL-Py-Po VN at 249.22 m, oriented 55 degrees TCA. 13 cm wide with patchy Po with CG, bright, "shotgun" Py overprinting Po within the vein and along VN walls. Vein selvages are wide, up to 3.7 m up hole and 1.2 m down hole, bleaching DOL altered LST to a light grey.	VN	50	n/a								m		f					
			275.69	278.77	3.08	LST	DOL	MO	Dark to medium grey, FG, intensely DOL altered, mottled LST, weakly exhibiting sBX textures. Small voids with sparry white DOL are weakly present throughout. Weak OX/Fe staining present on fracture faces. uCN and lCN are gradational, voids become increasingly sparry over 12 cm both up and down hole.	CN				i		w											
									FO is defined by orientation of mottled "blobs", 50 to 60 degrees TCA.	FO	50																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			280.30	283.89	3.59	LST	DOL	MO	Dark to light grey, intensely DOL altered, sBX LST, with moderate Fe staining/weathering. Rock appears blocky to rubbly (FT?) Fe (OX?) alteration is more pervasive in a narrow interval from 282.22 to 282.52 m.	FT				i				HEM	m								
									FO is defined by BX clast orientation, 50 degrees TCA.	FO	50																
			289.36	295.47	6.11	LST	DOL	MO	Dark grey, FG, intensely DOL altered, MO "camo" BX in texture, weakly FOS, LST with trace Py MX. Fossils present are trace bryzoan and coral fragments. Py is preset as bright yellow, subhedral MG growths preferential to dark, FG rock (dissolution textures?).					i						t							
									FO is defined by orientation of MO clasts, 60 to 70 degrees TCA.	FO	65																
									White to medium grey, CG, sparry DOL veinlets throughout, 2 to 7 mm wide, generally oriented parallel to FO. Py MX is present, preferential to VT's with darker grey DOL.	VN	60	0	3													
			315.10	346.71	31.61	LST	DOL	FG	Dark to light grey, FG, weakly BX, intensely DOL altered, laminated, weakly FOS LST. Fossils present are favocities fragments and trace narrow beds of crinoid packstone. Trace Py is present in narrow, dark lime mud beds and in CG veinlets/solution textures.					i						t							x
									FO is defined by laminations (bedding?), oriented 45 60 degrees TCA, generally 50 degrees.	FO	50																
									CG, Ca-DOL veinlets, 6 mm to 5.5 cm wide (locally BX host rock?) generally oriented near parallel to FO. Trace Py is present in veinlets and along selvages of a VT passing through dark, muddy interbedded LST at 331.92 m.	VN	60	0	1													
346.71	359.89	13.18				VOL		BN	Light grey to olive green to black, FG to MG, banded to mottled, variably calcareous VOL. Banding defined by layers of compositional and grain size differences (rhythmic bedding textures?) Moderate SER alteration present, preferential to certain bands. Moderate Py MX is present increasing with depth, Po is present in trace amounts at shallow depths.									SER	ms								

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			346.71	356.72	10.01	VOL		BN	Medium grey to olive green, FG to CG, variably SER altered, banded VOL with weak Py MX. Weak amounts of FG, black, (argillaceous?) beds through out. Py is present as MG disseminations to narrow, <1 mm bands of bright, euhedral yellow crystals. Po is present as trace bands (VT?) to blebs up to 4 mm in size preferential to darker, CHL bands. Banding (bedding?) become finer and more convolute with depth, at times appearing fractured/strained. Rock becomes more calcareous with depth, with a white Ca matrix present to lCN.									SER	ms	w							
									FO is defined by banding/bedding, oriented 45 to 55 degrees TCA.	FO	50																
			356.72	359.89	3.17	VOL		BN	Dark grey to black, FG, banded VOL with strong Py mineralization. Sub unit is very dark, soft, noncalcareous and vFG. XRF readings register a VOL signature (elevated Ti, K counts, etc). Py is present as dull, FG bands up to 2.6 cm wide to fine wisps. A second generation of Py is present as bright yellow, rims to blebs replacing dull Py. A gradational change is marked above the lCN, Py bands become increasingly convolute with depth. Rock is fissile, commonly fracturing along parallel beds oriented with Py bands.											s							
									A strong FO is defined by bands of Py and preferential fractures, oriented at 50 degrees TCA.	FO	50																
359.89	402.46	42.57				LST	DOL	BX	Dark to light grey, FG to CG, variably BX, intermittently recrystallized, intensely DOL altered LST hosting fair, intermittent Py MX throughout. Py MX locally strong to very intense. Weak hydrothermal DOL recrystalization seen throughout, generally rock is sBX to tBX in texture. Trace TLC alteration occurs.					i				TLC	t	f							
			359.89	378.13	18.24	LST	DOL	BX	Dark grey to white, FG to CG, variably sBX, intensely DOL altered LST. Weak Py MX is present with depth. Where FG, rock is darker, less sBX in texture and more cBX-mBX. Up hole, Py is present in VT selvages, downhole Py is seen as FG to MG, bright yellow "shotgun" blasts, to fine, euhedral disseminations. Dull, FG Py forms masses near veining, exhibiting overprinting textures by a bright yellow, euhedral Py. SIL alteration is present with depth.					i				SIL	w	w							

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
									FO is defined by weak BX orientation and bedding in FG layers, 30 to 40 degrees TCA.	FO	40																
									White to light grey, CG, DOL-Qz-Ca veinlet, oriented 35 degrees TCA, 270 degrees to FO, and is 7.5 cm wide. Py MX is present along veinlet selvages as dull, FG, small masses being overprinted by a late bright yellow euhedral MG Py.	VT	35	270														
									Light grey to white, MG to CG, DOL-Qz veinlets oriented 30 to 60 degrees TCA and variably to FO. Veinlets crosscut FG bedding and sBX textures.	VT	40															
									CG, light grey, translucent veinlet, oriented 30 degrees TCA, 270 degrees to FO. Veinlet selvages locally SIL altering host LST, up to 9 cm away from VT. Trace Py is present in VT selvages as dull, MG disseminations.	VT	30	270														
			378.12	380.10	1.98	LST	MX	BX	Dull, metallic yellow to medium and light grey, very intensely Py MX (Py vein?) sBX, intensely DOL altered LST. Py is present as dull, grey-yellow masses to MG "shotgun" disseminations of euhedra bright Py replacing dull Py along margins of mineralization. Qz appears CG, translucent, readily associated with upper margin of Py MX. Trace TLC alteration of host occurs proximal to Py MX.	VT				i				TLC	t	55			Qz	m			
			380.10	385.48	5.38	LST	DOL	BX	Dark to light grey, FG to CG, tBX to sBX, intensely DOL altered LST. Weak TLC alteration is associated with CG Qz MX. Py is present as MG, bright, euhedral "shotgun" masses to trace, FG, dull blebs. Typically, LST appears tBX with dark, angular clasts <2 cm in size supported by a MG-FG matrix of light to medium grey material. Where not tBX, rock exhibits typical rounded sBX textures.									TLC	w	w							
									FO is defined by fabric and orientation of clasts in tBX textures, 50 degrees TCA.	FO	50																
									CG, translucent grey, Qz VT. Upper VT margin is parallel to FO, lower margin is convolute. VT selvage exhibiting TLC alteration of host LST is up to 20 cm wide.	VN	55	0														

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			385.48	386.30	0.82	LST	DOL		Light to dark grey, FG to CG, intensely DOL altered sBX with moderate hydrothermal crystalline DOL. Unit exhibits a very weak "East Zone" appearance. Moderate Py MX is present as bright, MG euhedral, <2 mm crystals rimming dark BX clasts. Po is conspicuously absent. Weak TLC alteration of hydrothermal crystalline DOL is present.					i				TLC	w	m							
									FO is very weak, defined by BX fabric, oriented 60 to 70 degrees TCA.	FO	65																
			386.30	397.05	10.75	LST	DOL	BX	Dark to light grey, FG to CG, variably sBX to tBX, intensely DOL altered LST with moderate Py MX. sBX textures are more coarse, tBX textures increase with depth, becoming more MG-FG. Py MX present as "shotgun" masses of bright, euhedral, <3 mm crystals to finer, trace disseminations of cubes in tBX textures.					i						m							
									FO is defined by BX textures in both sBX and tBX, oriented at 60 to 70 degrees TCA.	FO	65																
									CG, translucent, white Ca vein, 9 mm wide, oriented 20 degrees TCA, 270 degrees to FO, crosscutting BX textures at 387.15 m.	VT	20	270														
									Narrow, CG Qz-Ca VT, oriented 10 degrees TCA, 2 mm wide with weak red Sp crystals throughout. VT is located at 390.30 m.	VT	15	n/a										Sp	w			
			397.05	402.46	5.41	LST	DOL		Dark to light grey, FG to MG, variably BX, weakly recrystallized, intensely DOL altered LST with strong Py MX. Py is present as FG, dullish yellow masses to wisps throughout, Py MX is strongest in dark, FG beds. A weak cBX to mBX texture is present throughout. lCN and uCN are gradational, exhibiting tBX textures bounding sub unit both above and below.	CN				i				SIL	w	s							
									CG, translucent grey Qz vein from 400.85 to 401.94 m, hosting undulose masses of FG Py. VN selvages exhibit SIL alteration.	VN	65	180														
402.56	409.96	7.40				LST	DOL	BX	Dark to light grey, FG to CG, tBX, intensely DOL altered LST with trace Py MX. Dark, angular clasts <4.7 cm in size are supported by a MG-FG, medium to light grey matrix. Weak sBX textures are exhibited from 402.98 to 403.12 m. Trace Py is present as dull yellow blebs associated with dark clasts in BX, amaeboidal in shape, <1.1 cm to 2 mm in size. tBX matrix appears weakly calcareous.					i						t							

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

COMMENTS

The hole was ended because it was successfully tested below the marble and found a slightly new style of mineralization.

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	0.61	0.61				OVB			Overburden - no recovery																		
0.61	1.50	0.89				LST	RBL		Very broken medium grey to dark grey LST with thin Ca VT running along the FO.																		
1.50	9.51	8.01				VOL			Medium blue grey, FG, non-calcareous, moderately to strongly dolomitized LST with patches of light orange alteration. MG, black, soft, non-magnetic spots are disseminated and patchy throughout along the following. Trace Po and As are also disseminated throughout. The uCN and lCN are both fairly altered an orange-brown colour. The lCN has moderate disseminated patchy Py.	FO	35			ms						t	t	t					
			1.50	4.50	3.00	VOL	OX		Light orange yellow, very broken, core to clay, predominantly rubble, some of which have planar surfaces with a sheen (SER). The lCN is gradational with trace Po in the VOL below.							s		SER	s			t				
			4.50	8.54	4.04	VOL			Medium blue grey, FG VOL with patches of light orange to green alteration. MG spots of black mineral with trace associated Po are aligned along the FO, defining a banded pattern. FG to MG, disseminated and subhedral As occurs trace throughout. Po is FG to MG, disseminated. Trace emerald green smeared spots of Fu. The first 50 cm of interval has < 1 cm white to buff variably calcareous clasts. The black spotting is locally altered to a light green colour.											t	t	Fu	t			
			8.54	9.51	0.97	VOL	Ca		Light green-grey to bright orange-brown, SER altered and OX altered, FG, FO Ca rich VOL. White, MG Ca spots with brown rims occur over a 15 cm patchy area. The last 10 cm have FG massive Py patches which continue to next interval (locally strong, but weak overall).										w							

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
9.51	14.06	4.55				LST	DOL		Light to medium grey, FG, variably DOL LST with medium grey to light buff SER altered VOL rich layers. Ca VT occur at various orientations. FG to CG, brassy, disseminated and patchy Py occurs throughout. The patches are up to 3 cm wide and found preferentially in VOL rich layers. Localized cBX of the more DOL altered areas occurs. The uCN has intense DOL alteration for the first 2 m which grades into increased VOL layering in LST that is increasingly MBL.					f						w							
14.06	21.16	7.10				VOL			Medium grey with light yellow to buff SER altered VOL zone that is variably magnetic and has conglomeratic zones. The clasts are <1 cm in diameter and variably contain calcite and quartz.																		
			14.06	16.05	1.99	VOL	SER		Light yellow-green to buff, FG, weakly calcareous, non-magnetic SER altered VOL. FG to MG Py is disseminated throughout defining the FO. Intense SER alteration occurs near an irregular Ca VT.									SER	i	t								
			16.05	21.16	5.11	VOL			Medium grey, spotty, variably magnetic, weakly calcareous VOL. The black spots are FG to MG variably magnetic and locally form rims around Ca patches. Zones up to 35 cm long of subrounded Qz conglomerate occur with clasts < 3 cm. The clasts are sometimes lithologically different. Zones of buff coloured SER alteration are often associated with Ca veinlets. The last 40 cm have weakly concentrated DOL/LST clasts that are < 1 cm long, subangular and locally elongate to a very weak FO. Orange brown OX zones > 10 cm occur. No MX was identified.																		
21.16	278.71	257.55				MBL			White to grey, FG to MG MBL with varying concentration of dark grey overprinted seams. These seams define the moderately define the FO.	uCN	70															
										FO	30																
			47.10	61.14	14.04				Light orange coloured MBL with bright orange-red alteration coating on fractures. Bold, dark grey seams that do not appear overprinted, have a weakly stylolitic texture and occur in addition to the overprinted variety.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			79.73	85.72	5.99				Grey to very pale green, FG to MG, weakly foliatec silty-argillaceous mudstone with very weak primary textures.																		
									The foliation is defined by grain size separation ir pseudo-layering	FO	35																
			89.55	104.00	14.45	MBL			White to pale pink to purple, non foliated MBL, with abundant broken core. Undulation fractures around 0 deg TCA are often filled green to brown gouge material. Fracture surfaces are commonly red-rusty																He	t	
									Foliation is weakly defined by brittle fracturing	FO	0																
			160.63	164.00	3.37	MBL			MBL with trace magnetite in dark wisps defining the foliation.	FO	50														Mg	t	
			248.00							FO	25																
			260.00							FO	35																
			271.00	278.00	7.00	MBL			White Italian MBL with black to deep green to brown infilling of a sBx like structure/texture, with associated fine-grained anhedral Py. The brown portions are rich in Bi while the green are rich in Cl.											ms							
278.71	287.48	8.77				VOL	Mg	CGL	Dark grey to deep pale green VOL with a spotted tc foliated magnetic pebble conglomerate texture. The unit varies from well foliated with distinct foliation bands of grey to green minerals to a deep grey colour with magnetite clasts are that elongated with the foliation. The classic pebble conglomerate clasts and matrix are somewhat distorted with strain but some obvious clasts are visible. This unit is moderate to strongly magnetic and has undergone shear.																Mg	ms	
			278.71						Moderate foliation defined by elongation of pebbl clasts.	FO	30																
			285.00						Moderate foliation defined by elongation of pebbl clasts.	FO	65																
287.48	330.54	43.06				LEP			Brown to white-grey foliated LEP unit. Ca and Bi overprint and intrude along a foliation and comprise the majority of the unit. This intruding phase chews up and destroys wispy grey to pale yellow SER altered pumice clasts. This is therefore most likely a volcanic ash fall. Py and Po occur in anhedral masses within the calcite flooded areas as well as being associated with minor Fu. At the lCN includes irregular rhodenite and Qz veins.											w		w						

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

330.54	341.00	10.46				LST			Foliated grey FG LST with minor strained appearance. uCN has minor sBx with dogtooth Ca spar infill and thin veneers of bitumen lining spar. Sporadic vein flooded intervals of overprinting sparry DOL and Qz occur throughout. Late FG anhedral dissemination Py and Po overprinting the unit as a whole. Medium subhedral splashy Py occurs with the DOL at the lower contact.										t		t	Sp	t			
			331.00							FO	40																
			339.00						Undulating	FO	0																
341.00	368.51	27.51				DOL	MX		White to light grey CG sparry DOL with disseminated Py, As, Po ad Bs. The DOL brittly fractures along he foliation and follow angular DOL grain boundaries. The foliation hosts fine-grained anhedral to subhedral, dull to shiny Py and Po. Trace Bs occurs associated with Po. As also occurs in coarse-euhedral disseminated crystals within the DOL. Euhedral ANK, DOL, Qz, Ac and euhedral Po occur within the spaces between coarse grained crystals. Fracture surfaces host euhedral fine-grained Mg as well as smeared Cl and small white radiating Tc crystals. As is concentrated within sparry DOL and also associated with an increase in Py and Po concentration increase at the lCN. The Py and Po overprint the DOL and As well as occurring within the foliation.					100	t				m	w	m	Bs	t			x

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
368.51	387.25	18.74				LST	MX		Grey FG extensively solution collapse brecciated LST with subsequent matrix infilling of a Ca dogtooth spar lined with a thin veneer of tabular bitumen clasts and final vug filling Qz. This LST is fairly strained and often forms a foliation with pinching and swelling portions that help define the foliation along with stylolitic dissolution. This unit is overprinted by a white CG sparry DOL phase in random locations. Overprinting the dolomitized limestone, occurring between grain boundaries is a FG anhedral Po and a MG subhedral Py. CG euhedral disseminated to patchy As occurs in trace amounts within the LST. Some fibrous DOL vein opening occurs and has since been irregularly deformed. The lCN is intruded by coarse grey anhedral Qz and a higher concentration of Py and Po between Qz grains. Green fibrous to plumose Tc occurs and has been since silicified.					w							f	w	f					x
			373.00							FO	45																
			383.00						Low angle and dolomitizec	FO	20																
387.25	490.54	103.29				LEP			Dark brown to grey, episodically foliated to massive Ca rich and Bi rich LEP. Clasts are often brown to grey, wispy, irregular 1 mm- 1 cm in size and rimmed by Bi and Ca. Trace disseminated Py and Po occurs throughout. Coarse Qz Ca veins occur and cut the LEP unit and have associated Po and green Cl? LEP is occasionally mottled by a dark brown to dark-grey colouration.													t		t					x

									The LEP becomes more pervasively brown with increased Bi, Py and Po content. Small off-white angular fragments occur near the contact, some are possibly fossil fragments mixed up with VOL ash.	ICN										w		w					
			455.00							FO	30																
			466.00							FO	30																
			489.00							FO	30																
490.54	504.88	14.34				LST	VOL		Grey to brown to pale yellow interfingering DOL and soft sediment deformed wackestones and wispy argillaceous to ash rich silicified altered VOL. Contacts of the interfingering lithologies are sharp. LST is grey, foliated, soft sediment deformed with rare cryptic fossil fragments. Bioturbitation causes irregular bedding in various shades of grey with minor black lime mud. The VOL is light grey to pale yellow, fine-grained, wispy and foliated. Many of the fragments resemble ash-pumice fragments that have since been sericitized. Py is FG anhedral and disseminated and commonly concentrates around VOL clasts. Po is massive anhedral and occurs in masses along foliation as well as in a massive overprinting texture associated with grey to white anhedral Qz. Minor Fu occurs throughout the VOL.					t				SER	w	w		w						
									Foliation is mainly defined by bedding with minor strain.	FO	40																
504.88	575.55	70.67				LST			Grey FG fossil-poor lime-mudstone with variable sections of marbleized LST and episodic sBX LST. Moderately foliation is defined by bedding that has undergone moderate bioturbation and soft-sediment deformation. Small areas of heterogeneous strain partitioning has separated the unit into more rheologically competent units. Minor beds of bryozoans occur.	sBx									t			Sp	t			
									Weak foliation defined by bioturbated and sofl sediment deformation textures.	FO	40																
									Irregular Qz-Ca vein with the same composition as sBx vug infilling fluids.	VN																	
			515.92	518.07	2.15	LST			Numerous black 1 cm-scale brittely broken up chert nodules within lime-mudstone.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			530.56	544.40	13.84	LST			Extensively sBx limestone unit, vugs are lined by Ca dogtooth spar and minor bitumen, followed by vug infilling of Qz-Ca. Minor red sphalerite occurs with this quartz phase and along late brittle fractures. Minor fibrous green to white Tc also occurs.																		
			558.56	565.29	6.73	LST	MX													f		t					
									A fair foliation is defined by bedding	FO	40																
									CG DOL-Ca-Tc vein that runs parallel to the foliation.	VN	40																
									Marbleized LST forms a gradational contact into the massive Po of the next unit.	LCN																	
			570.54	575.55	5.01	LST	MX		Grey fine grained lime-mudstone with variable amounts of intruding Qz and DOL, weak Po and trace Py throughout. Sulphides occur with and between Qz grain boundaries as Qz intrudes irregularly, and is associated with fibrous green Tc. Coarse grained, grey DOL also occurs with close proximity to the Qz veining. The lime mud is mildly bioturbated but mostly laminar foliations that resemble bedding, which is later broken up by fluids.						w					t		w						
									A fair foliation is defined by bedding	FO	40																
575.55	585.00	9.45				VOL	ALT		Brown to grey to pale yellow banded and SER altered VOL. Bands consist of brown Bi rich, grey silicified ash and argillaceous material, and pale yellow wispy SER VOL ash with minor Cl. Po and minor Py intrudes irregularly and along a foliation in massive anhedral masses up to 15 cm wide. patchy Qz also occurs irregularly.											t		w						
									Ca-Po-Py and minor Ca veinlet	VN	30	185	2														
										FO	50																
									20 cm of massive Po.	uCN																	
									Marbleized LST	lCN																	
585.00	593.45	8.45				LST			Grey to dark grey lime-mudstone with minor cBx and marbleization. Minor bioturbation makes bedding slightly irregular, upper contact is marbleized. Small traces of cryptic fossil fragments are present but unidentifiable.																		
									593.45 m: E.O.H. - The hole was ended because it was very deep and had successfully tested the lowe side of the marble.																		

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

SAMPLES

Numbers: I074501-I074556

Total: 57

Batch: 1, 2

Date Sent: June 7

Certificate: VA10073648, VA10073649

COMMENTS

The hole was ended because it was well into the felsic intrusion with no signs of a significant source for the high magnetic anomaly.

0.00	4.70	4.70				OVB			Overburden - no recovery																		
4.70	16.31	11.61				TIL			Dark grey glacial till, mostly silt and clay with dispersed cobble sized angular fragments.																		
			15.24	16.31	1.07	TIL			Dark grey banded silts and clays.	FO	55																
16.31	59.18	42.87				LST	MBL		Grey to dark grey fine-grained limestone interfingered with coarse grained marbleized zones. Marbleized zones are very impure and dirty, with a rust-cinnamon colour to white sugary colour. Often associated with crackle breccia.									MBL	ms								X
									Moderately defined foliation	FO	60																
									Oblique to foliation are calcite veinlets at the sub-cm scale associated with a rusty oxidized colour.	VN	30	180	5														
			34.55	40.30	5.75					cBr																		
59.18	128.98	69.80				MBL			Coarse-grained impure marble. Brick red to buff white with a dark gray foliation.																		X
										FO	40																
										VN	30	225	4														
			99.60	100.00	0.40				Foliation is perpendicular TCA	FO	0																
			99.60	99.70	0.10			Fg																				
			99.60	128.98	29.38	MBL			Marble subunit is quite dirty and red-rust colour with grey foliations.	FO	80																X
			123.10						Dark green CG soft Ca/Cl VT	VN	15	90	4														
128.98	141.43	12.45				INT	FEL		Fine to medium-grained felsic intrusive, light to medium grey in colour with 10 cm zones of graphic to granophyric quartz. vCG pegmatitic texture is also present. Usually 70% quartz, both smoky and white quartz. 15 % plag, 15% tremolite/actinolite? Quartz crystals up to 3 cm. Plag crystals up to 1 cm long and hard to distinguish between white quartz since both are hard around 6-7. Mafic crystals are up to 1 cm and 2-3 mm wide forming fibrous bowtie shape bundles. Zones of yellow cream alteration occur bounded by 1 cm of a deep-green mineral with yellow-cream alteration. Trace FG Py is hosted as disseminations in dark minerals. Start to see orange-red very soft alteration at 139.43 - 140.28 m felsic fault gouge area. Fault gouge has some small red garnets occurs weakly.														Gn	w			X

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUBINTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
									Upper contact is sharp and has a 5 cm green alteration halo of actinolite.	uCN	60																
			139.10	141.43	2.33					lCN																	
141.43	171.90	30.47				MBL			Light to medium grey coarse-grained marble, very clean with distinct foliations.																	
									Foliation undulates up to 20 degrees in either direction from measurement.	FO	5																
			170.00	171.90	1.90				Foliation steepens closer to contact with basal unit. Some breaks in core along the foliation reveal an anhedral purple mineral in the sub-mm size.	FO	50																
171.90	173.55	1.65				SKN			Dark green unit consisting of 60 % fibrous actinolite, minor fine-grained euhedral pyrite parallel to wavy laminations. Pyrite also occurs as 0.7 mm dodecahedral-euhedral crystals in bands up to 4 cm thick. Light-grey to cream coloured interfingerings of fine-grained marble occur throughout unit. Also small sub-angular fluorescent mineral occurs in trace amounts and sub-mm in size.											w							X
									The wavy foliation is defined as bands of marble with minor actinolite and actinolite with pyrite.	FO	40																
173.55	193.97	20.42				MBL			Light to grey coarse-grained clean marble with strong undulating foliations. Some partial intersections with skarn zones occur at 193.07 m as dark green actinolite rich with some fine-grained pyrite.											t							
									Strong yet undulating. Foliation become less apparent closer to the interfingerings of skarn mineralization.	FO	10																
										CN	20																
193.97	194.75	0.78				SKN			Deep green fibrous actinolite 90 %, alternating with light green actinolite to produce foliation. Pyrite is fine-grained and occurs as zones within the foliation as well as disseminated.																		
										FO	50																
194.75	217.00	22.25				MBL			Light to medium grey coarse grained clean marble with a strong foliation. Unit is interfingered with skarn mineralization and calcite veins.											t		t					
										FO	50

			210.30	212.00	1.70			FT	Calcite rock flour and gouge																		
			212.00	213.00	1.00				Undulating foliation.	FO	0																
			213.00	217.00	4.00				Contact with basal intrusive is parallel to this foliation	FO	50																
217.00	222.30	5.30				INT	FEL		Medium to coarse-grained light to medium grey felsic intrusive. About 90% quartz both angular smoky quartz and white quartz. Often graphic quartz texture is present in small sections. Po and Py are FG subcrystalize overprints to fine wispyveinlets. Trace Mg with crystals up to 4 mm long.										t		t	Mg	t				
									Sharply grades into intrusive from Skarn mineralogy over a 15 cm interval.	uCN																	
222.30	225.70	3.40				MBL			Coarse-grained grey clean marble with strong foliation.																		
										FO	50																
									Calcite with small anhedral black and green minerals, amphibole-epidote?.	VN	45		0.5														
225.70	227.33	1.63				INT	FEL		Coarse-grained felsic intrusive 70-90% quartz both smoky and white. Intergranular actinolite is also present. Upper contact is abrupt and highly enriched in actinolite, lower contact is similar but smaller.																		
227.33	231.00	3.67				MBL			Coarse-grained grey foliated marble.																		
										FO	85																
									0.2 cm calcite vein.	VN	15	100															
										FO	60																

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

GEOLOGY LOG

INTERVAL			SUBINTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS								
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	Photo
231.00	269.75	38.75				INT	FEL		Coarse-grained felsic intrusive grey in colour. Around 80% quartz both as smoky and white variety, 20% dark-pale green to creamy mineral epidote/fluorite? 5-10 % biotite and hornblende as 1-5 mm euhedral crystals dispersed in the rock. 1-2 cm plagioclase laths dispersed throughout interval, appears to be very weathered in basal part of section. The green mineral ranges from deep-green to a light creamy green and is generally softer with lighter colour. The deep green minerals occur together and grade into the creamy green minerals, maybe fluid alteration front?											t	t	t	Sp	t			X
			231.00	249.00	18.00				All the plagioclase and green minerals in this portion are as hard as the quartz which lies interstitial to these minerals.									SIL	S								X
			249.00	269.00	20.00				Deep green minerals become very soft as well as plagioclase shows argillic alteration and a higher percentage of clay minerals in the core. Muscovite (?) in trace amounts. Green mineral hardness changes from 6 to 2.5. The core is visibly more altered and has weathered pits and breaks readily. Trace disseminated FG Py throughout.									Alt		t							X
									Sparse 1 cm to 0.5 cm veins filled with coarse-grained euhedral dolomite/ankerite rimmed with trace fine-grained pyrite and arsenopyrite and mayb pyrrhotite and sphalerite. Veins are high angle therefore vein density may not be indicative of a representative the real sample density. Veins only occur near the end of the hole.	VN	10		0.2								t	t	t	Sp	t			
									269.75 m: E.O.H. The hole was ended because it getting quite deep and had achieved the targeted Rackla Pluton.

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	2.75	2.75				OVB			Recovery for this interval is zero																		
2.75	5.77	3.02				LST	RBL		Grey blue to rusty brown dolomitized LST rubble. Approximately 50% of this interval exhibits a moderate degree of oxidation.					i		m											
5.77	12.50	6.73				LST	DOL		Pale grey to rusty brown intensely dolomitized moderately oxidized LST. More competent sections consist of a bleached dolomitized LST showing a lesser degree of oxidation and pre dolomitization features such as the original dark blue colour and calcite veining associated with most of the unaltered LST at Rau. Approximately half of the interval consists of a rubbly dolomitized LST exhibiting a higher degree of oxidation. Stockwork fracturing is present to varying degrees					i		m											
12.50	112.17	99.67				LST	FOS		Dark blue to dark grey fossiliferous LST ranging from wackestone to mudstone in composition. sBX textures has dark blue LST clasts surrounded by a white calcareous matrix. Where less pervasive sBX, have blue-grey to black mottled texture. Black carbonaceous interclasts and sinuous bands occur. Fossils include one hole crinoids, star crinoids, brachiopods, favocites coral, rugose coral and cephalopods, with an unusually high abundance of brachiopods. Weak dolomitization is present throughout the majority of the interval determined by reaction of LST with HCl (early marine dolomitization?). Trace fine grained, dull, anhedral pyrite is generally associated with black sinuous bands of carbonaceous material and quartz veins/veinlets.					w													
									Veining consists of quartz and calcite veins/veinlets with the majority of veins oriented approximately 45 degrees TCA. A large white calcareous 10 cm wide vein 90 degrees TCA is present at 30.17 m. This vein hosts oxidation bands within it. Stockwork patterns of quartz and calcite veins/veinlets are present intermittently.	VN	90															
									Quartz veinlets/veinlets generally occur at 45 degrees TCA and at a much lower density than calcite veins/veinlets.	VT	45															

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

									Calcite veins/veinlets occur at a higher frequency than quartz veins/veinlets.	VT	50		5														
									2.2 cm wide quartz vein is present at 103.85m.	VN	45																
									A 1 cm wide quartz vein is present at 112m.	VN	50																
			46.58	66.14	19.56	LST	FOS	FO	Dark grey to dark blue fossiliferous weak MBL LST with foliation defined by banding. Fossils present include crinoids, cephalopods and rugose corals with crinoids being the most abundant. LST ranges from mudstone to wackestone in composition. This sub interval lacks classic sBX LST texture. Foliation is defined by banding of dark blue to light grey layers as well as brown wisps of non-calcareous material appearing volcanic in origin. Trace FG anhedral pyrite is associated with brown volcanic bands. No dolomitization is evident. Foliation is variable and decreases with respect TCA down the interval.									MBL	w	t						
									Foliation at the start of the interval is approximately 60 degrees TCA.	FO	60																
									Foliation angle decreases with respect TCA as depth increases to 45 degrees TCA near the end of the interval.	FO	45																
									Calcite veins/veinlets are present with no apparent trend in orientation.	VT	70		5														
										VT	40	180														
112.17	122.88	10.71				LST	MBL	FO	Light grey to dark blue moderately marbleized LST exhibiting a foliation defined by banding of dark blue and light grey layers. The upper portion of this interval consists of a non-foliated fossiliferous wackestone exhibiting a dark blue to light grey mottled texture. Sinuous bands of black calcareous carbonaceous material and brown non-calcareous volcanic material are present as part of the foliation, and are associated with trace amounts of fine grained anhedral pyrite.									MBL	m	t						
									Foliation appears to remain relatively constant at approximately 55 degrees TCA.	FO	55

																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
122.88	150.00	27.12				LST	VOL	FO	Dark blue to light grey moderately marbleized LST interfingered with dark biotite brown and light brownish green sericite altered volcanic material. Dark black non-calcareous (volcanic?) bands are also interfingered with the LST. The presence of the volcanic fraction is variable and more dense in certain sections. Sections that lack a high density of volcanic bands reveal that the original protolith consisted of fossiliferous LST ranging from wackestone to packstone in composition. A foliation defined by banding of dark blue to light grey LST layers, dark to greenish brown volcanic layers and non-calcareous dark black layers is pervasive throughout the interval. Trace Po mineralization appears to be associated with dark black non-calcareous bands, brown volcanic bands and quartz/calcite veins/veinlets. Po occurs as a fine grained anhedral variety. Trace pyrite is found disseminated throughout the interval and is associated mostly with the sericite altered volcanic bands.									MBL	m	t		t						
									Foliation ranges from 50 to 75 degrees TCA generally increasing in angle with respect TCA with increasing depth.	FO	50															
										FO	55																
										FO	75																
									Quartz and calcite veins and veinlets occur at a relatively low density throughout the interval and appear to be associated with Po mineralization. A set of calcite veinlets ~1 mm wide sharing a common orientation of 60 degrees TCA occurs at 143.50 m. Overprinting of this veinlet set by dark brown sinuous volcanic bands is observable.	VT	60		5														
									Quartz-Po veins ranging from 1-3 cm in width are present between 146 m and 147 m. These veins share a common orientation of ~80 degrees TCA.	VN	80	90	3														

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

150.00	177.66	27.66				LST	FOS	FO	Dark blue to bleached grey moderately marbleized LST ranging from wackestone to packstone in composition. Crinoid stems in plan view and cross section are the dominant fossil type. Fossil density is variable throughout. A foliation defined by banding o dark blue and grey layers is present. The foliation is better defined and fossil density is lower within grey layers. In darker blue more fossiliferous sections the foliation is less evident. Some sections exhibit a granular, dark blue/bleached grey spotted texture. Foliation is not well defined in these intervals and fossil fragments appear distorted. Foliation remains constant at 65 degrees TCA throughout. Trace Po-Py mineralization is disseminated throughout the interval and associated with quartz/calcite veins/veinlets.	FO	65							MBL	ms	t		t						
									Veining consists of early stage calcite veins/veinlets visibly overprinted by textures associated with marbleization such as bleaching and granular textures.	VT	45		3														
										VN	55																
									Later stage unaltered quartz veins/veinlets are also present at a much lower density than calcite veins/veinlets.	VT	60		140														
										VN	45																
177.66	210.68	33.02				LST	VOL	FO	Banded dark blue to bleached grey moderately marbleized LST interfingered with brown volcanic bands. Approximately 90% of the interval consists of banded LST with the remaining 10% being comprised of banded locally SER volcanic material. Distorted crinoid fossil fragments are present throughout. Disseminated fine grained Po is found throughout and appears to be associated with the volcanic bands. A pervasive foliation defined by banding is present and remains relatively constant a approximately 70 degrees TCA.	FO	70							MBL	m			t						
									Calcite and quartz veins/veinlets are present. Calcite veinlets occur a much higher density. Mineralization does not appear to be associated with veining.	VN	45	20															
										VT	60	315	5														

n = none, t= <1%, w = 1-3%, f = 3-5%, m = 5-7%, ms = 7-10%, s = 10-15%, l = 15-20%, (write % for >20%)

			208.00	210.68	2.68	VOL	LST	FO	Dark brown and white, spotted calcareous interval resembling the leopard unit in appearance. Sections of dark blue LST and beige sericite altered volcanic bands with trace fuchsite are present. These bands contain trace Py and Po mineralization. A foliation defined by banding of sericite altered material is pervasive throughout. Foliation remains constant at 50 degrees TCA.	FO	50								t		t	Fr	t			
									The upper contact is sharp and occurs 25 degrees TCA. The lower contact into the volcanic unit below is gradational.	UCN	25															
									Calcite veins/veinlets are present throughout. Large stockwork Po-Py account for most of intervals mineralization.																	
									A 4 cm wide calcareous vein is present at 208.70 m. Mineralization associated with this vein includes fine to coarse grained anhedral Po and a light, brownish pink, non calcareous mineral that is approximately 5 to 6 on moh's hardness scale (Rhodonite?).	VN	55	180									t					
									A 4.5 cm wide calcite vein is present at 210 m. This vein is not associated with mineralization.	VN	55	15														
									A calcite-biotite veinlet is present at 210.60 m containing trace amounts of purple and green fluorite and Po.	VT	45	180									t	Bi	m	Fl	t	
210.68	215.11	4.43				VOL	FO	AM	Black to dark brown amygdaloidal volcanic. 95% of the interval consists of dark black volcanic with the remaining 5% a banded, dark brown to light green/brown sericite altered volcanic. Approximately 50% of the amygdules contain calcite and 50% contain quartz. A foliation defined by banding of dark brown and light brown sericite altered material is present intermittently throughout. Banded zones of highly altered LST exhibiting distorted fossil fragments are present and associated with sericite altered VOL. Trace amounts of fine grained Po and Py are disseminated throughout. The majority of mineralization is present in the form of massive Po-Py veins/veinlets.									t		t					
									Foliation defined by banding tends to vary from 60 70 degrees TCA throughout.	FO	70															
										FO	60

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
			275.95	283.47	7.52	VOL	CGL	FO	Black to light grey volcanic conglomerate unit with variable bleaching and sericite alteration. Pervasive magnetism is present throughout. Foliation defined by banding of volcanic matrix, clast elongation and Po veinlets. The upper portion of this interval exhibits a greater degree of SER and BLE alteration Both of these alterations tend to gradationally decrease with increasing depth until the lower contact. Bleaching is present in the upper portion of the interval as a light grey matrix containing a high density of Po veinlets. Elongated clasts within the bleached matrix display varying degrees of sericite alteration. Trace fuchsite is present within the sericite altered elongated clasts. An opaque green mineral (fluorite?) is present in the upper portion of the interval and appears to be associate with bleaching. The lower section of this interval is black to dark grey volcanic CGL and is not sericite altered of bleached. Foliation appears to remain constant at 60 degrees TCA throughout.	FO	60							BLE	w	t		w	Fu	t	Fl	t	
									Fine grained Po and Py disseminated throughout as anhedral blebs. Po and Py mineralization is also associated with veining. Po appears to be responsible for the majority of magnetism.									SER	t				Mg	t			
									Veining consists of calcite, quartz and fluorite veins/veinlets associated with trace Po and Py mineralization.	VN	65	0	3							t		t					
									A large quartz vein is present from 277.24m to 277.61m and contains Po-Py mineralization within it.	VN	15									t		t					
									The lower contact to this unit is gradational and consist of bleached volcanic CGL with sericite/fuchsite altered clast supported within a bleached Po, Mg rich matrix.	ICN																
			283.47	287.56	4.09	VOL	VN	FO	Black to dark forest-green heavily calcite veinec variably magnetic volcanic. Preferential orientation c high density calcite veining defines FO. Trace FG anhedral Py and Po mineralization is present throughout. Veining is not generally responsible for mineralization.	FO	60							CHL	w	t		t	Mg	w

COMMENTS

The hole was ended because it was passed the target depth.

GEOLOGY LOG

HOLE: RauSC10-07

INTERVAL			SUB-INTERVAL			LITHOLOGY			DETAILED DESCRIPTION	STRUCTURE				ALTERATION						MINERALS							Photo
																		Other					Other		Other		
From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
0.00	1.30	1.30				OVB			Overburden - No recovery																		
1.30	47.02	45.72				LST	FOS	FO	Medium grey fairly fossiliferous LST with a strong FO. Crinoid stem fragments are most common, but favocites mounds up to 5 cm in diameter occur as well. The unit shows no sign of sBX or cBX, just a very obvious strain induced banding that defines the FO. Trace FG yellow pyrite and weak pinkish/brown Po are both disseminated throughout. The Po tends to occur in groups of disseminations up to 5 cm wide separated by 10's of cm's showing no mineralization. Py is more evenly spread throughout.	FO	60									t		w					
									Coarse grained DOL veins with fairly sharp boundaries cut the FO.	VN	30	100															
47.02	50.82	3.80				VOL	BIO		Medium brown/grey obviously banded VOL with small intervals of marbleized LST within.																		
									Banding occurs at 70 deg TCA and is defined by <1 mm to 2 cm thick slightly varied-coloured bands.	FO	70																
			48.49	49.58	1.09	LST	MBL		Intensely marbleized LST within the VOL.									MBL	i								
50.82	70.50	19.68				LST	MBL	FO	Medium to light grey, moderately marbleized LST with Ca/SID veinlets cutting throughout and a highly banded appearance is a character of the strain and occurs at 70 deg TCA.	FO	70							MBL	m								
									The veinlets are 1-3 mm thick and cut the core at 25 deg TCA.	VT	25																
			62.43	66.14	3.71	LST	MBL		The banding in the LST has become extremely swaley with a general FO at 40 deg TCA.																		
70.50	81.23	10.73				LST	FOS	FO	Medium to dark grey fossiliferous LST that shows soft sediment deformation textures and a strong FO. Fossils include 3 mm to 1cm crinoid fragments generally occurring in packed bands with a dark grey matrix. The upper contact is very gradational, while the lower contact is marked by 3 cm of white marble. Weak Pyrite occurs as disseminated FG-MG subhedral to euhedral isolated crystals.	CN									w							
									FO is strong and defined by strain banding.	FO	60

From (m)	To (m)	Interval (m)	From (m)	To (m)	Interval (m)	Unit	Modifier	Texture		Type	Attitude (tca)	Attitude (tfa)	Density (frequency/m)	Dolomite	Ankerite	Oxidation	Siderite	Type	Intensity	Pyrite	Arsenopyrite	Pyrrhotite	Type	Intensity	Type	Intensity	
81.23	89.37	8.14				VOL	SER		Medium to light greenish grey strongly foliated VOL with weakly disseminated FG patches of Po. Weak sericite alteration occurs throughout. The unit is cut by Qz/Ca/DOL veins with associated Po, Py, Cp, Sp, Gn mineralization.									SER	w	f		f	Cp	t	Gn	w	
																							Sp	w			
									Fo is strong, defined by slight colour variation in bands at 50 deg TCA.	FO	50																
			81.33	81.68	0.35				Coarse grained Qz, Ca, DOL vein with large patches of Po and associated Py and Cp. The Cp appears to overprint both the Po and the Py. A 1 cm wide euhedral dolomite crystal occurs within the vein. The contacts of the vein are very irregular and not well defined.	VN	n/a																
			84.00	84.22	0.22				A vuggy patch of Py and minor Po occur over this interval. The Py is fine grained and patchy to semi-massive while the Po occurs in vFG associated veinlet.	VT	55									40		ms					
			84.70	85.20	0.50				2 cm thick Qz/DOL vein with 0.5-1 cm patches of FG Py overprinted by weak fine grained 2 mm patches of Cp.	VN	15	90								m			Cp	w			
										FO	45																
			85.30	85.85	0.55	VOL			Dark brownish black weakly foliated VOL with FG disseminated Po throughout. The FO is weak at 60 deg TCA.	FO	60											w					
									<1 mm wide veinlets cause bleaching and cut oblique to FO at 20 and 40 deg TCA.	VT	20	90															
										VT	40	180															
			88.80	89.15	0.35				A zone of weak fine grained disseminated fair red Sp and galena.														Sp	f	Gn	w	
89.37	105.37	16.00				LST	MBL		Medium grey moderate to strongly marbleized LST with a strongly defined FO at 60 deg TCA. FG-MG pyrite patches occur disseminated throughout. A 10 cm wide MG-CG, Ca-DOL-Qz veinlet with patchy Py occurs within.									MBL	ms	w								
			95.50	95.60	0.10	LST	OX		A thin zone of moderately oxidized LST associated with strongly oxidized fractures.							m											
105.37	113.11	7.74				VOL	CHL		A combination of medium green and dark brown chlorite and biotite with a strong FO and weak calcite within very thin Ca veinlets and thicker bands.									CHL	ms									
																w		BIO	ms

									The upper contact is marked by more intense marbleization. The lower contact is also marked by an increase in intensity marbleization.																		
									FO occurs at between 45-55 deg TCA, defined by <1 mm Ca veinlets. Ca bands parallel the FO and have a halo of brown VOL around them (on both sides) within the green VOL.	FO	50															x
										VT	15	190															
			106.64	106.80	0.16				A ~ 4 cm wide skarn-like Qz/Po/Py/Cp vein cuts the VOL at 30 deg TCA and 190 deg to FO. The vein has slightly irregular boundaries and contains semi-massive patches of Po with weak patches of Py and trace Cp.	VN	30	190								w		i	Cp	t			
			112.52	112.65	0.13				A skarn-like Qz/Ca/Py vein cuts the VOL at 30 deg TCA and 190 deg to FO. It contains moderately strong fine grained patchy Py and has a slightly pitted/vuggy texture.	VN	30	190								ms							
			112.84	112.89	0.05	FLT			Possible fault within the VOL. It contains up to 1 cm angular to subrounded clasts that are weakly matrix supported within a claylike calcareous matrix.																		
113.11	144.72	31.61				LST	MBL		Medium to light grey FG-MG, FOS, variably MBL altered LST with moderate FO. The fossils are weak in concentration overall and mainly consist of small crinoid stem fragments. MBL is fair overall but varies from weak to strong.									MBL	f								
									2-5 cm thick MG-CG Qz/Ca veins cut at 40 deg to CA.	VN	40		0.5														
			120.40	122.10	1.70				Weak oxidation occurs on fractured surfaces within this fairly rubbly interval.							w											
			134.62	137.34	2.72	LST	MBL		White to light grey intensely MBL altered LST with a very faint FO defined by slight banding at 40 deg TCA. The upper contact is very sharp at 40 deg to CA, while the lower contact is gradational over 10 cm.	FO	40							MBL	i								
			137.34	144.65	7.31	LST	MBL		Medium to light grey weakly foliated LST with a weak concentration of crinoid stem fragments and trace FG Py disseminated throughout.									MBL	m	t							
									FO is weak and at times disrupted at 45 deg to CA.	FO	45																
									Both the upper and lower contacts show gradational increases in marbleization, but the lCN is lithologically very sharp at 40 deg to CA.	lCN	40

Certificate of Analysis

RAU Standard 2010 A

Element	Certified Mean	Two Standard Deviations (between lab)
FA Au	**0.437 g/t**	**0.048 g/t**

Means and standard deviations were calculated from data supplied by six laboratories using a fire assay, ICP-ES finish.

The participating laboratories were:

ALS Chemex, Vancouver
Acme, Vancouver
Actlabs, Ancaster
IPL, Vancouver
TSL, Saskatoon
Ecotech, Kamloops

The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. This was done by using a Student's t test of means where a laboratory was removed from the data base if failing the t test. The means and standard deviations from the remaining data were calculated. Any analysis that fell outside of the mean ± 2SD was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data (shown as the 1st Iteration in the attached Excel spreadsheets). The final standard deviation is known as the "Between Lab" deviation, and can be used to monitor accuracy of a single analysis.

Elements are certified if the Relative Standard Deviation (RSD) is near 5 % or less. Elements that have a RSD of between 5 % and 15 % are given a Provisional mean and elements that have a RSD of more than 15 %, or have insufficient data are not certified but given an Indicated Mean.

Certificate of Analysis

RAU Standard 2010 B

Element	Certified Mean	Two Standard Deviations (between lab)
FA Au	**1.83 g/t**	**0.21 g/t**

Means and standard deviations were calculated from data supplied by six laboratories using a fire assay, ICP-ES finish.

The participating laboratories were:

ALS Chemex, Vancouver
Acme, Vancouver
Actlabs, Ancaster
IPL, Vancouver
TSL, Saskatoon
Ecotech, Kamloops

The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. This was done by using a Student's t test of means where a laboratory was removed from the data base if failing the t test. The means and standard deviations from the remaining data were calculated. Any analysis that fell outside of the mean ± 2SD was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data (shown as the 1st Iteration in the attached Excel spreadsheets). The final standard deviation is known as the "Between Lab" deviation, and can be used to monitor accuracy of a single analysis.

Elements are certified if the Relative Standard Deviation (RSD) is near 5 % or less. Elements that have a RSD of between 5 % and 15 % are given a Provisional mean and elements that have a RSD of more than 15 %, or have insufficient data are not certified but given an Indicated Mean.

ORE REFERENCE STANDARD: CDN-SE-1

Recommended values and the "Between Lab" Two Standard Deviations

Gold	***0.480***	***± 0.034 g/t***
Silver	***712***	***± 57 g/t***
Copper	***0.097***	***± 0.005 %***
Lead	***1.92***	***± 0.09 %***
Zinc	***2.65***	***± 0.20 %***

PREPARED BY: CDN Resource Laboratories Ltd.
CERTIFIED BY: Duncan Sanderson, B.Sc., Licensed Assayer of British Columbia
INDEPENDENT GEOCHEMIST: Dr. Barry Smee., Ph.D., P. Geo.
DATE OF CERTIFICATION: May 15, 2007

METHOD OF PREPARATION:

Reject ore material was dried, crushed, pulverized and then passed through a 200 mesh screen. The +200 material was discarded. The -200 material was mixed for 6 days in a double-cone blender. Splits were taken and sent to twelve laboratories for round robin assaying.

ORIGIN OF REFERENCE MATERIAL:

The ore was supplied by Silver Eagle Mines Inc. from their Miguel Auza property. The material is from a relatively coarse-grained, epithermal Pb-Zn-Ag vein with accessory pyrite, calcite, quartz, sericite and clays. Principal ore minerals are galena, sphalerite, argentite, native silver (electrum?) and minor silver sulphosalts.The latter may comprise one or more of iodargyrite, proustite-pyrargyrite, pearceite-polybasite, nuammanite, aguilarite and eucarite. Arsenic, lesser antimony and copper and minor selenium are all present. The sample was taken from the transition zone between the near-surface oxidized zone and the unweathered (protore) zone of primary sulphides. As such, some cerussite ($PbCO_3$) and smithsonite ($ZnCO_3$) are probably present.

Approximate chemical composition is as follows:

	Percent			Percent
SiO_2	51.6		Na_2O	0.1
Al_2O_3	8.3		MgO	0.6
Fe_2O_3	17.0		K_2O	3.1
CaO	2.8		TiO_2	0.4
MnO	0.3		LOI	12.2
S	12.7		C	1.1

Statistical Procedures:

The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. Data from any one laboratory was removed from further calculations when the mean of all analyses from that laboratory failed a t test of the global means of the other laboratories. The means and standard deviations were calculated using all remaining data. Any analysis that fell outside of the mean ±2 standard deviations was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data. Outliers were defined as samples beyond the mean ± 2 Standard Deviations from all data. These outliers were removed from the data and a new mean and standard deviation was determined. This method is different from that used by Government agencies in that the actual "between-laboratory" standard deviation is used in the calculations. This produces upper and lower limits that reflect actual individual analyses rather than a grouped set of analyses. The limits can therefore be used to monitor accuracy from individual analyses, unlike the Confidence Limits published on other standards.

STANDARD REFERENCE MATERIAL CDN-SE-1

Assay Procedures:

Au: Fire assay pre-concentration, AA or ICP finish (30g sub-sample).
Ag: either fire assay, gravimetric or 4 acid digestion, ICP finish
Cu, Pb, Zn: 4-acid digestion, AA or ICP finish.

Round-robin assay results:

Recommended values and the "Between Lab" Two Standard Deviations

Gold	***0.242***	***±***	***0.018 g/t***
Silver	***354***	***±***	***21 g/t***
Copper	***0.049***	***±***	***0.003 %***
Lead	***0.957***	***±***	***0.044 %***
Zinc	***1.34***	***±***	***0.11 %***

PREPARED BY: CDN Resource Laboratories Ltd.
CERTIFIED BY: Duncan Sanderson, B.Sc., Licensed Assayer of British Columbia
INDEPENDENT GEOCHEMIST: Dr. Barry Smee., Ph.D., P. Geo.
DATE OF CERTIFICATION: May 15, 2007

METHOD OF PREPARATION:

Reject ore material was dried, crushed, pulverized and then passed through a 200 mesh screen. The +200 material was discarded. The -200 material was mixed for 6 days in a double-cone blender. Splits were taken and sent to twelve laboratories for round robin assaying.

ORIGIN OF REFERENCE MATERIAL:

The ore was supplied by Silver Eagle Mines Inc. from their Miguel Auza property. The material is from a relatively coarse-grained, epithermal Pb-Zn-Ag vein with accessory pyrite, calcite, quartz, sericite and clays. Principal ore minerals are galena, sphalerite, argentite, native silver (electrum?) and minor silver sulphosalts.The latter may comprise one or more of iodargyrite, proustite-pyrargyrite, pearceite-polybasite, nuammanite, aguilarite and eucarite. Arsenic, lesser antimony and copper and minor selenium are all present. The sample was taken from the transition zone between the near-surface oxidized zone and the unweathered (protore) zone of primary sulphides. As such, some cerussite (PbCO3) and smithsonite (ZnCO3) are probably present. Standard CDN-SE-2 was prepared by mixing the primary ore 50:50 with A blank granitic material.

Approximate chemical composition is as follows:

	Percent			Percent
SiO2	60.7		Na2O	1.6
Al2O3	10.4		MgO	1.5
Fe2O3	11.3		K2O	2.0
CaO	3.2		TiO2	0.5
MnO	0.2		LOI	6.8
S	6.3		C	0.6

Statistical Procedures:

The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. Data from any one laboratory was removed from further calculations when the mean of all analyses from that laboratory failed a t test of the global means of the other laboratories. The means and standard deviations were calculated using all remaining data. Any analysis that fell outside of the mean ±2 standard deviations was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data. Outliers were defined as samples beyond the mean ± 2 Standard Deviations from all data. These outliers were removed from the data and a new mean and standard deviation was determined. This method is different from that used by Government agencies in that the actual "between-laboratory" standard deviation is used in the calculations. This produces upper and lower limits that reflect actual individual analyses rather than a grouped set of analyses. The limits can therefore be used to monitor accuracy from individual analyses, unlike the Confidence Limits published on other standards.

STANDARD REFERENCE MATERIAL CDN-SE-2

Assay Procedures:

Au: Fire assay pre-concentration, AA or ICP finish (30g sub-sample).
Ag: either fire assay, gravimetric or 4 acid digestion, ICP finish
Cu, Pb, Zn: 4-acid digestion, AA or ICP finish.

Round-robin assay results:

Control Statistic Details

Control statsitics were produced from results accumulated in the :

April-2006	Geostats Pty Ltd Laboratory Round Robin Program.
85	laboratories tested this material using 50 gram Fire Assay.
39	laboratories tested it using an Aqua Regia Technique.
1	laboratories tested this material using Neutron Activation Analysis.

Source Material

Prior to homogenisation and testing, this material was sourced from
Cut-off Ore Oxide Material

Colour Designation

Grayish pink

Usage

This product is for use in the mining industry as reference materials for monitoring and testing the accuracy of laboratory assaying.

Preparation and Packaging

All standards are dried in an oven for a minimum of 12 hours at 110C. The dry material is then pulverised to better than 75 micron (nominal mean of 45 micron) using an Air Classifier. The material is then homogenised and stored in a sealed, stable container ready for final packaging.

Materials are statistically sampled from stores, then packaged into either heat sealed, air tight, plastic pulp packets or screw top sealed plastic containers ready for distribution. All packaging has been chosen to ensure minimal contamination from outside sources during shipment, use and storage.

Assay Testwork

All standards are tested thoroughly in the Geostats bi-annual laboratory survey. This involves assaying by a minimum of 50 reputable laboratories selected from across the world. Results are compiled into a comprehensive report detailing statistics for each standard. Assay distributions are checked and processed statistically, producing monitoring statistics for these standards. Materials are tested regularly to ensure stability and homogeneity.

Control Statistic Details

Control statsitics were produced from results accumulated in the :

April-1999	Geostats Pty Ltd Laboratory Round Robin Program.
100	laboratories tested this material using 50 gram Fire Assay.
66	laboratories tested it using an Aqua Regia Technique.
1	laboratories tested this material using Neutron Activation Analysis.

Source Material

Prior to homogenisation and testing, this material was sourced from
Oxides in the Kalgoorlie Region

Colour Designation

Pinkish gray

Usage

This product is for use in the mining industry as reference materials for monitoring and testing the accuracy of laboratory assaying.

Preparation and Packaging

All standards are dried in an oven for a minimum of 12 hours at 110C. The dry material is then pulverised to better than 75 micron (nominal mean of 45 micron) using an Air Classifier. The material is then homogenised and stored in a sealed, stable container ready for final packaging.

Materials are statistically sampled from stores, then packaged into either heat sealed, air tight, plastic pulp packets or screw top sealed plastic containers ready for distribution. All packaging has been chosen to ensure minimal contamination from outside sources during shipment, use and storage.

Assay Testwork

All standards are tested thoroughly in the Geostats bi-annual laboratory survey. This involves assaying by a minimum of 50 reputable laboratories selected from across the world. Results are compiled into a comprehensive report detailing statistics for each standard. Assay distributions are checked and processed statistically, producing monitoring statistics for these standards. Materials are tested regularly to ensure stability and homogeneity.

Certificate of Analysis

Mike Lake Standard ML-1

Element	Certified Mean	Two Standard Deviations (between lab)
Tot. Cu	0.082 %	0.008 %
Tot As	0.965 %	0.072 %
FA Au	0.332 g/t	0.026 g/t

Element	Indicated Mean
Tot. Ag	2.7 ppm
Tot. W	19 ppm

Means and standard deviations were calculated from data supplied by five laboratories using a four acid digestion and an ICP-ES or AAS finish for Total Cu, As, and Ag and a combination of a total digestion or XRF for W, and fire assay with instrument finish for Au where reported.

The participating laboratories were:
ALS Chemex Brisbane
ALS Chemex, Vancouver
Acme, Vancouver
OMAC, Ireland
Genalysis, Perth

The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. This was done by using a Student's t test of means where a laboratory was removed from the data base if failing the t test. The means and standard deviations from the remaining data were calculated. Any analysis that fell outside of the mean ± 2SD was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data (shown as the 1st Iteration in the attached Excel spreadsheets). The final standard deviation is known as the "Between Lab" deviation, and can be used to monitor accuracy of a single analysis.

Elements are certified if the Relative Standard Deviation (RSD) is near 5 % or less. Elements that have a RSD of between 5 % and 15 % are given a Provisional mean and elements that have a RSD of more than 15 %, or have insufficient data are not certified but given an Indicated Mean.

Smee and Associates Consulting Ltd.

REPORT ON A HELICOPTER-BORNE Z-AXIS, TIPPER ELECTROMAGNETIC GEOPHYSICAL SURVEY

Rau Block
Mayo, Yukon

Executive Summary

During May 27th to June 6th, 2010 Geotech Ltd. carried out a helicopter-borne geophysical survey for ATAC Resources Ltd. over the Rau Block situated near Mayo, Yukon Canada.

Principal geophysical sensors included a Z-Axis Tipper electromagnetic (ZTEM) system, and a caesium magnetometer. Ancillary equipment included a GPS navigation system and a radar altimeter. A total of 331 line-kilometres were planned to be flown.

The survey operations were based out of the town of Mayo, Yukon. In-field data quality assurance and preliminary processing were carried out on a daily basis during the acquisition phase. Preliminary and final data processing, including generation of final digital data and map products were undertaken from the office of Geotech Ltd. in Aurora, Ontario.

The survey report describes the procedures for data acquisition, processing, final image presentation and the specifications for the digital data set. There is no summary interpretation included in this report.

1. INTRODUCTION

1.1 General Considerations

These services are the result of the Agreement made between Geotech Ltd. and ATAC Resources Ltd to perform a helicopter-borne geophysical survey over the Rau Block located near Mayo Yukon, Canada (Figure 1).

Graham Downs acted on behalf of ATAC Resources Ltd. during the data acquisition and data processing phases of this project.

The geophysical surveys consisted of helicopter borne AFMAG Z-axis Tipper electromagnetic (ZTEM) system and aero magnetics using a caesium magnetometer. A total of 332 line kilometres of geophysical data were acquired during the survey. The survey area is shown in Figure 2.

In a ZTEM survey, a single vertical-dipole air-core receiver coil is flown over the survey area in a grid pattern, similar to regional airborne EM surveys. Two orthogonal, air-core horizontal axis coils are placed close to the survey site to measure the horizontal EM reference fields. Data from the three coils are used to obtain the Z/X and Z/Y Tipper (Vozoff, 1972) components at six frequencies in the 30 to 720 Hz band. The ZTEM was used to map geology using resistivity contrasts and magnetometer data were also collected to help map geology using magnetic susceptibility contrasts.

Figure 1 -Property Location

The crew was based in Mayo, Yukon, for the acquisition phase of the survey. Survey flying started on May 27th and was completed on June 6th, 2010.

Data quality control and quality assurance, and preliminary data processing were carried out on a daily basis during the acquisition phase of the project. Final reporting, data presentation and archiving were completed from the Aurora office of Geotech Ltd. in June, 2010.

1.2 Survey Location

The Block is located approximately 94 kilometres to the northeast of Mayo, Yukon as shown in Figure 2.

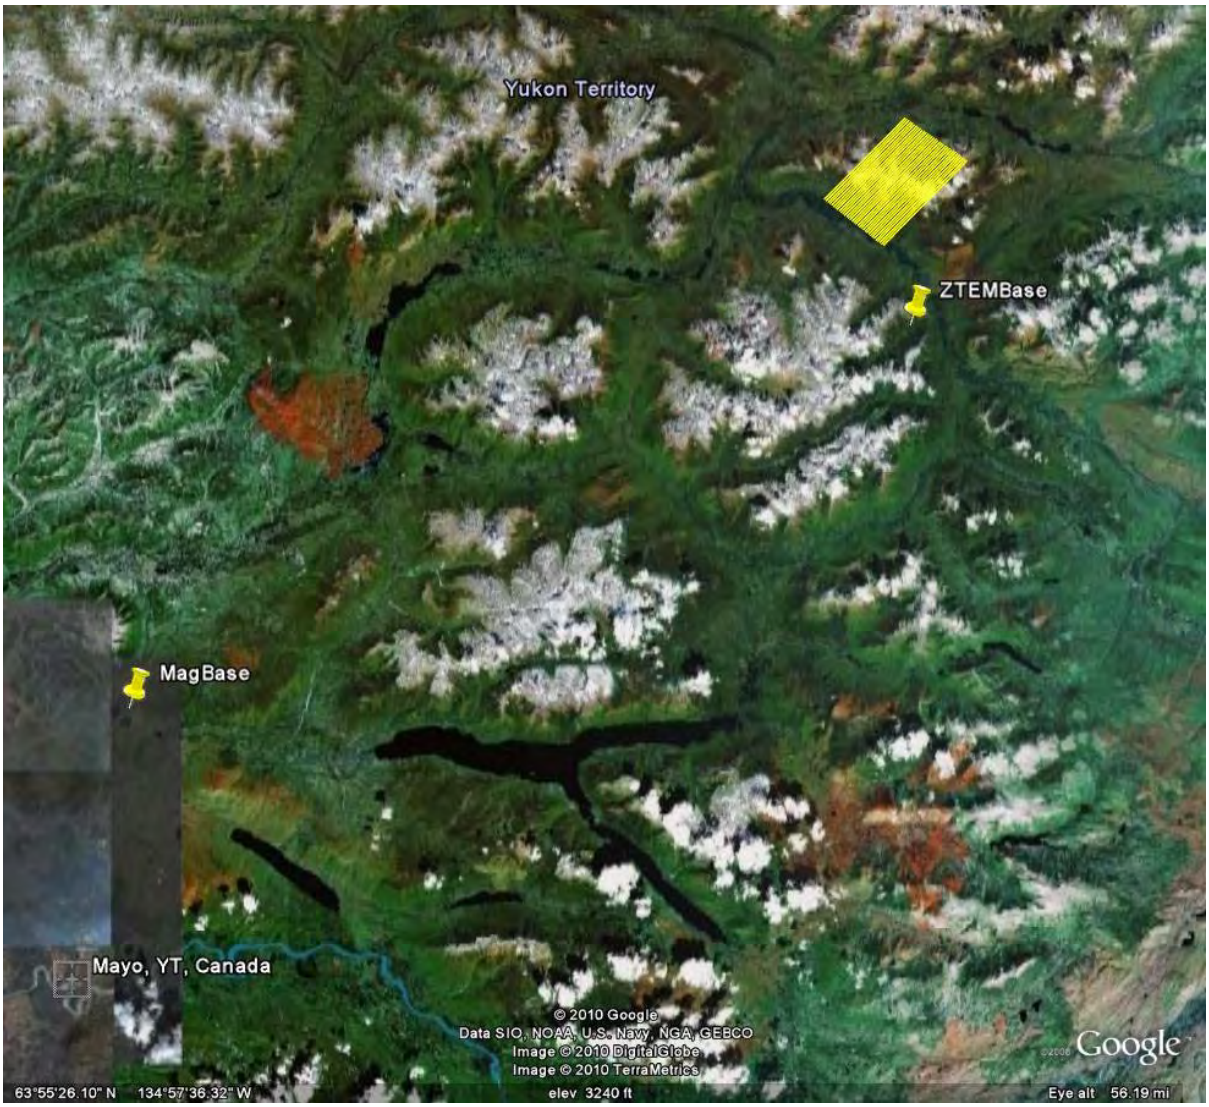

Figure 2 – The Block, with ZTEM and Magnetic Base Station Locations

The block was flown in a Southwest to Northeast (N 45° E / N 225° E) direction, with a flight line spacing of 200 metres, as depicted in Figure 3. Tie lines were neither planned nor flown. For more detailed information on the flight spacing and direction see Table 1.

1.3 Topographic Relief and Cultural Features

The Block exhibits a high relief covering 65.2 square kilometres, with an elevation ranging from 649 to 1764 meters above sea level (see Figure 3). The survey area has no visible signs of culture such as, roads, trails and buildings throughout the survey. There are also numerous river and streams which connect various lakes and wetlands. Special care is recommended in identifying any other potential cultural features from other sources that might be recorded in the data. The survey block covers a number of Yukon Mining Claims, which are shown in Appendix A. The survey block is covered by NTS (National Topographic Survey) of Canada sheets 106D07, 106D08, 106D02, and 106D01.

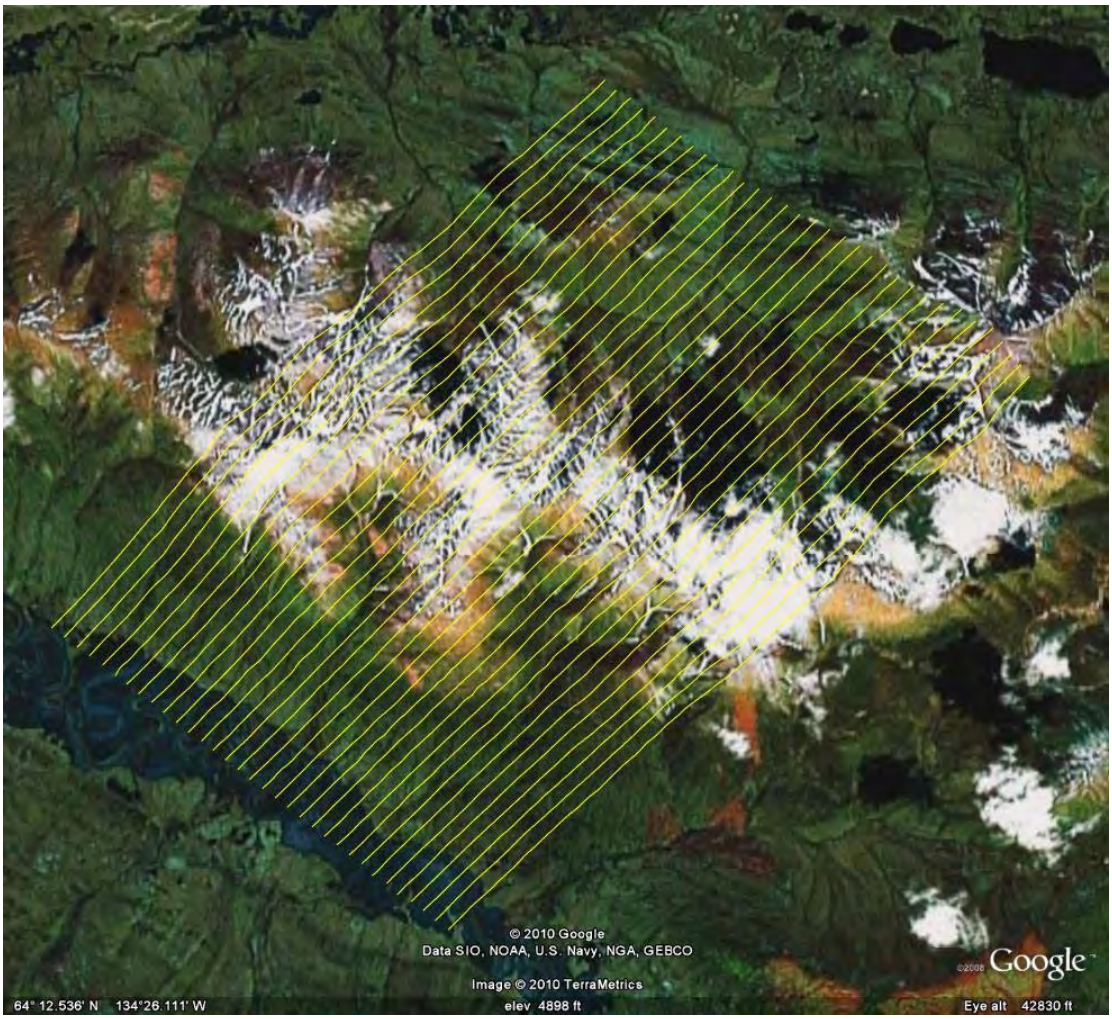

Figure 3 – Google Earth image of the block

2. DATA ACQUISITION

2.1 Survey Area

The survey block (see Location map in Appendix A and Figure 2) and general flight specifications are as follows:

Table 1 - Survey Specifications

Survey block	Traverse Line spacing (m)	Area (Km^2)	Planned Line-km	Actual[1] Line-km	Flight direction	Line numbers
Block	Traverse: 200	65.2	331.	332.9	N 45° E / N 225° E	L1000 – L1320
	Tie: n/a				n/a	n/a
TOTAL		**65.2**	**331**	**332.9**		

Survey block boundaries co-ordinates are provided in Appendix B.

2.2 Survey Operations

p

Survey operations were based out of Mayo, Yukon on May 27th to June 6th, 2010. The following table shows the timing of the flying.

Table 2 - Survey schedule

Date	Flight #	Block	Crew location	Comments
5-27-2010			Mayo Yukon	System Installation
5-28-2010	1,2,3	331	Mayo Yukon	Production
5-29-2010			Mayo Yukon	Technical issues
5-30-2010			Mayo Yukon	Technical issues
5-31-2010			Mayo Yukon	Technical issues
6-01-2010			Mayo Yukon	Technical issues
6-02-2010			Mayo Yukon	Technical issues
6-03-2010			Mayo Yukon	Re-flights
6-04-2010			Mayo Yukon	Job Complete

[1] Actual line-km represents the total line-km contained in the final databases. These line-km normally exceed the Planned line-km's, as indicated in the survey NAV files.

2.3 Flight Specifications

During the survey the helicopter was maintained at a mean height of 228 metres above the ground with a nominal survey speed of 80 km/hour for the survey block. This allowed for a nominal EM sensor terrain clearance of 154 metres and a magnetic sensor clearance of 171 metres.

The output data sampling rate from the acquisition program was 0.4 second for electromagnetics, 0.1 second for magnetometer and 0.2 second for altimeter and GPS. This translates to electromagnetic readings at approximately 10m intervals and magnetic readings roughly every 2 to 5 metres along flight track. Navigation was assisted by a CDGPS receiver and data acquisition system, which reports GPS co-ordinates as latitude/longitude and directs the pilot over a pre-programmed survey flight path.

The operator was responsible for monitoring of the system integrity. He also maintained a detailed flight log during the survey, tracking the times of the flight as well as any unusual geophysical or topographic feature.

On return of the aircrew to the base camp the survey data was transferred from a compact flash card (PCMCIA) to the data processing computer. The data were then uploaded via ftp to the Geotech office in Aurora for daily quality assurance and quality control by trained personnel, operating remotely.

2.4 Aircraft and Equipment

2.4.1 Survey Aircraft

The survey was flown using a Eurocopter Aerospatiale (Astar) 350 B3 helicopters, registration number C-FEDS. The helicopters were owned and operated by Geotech Aviation. Installation of the geophysical and ancillary equipment was carried out by Geotech Ltd.

2.4.2 Airborne Receiver

The airborne ZTEM receiver coil measures the vertical component (Z) of the EM field. The receiver coil is a Geotech Z-Axis Tipper (ZTEM) loop sensor which is isolated from most vibrations by a patented suspension system and is encased in a fibreglass shell. It is towed from the helicopter using a 90 metre long cable as shown in Figure 4. The cable is also used to transmit the measured EM signals back to the data acquisition system.

The coil has a 7.4 metre diameter with an orientation to the Vertical Dipole. The digitizing rate of the receiver is 2000 Hz. Attitudinal positioning of the receiver coil is enabled using 3 GPS antennas mounted on the coil. The output sampling rate is 0.4 seconds (see Section 2.4.7)

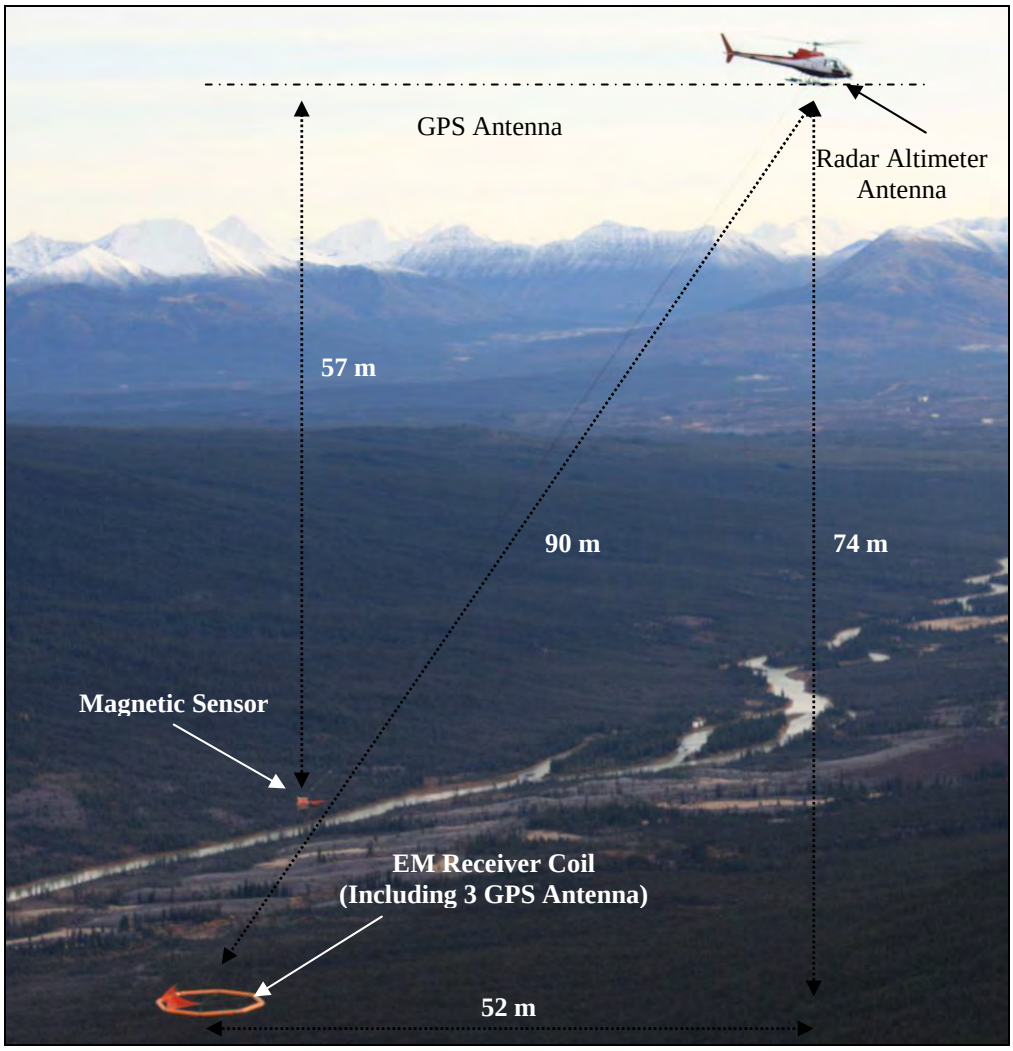

Figure 4 - ZTEM System Configuration

2.4.3 Base Station Receiver

The two Geotech ZTEM base station receiver coils measure the orthogonal, horizontal X and Y components of the EM reference field. They are set up perpendicular to each other and roughly oriented according to the flight line direction. The orientation of both units is not critical as the horizontal field can be further decomposed into the two orientations of the survey flight. The orientation of the base stations were measured using a compass.

The base station coils each have a diameter of 3.5 meters, with the coil orientations to the horizontal dipole, as shown in Figure 5.

The Block base station receiver coils were installed in a remote area outside the survey block (64°097' N, 134°420' W). The coils were oriented perpendicular to each other: Coil A was oriented at an N 358° E direction, with coil B oriented at an N 88° E direction.

Figure 5 - ZTEM base station receiver coils.

2.4.4 Airborne magnetometer

The magnetic sensor utilized for the survey was a Geometrics split-beam optically pumped caesium vapour magnetic field sensor, mounted in a separate bird, and towed on a cable at a mean distance of 57 metres below the helicopter (Figure 4). The sensitivity of the magnetic sensor is 0.02 nanoTesla (nT) at a sampling interval of 0.1 seconds. The magnetometer will perform continuously in areas of high magnetic gradient with the ambient range of the sensor approximately 20k-100k nT. The Aerodynamic magnetometer noise is specified to be less than 0.5 nT. The magnetometer sends the measured magnetic field strength as nanoTesla to the data acquisition system via the RS-232 port.

2.4.5 Radar Altimeter

A Terra TRA 3000/TRI 40 radar altimeter was used to record terrain clearance. The antenna was mounted beneath the bubble of the helicopter cockpit.

2.4.6 GPS Navigation System

The navigation system used was a Geotech PC104 based navigation system utilizing a NovAtel CDGPS (Canada-Wide Differential Global Positioning System Correction Service) enabled Propak V3-RT20 GPS receiver. Geotech's Navigate software, using a full screen display with controls in front of the pilot, allows him to direct the flight.

5 NovAtel GPS antennas are utilized during the survey; one is mounted on the helicopter tail (Figure 4), one installed with the Receiver Base Station (Figure 5) and three are mounted on the airborne receiver (Figure 4). As many as 14 GPS and two CDGPS satellites may be monitored at any one time. The horizontal positional accuracy or circular error probability (CEP) is 1.8 m, with CDGPS active, it is 0.6 m. The co-ordinates of the block were set-up prior to the survey and the information was fed into the airborne navigation system.

2.4.7 Digital Acquisition System

The power supply and the data acquisition system are mounted on an equipment rack which is installed into the helicopter. Signal and power wires are run through the helicopter to connect on to the tow cable outside. The tow cable supports the ZTEM and magnetometer birds during flight via a safety shear pin connected to the helicopter hook. The major power and data cables have a quick disconnect safety feature as well. The installation was undertaken by the Geotech Ltd. crew and was certified before surveying.

A Geotech data acquisition system recorded the digital survey data on an internal compact flash card. Data is displayed on an LCD screen as traces to allow the operator to monitor the integrity of the system. The data type and sampling interval as provided in Table 3.

Table 3 - Acquisition and Processing Sampling Rates

DATA TYPE	ACQUISITION SAMPLING	PROCESSING SAMPLING
ZTEM Receiver	0.0005 sec	0.4 sec
Magnetometer	0.1 sec	0.4 sec
GPS Position	0.2 sec	0.4 sec
Radar Altimeter	0.2 sec	0.4 sec
ZTEM Base station	0.0005 sec	– –

2.4.8 Mag Base Station

A combined magnetometer/GPS base station was utilized on this project. A Geometrics Caesium split-beam vapour magnetometer was used as a magnetic sensor with a sensitivity of 0.001 nT. The base station was recording the magnetic field together with the GPS time at 1 Hz on a base station computer.

The base station magnetometer sensors for the Block (63 48’ 14.8”N, 135 47’ 48.3”W) were installed behind the lodge away from electric transmission lines and moving ferrous objects such as motor vehicles. The base station data were backed-up to the data processing computer at the end of each survey day.

3. PERSONNEL

The following Geotech Ltd. personnel were involved in the project.

Field:

Project Manager:	Darren Tuck (Office)
Data QA/QC:	Rafael Coyoli (Ofice)
Crew chief:	Roger Leblanc
System Operators:	Brandon Gray

The survey pilot and the mechanical engineer were employed directly by the helicopter operator –Geotech Aviation Ltd.

Pilot:	Brad MacRae
Mechanical Engineer:	Tyler McLellan

Office:

Preliminary Data Processing:	Biljana Milicevic
Final Data Processing:	Biljana Milicevic
Final Data QC:	Jean Legault
Reporting/Mapping:	Wendy Acorn

Data acquisition phase was carried out under the supervision of Andrei Bagrianski, P. Geo, Surveys Manager. Processing phase was carried out under the supervision of Gord Smith, Manager of Data Processing. The Interpretation phase was under the supervision of Jean Legault, P. Geo. The overall contract management and customer relations were by Paolo Berardelli.

4. DATA PROCESSING AND PRESENTATION

Data compilation and processing were carried out by the application of Geosoft OASIS Montaj and programs proprietary to Geotech Ltd.

4.1 Flight Path

The flight path, recorded by the acquisition program as WGS 84 latitude/longitude, was converted into the WGS84, UTM Zone 10 North coordinate system in Oasis Montaj.

The flight path was drawn using linear interpolation between x, y positions from the navigation system. Positions are updated every second and expressed as UTM easting's (x) and UTM northing's (y).

4.2 In-field Processing and Quality Control

In-Field data processing and quality control are done on a flight by flight basis by a qualified data processor (see Section 3.0). Processing steps and check up procedures are designed to assure the best possible final quality of ZTEM survey data. A general overview of those steps is presented in the following paragraphs.

The In-Field quality control can be separated into several phases:

a. GPS Processing Phase: GPS Data are first examined and evaluated during the GrafMov processing.
b. Raw data, ZTEM viewer phase:

   Data can be viewed, examined for consistency, individual channel spectra examined and overall noise estimated in the viewer provided by the ZTEM proprietary software, on the raw flight data and raw base station data separately, on the merged data, and finally on the data that have undergone ZTEM processing.
c. Field Geosoft phase:

   Magnetic data, Radar altimeter data, GPS positioning data are re-examined and processed in this phase. Prior to splitting the lines EM data are examined flight by flight and the effectiveness of applying the attitude correction evaluated. After splitting the lines, a set of grids are generate for each parameter and their consistency evaluated. Data profiles are also re-evaluated on a line to line basis. A power line monitor channel is available in order to identify power line noise.

4.3 GPS Processing

Three GPS sensor (mounted on the airborne receiving loop) measurements were differentially corrected using the Waypoint GrafMov^{TM} software in order to yield attitude corrections to recorded EM data.

4.4 ZTEM Electromagnetic Data

The ZTEM data were processed using proprietary software. Processing steps consist of the following preliminary and final processing steps:

4.4.1 Preliminary Processing

a. Airborne EM, Mag, radar altimeter and GPS data are first merged with EM base station data into one file.
b. Merged data are viewed and examined for consistency in an incorporated viewer
c. In the next, processing phase, the following entities are taken into account:
   - the Base station coils orientation with respect to the Magnetic North,
   - the Local declination of the magnetic field,
   - Suggested direction of the X coordinate (North or line direction),
   - Sensitivity coefficient that compensates for the difference in geometry between the base station and airborne coils.
   - Rejection filters for the 60 Hz and helicopter generated frequencies.
d. Six frequencies (In phase and Quadrature components) are extracted from the airborne EM coil response in the windows of 0.4 seconds and the base station coils in the windows of 1.0 seconds (30, 45, 90, 180, 360, and 720 Hz).
e. The ratios between the real parts (in phase) of the vertical Z component (airborne) over the horizontal X component (base station), and Z component over horizontal orthogonal Y component, as well as the ratios of their imaginary parts (quadrature), are calculated.
f. Such processed EM data are then merged with the GPS data, magnetic base station data and exported into a Geosoft xyz file.

4.4.2 Geosoft Processing

Next stage of the preliminary data processing is done in a Geosoft ™ environment, using the following steps:

a. Import the output xyz file from the AFMAG processing, as well as the base Mag data into one database.
b. Split lines according to the recorded line channel,
c. GPS processing, flight path recovery (correcting, filtering, calculating Bird GPS coordinates, line splitting)
d. Radar altimeter processing, yielding the altitude values in metres.
e. Magnetic spike removal, filtering (applied to both airborne and base station data). Calculation of a base station corrected mag.
f. Apply preliminary attitude corrections to EM data (In phase and Quadrature), filter and make preliminary grids and profiles of all channels.

4.4.3 Final Processing

Final data processing and quality control were undertaken by Geotech Ltd headquarters in Aurora, Ontario by qualified senior data processing personnel.

A quality control step consisted of re-examining all data in order to validate the preliminary data processing and to allow for final adjustments to the data.

Attitude corrections were re-evaluated, and re-applied, on component by component, flight by flight, and frequency by frequency bases. Any remaining line to line system noise was removed by applying a mild additional levelling correction.

4.4.4 ZTEM Profile Sign Convention

Z/X and Z/Y components do not exhibit maxima or minima above conductors, resistors or at contacts; in fact they produce cross-over type anomalies (Ward, 1959). The crossover polarity sign convention for ZTEM is according to the right hand Cartesian rule (Z positive –up) that is commonly used for multi-component transient electromagnetic methods.

For the Northeast Southwest lines at the Block the sign convention for the Z/X in-line component crossover is positive-negative pointing southwest to northeast for tabular conductors perpendicular to the profile (Figure 6). The corresponding Z/Y component in-phase cross-over polarity is positive-negative pointing southeast to northwest (90 degrees counter clockwise to Z/X) according to the right hand Cartesian rule.

Conversely, tabular resistive bodies produce In-Phase cross-over's that are opposite in sign to conductors. A brief discussion of ZTEM and AFMAG, along with selected forward model responses is presented in Appendix D.

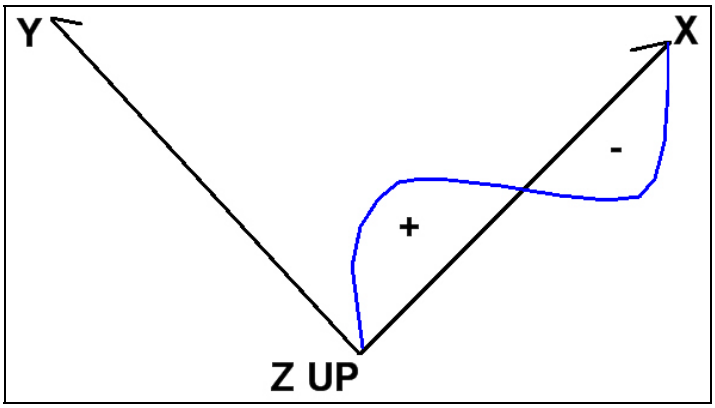

Figure 6 - ZTEM Crossover Polarity Convention of the Block

4.4.5 ZTEM Quadrature Sign Dependence

One important note regarding the sign of the ZTEM Quadrature, relative to the In-Phase component, particularly with regards to computer modeling and inversion.

The sign of the magnetotelluric Quadrature relative to the In-Phase tipper transfer function component pertains to the Fourier transformation of the time series to give frequency domain spectra. There are two widely used conventions for time dependence in the transformations, **exp(+iωt)** and **exp(-iωt).** That which is implemented largely is a matter of personal preference and precedent. The importance of the In-Phase and Quadrature sign convention is not critical, provided that it is known and documented.

In ZTEM, the data processing code used for the Fourier transformation the time-series data to frequency domain spectra adopts a **exp(-iωt)** time dependence (J. Dodds, Geo Equipment Manufacturing, pers. comm., Nov-2009). Whereas in the forward modeling and inversion program Zvert2d, the sign of the Quadrature relative to the In-Phase transfer function assumes an **exp(+iωt)** dependence[2].

The reasons for adopting $\mathbf{e^{-i\omega t}}$ used in ZTEM are several: a) In-phase and Quadrature profile and contour plan maps can be readily compared, since they are usually in the same-sign and quadrant (i.e.Figure 7); b) Phase-rotation and Total Divergence (DT) parameters need not be changed when comparing In-Phase versus Quadrature data.

As a result, for users interested in computer modeling and inversion of ZTEM data, the sign of the Quadrature will need to be reversed, relative to the In-Phase component, in order to provide a proper result (Figure 7). Indeed this reverse Quadrature polarity convention is assumed in all forward modeling and inversion of ZTEM data, as described in Figures 5-7 in Appendix D.

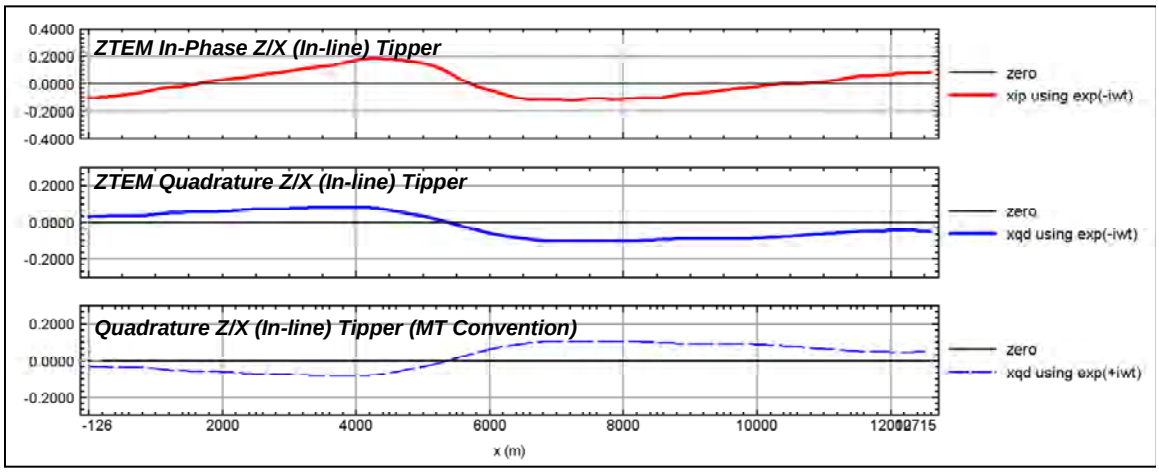

Figure 7 - Illustration of ZTEM In-Phase & Quadrature Tipper transfer function polarity convention (e-iωt) relative to equivalent MT Tipper Quadrature polarity convention (e+iωt) for a graphitic conductor in Athabasca Basin, SK.

2 Phillip E. Wannamaker (2009): Two-dimensional Inversion of ZTEM data: Synthetic Model Study and Test Profile Images, Internal Geotech technical report by Emblem Exploration Services Inc., January 22, 2009, 32 pp.

4.4.6 Total Divergence and Phase Rotation Processing

In a final processing step DT (Total Divergence) and PR (Phase Rotation) processing are applied to the multi-frequency In-phase and Quadrature ZTEM data. This is due to the crossover nature of the Tipper Responses; these additional processing steps are applied to convert them into local maxima for easier interpretation.

To present the data from both tipper components into one image, the Total Divergence parameter, termed the DT is calculated from the horizontal derivatives of the Z/X and Z/Y tippers (Lo and Zang, 2008). It is analogous to the "Peaker" parameter in VLF (Pedersen, 1998).

Total Divergence DT:	***DT = DIV (Z/X, Z/Y)*** ***= d(Z/X)/dx+d(Z/Y)/dy***

This DT parameter was introduced by Petr Kuzmin (Milicevic, 2007, p. 13) and is derived for each of the In Phase and Quadrature components at individual frequencies. These in turn allow for minima over conductors and maxima over resistive zones. DT grids for each of the extracted frequencies were generated accordingly, using a reverse colour scheme with warm colours over conductors and cool colours over resistors.

The DT gives a clearer image of conductor's location and shape but, as a derivative, it does not preserve some of the long wavelength information and is also sensitive to noise.

As an alternative, a 90 degree Phase Rotation (PR) technique is also applied to the grids of each individual component (Z/X and Z/Y). It transforms bipolar (cross over) anomalies into single pole anomalies with a maximum over conductors, while preserving long wavelength information (Lo et al., 2009). The two orthogonal grids are then usually added to obtain a Total Phase Rotated grid for the In-Phase and Quadrature.

Total Phase-Rotation:	***= PR (Z/X) + PR (Z/Y)***

A presentation of the ZTEM test survey results over unconformity uranium deposits that illustrates DT and TPR examples, as documented by Lo et al. (2009) is provided in Appendix E.

4.4.7 2D EM Inversion

2d inversions of the ZTEM results were performed over selected lines using the Geotech Zvert2d software developed by Phil Wannamaker, U. of Utah, for Geotech Ltd. The inversion algorithm is based on the 2D inversion code with Jacobians of de Lugao and Wannamaker (1996), the 2D forward code of Wannamaker et al (1987), and the Gauss-Newton parameter step equations of Tarantola (1987). Zvert2d has been developed/modified for use with our ZTEM platform by taking into account the 75-80m air-layer between radar bird and ground surface.

The 2D code only considers the In-Line (Z/X) data and assumes that the strike lengths of bodies are infinite and orthogonal to the profile. The code is designed to account for the ZTEM vertical coil receiver and fixed base station reference measurements – although this option was not used in this study. The inversion uses a model-mesh consisting of 440 cells laterally and 62 cells vertically. Typically the ZTEM data are de-sampled to 180-200 pts, in order to allow the inversion to run in 10minutes or less. Typically, between 1-2% errors are added to the In-line in-phase (XIP) and Quadrature (XQD) data obtained at 30,45,90,180,360 & 720Hz. Errors are adjusted until numerical convergence (<1.0 rms) is attained in 8 iterations or less. All inversions are based on a 1k ohm-m homogeneous starting half-space model.

4.5 Magnetic Data

The processing of the total magnetic field intensity (TMI) data involved the correction for diurnal variations by using the digitally recorded ground base station magnetic values. The base station magnetometer data was edited and merged into the Geosoft GDB database on a daily basis. The aeromagnetic data was corrected for diurnal variations by subtracting the observed magnetic base station deviations.

Due to the absence of tie-lines, further tie-line or micro levelling were not applied to the magnetic data.

The corrected magnetic data was interpolated between survey lines using a random point gridding method to yield x-y grid values for a standard grid cell size of 50 metres. The Minimum Curvature algorithm was used to interpolate values onto a rectangular regular spaced grid.

5. DELIVERABLES

5.1 Survey Report

The survey report describes the data acquisition, processing, and final presentation of the survey results. The survey report is provided in two paper copies and digitally in PDF format.

5.2 Maps

Final maps were produced at scale of 1:20,000. The coordinate/projection system used was WGS84, UTM Zone 8 North. All maps show the flight path trace and topographic data; latitude and longitude are also noted on maps.

The preliminary and final results of the survey are presented as profile plans for the EM data that were generated for individual real (In-Phase) and imaginary parts (Quadrature) of the Z/X and Z/Y components. Colour contour maps of the corresponding TPR (Total Phase Rotated) Grids for three of the six frequencies, (30, 45, 90, 180, 360 and 720Hz), as well as for corresponding Phase Rotated Grids for individual components.

3D views have been constructed by plotting the DT and TPR grids at their respective penetration depths using a 1000 ohm-m half space, using the Bostick skin depth rule (Murakami, 1985) see Appendix D.

Final maps were chosen, in consultation with the client, to represent all collected data, are listed in Section 5.3.

Sample maps of the related 3D view, Magnetic and Total Divergence are included in this report and presented in Appendix C.

5.3 Digital Data

- Two copies of the data and maps on DVD were prepared to accompany the report. Each DVD contains a digital file of the line data in GDB Geosoft Montaj.
- DVD structure.

  There are two (2) main directories;
  Data contains databases, grids and maps, as described below.
  Report contains a copy of the report and appendices in PDF format.

  Databases in Geosoft GDB format, containing the channels listed in Table 4.

Table 4 - Geosoft GDB Data Format

Column	Description
X:	UTM Easting WGS84 Zone 8, (Centre of the ZTEM loop) (meters)
Y:	UTM Northing WGS84 Zone 8 , (Centre of the ZTEM loop) (meters)

6. CONCLUSIONS AND RECOMMENDATIONS

6.1 Conclusions

A helicopter-borne ZTEM and aeromagnetic geophysical survey has been completed over the Rau Block located near Mayo, Yukon Territory.

The total area coverage is 65.2 km^2. Total survey line coverage is 332.9 line kilometres. The principal sensors included a Z-Axis Tipper electromagnetic (ZTEM) system and a caesium magnetometer. Results have been presented as stacked profiles and contour colour images at a scale of 1:20,000.

There is no summary interpretation included in this report.

6.2 Recommendations

Based on the geophysical results obtained, a number of interesting conductive structures were identified across the property. The magnetic results also contain worthwhile information in support of exploration targets of interest. We therefore recommend a more detailed interpretation of the available geophysical data, including VTEM, in conjunction with the geology, prior to ground follow up and drill testing.

APPENDIX D

ZTEM THEORETICAL CONSIDERATIONS

A brief section on the theory behind the AFMAG technique is provided for completeness and a more comprehensive development of the theory can be found in standard texts. The natural EM field is normally horizontally polarized. Subsurface lateral variations of conductivity generate a vertical component, which is linearly related to the horizontal field. Although the fields look like random signals, they may be treated as the sum of sinusoids. At each frequency the field can be expressed as a complex number with magnitude and argument equal to the amplitude and phase of the sinusoid. The relation between the field components can then be expressed by a linear complex equation with two complex coefficients at any one frequency. These coefficients are dependent upon the subsurface and not upon the horizontal field present at any particular time and are appropriate parameters to measure (Vozoff, 1972).

$$\mathbf{Hz(f) = Tx(f)\ Hx(f) + Ty(f)\ Hy(f),} \qquad \mathbf{(1)}$$

Where

Hx(f), Hy(f) and Hz(f) are x, y and z components of the field,

Tx(f) and Ty(f) are the "tipper" coefficients.

In the case of a horizontally homogeneous environment, Tx and Ty are equal to zero because Hz =0. They show certain anomalies only by the presence of changes in subsurface conductivity in the horizontal direction. The real parts of the coefficients correspond to tangents of tilt angles measured with a controlled source. The complex tensor [Tx, Ty] known as the "tipper" defines the vertical response to horizontal fields in the x and y directions respectively.

Tx and Ty are two unknown coefficients in one equation, and we therefore must combine two or more sets of measurements to solve them. To reduce effects of noise, multiple sets of measurements can be made, and the coefficients, which minimize the squared error in predicting the measured Z from X and Y, can be found. This leads to next formulas for estimating the coefficients.

$$\mathbf{Tx = ([HzHx^*]\ [HyHy^*] - [HzHy^*]\ [HyHx^*])\ /\ ([HxHx^*]\ [HyHy^*] - [HxHy^*]\ [HyHx^*]),} \qquad \mathbf{(2)}$$

and

$$\mathbf{Ty = ([HzHy^*]\ [HxHx^*] - [HzHx^*]\ [HxHy^*])\ /\ ([HxHx^*]\ [HyHy^*] - [HxHy^*]\ [HyHx^*]\ .} \qquad \mathbf{(3)}$$

Where

[HxHy*] (For example) denotes a sum of the product of Hx with the complex conjugate of Hy.

In practical processing algorithms, all numbers Hx, Hy and Hz can be obtained by applying the same digital band-pass filters to three incoming parallel data signals. FFT algorithms are also applicable. All sums like [HxHy*] can be calculated on the basis of a discrete time interval in the range from 0.1 to 1 sec or on a sliding time base.

Using platform attitude data in the EM data processing can be done at different stages of the signal processing. The most obvious idea is to transform parallel data from local coordinates of the platform into absolute geographical coordinates before the main signal processing procedure. Unfortunately, the proper algorithms of attitude data obtained, often require some post-processing algorithms such as using post-calculated accelerations based on GPS data etc. That is why it is preferable to treat x-y-z coordinates in formulas above in the local coordinate system of the platform and to recalculate resulting local tilt angles into a geographical or global coordinate system later, during the data post processing.

In weak field conditions where the level of the signal is comparable with input noise levels in preamplifiers, the bias in the estimated values of Tx and Ty caused by noise in the horizontal signals become substantial and can not be reduced by any averaging. This bias can be removed by the use of separate reference signals containing noise uncorrelated with noise in signals Hx and Hy. (Anav et al., 1976).

$$Tx = ([HzRx^*]\,[HyRy^*] - [HzRy^*]\,[HyRx^*]) / ([HxRx^*]\,[HyRy^*] - [HxRy^*]\,[HyRx^*]), \quad (4)$$

and

$$Ty = ([HzRy^*]\,[HxRx^*] - [HzRx^*]\,[HxRy^*]) / ([HxRx^*]\,[HyRy^*] - [HxRy^*]\,[HyRx^*]). \quad (5)$$

Where:

Rx is the reference field x component,
Ry is the reference field y component.

An additional two electromagnetic sensors, providing these reference signals can be placed at some distance away from the main x, y and z sensors. Currently, though, no additional remote-reference processing are applied to ZTEM data.

Numerical Modelling

In order to understand the airborne AFMAG responses to conductors for a variety of geological environments, EMIGMA^{TM} modelling code from PetRos EiKon (Toronto, ON) was obtained to conduct the formulated model studies.

Below are some of the modelling results from their study.

Modelling assumption:

The assumptions for the modelling are that:

3 components of the magnetic field are measured and they are processed according to:

$$Hz(f) = Tx(f)\,Hx(f) + Ty(f)\,Hy(f)$$

The vector (Tx,Ty) is usually referred to as the 'tipper' vector and is determined in the frequency domain through processing. This is normally done by determining transfer functions from an extended time series.

For the modelling exercise, the 3 components of the magnetic vector (Hx,Hy,Hz) are modelled twice for 2 orthogonal polarizations of a plane wave source field and then the tipper is calculated from a matrix calculation using the results of the 2 source polarizations' models. For the 2D forward modelling results, the tipper vectors are shown as a function of frequency

Basic Model Response

For the initial models, we assume a thin plate-like model. The model is perpendicular to the flight direction. Initially, we will assume very long strike directions. From this quasi-2D model, there are 2 basic responses. The so-called TE response and the so-called TM response.

For the initial models, we will assume the strike is in the y (North) directions and the flight is in the x (East) direction Sensor heights are 30m above ground.

TE Mode: For the TE response, the electric field excitation flows along strike (current channelling) and the horizontal H field (Hx) flows perpendicular to strike thus causing induction through Faraday's law. The Hz response is generated both from channelling and induction.

TM Mode: For this response, the electric field excitation flows perpendicular to strike generating quasi-static charges on faces and the horizontal H field (Hx) flows parallel to strike. Since, the XZ face is very small for this model, little current is induced. The charges on the faces have a small dipole moment due to the thinness of the model.

For the rest of the models unless otherwise noted, the parameters used are:

Strike Length: 1km
Depth Extent: 1km
Conductance: 100S
Depth to Top: 10m
Background: Thin-overburden (10m), Resistive Basement (1000 Ohm-m)

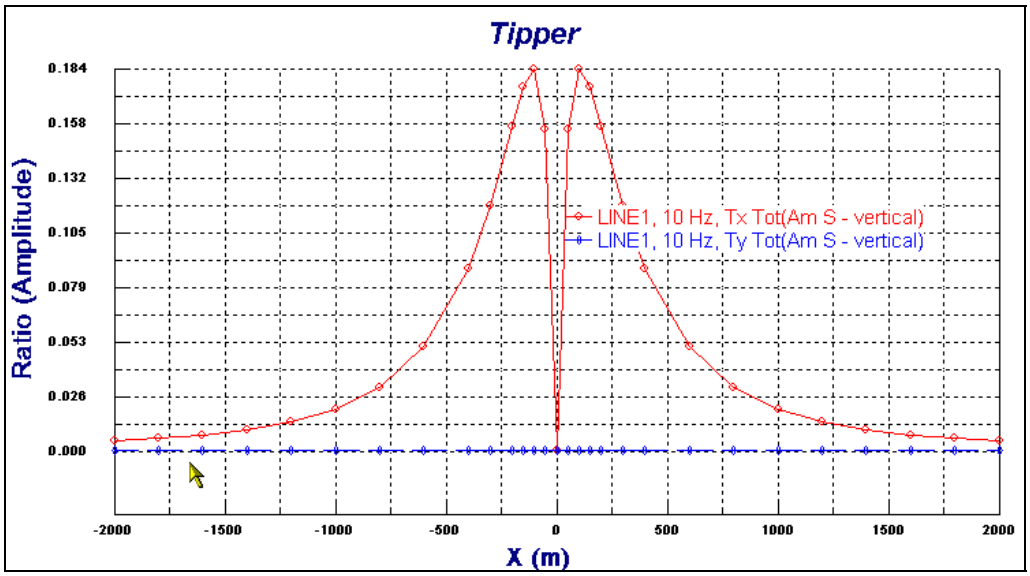

Figure D-1 – Calculated Tipper components at 10 Hz for above model parameters.

Figure D1 shows the Tipper (Tx,Ty) Amplitudes at 10Hz using a10Ωm overburden. Note small Ty (ie quasi-TM response)

Amplitude Response

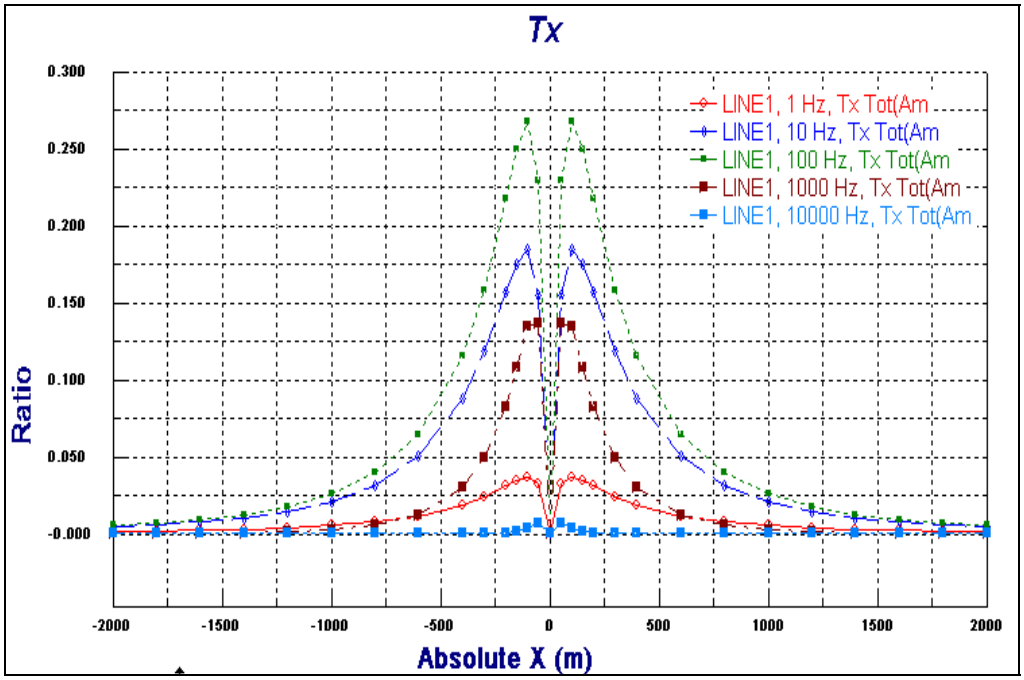

Figure D-2 – Calculated Tx component of the Tipper at various frequencies

The (Tx) response amplitude at 1,10,100,1000,10000 Hx. Peak amplitude at 100Hz

Inphase and Quadrature Response

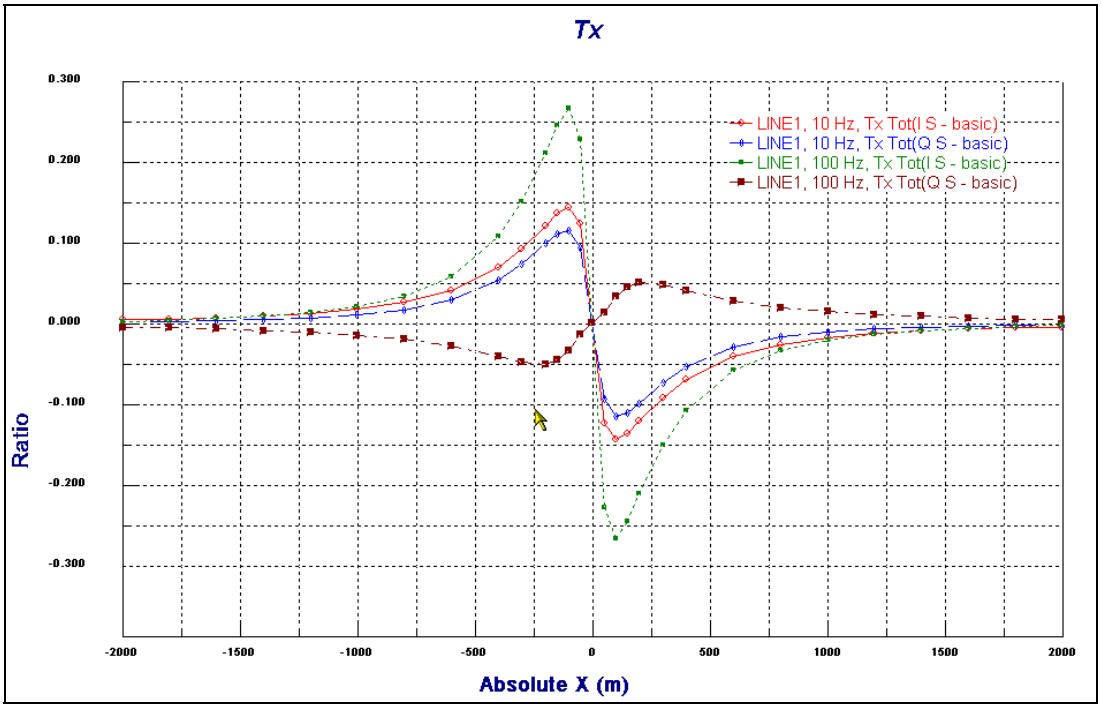

Figure D-3 – Calculated In-phase and Quadrature of the Tx component at various frequencies

Figure D-3 shows the In-phase and Quadrature response at 10 and 100Hz. Note the crossovers in the In-phase and Quadrature, and the phase reversal in the Quadrature responses from low to high frequencies.

AFMAG Source Fields and ZTEM method[1]

AFMAG uses naturally occurring audio frequency magnetic fields as the source of the primary field signal, and therefore requires no transmitter (Ward, 1959). The primary fields resemble those from VLF except that they are lower frequency (tens & hundreds of Hz versus tens of kHz) and are usually not as strongly directionally polarized (Labson et al., 1985). These EM fields used in AFMAG are derived from world wide atmospheric thunderstorm activity, have the unique characteristic of being uniform, planar and horizontal, and also propagate vertically into the earth – to great depth, up to several km, as determined by the magnetotelluric (MT) skin depth (Vozoff, 1972), which is directly proportional to the ratio of the bedrock resistivity to the frequency (Figure D4).

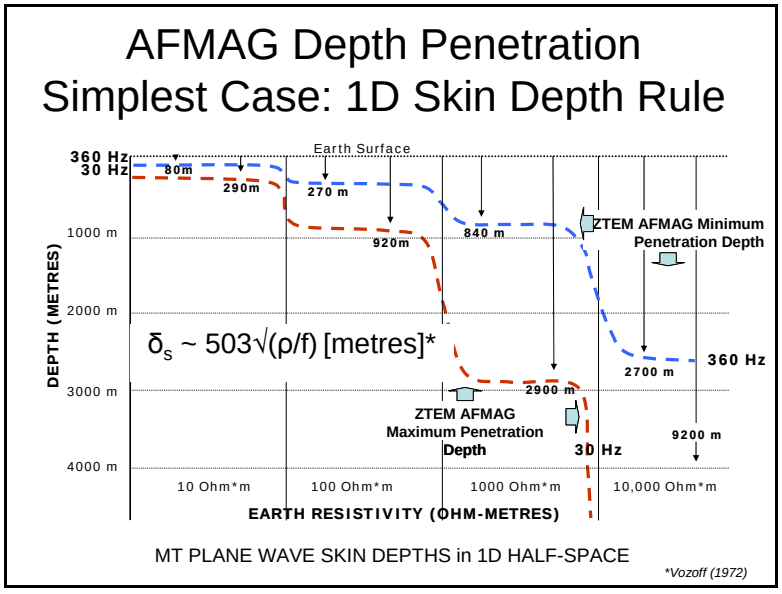

Figure D4: MT Skin Depth Penetrations for ZTEM in 30-360Hz and 10-1000 ohm resistivity

At the frequencies used for ZTEM, the penetration depths likely range between approx. 600m to 2km in this region (approx. 1k ohm-m avg. resistivity assumed), according to the following equation for the Bostick skin depth $\delta_B = 356 * \sqrt{(\rho / f)}$ metres (Murakami, 1985), which is considered appropriate as a rule of thumb equivalent depth estimate.

The other unique aspect of AFMAG fields is that they react to relative contrasts in the resistivity, and therefore do not depend on the absolute conductance, as measured using inductive EM systems, such as VTEM. Hence poorly, conductive targets, such as alteration zones and fault zones can be mapped, as well as higher conductance features, like graphitic units. Conversely, resistive targets can also be detected using AFMAG– provided they are of a sufficient size and contrast to produce a vertical field anomaly. Indeed resistors produce reversed anomalies relative to conductive features. Hence AFMAG can be effective as an

all-round resistivity mapping tool, making it unique among airborne EM methods. A series of 2D synthetic models that illustrate these aspects have been created using the 2D forward MT modelling code of Wannamaker et al. (1987) and are presented in figures D5-D7.

The tipper from a single site contains information on the dimensionality of the subsurface (Pedersen, 1998), for example, in a horizontally stratified or 1D earth, $\boldsymbol{T}$=0 and as such H_Z is absent. For a 2D earth with the y-axis along strike, T_Y=0 and $H_Z = T_X * H_X$. In 3D earths, both T_X and T_Y will be non-zero. H_Z is therefore only present, as a secondary field, due to a lateral resistivity contrast, whereas the horizontal H_X and H_Y fields are a mixture of secondary and primary fields (Stodt et al., 1981). But, as an approximation, as in the telluric-magnetotelluric method (T-MT; Hermance and Thayer, 1975) used by distributed MT acquisition systems, the horizontal fields are assumed to be practically uniform, which is particularly useful for rapid reconnaissance mapping purposes. By measuring the vertical magnetic field H_X, using a mobile receiver and the orthogonal horizontal H_X and H_Y fields at a fixed base station reference site, ZTEM is a direct adaptation of this technique for airborne AFMAG surveying.

ZTEM (AIRBORNE AFMAG) TESTS OVER UNCONFORMITY URANIUM DEPOSITS[5]

Key Words: ZTEM, AFMAG, electromagnetic, airborne, uranium, Athabasca.

INTRODUCTION

A series of demonstration tests were conducted using the ZTEM, airborne AFMAG system over deep targets in the Athabasca Basin of Saskatchewan, Canada. These tests were conducted in mid-2008 and were flown to test ZTEM's ability to detect large conductive targets at depth; deeper than conventional airborne EM methods. Data are presented over areas where the conductors are located 450-600 metres beneath the surface. As well, a case of ZTEM following the plunge of a conductor to over 800 metres depth is shown.

BACKGROUND

The ZTEM system is the latest implementation of an airborne AFMAG system first commercialized in late 2006. ZTEM uses a large, 8 metre diameter airborne air core coil, slung from a helicopter, to measure the vertical component of the AFMAG signal. Two 4 metre square coils are deployed on the ground to measure the horizontal field. The ZTEM system has flown successful demonstration surveys over porphyry copper deposits in the southwest USA (Zang et al., 2008).

ZTEM was tested in the Athabasca Basin in Canada in May of 2008 to determine its depth of investigation and to determine its suitability for mapping deep conductors in the crystalline basement. Over 30% of the world's U3O8 is mined in the Athabasca Basin from unconformity uranium deposits. Unconformity uranium deposits of the Athabasca Basin are often associated with conductors located in the crystalline basement. The search for economic uranium deposits is moving to areas of the basin which are deeper and beyond the detection limits of modern airborne instrumentation. This creates the requirement for a system which can detect conductivity past the detection limits of modern traditional EM systems. This was the motivation behind the field trials of the ZTEM system in the Athabasca Basin. Several areas where known deep conductors (450-600m+) were located were flown. Also, a test survey block in the northern part of the basin was able to trace a deep and plunging conductor to depths that no other airborne EM system has been able to achieve.

ATHABASCA BASIN GEOLOGY

The high-grade uranium deposits within the Athabasca Basin are associated with the unconformity between the essentially flat-lying Proterozoic Athabasca Group sandstones and the underlying Archean-Paleoproterozoic metamorphic and igneous basement rocks. The deposits occupy a range of positions from wholly basement-hosted to wholly sediment-hosted, at structurally favourable sites in the interface between the deeply weathered basement and overlying sediments of the Athabasca Basin (Ruzicka, 1997). The locations of These deposits are lithologically and structurally controlled by the sub-Athabasca unconformity and basement faults and fracture zones, which are localized in graphitic pelitic gneisses that may flank structurally competent Archean granitoid domes (Quirt, 1989).

In general, most of the known important deposits tend to occur within a few tens to a few hundred metres of the unconformity and within 500 m of the current ground surface. This may be more of a limitation of exploration techniques. There is no reason to believe that the distribution of the deposits is dependent on the modern day depth of

[5] Extended abstract submitted to 20[TH] ASEG International Geophysical Conference & Exhibition, Adelaide, AU, 22-26 Feb, 2009.

burial.
Empirically, the geophysical exploration for unconformity type uranium targets have been to search for large basement structures which post date the sandstone deposition of the basement (Matthews et. al, 1997). All the deposits located so far are associated with fault structures associated with a graphitic conductive basement. An alteration zone of clay silicification and enrichment around the deposits probably leads to magnetite destruction causing the magnetic low observed around the deposits. The clay alteration should give rise to a resistivity low signature about the deposits. The low conductivity of the clay alteration makes it a difficult target for airborne EM if it is buried at significant depth.

ZTEM INSTRUMENTATION AND PRESENTATION

ZTEM is an airborne AFMAG system introduced by Geotech Ltd. of Canada in early 2007 (Lo et al., 2008). In a ZTEM survey, a single vertical dipole air-core coil is flown over the survey area in a grid pattern similar to other airborne electromagnetic surveys. Two orthogonal, air-core, horizontal axis coils placed close to the survey site measures the horizontal EM fields for reference. A GPS array on the airborne coil monitors its attitude for post-flight corrections.

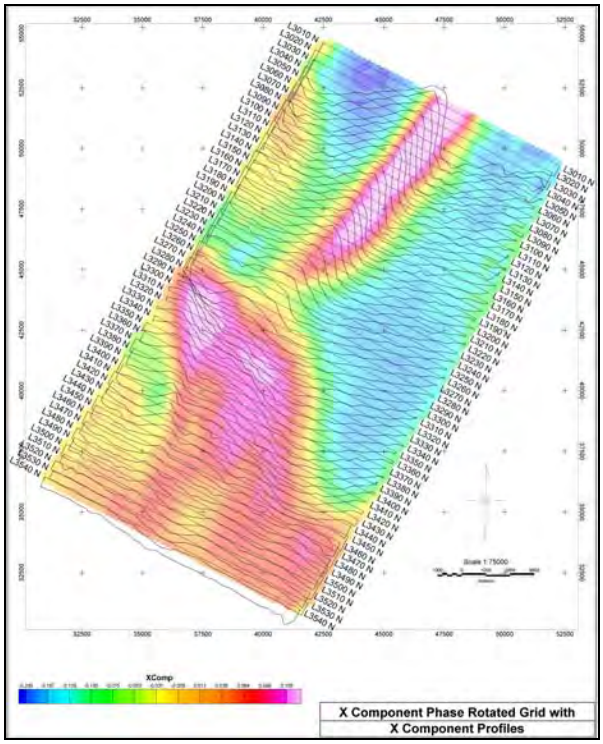

Figure 1 – Stacked profiles of the x-component Tipper over the gridded values of the phase rotated x-component data. Note that the cross-overs in the profiles are now peaks on the image.

As the source field is assumed to be far away, the excitation of the ground is more or less uniform. For large structures, the signal fall-off will be much slower than from a dipole source, such as those energized by traditional airborne systems. With the ZTEM system being less susceptible to terrain clearance, the planned ground clearance height is higher and the terrain drape is looser as compared to standard helicopter EM surveys.

The two Tippers obtained from the relationship between the vertical airborne coil and the two ground coils have a cross-over over a steeply dipping, plate-like body. The cross-overs can be made into local maxima via a 90 degree phase rotation which allows for easier interpretation of the gridded values. Figure 1 is an example of this transformation.

To present the data of both Tippers as one image, we calculate a parameter termed the DT which is the horizontal divergence of the two Tippers, much in the same manner as the "peaker" parameter in VLF (Pedersen, 1998). The DT is typically plotted with an inverted colour bar as it is negative over a steeply dipping thin body.

ZTEM RESULTS – NORTHERN ATHABASCA BASIN

Figure 2 shows gridded values from a number of ZTEM lines over an area where the sedimentary cover is approximately 450-600 metres thick. A number of traditional EM systems have also been flown over this block. While they were able to detect conductors, the resolution of the conductive features is not nearly as detailed as the information provided by ZTEM.

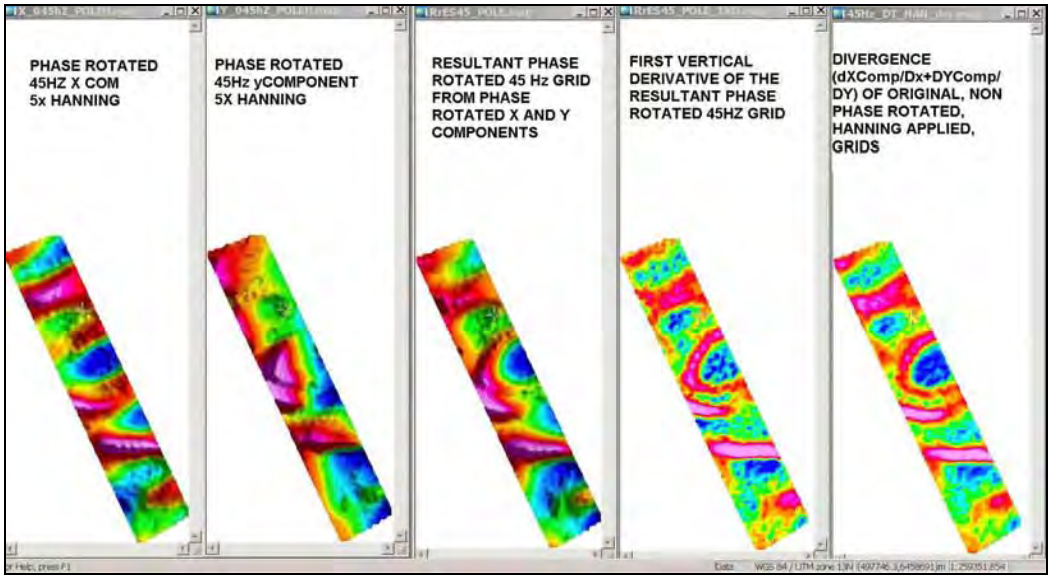

Figure 2 – ZTEM results over an area of 450-600 metre thick sedimentary cover.

Figure 3, from another area, shows the data from one of the larger blocks that was flown. It is a 3D composite image of the DT at various frequencies plotted at the equivalent skin depth assuming a 1,000 ohm-m average resistivity.

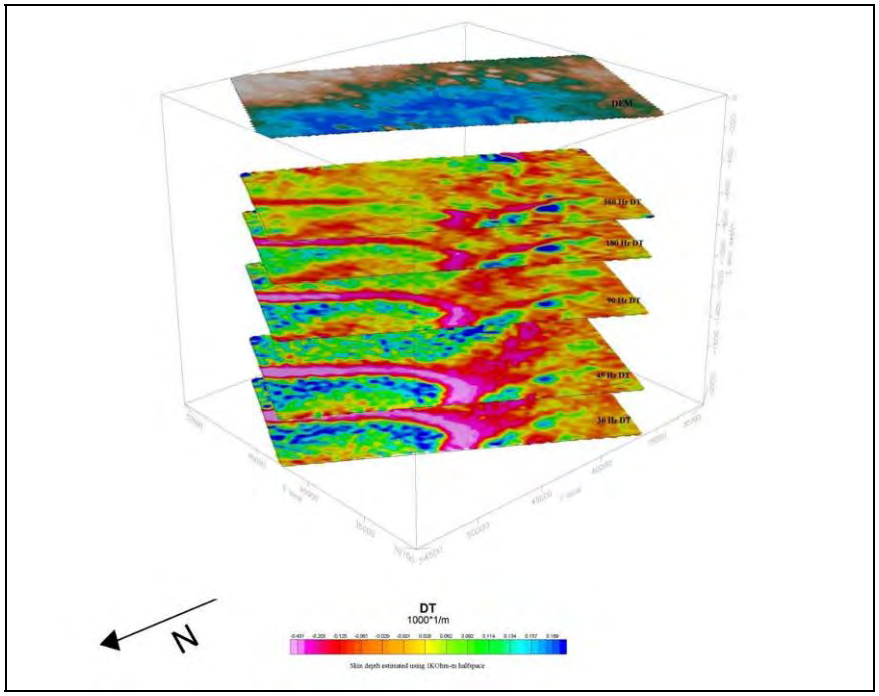

Figure 3 - Perspective view of DT's of different frequencies plotted at the skin depth (using a 1,000 ohm-m Earth.

The data in Figure 3 come from a survey over the north rim of the Athabasca Basin. The sandstone cover is about 500m on the left hand side of the image, and progressively getting deeper to the right. It is about 700m in the middle part of the image and over 800 metres thick on the right middle portion where exploration drilling is concentrated. Starting in the middle left and trending to the right of the image, there is a known graphitic shear.

In the uppermost (600m) "depth slice", Figure 3 shows a linear conductive feature that progressively weakens as one moves to the right until it is no longer seen. This is interpreted to be due to the graphitic shear conductor plunging deeper past the depth of investigation of the 360 Hz data. The lower frequencies penetrate more into the sedimentary cover that is deeper towards the right. DT's of decreasing frequency show the linear conductive feature extending more and more to the right. The feature also strengthens/sharpens into a synformal shape with lower frequencies. This fits with what the known geology of a plunging conductor at depth is doing.

At the nose of the fold, in the right third of the images, we also see another, broader anomalous zone that trends towards the back of the image. At this location, two radioactive springs are situated. These spring waters which are anomalously high in uranium and radon may reflect the upward migration of deep waters along faults, suggesting structural targets in areas where basinal waters may have tapped a radioactive source. This broad DT trend might be the plunge of the fold axis that is aligned away from the front of the image. An anomaly along this trend, at the highest frequency, that steadily grows with each decreasing frequency can be seen. This might represent an alteration zone in the sandstone that is detected at the shallowest depth. By about the 90Hz DT depth slice or so, we are possibly in the deeper basement and into a basement graphitic unit.

CONCLUSIONS

A number of successful ZTEM tests were conducted over the Athabasca Basin. The tests demonstrated that ZTEM can easily detect conductivity to 800 metres beneath relatively resistive sedimentary cover. Assuming a 1,000 ohm-metre

resistivity, the skin depth of the 30 Hz data is approximately 2,000 metres. The 30 Hz data presented have good signal to noise ratios indicating a deep depth of exploration. The observation that ZTEM may be detecting the clay alteration above the crystalline basement is a significant advantage for exploration of unconformity uranium deposits.

More demonstration surveys are planned in the Athabasca Basin later this year. And more target types for testing are also planned.

ACKNOWLEDGEMENTS

The authors thank Geotech Ltd. for allowing them to publish this work and for providing the support required to write this abstract and to present this paper.

APPENDIX F
Zvert2d Inversion Summary

General Geology

The Rau Project is located 55 km northeast of Keno City in Central Yukon (Figure F1). The Rau Block hosts replacement-style, gold-bearing sulphide and oxide mineralization that occurs in Bouvette Formation shallow water limestone, dolomite, and calcareous siltstone of Cambrian to Devonian age. Carbonate strata at the southeast end of the ridge system is intruded by a small early Tertiary (62.9+0.5 Ma) granite stock. The Tiger Zone is a stratigraphically-controlled gold deposit that trends northwest and dips moderately northeast and is characterized by replacement of host carbonates (Figure F1). The Tiger Zone is currently 650 m long, 100 to 200 m wide, and up to 96 m thick. Mineralization is contained within a 40 m to 150 m wide zone of small-scale folding and shearing. Gold occurs in both sulphide and oxide material that ranges from disseminated to banded pyrite, with subordinate arsenopyrite and pyrrhotite, and minor bismuthinite and sphalerite (www.atacresources.com).

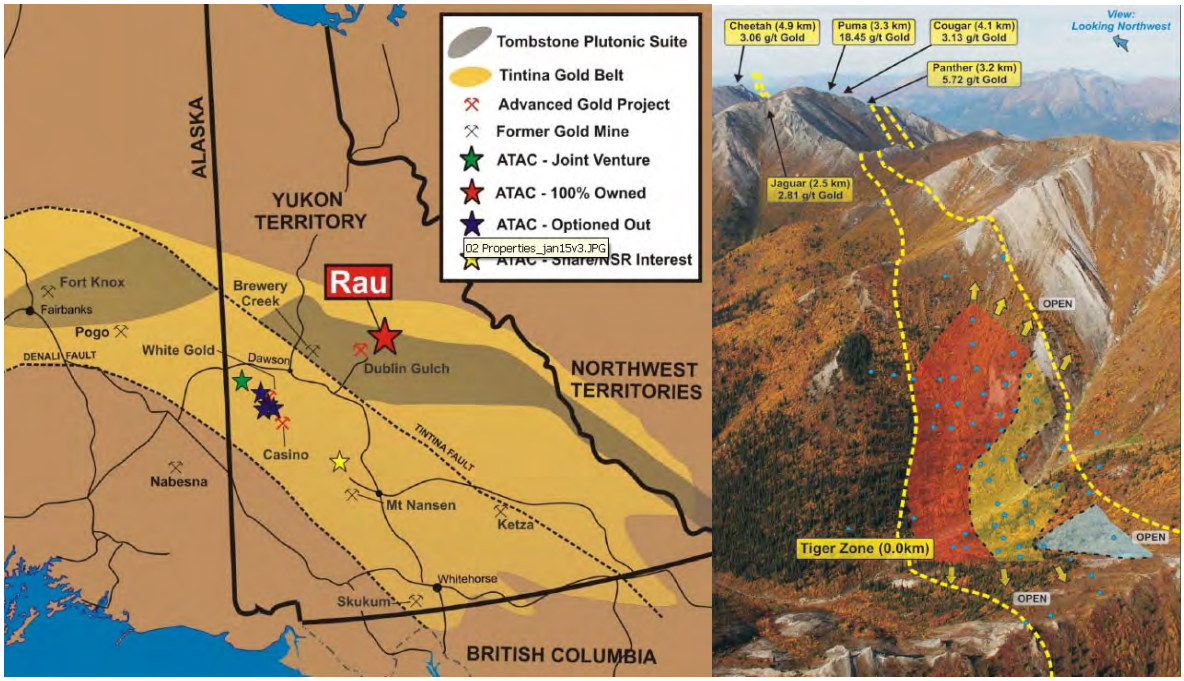

Figure F1: a) Rau Block ZTEM general location and b) Tiger zone gold mineralization setting (from www.atacresources.com).

High and low frequency DT (total divergence) images of the In-Phase (IP) tipper are shown in Figure F2, along with the total magnetic intensity and overlays of the 90Hz In-line IP and Quadrature profiles for the three survey lines under study. From these images, a major NW-SE trending conductive structure is observed in the center, that extends through the Tiger Zone, which appears at its southeastern tip. The ZTEM structure also appears to coincide with a linear magnetic low. Other conductive NW-SE lineaments flank the Tiger horizon to the NE and SW.

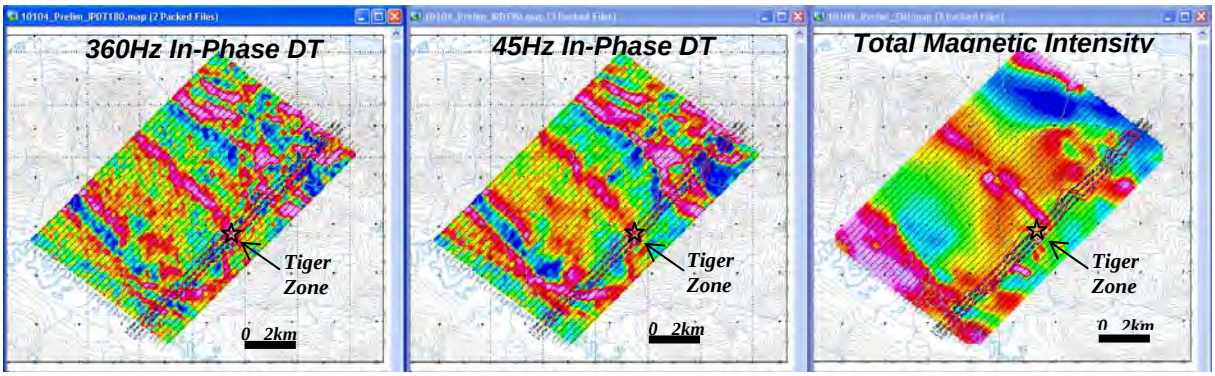

Figure F2: Rau Lake Block ZTEM 360Hz In-Phase DT (left), 45Hz In-Phase DT (center) and Total Magnetic Intensity (right), with 90Hz XIP & XQD profiles over 6 lines selected for inversion.

ZTEM 2D Inversions

ZTEM 2d inversions were performed across 3 lines (1250, 1260, 1270) from the Rau Block survey area, at the request of the client-consultant (R. Irvine, Condor Consulting, email comm., 7-Jun-2010), directly over the Tiger Zone.

The inversions were performed using the Zvert2d code developed for Geotech that is based on the 2D inversion code with Jacobians of de Lugao and Wannamaker (1996), the 2D forward code of Wannamaker et al (1987), and the Gauss-Newton parameter step equations of Tarantola (1987). The inversions utilized the In-line (Z/X) component, In-Phase & Quadrature data – spanning 30Hz to 720Hz – because of the 2D assumption the Cross-line (Z/Y) data were not utilized. The start model for the inversions was a 1k ohm-m half-space. The 150m average flight height of the receiver above the ground surface was accounted for during the inversion. The Zvert2d inversions also assume that the ZTEM Hz receiver data were referenced to a fixed base-station reference (Hx) situated 10km south. Using an error floor of 3.3-3.7%, the inversion converged to 0.98-0.99RMS in 5-6 iterations.

The inversion results for the 3 lines are shown as composite images in Figures F3-F5. In each figure, clockwise from upper left are: a) the raw data for each inversion line are shown in profile form, for the In-line (Z/X) In-Phase (XIP) over Quadrature (XQD), with the 90Hz data emphasized, and the Total Magnetic Intensity (TMI); b) the 90Hz (mid frequency) In-Phase DT (total divergence) grid, which converts cross-overs to peaks, along with the selected profile location, with 90Hz XIP and XQD emphasized; b) the corresponding 2d forward model profile curves from the inversion, with 90Hz XIP and XQD results emphasized; and d) the Zvert2d resistivity section, looking north, from surface to 2km depth, showing the observed versus calculated model fits for 90Hz – notice the good fit between the measured and calculated responses.

For each of the figures (F3-F5), each square is 1x1km. Resistivity highs in cool colours (max ~8k Ω-m) and lows in warm colours (min ~50 Ω-m). The 2D cross-sections are presented according to elevation, however the inversion results have been draped below the DEM topographic profile – topography was not accounted for during the inversion (flat-earth assumption). The approx. 0.99RMS fit indicates that the inversion model have converged, with a 3.0-4.0% error floor applied to IP & QD at all frequencies considered relatively moderate and indicative of mild 3D behaviour. The +/- 20-40% profile responses are relatively moderate amplitude, and the relative smoothness of the profiles are indicative of relatively high data quality. However these also likely reflect the fact that the contrasts are either moderate to strong or the targets are shallow, relative to other mining settings that have been observed previously – particularly for gold targets. But otherwise the patterns that observed are the same. The inversions each took roughly10 minutes to complete. The data were desampled to every 5-6 pts, or roughly 1pt per 50-60m, to allow for up to 200 pts to be input into the inversion. The statistical fit is good between modeled and observed (see 2d section profiles in Fig. F2-F5) and, overall, these look to be reasonable model results that appear to fit the geology.

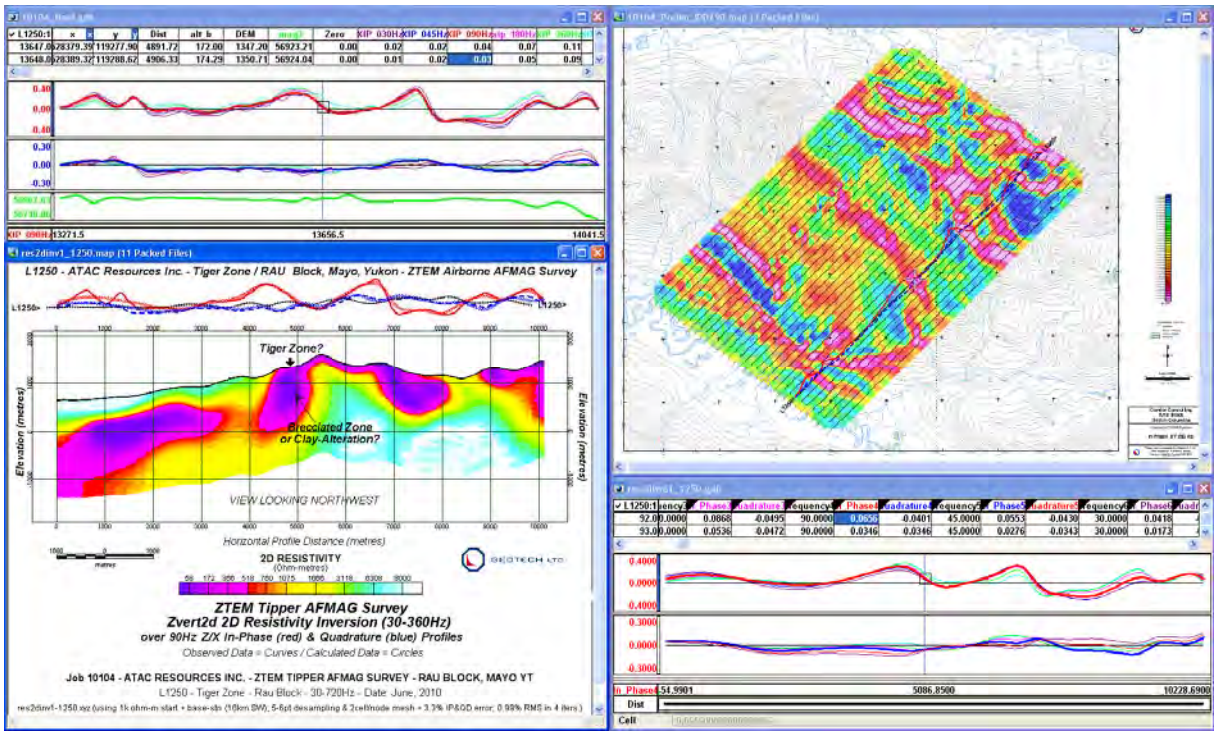

Figure F3: Composite image for **L1250** of a) ZTEM observed In-line (Z/X) & TMI profile data, b) ZTEM In-Phase 90Hz DT with L1250 highlighted and 90Hz XIP & XQD profiles; c) Zvert2d calculated In-line (Z/X) profile data, and d) Zvert2d resistivity inversion, and 90Hz Obs. Vs. Fwd XIP & XQD profile data.

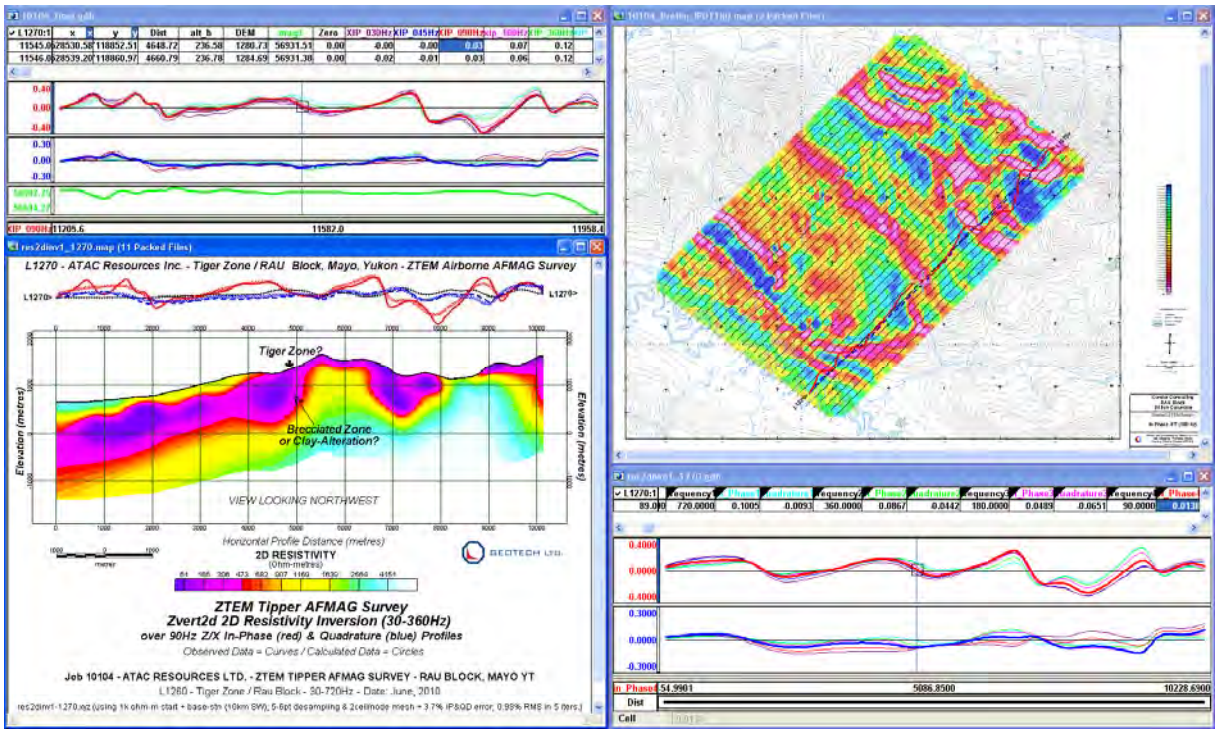

Figure F5. Composite image for **L1270** of a) ZTEM observed In-line (Z/X) & TMI profile data, b) ZTEM In-Phase 90Hz with L1270 highlighted and 90Hz XIP & XQD profiles; c) Zvert2d calculated In-line (Z/X) profile data, and d) Zvert2d resistivity inversion, and 90Hz Obs. Vs. Fwd XIP & XQD profile data.

The Zvert2d inversion of the ZTEM results for selected lines at Rao Block have defined bedrock resistivity structures that coincide with the Tiger Zone horizon and support the presence of 200-300m wide basement conductive zone that dips steeply and strengthens at 500-600m depth below the surface, before pinching at 1-1.3km depths. The 50 ohm-m minimum resistivities associated with the zone are consistent with either stringer to semi massive sulphides, alternately pervasive clay-alteration and/or brecciation. It appears to be associated with a flat-lying, stratigraphic or layer-like horizon that extends southeast, at 300-500m depths. A similar conductive, NE-striking structure, with moderate NE dips and lying roughly 2km further northeast, represents another favourable target.

Additional modeling and inversion are recommended for the ZTEM results and comparisons with VTEM data for potential more massive sulphide type mineralization. Better resolution will be obtained across shorter (4-5km) windowed profiles. Areas with pronounced cross-line behaviour are recommended to be interpreted using 3D modeling and inversion. More accurate models and depth estimates are expected when better apriori information on bulk resistivity are available and used as starting models for the inversions. Derivative analyses and more advanced magnetic modeling may provide insight on the nature and geometry of accompanying magnetic structures. Ground follow-up with induced polarization, audio-magnetotellurics or fixed loop EM are recommended prior to drill-testing.

REPORT ON A HELICOPTER-BORNE Z-AXIS, TIPPER ELECTROMAGNETIC GEOPHYSICAL SURVEY

Rau Project
Mayo, Yukon

Executive Summary

During June 14th to June 22nd, 2010 Geotech Ltd. carried out a helicopter-borne geophysical survey for ATAC Resources Ltd. over the Rau Project situated near Mayo, Yukon, Canada.

Principal geophysical sensors included a Z-Axis Tipper electromagnetic (ZTEM) system, and a caesium magnetometer. Ancillary equipment included a GPS navigation system and a radar altimeter. A total of 3018.6 line-kilometres were planned to be flown.

The survey operations were based out of McQuesten Camp near Mayo, Yukon. In-field data quality assurance and preliminary processing were carried out on a daily basis during the acquisition phase. Preliminary and final data processing, including generation of final digital data and map products were undertaken from the office of Geotech Ltd. in Aurora, Ontario.

The survey report describes the procedures for data acquisition, processing, final image presentation and the specifications for the digital data set. There is no summary interpretation included in this report. However, for final presentation purposes data from Geotech job 10104 for ATAC Resources Ltd. have been merged with this data set.

1. INTRODUCTION

1.1 General Considerations

These services are the result of the Agreement made between Geotech Ltd. and ATAC Resources Ltd to perform a helicopter-borne geophysical survey over the Rau Project located near Mayo Yukon, Canada (Figure 1).

Richard Irvine and Graham Downs acted on behalf of ATAC Resources Ltd. during the data acquisition and data processing phases of this project.

The geophysical surveys consisted of helicopter borne AFMAG Z-axis Tipper electromagnetic (ZTEM) system and aero magnetics using a caesium magnetometer. A total of 3045.3 line kilometres of geophysical data were acquired during the survey. The survey area is shown in Figure 2.

In a ZTEM survey, a single vertical-dipole air-core receiver coil is flown over the survey area in a grid pattern, similar to regional airborne EM surveys. Two orthogonal, air-core horizontal axis coils are placed close to the survey site to measure the horizontal EM reference fields. Data from the three coils are used to obtain the Z/X and Z/Y Tipper (Vozoff, 1972) components at six frequencies in the 30 to 720 Hz band. The ZTEM was used to map geology using resistivity contrasts and magnetometer data were also collected to help map geology using magnetic susceptibility contrasts.

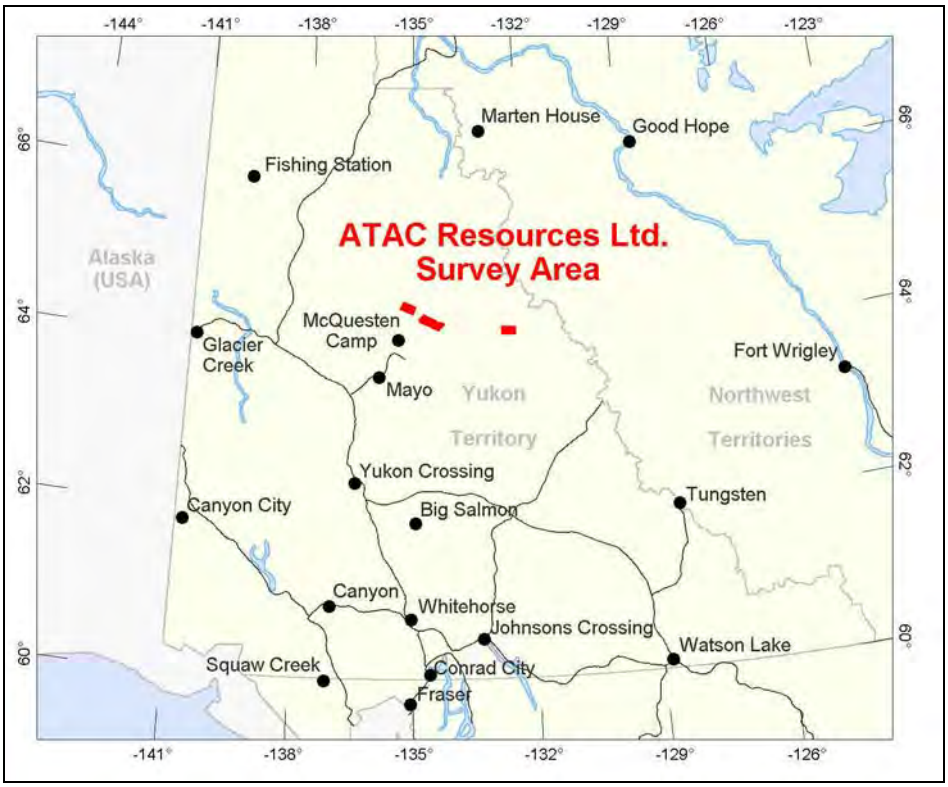

Figure 1 -Property Location

The crew was based in McQuesten Camp near Mayo, Yukon, for the acquisition phase of the survey. Survey flying started on June 14th and was completed on June 22nd, 2010.

Data quality control and quality assurance, and preliminary data processing were carried out on a daily basis during the acquisition phase of the project. Final reporting, data presentation and archiving were completed from the Aurora office of Geotech Ltd. in August, 2010.

1.2 Survey Location

The Rau Project is located approximately 95 kilometres to the northeast of Mayo, Yukon as shown in Figure 2.

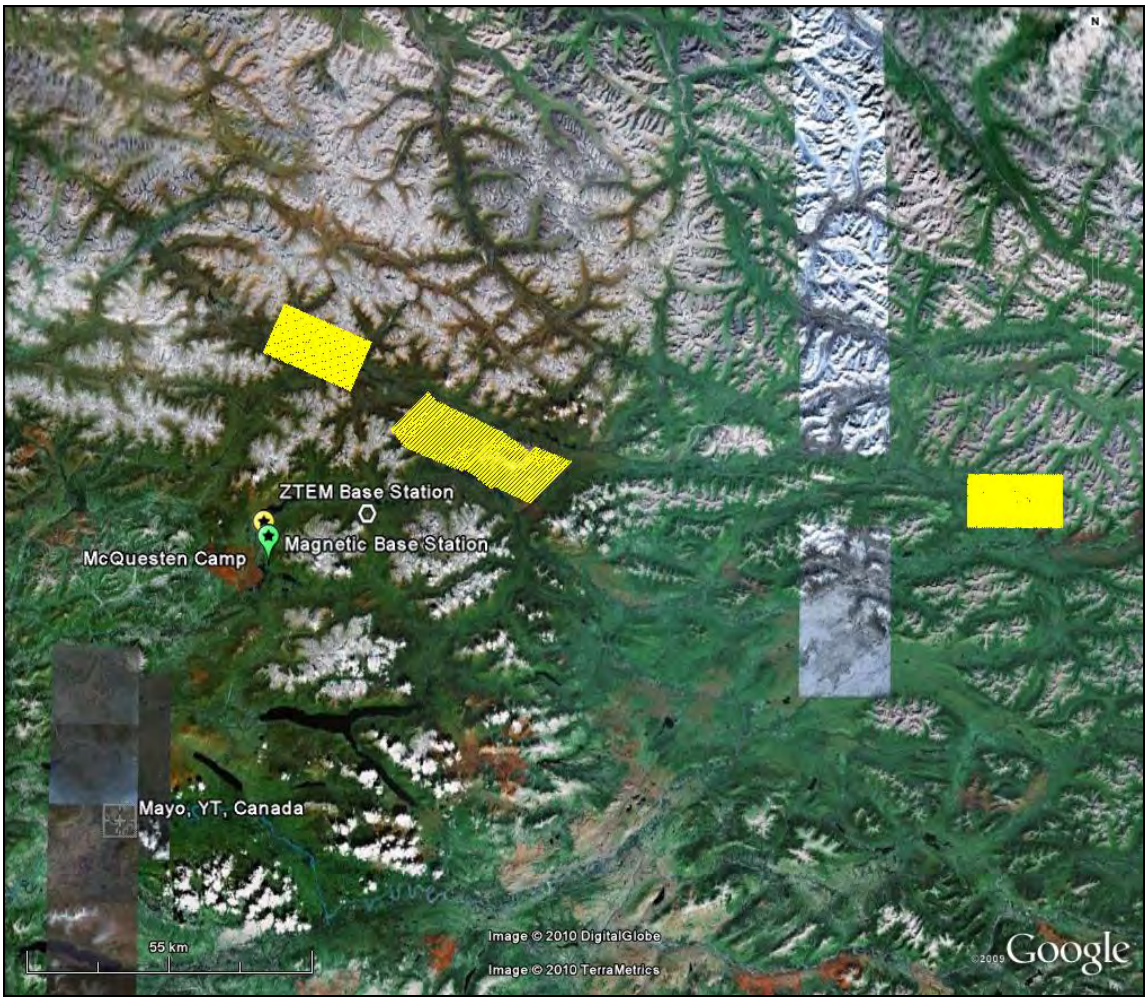

Figure 2 – Rau Project, with ZTEM and Magnetic Base Station Locations

The Rau Project was flown in Southwest to Northeast directions for the Central (N 45° E / N 225° E) and West (N 24° E / N 204° E) sections and a North to South (N 0° E / N 180° E) for the East section, with a flight line spacing of 200 metres, as depicted in Figure 3. Tie lines were neither planned nor flown. For more detailed information on the flight spacing and direction see Table 1.

1.3 Topographic Relief and Cultural Features

The Rau Project exhibits high relief covering a total of approximately 600 square kilometres, with elevations ranging from 565 to 1996 meters above sea level (see Figure 3). There are numerous rivers, streams, and small lakes located throughout the survey area. There is also a road running North-South through the Central section of the survey area. Special care is recommended in identifying any other potential cultural features from other sources that might be recorded in the data. The survey block covers a number of Yukon Mining Claims, which are shown in Appendix A. The survey block is covered by NTS (National Topographic Survey) of Canada sheets 106D01, 106D02, 106D06, 106D07, 106D08, 106C01, and 106C02.

2. DATA ACQUISITION

2.1 Survey Area

The survey block (see Location map in Appendix A and Figure 2) and general flight specifications are as follows:

Table 1 - Survey Specifications

Survey block	Traverse Line spacing (m)	Area (Km^2)	Planned Line-km	Actual[1] Line-km	Flight direction	Line numbers[2]
West	Traverse: 200	180	912	922.9	N 24° E / N 204° E	L7000 – L7900
	Tie: n/a				n/a	n/a
Central	Traverse: 200 Tie: n/a	240	1194.4	1199.3	N 45° E / N 225° E	L5880 – L6980
					n/a	n/a
East	Traverse: 200 Tie: n/a	180	912.2	923.1	N 0° E / N 180° E	L1000 – L1900
					n/a	n/a
TOTAL		**600**	**3018.6**	**3045.3**		

Survey block boundaries co-ordinates are provided in Appendix B.

2.2 Survey Operations

Survey operations were based out of McQuesten Camp, Yukon from June 14th to June 22nd, 2010. The following table shows the timing of the flying.

Table 2 - Survey schedule

Date	Flight #	Block	Crew location	Comments
06-14-2010	1,2	Central	McQuesten Camp	Production
06-15-2010	3,4,5,6	Central	McQuesten Camp	Production
06-16-2010	7,8,9	Central	McQuesten Camp	Production
06-17-2010	10,11,12,13	Central/West	McQuesten Camp	Production
06-18-2010	14,15,16,17,18	West	McQuesten Camp	Production
06-19-2010			McQuesten Camp	No Production due to weather
06-20-2010	19,20,21,22,23	West/East	McQuesten Camp	Production
06-21-2010	24,25,26,27	East	McQuesten Camp	Production
06-22-2010	28,29,30	East	McQuesten Camp	Production Job Complete

[1] Actual line-km represents the total line-km contained in the final databases. These line-km normally exceed the Planned line-km's, as indicated in the survey NAV files.

[2] Note that lines 4000 – 4310 are from Geotech job 10104 for ATAC Resources Ltd.

2.3 Flight Specifications

During the survey the helicopter was maintained at a mean height of 260 metres above the ground with a nominal survey speed of 80 km/hour for the survey block. This allowed for a nominal EM sensor terrain clearance of 186 metres and a magnetic sensor clearance of 203 metres.

The output data sampling rate from the acquisition program was 0.4 second for electromagnetics, 0.1 second for magnetometer and 0.2 second for altimeter and GPS. This translates to electromagnetic readings at approximately 10m intervals and magnetic readings roughly every 2 to 5 metres along flight track. Navigation was assisted by a CDGPS receiver and data acquisition system, which reports GPS co-ordinates as latitude/longitude and directs the pilot over a pre-programmed survey flight path.

The operator was responsible for monitoring of the system integrity. He also maintained a detailed flight log during the survey, tracking the times of the flight as well as any unusual geophysical or topographic feature.

On return of the aircrew to the base camp the survey data was transferred from a compact flash card (PCMCIA) to the data processing computer. The data were then uploaded via ftp to the Geotech office in Aurora for daily quality assurance and quality control by trained personnel, operating remotely.

2.4 Aircraft and Equipment

2.4.1 Survey Aircraft

The survey was flown using a Eurocopter Aerospatiale (Astar) 350 B3 helicopter, registration number C-FEDS. The helicopter was owned and operated by Geotech Aviation. Installation of the geophysical and ancillary equipment was carried out by Geotech Ltd.

2.4.2 Airborne Receiver

The airborne ZTEM receiver coil measures the vertical component (Z) of the EM field. The receiver coil is a Geotech Z-Axis Tipper (ZTEM) loop sensor which is isolated from most vibrations by a patented suspension system and is encased in a fibreglass shell. It is towed from the helicopter using a 90 metre long cable as shown in Figure 6. The cable is also used to transmit the measured EM signals back to the data acquisition system.

The coil has a 7.4 metre diameter with an orientation to the Vertical Dipole. The digitizing rate of the receiver is 2000 Hz. Attitudinal positioning of the receiver coil is enabled using 3 GPS antennas mounted on the coil. The output sampling rate is 0.4 seconds (see Section 2.4.7)

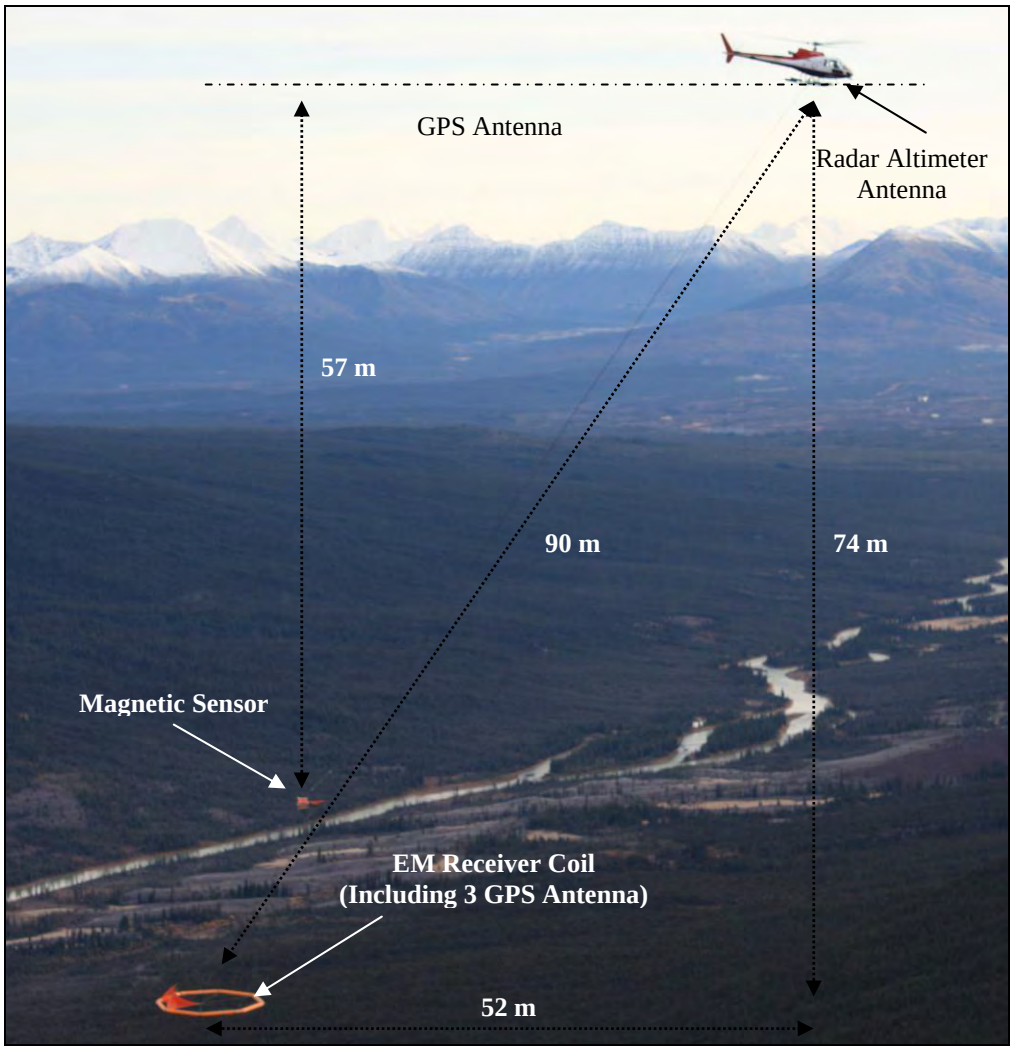

Figure 6 - ZTEM System Configuration

2.4.3 Base Station Receiver

The two Geotech ZTEM base station receiver coils measure the orthogonal, horizontal X and Y components of the EM reference field. They are set up perpendicular to each other and roughly oriented according to the flight line direction. The orientation of both units is not critical as the horizontal field can be further decomposed into the two orientations of the survey flight. The orientation of the base stations were measured using a compass.

The base station coils each have a diameter of 3.5 meters, with the coil orientations to the horizontal dipole, as shown in Figure 7.

The Rau Project base station receiver coils were installed in a remote area outside the survey block (64.119913°N, 134.477561° W). The coils were oriented perpendicular to each other: Coil A was oriented at a N 31° E direction, with coil B oriented at an N 301° E direction.

Figure 7 - ZTEM base station receiver coils.

2.4.4 Airborne magnetometer

The magnetic sensor utilized for the survey was a Geometrics split-beam optically pumped caesium vapour magnetic field sensor, mounted in a separate bird, and towed on a cable at a mean distance of 57 metres below the helicopter (Figure 6). The sensitivity of the magnetic sensor is 0.02 nanoTesla (nT) at a sampling interval of 0.1 seconds. The magnetometer will perform continuously in areas of high magnetic gradient with the ambient range of the sensor approximately 20k-100k nT. The Aerodynamic magnetometer noise is specified to be less than 0.5 nT. The magnetometer sends the measured magnetic field strength as nanoTesla to the data acquisition system via the RS-232 port.

2.4.5 Radar Altimeter

A Terra TRA 3000/TRI 40 radar altimeter was used to record terrain clearance. The antenna was mounted beneath the bubble of the helicopter cockpit.

2.4.6 GPS Navigation System

The navigation system used was a Geotech PC104 based navigation system utilizing a NovAtel CDGPS (Canada-Wide Differential Global Positioning System Correction Service) enabled Propak V3-RT20 GPS receiver. Geotech's Navigate software, using a full screen display with controls in front of the pilot, allows him to direct the flight.

5 NovAtel GPS antennas are utilized during the survey; one is mounted on the helicopter tail (Figure 6), one installed with the Receiver Base Station (Figure 7) and three are mounted on the airborne receiver (Figure 6). As many as 14 GPS and two CDGPS satellites may be monitored at any one time. The horizontal positional accuracy or circular error probability (CEP) is 1.8 m, with CDGPS active, it is 0.6 m. The co-ordinates of the block were set-up prior to the survey and the information was fed into the airborne navigation system.

2.4.7 Digital Acquisition System

The power supply and the data acquisition system are mounted on an equipment rack which is installed into the helicopter. Signal and power wires are run through the helicopter to connect on to the tow cable outside. The tow cable supports the ZTEM and magnetometer birds during flight via a safety shear pin connected to the helicopter hook. The major power and data cables have a quick disconnect safety feature as well. The installation was undertaken by the Geotech Ltd. crew and was certified before surveying.

A Geotech data acquisition system recorded the digital survey data on an internal compact flash card. Data is displayed on an LCD screen as traces to allow the operator to monitor the integrity of the system. The data type and sampling interval as provided in Table 3.

Table 3 - Acquisition and Processing Sampling Rates

DATA TYPE	ACQUISITION SAMPLING	PROCESSING SAMPLING
ZTEM Receiver	0.0005 sec	0.4 sec
Magnetometer	0.1 sec	0.4 sec
GPS Position	0.2 sec	0.4 sec
Radar Altimeter	0.2 sec	0.4 sec
ZTEM Base station	0.0005 sec	– –

2.4.8 Mag Base Station

A combined magnetometer/GPS base station was utilized on this project. A Geometrics Caesium split-beam vapour magnetometer was used as a magnetic sensor with a sensitivity of 0.001 nT. The base station was recording the magnetic field together with the GPS time at 1 Hz on a base station computer.

The base station magnetometer sensors for the Rau Project (64°03’25”N, 135°21’ 07”W) were installed to the west of the camp away from electric transmission lines and moving ferrous objects such as motor vehicles. The base station data were backed-up to the data processing computer at the end of each survey day.

3. PERSONNEL

The following Geotech Ltd. personnel were involved in the project.

Field:

Project Manager:	Darren Tuck (Office)
Data QA/QC:	Rafael Coyoli (Office)
Crew chiefs:	Robert Rus, Roger LeBlanc
System Operator:	Brandon Gray

The survey pilot and the mechanical engineer were employed directly by the helicopter operator –Geotech Aviation Ltd.

Pilot:	Lorne Coleman
Mechanical Engineer:	Mike Rozon

Office:

Preliminary Data Processing:	Rafael Coyoli
Final Data Processing:	Biljana Milicevic
Final Data QC:	Greg Roman
Reporting/Mapping:	Kyle Orlowski

Data acquisition phase was carried out under the supervision of Andrei Bagrianski, P. Geo, Surveys Manager. Processing phase was carried out under the supervision of Gord Smith, Manager of Data Processing. The Interpretation phase was under the supervision of Jean Legault, P. Geo. The overall contract management and customer relations were by Paolo Berardelli.

4. DATA PROCESSING AND PRESENTATION

Data compilation and processing were carried out by the application of Geosoft OASIS Montaj and programs proprietary to Geotech Ltd.

4.1 Flight Path

The flight path, recorded by the acquisition program as WGS 84 latitude/longitude, was converted into the WGS84, UTM Zone 8 North coordinate system in Oasis Montaj.

The flight path was drawn using linear interpolation between x, y positions from the navigation system. Positions are updated every second and expressed as UTM easting's (x) and UTM northing's (y).

4.2 In-field Processing and Quality Control

In-Field data processing and quality control are done on a flight by flight basis by a qualified data processor (see Section 3.0). Processing steps and check up procedures are designed to assure the best possible final quality of ZTEM survey data. A general overview of those steps is presented in the following paragraphs.

The In-Field quality control can be separated into several phases:

a. GPS Processing Phase: GPS Data are first examined and evaluated during the GrafMov processing.
b. Raw data, ZTEM viewer phase:

   Data can be viewed, examined for consistency, individual channel spectra examined and overall noise estimated in the viewer provided by the ZTEM proprietary software, on the raw flight data and raw base station data separately, on the merged data, and finally on the data that have undergone ZTEM processing.
c. Field Geosoft phase:

   Magnetic data, Radar altimeter data, GPS positioning data are re-examined and processed in this phase. Prior to splitting the lines EM data are examined flight by flight and the effectiveness of applying the attitude correction evaluated. After splitting the lines, a set of grids are generate for each parameter and their consistency evaluated. Data profiles are also re-evaluated on a line to line basis. A power line monitor channel is available in order to identify power line noise.

4.3 GPS Processing

Three GPS sensor (mounted on the airborne receiving loop) measurements were differentially corrected using the Waypoint GrafMov^{TM} software in order to yield attitude corrections to recorded EM data.

4.4 ZTEM Electromagnetic Data

The ZTEM data were processed using proprietary software. Processing steps consist of the following preliminary and final processing steps:

4.4.1 Preliminary Processing

a. Airborne EM, Mag, radar altimeter and GPS data are first merged with EM base station data into one file.
b. Merged data are viewed and examined for consistency in an incorporated viewer
c. In the next, processing phase, the following entities are taken into account:
   - the Base station coils orientation with respect to the Magnetic North,
   - the Local declination of the magnetic field,
   - Suggested direction of the X coordinate (North or line direction),
   - Sensitivity coefficient that compensates for the difference in geometry between the base station and airborne coils.
   - Rejection filters for the 60 Hz and helicopter generated frequencies.
d. Six frequencies (In phase and Quadrature components) are extracted from the airborne EM coil response in the windows of 0.4 seconds and the base station coils in the windows of 1.0 seconds (30, 45, 90, 180, 360, and 720 Hz).
e. The ratios between the real parts (in phase) of the vertical Z component (airborne) over the horizontal X component (base station), and Z component over horizontal orthogonal Y component, as well as the ratios of their imaginary parts (quadrature), are calculated.
f. Such processed EM data are then merged with the GPS data, magnetic base station data and exported into a Geosoft xyz file.

4.4.2 Geosoft Processing

Next stage of the preliminary data processing is done in a Geosoft ™ environment, using the following steps:

a. Import the output xyz file from the AFMAG processing, as well as the base Mag data into one database.
b. Split lines according to the recorded line channel,
c. GPS processing, flight path recovery (correcting, filtering, calculating Bird GPS coordinates, line splitting)
d. Radar altimeter processing, yielding the altitude values in metres.
e. Magnetic spike removal, filtering (applied to both airborne and base station data). Calculation of a base station corrected mag.
f. Apply preliminary attitude corrections to EM data (In phase and Quadrature), filter and make preliminary grids and profiles of all channels.

4.4.3 Final Processing

Final data processing and quality control were undertaken by Geotech Ltd headquarters in Aurora, Ontario by qualified senior data processing personnel.

A quality control step consisted of re-examining all data in order to validate the preliminary data processing and to allow for final adjustments to the data.

Attitude corrections were re-evaluated, and re-applied, on component by component, flight by flight, and frequency by frequency bases. Any remaining line to line system noise was removed by applying a mild additional levelling correction.

4.4.4 ZTEM Profile Sign Convention

Z/X and Z/Y components do not exhibit maxima or minima above conductors, resistors or at contacts; in fact they produce cross-over type anomalies (Ward, 1959). The crossover polarity sign convention for ZTEM is according to the right hand Cartesian rule (Z positive –up) that is commonly used for multi-component transient electromagnetic methods.

For the Northeast - Southwest lines of the West and Central sections the sign convention for the Z/X in-line component crossover is positive-negative pointing southwest to northeast for tabular conductors perpendicular to the profile (Figure 8). The corresponding Z/Y component in-phase cross-over polarity is positive-negative pointing southeast to northwest (90 degrees counter clockwise to Z/X) according to the right hand Cartesian rule.

For the North - South lines of the East section the sign convention for the Z/X in-line component crossover is positive-negative pointing south to north for tabular conductors perpendicular to the profile (Figure 8). The corresponding Z/Y component in-phase cross-over polarity is positive-negative pointing west to east (90 degrees counter clockwise to Z/X) according to the right hand Cartesian rule.

Conversely, tabular resistive bodies produce In-Phase cross-over's that are opposite in sign to conductors. A brief discussion of ZTEM and AFMAG, along with selected forward model responses is presented in Appendix D.

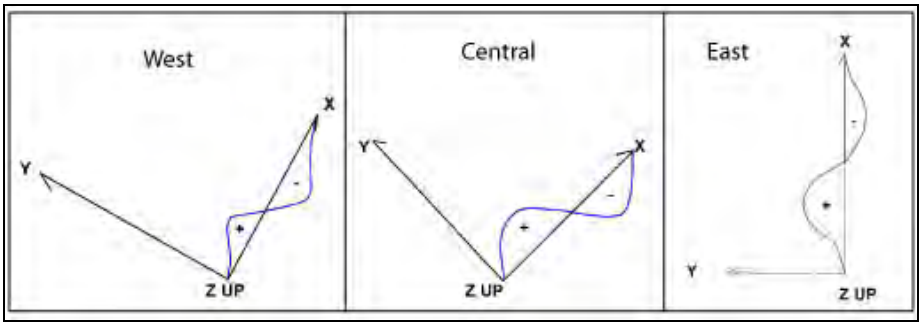

Figure 8 - ZTEM Crossover Polarity Conventions of the Rau Project

4.4.5 ZTEM Quadrature Sign Dependence

One important note regarding the sign of the ZTEM Quadrature, relative to the In-Phase component, particularly with regards to computer modeling and inversion.

The sign of the magnetotelluric Quadrature relative to the In-Phase tipper transfer function component pertains to the Fourier transformation of the time series to give frequency domain spectra. There are two widely used conventions for time dependence in the transformations, **exp(+iωt)** and **exp(-iωt).** That which is implemented largely is a matter of personal preference and precedent. The importance of the In-Phase and Quadrature sign convention is not critical, provided that it is known and documented.

In ZTEM, the data processing code used for the Fourier transformation the time-series data to frequency domain spectra adopts a **exp(-iωt)** time dependence (J. Dodds, Geo Equipment Manufacturing, pers. comm., Nov-2009). Whereas in the forward modeling and inversion program Zvert2d, the sign of the Quadrature relative to the In-Phase transfer function assumes an **exp(+iωt)** dependence[3].

The reasons for adopting $\mathbf{e^{-i\omega t}}$ used in ZTEM are several: a) In-phase and Quadrature profile and contour plan maps can be readily compared, since they are usually in the same-sign and quadrant (i.e. Figure 9); b) Phase-rotation and Total Divergence (DT) parameters need not be changed when comparing In-Phase versus Quadrature data.

As a result, for users interested in computer modeling and inversion of ZTEM data, the sign of the Quadrature will need to be reversed, relative to the In-Phase component, in order to provide a proper result (Figure 9). Indeed this reverse Quadrature polarity convention is assumed in all forward modeling and inversion of ZTEM data, as described in Figures 5-7 in Appendix D.

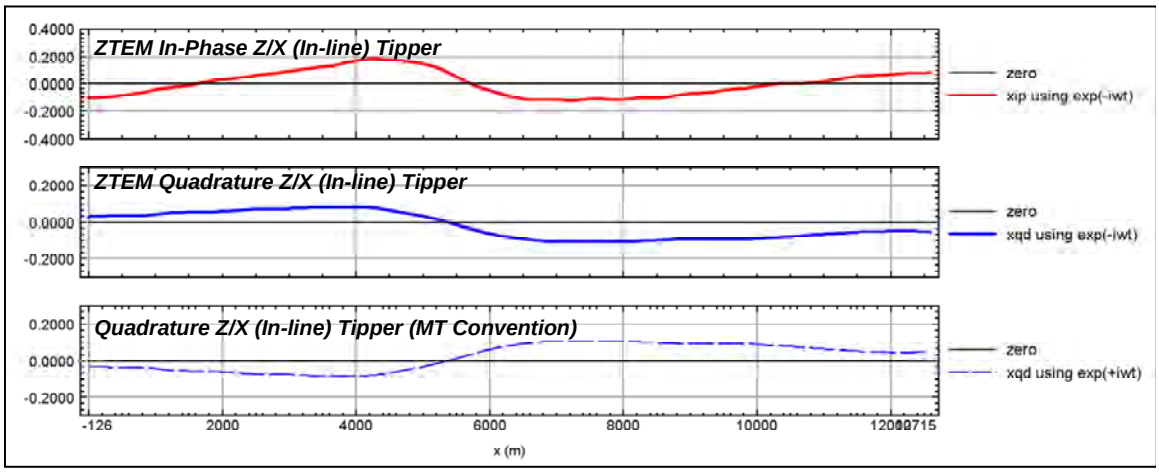

Figure 9 - Illustration of ZTEM In-Phase & Quadrature Tipper transfer function polarity convention (e-iωt) relative to equivalent MT Tipper Quadrature polarity convention (e+iωt) for a graphitic conductor in Athabasca Basin, SK.

3 Phillip E. Wannamaker (2009): Two-dimensional Inversion of ZTEM data: Synthetic Model Study and Test Profile Images, Internal Geotech technical report by Emblem Exploration Services Inc., January 22, 2009, 32 pp.

4.4.6 Total Divergence and Phase Rotation Processing

In a final processing step DT (Total Divergence) and PR (Phase Rotation) processing are applied to the multi-frequency In-phase and Quadrature ZTEM data. This is due to the crossover nature of the Tipper Responses; these additional processing steps are applied to convert them into local maxima for easier interpretation.

To present the data from both tipper components into one image, the Total Divergence parameter, termed the DT is calculated from the horizontal derivatives of the Z/X and Z/Y tippers (Lo and Zang, 2008). It is analogous to the "Peaker" parameter in VLF (Pedersen, 1998).

Total Divergence DT:	***DT = DIV (Z/X, Z/Y)*** ***= d(Z/X)/dx+d(Z/Y)/dy***

This DT parameter was introduced by Petr Kuzmin (Milicevic, 2007, p. 13) and is derived for each of the In Phase and Quadrature components at individual frequencies. These in turn allow for minima over conductors and maxima over resistive zones. DT grids for each of the extracted frequencies were generated accordingly, using a reverse colour scheme with warm colours over conductors and cool colours over resistors.

The DT gives a clearer image of conductor's location and shape but, as a derivative, it does not preserve some of the long wavelength information and is also sensitive to noise.

As an alternative, a 90 degree Phase Rotation (PR) technique is also applied to the grids of each individual component (Z/X and Z/Y). It transforms bipolar (cross over) anomalies into single pole anomalies with a maximum over conductors, while preserving long wavelength information (Lo et al., 2009). The two orthogonal grids are then usually added to obtain a Total Phase Rotated grid for the In-Phase and Quadrature.

Total Phase-Rotation:	***= PR (Z/X) + PR (Z/Y)***

A presentation of the ZTEM test survey results over unconformity uranium deposits that illustrates DT and TPR examples, as documented by Lo et al. (2009) is provided in Appendix E.

4.4.7 2D EM Inversion

2d inversions of the ZTEM results were performed over selected lines using the Geotech Zvert2d software developed by Phil Wannamaker, U. of Utah, for Geotech Ltd. The inversion algorithm is based on the 2D inversion code with Jacobians of de Lugao and Wannamaker (1996), the 2D forward code of Wannamaker et al (1987), and the Gauss-Newton parameter step equations of Tarantola (1987). Zvert2d has been developed/modified for use with our ZTEM platform by taking into account the 75-80m air-layer between radar bird and ground surface.

The 2D code only considers the In-Line (Z/X) data and assumes that the strike lengths of bodies are infinite and orthogonal to the profile. The code is designed to account for the ZTEM vertical coil receiver and fixed base station reference measurements – although this option was not used in this study. The inversion uses a model-mesh consisting of 440 cells laterally and 62 cells vertically. Typically the ZTEM data are de-sampled to 180-200 pts, in order to allow the inversion to run in 10minutes or less. Typically, between 1-2% errors are added to the In-line in-phase (XIP) and Quadrature (XQD) data obtained at 30,45,90,180,360 & 720Hz. Errors are adjusted until numerical convergence (<1.0 rms) is attained in 8 iterations or less. All inversions are based on a 1k ohm-m homogeneous starting half-space model.

4.5 Magnetic Data

The processing of the total magnetic field intensity (TMI) data involved the correction for diurnal variations by using the digitally recorded ground base station magnetic values. The base station magnetometer data was edited and merged into the Geosoft GDB database on a daily basis. The aeromagnetic data was corrected for diurnal variations by subtracting the observed magnetic base station deviations.

Due to the absence of tie-lines, further tie-line or micro levelling were not applied to the magnetic data.

The corrected magnetic data was interpolated between survey lines using a random point gridding method to yield x-y grid values for a standard grid cell size of 50 metres. The Minimum Curvature algorithm was used to interpolate values onto a rectangular regular spaced grid.

5. DELIVERABLES

5.1 Survey Report

The survey report describes the data acquisition, processing, and final presentation of the survey results. The survey report is provided in two paper copies and digitally in PDF format.

5.2 Maps

Final maps were produced at scale of 1:20,000. The coordinate/projection system used was WGS84, UTM Zone 8 North. All maps show the flight path trace and topographic data; latitude and longitude are also noted on maps.

The preliminary and final results of the survey are presented as profile plans for the EM data that were generated for individual real (In-Phase) and imaginary parts (Quadrature) of the Z/X and Z/Y components. Colour contour maps of the corresponding TPR (Total Phase Rotated) Grids for three of the six frequencies, (30, 45, 90, 180, 360 and 720Hz), as well as for corresponding Phase Rotated Grids for individual components.

3D views have been constructed by plotting the DT and TPR grids at their respective penetration depths using a 1000 ohm-m half space, using the Bostick skin depth rule (Murakami, 1985) see Appendix D.

Final maps were chosen, in consultation with the client, to represent all collected data, are listed in Section 5.3.

Sample maps of the related 3D view, Magnetic and Total Divergence are included in this report and presented in Appendix C.

5.3 Digital Data

- Two copies of the data and maps on DVD were prepared to accompany the report. Each DVD contains a digital file of the line data in GDB Geosoft Montaj.
- DVD structure.

  There are two (2) main directories;
  Data contains databases, grids and maps, as described below.
  Report contains a copy of the report and appendices in PDF format.

  Databases in Geosoft GDB format, containing the channels listed in Table 4.

Table 4 - Geosoft GDB Data Format

Column	Description
X:	UTM Easting WGS84 Zone 8, (Centre of the ZTEM loop) (meters)
Y:	UTM Northing WGS84 Zone 8 , (Centre of the ZTEM loop) (meters)
Longitude:	Longitude – WGS84 (Centre of the ZTEM loop) (Decimal degree)
Latitude	Latitude – WGS84 (Centre of the ZTEM loop) (Decimal degree)
Z:	Elevation- WGS84 (Centre of the ZTEM loop) (metres)
Radar:	Helicopter terrain clearance from radar altimeter (metres - AGL)
Radar_B:	Calculated ZTEM Bird terrain clearance (metres)
DEM	Digital Elevation Model (meters)
Gtime	GPS Time (seconds)
basemag	Base station mag
Mag1	Measured Total Magnetic Intensity, raw (de-spiked)
Mag2	Measured Total Magnetic Intensity, diurnal corrected
Mag3:	Levelled Total Magnetic field data
xIp_030Hz:	Z/X In-Phase 30 Hz final corrected
xIp_045Hz:	Z/X In-Phase 45 Hz final corrected
xIp_090Hz:	Z/X In-Phase 90 Hz final corrected
xIp_180Hz:	Z/X In-Phase 180 Hz final corrected
xIp_360Hz:	Z/X In-Phase 360 Hz final corrected
xIp_720Hz:	Z/X In-Phase 720 Hz final corrected
xQd_030Hz:	Z/X Quadrature 30 Hz final corrected
xQd_045Hz:	Z/X Quadrature 45 Hz final corrected
xQd_090Hz:	Z/X Quadrature 90 Hz final corrected
xQd_180Hz:	Z/X Quadrature 180 Hz final corrected
xQd_360Hz:	Z/X Quadrature 360 Hz final corrected
xQd_720Hz:	Z/X Quadrature 720 Hz final corrected
yIp_030Hz:	Z/Y In-Phase 30 Hz final corrected
yIp_045Hz:	Z/Y In-Phase 45 Hz final corrected
yIp_090Hz:	Z/Y In-Phase 90 Hz final corrected
yIp_180Hz:	Z/Y In-Phase 180 Hz final corrected
yIp_360Hz:	Z/Y In-Phase 360 Hz final corrected
yIp_720Hz:	Z/Y In-Phase 720 Hz final corrected
yQd_030Hz:	Z/Y Quadrature 30 Hz final corrected
yQd_045Hz:	Z/Y Quadrature 45 Hz final corrected
yQd_090Hz:	Z/Y Quadrature 90 Hz final corrected
yQd_180Hz:	Z/Y Quadrature 180 Hz final corrected
yQd_360Hz:	Z/Y Quadrature 360 Hz final corrected
yQd_720Hz:	Z/Y Quadrature 720 Hz final corrected
PLM:	Power Line Monitor (60Hz)

- Grids in Geosoft GRD format, as follows:

MAG: Total Magnetic Intensity
DEM: Digital Elevation Model
XIP_30Hz_PR: Z/X In-Phase Component Phase Rotated grid at 30 Hz
XIP_45Hz_PR: Z/X In-Phase Component Phase Rotated grid at 45 Hz

Maps are also presented in PDF format.

1:50,000 topographic vectors were taken from the NRCAN Geogratis database at; http://geogratis.gc.ca/geogratis/en/index.html.

A Google Earth file *"10116_Flightpath.kml"* is included, showing the flight path of each block. Free versions of Google Earth software from: http://earth.google.com/download-earth.html.

6. CONCLUSIONS AND RECOMMENDATIONS

6.1 Conclusions

A helicopter-borne ZTEM and aeromagnetic geophysical survey has been completed over the Rau Project located near Mayo, Yukon Territory.

The total area coverage is 600 km^2. Total survey line coverage is 3045.3 line kilometres. The principal sensors included a Z-Axis Tipper electromagnetic (ZTEM) system and a caesium magnetometer. Results have been presented as stacked profiles and contour colour images at a scale of 1:20,000.

There is no summary interpretation included in this report.

6.2 Recommendations

Based on the geophysical results obtained, a number of interesting conductive structures were identified across the property. The magnetic results also contain worthwhile information in support of exploration targets of interest. We therefore recommend a more detailed interpretation of the available geophysical data, including VTEM, in conjunction with the geology, prior to ground follow up and drill testing.

APPENDIX D

ZTEM THEORETICAL CONSIDERATIONS

A brief section on the theory behind the AFMAG technique is provided for completeness and a more comprehensive development of the theory can be found in standard texts. The natural EM field is normally horizontally polarized. Subsurface lateral variations of conductivity generate a vertical component, which is linearly related to the horizontal field. Although the fields look like random signals, they may be treated as the sum of sinusoids. At each frequency the field can be expressed as a complex number with magnitude and argument equal to the amplitude and phase of the sinusoid. The relation between the field components can then be expressed by a linear complex equation with two complex coefficients at any one frequency. These coefficients are dependent upon the subsurface and not upon the horizontal field present at any particular time and are appropriate parameters to measure (Vozoff, 1972).

$$\mathbf{Hz(f) = Tx(f)\ Hx(f) + Ty(f)\ Hy(f),} \qquad \mathbf{(1)}$$

Where

Hx(f), Hy(f) and Hz(f) are x, y and z components of the field,

Tx(f) and Ty(f) are the "tipper" coefficients.

In the case of a horizontally homogeneous environment, Tx and Ty are equal to zero because Hz =0. They show certain anomalies only by the presence of changes in subsurface conductivity in the horizontal direction. The real parts of the coefficients correspond to tangents of tilt angles measured with a controlled source. The complex tensor [Tx, Ty] known as the "tipper" defines the vertical response to horizontal fields in the x and y directions respectively.

Tx and Ty are two unknown coefficients in one equation, and we therefore must combine two or more sets of measurements to solve them. To reduce effects of noise, multiple sets of measurements can be made, and the coefficients, which minimize the squared error in predicting the measured Z from X and Y, can be found. This leads to next formulas for estimating the coefficients.

$$\mathbf{Tx = ([HzHx^*]\ [HyHy^*] - [HzHy^*]\ [HyHx^*])\ /\ ([HxHx^*]\ [HyHy^*] - [HxHy^*]\ [HyHx^*]),} \qquad \mathbf{(2)}$$

and

$$\mathbf{Ty = ([HzHy^*]\ [HxHx^*] - [HzHx^*]\ [HxHy^*])\ /\ ([HxHx^*]\ [HyHy^*] - [HxHy^*]\ [HyHx^*]\ .} \qquad \mathbf{(3)}$$

Where

[HxHy*] (For example) denotes a sum of the product of Hx with the complex conjugate of Hy.

In practical processing algorithms, all numbers Hx, Hy and Hz can be obtained by applying the same digital band-pass filters to three incoming parallel data signals. FFT algorithms are also applicable. All sums like [HxHy*] can be calculated on the basis of a discrete time interval in the range from 0.1 to 1 sec or on a sliding time base.

Using platform attitude data in the EM data processing can be done at different stages of the signal processing. The most obvious idea is to transform parallel data from local coordinates of the platform into absolute geographical coordinates before the main signal processing procedure. Unfortunately, the proper algorithms of attitude data obtained, often require some post-processing algorithms such as using post-calculated accelerations based on GPS data etc. That is why it is preferable to treat x-y-z coordinates in formulas above in the local coordinate system of the platform and to recalculate resulting local tilt angles into a geographical or global coordinate system later, during the data post processing.

In weak field conditions where the level of the signal is comparable with input noise levels in preamplifiers, the bias in the estimated values of Tx and Ty caused by noise in the horizontal signals become substantial and can not be reduced by any averaging. This bias can be removed by the use of separate reference signals containing noise uncorrelated with noise in signals Hx and Hy. (Anav et al., 1976).

$$Tx = ([HzRx^*]\,[HyRy^*] - [HzRy^*]\,[HyRx^*]) / ([HxRx^*]\,[HyRy^*] - [HxRy^*]\,[HyRx^*]), \quad (4)$$

and

$$Ty = ([HzRy^*]\,[HxRx^*] - [HzRx^*]\,[HxRy^*]) / ([HxRx^*]\,[HyRy^*] - [HxRy^*]\,[HyRx^*]). \quad (5)$$

Where:

Rx is the reference field x component,
Ry is the reference field y component.

An additional two electromagnetic sensors, providing these reference signals can be placed at some distance away from the main x, y and z sensors. Currently, though, no additional remote-reference processing are applied to ZTEM data.

Numerical Modelling

In order to understand the airborne AFMAG responses to conductors for a variety of geological environments, EMIGMA^{TM} modelling code from PetRos EiKon (Toronto, ON) was obtained to conduct the formulated model studies.

Below are some of the modelling results from their study.

Modelling assumption:

The assumptions for the modelling are that:

3 components of the magnetic field are measured and they are processed according to:

$$Hz(f) = Tx(f)\,Hx(f) + Ty(f)\,Hy(f)$$

The vector (Tx,Ty) is usually referred to as the 'tipper' vector and is determined in the frequency domain through processing. This is normally done by determining transfer functions from an extended time series.

For the modelling exercise, the 3 components of the magnetic vector (Hx,Hy,Hz) are modelled twice for 2 orthogonal polarizations of a plane wave source field and then the tipper is calculated from a matrix calculation using the results of the 2 source polarizations' models. For the 2D forward modelling results, the tipper vectors are shown as a function of frequency

Basic Model Response

For the initial models, we assume a thin plate-like model. The model is perpendicular to the flight direction. Initially, we will assume very long strike directions. From this quasi-2D model, there are 2 basic responses. The so-called TE response and the so-called TM response.

For the initial models, we will assume the strike is in the y (North) directions and the flight is in the x (East) direction Sensor heights are 30m above ground.

TE Mode: For the TE response, the electric field excitation flows along strike (current channelling) and the horizontal H field (Hx) flows perpendicular to strike thus causing induction through Faraday's law. The Hz response is generated both from channelling and induction.

TM Mode: For this response, the electric field excitation flows perpendicular to strike generating quasi-static charges on faces and the horizontal H field (Hx) flows parallel to strike. Since, the XZ face is very small for this model, little current is induced. The charges on the faces have a small dipole moment due to the thinness of the model.

For the rest of the models unless otherwise noted, the parameters used are:

Strike Length: 1km
Depth Extent: 1km
Conductance: 100S
Depth to Top: 10m
Background: Thin-overburden (10m), Resistive Basement (1000 Ohm-m)

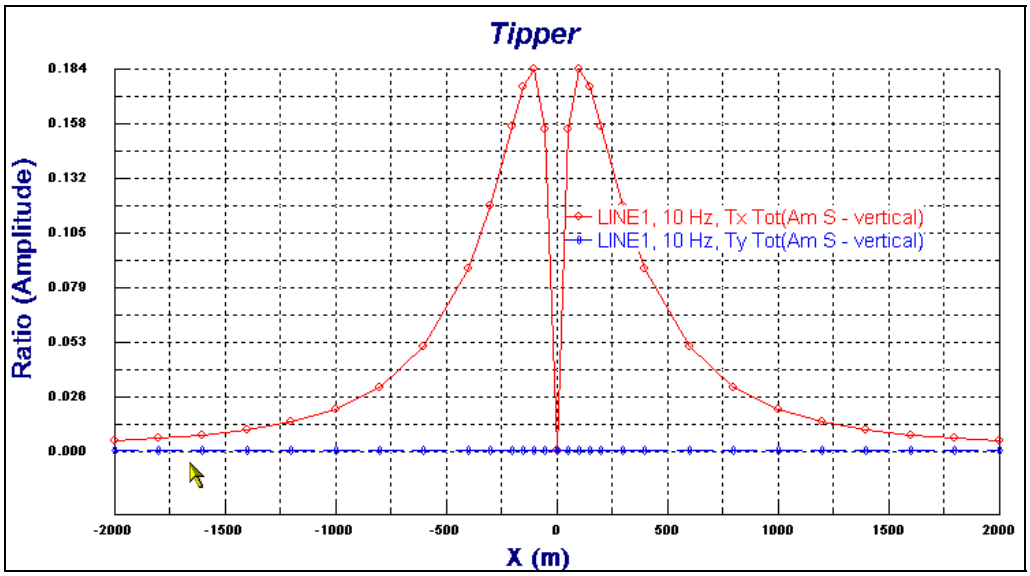

Figure D-1 – Calculated Tipper components at 10 Hz for above model parameters.

Figure D1 shows the Tipper (Tx,Ty) Amplitudes at 10Hz using a10Ωm overburden. Note small Ty (ie quasi-TM response)

Amplitude Response

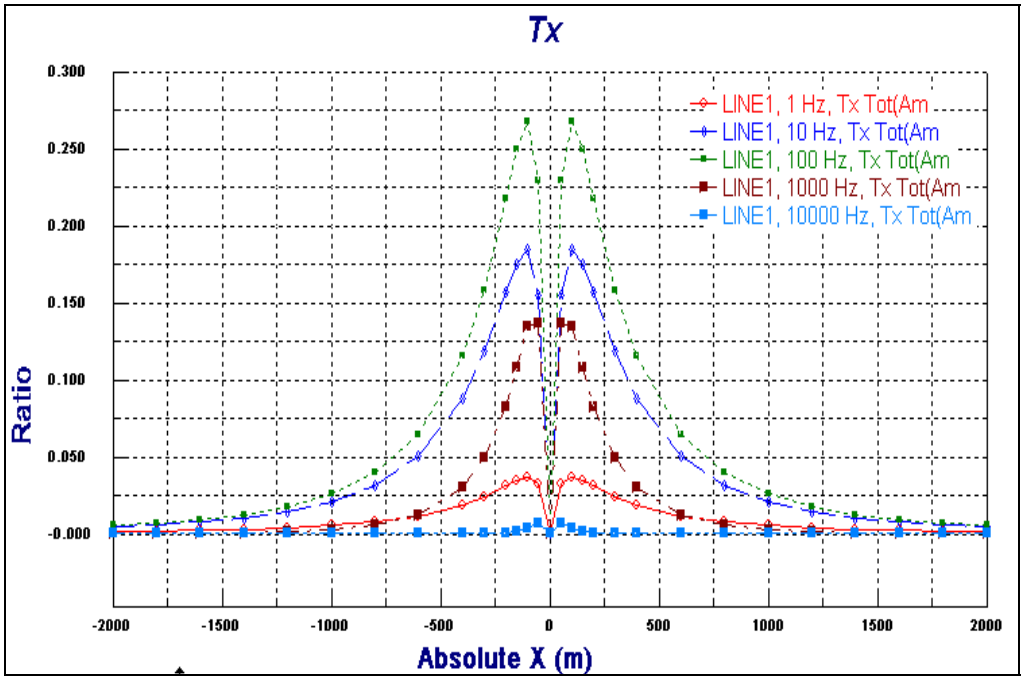

Figure D-2 – Calculated Tx component of the Tipper at various frequencies

The (Tx) response amplitude at 1,10,100,1000,10000 Hx. Peak amplitude at 100Hz

Inphase and Quadrature Response

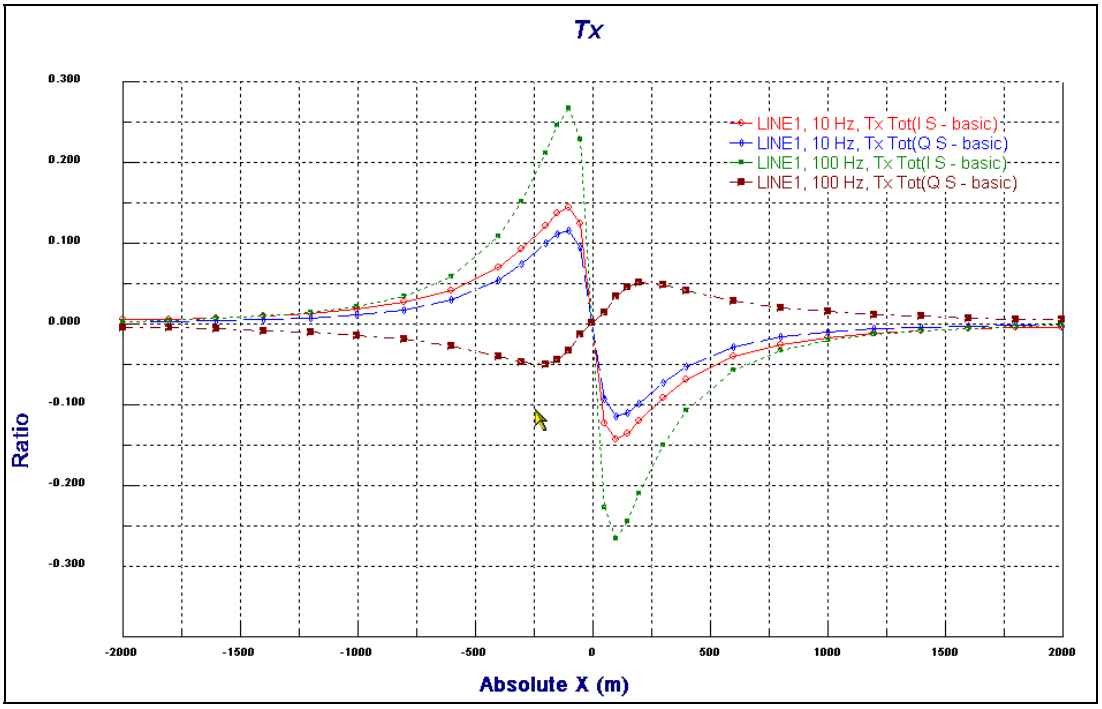

Figure D-3 – Calculated In-phase and Quadrature of the Tx component at various frequencies

Figure D-3 shows the In-phase and Quadrature response at 10 and 100Hz. Note the crossovers in the In-phase and Quadrature, and the phase reversal in the Quadrature responses from low to high frequencies.

AFMAG Source Fields and ZTEM method[1]

AFMAG uses naturally occurring audio frequency magnetic fields as the source of the primary field signal, and therefore requires no transmitter (Ward, 1959). The primary fields resemble those from VLF except that they are lower frequency (tens & hundreds of Hz versus tens of kHz) and are usually not as strongly directionally polarized (Labson et al., 1985). These EM fields used in AFMAG are derived from world wide atmospheric thunderstorm activity, have the unique characteristic of being uniform, planar and horizontal, and also propagate vertically into the earth – to great depth, up to several km, as determined by the magnetotelluric (MT) skin depth (Vozoff, 1972), which is directly proportional to the ratio of the bedrock resistivity to the frequency (Figure D4).

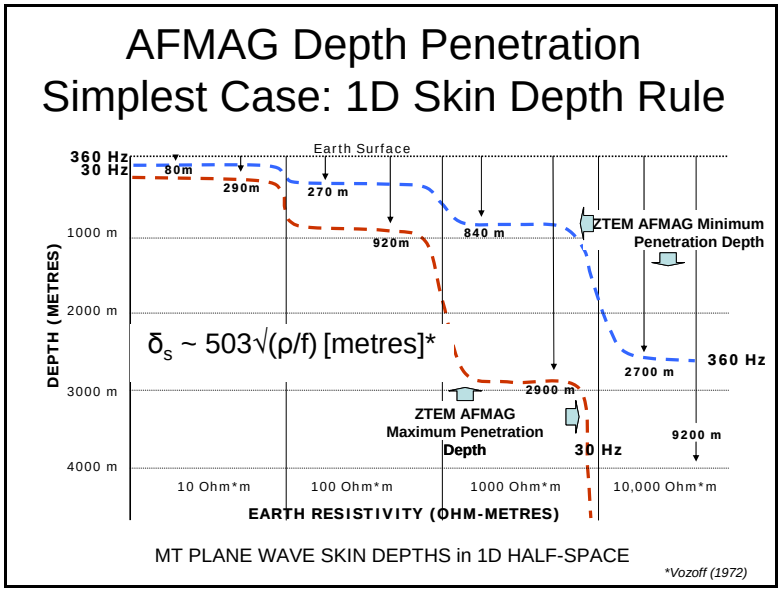

Figure D4: MT Skin Depth Penetrations for ZTEM in 30-360Hz and 10-1000 ohm resistivity

At the frequencies used for ZTEM, the penetration depths likely range between approx. 600m to 2km in this region (approx. 1k ohm-m avg. resistivity assumed), according to the following equation for the Bostick skin depth $\delta_B = 356 * \sqrt{(\rho / f)}$ metres (Murakami, 1985), which is considered appropriate as a rule of thumb equivalent depth estimate.

The other unique aspect of AFMAG fields is that they react to relative contrasts in the resistivity, and therefore do not depend on the absolute conductance, as measured using inductive EM systems, such as VTEM. Hence poorly, conductive targets, such as alteration zones and fault zones can be mapped, as well as higher conductance features, like graphitic units. Conversely, resistive targets can also be detected using AFMAG– provided they are of a sufficient size and contrast to produce a vertical field anomaly. Indeed resistors produce reversed anomalies relative to conductive features. Hence AFMAG can be effective as an

[1] From: Legault, J.M., Kumar, H., and Milicevic, B. (2009): ZTEM tipper AFMAG and 2D inversion results over an unconformity uranium target in northern Saskatchewan, Expanded Abstract submitted to Society of Exploration Geophysics SEG conference, Houston, Tx, Nov-2009, 5 pp.

all-round resistivity mapping tool, making it unique among airborne EM methods. A series of 2D synthetic models that illustrate these aspects have been created using the 2D forward MT modelling code of Wannamaker et al. (1987) and are presented in figures D5-D7.

The tipper from a single site contains information on the dimensionality of the subsurface (Pedersen, 1998), for example, in a horizontally stratified or 1D earth, $\boldsymbol{T}$=0 and as such H_Z is absent. For a 2D earth with the y-axis along strike, T_Y=0 and $H_Z = T_X * H_X$. In 3D earths, both T_X and T_Y will be non-zero. H_Z is therefore only present, as a secondary field, due to a lateral resistivity contrast, whereas the horizontal H_X and H_Y fields are a mixture of secondary and primary fields (Stodt et al., 1981). But, as an approximation, as in the telluric-magnetotelluric method (T-MT; Hermance and Thayer, 1975) used by distributed MT acquisition systems, the horizontal fields are assumed to be practically uniform, which is particularly useful for rapid reconnaissance mapping purposes. By measuring the vertical magnetic field H_X, using a mobile receiver and the orthogonal horizontal H_X and H_Y fields at a fixed base station reference site, ZTEM is a direct adaptation of this technique for airborne AFMAG surveying.

INTRODUCTION

A series of demonstration tests were conducted using the ZTEM, airborne AFMAG system over deep targets in the Athabasca Basin of Saskatchewan, Canada. These tests were conducted in mid-2008 and were flown to test ZTEM's ability to detect large conductive targets at depth; deeper than conventional airborne EM methods. Data are presented over areas where the conductors are located 450-600 metres beneath the surface. As well, a case of ZTEM following the plunge of a conductor to over 800 metres depth is shown.

BACKGROUND

The ZTEM system is the latest implementation of an airborne AFMAG system first commercialized in late 2006. ZTEM uses a large, 8 metre diameter airborne air core coil, slung from a helicopter, to measure the vertical component of the AFMAG signal. Two 4 metre square coils are deployed on the ground to measure the horizontal field. The ZTEM system has flown successful demonstration surveys over porphyry copper deposits in the southwest USA (Zang et al., 2008).

ZTEM was tested in the Athabasca Basin in Canada in May of 2008 to determine its depth of investigation and to determine its suitability for mapping deep conductors in the crystalline basement. Over 30% of the world's U3O8 is mined in the Athabasca Basin from unconformity uranium deposits. Unconformity uranium deposits of the Athabasca Basin are often associated with conductors located in the crystalline basement. The search for economic uranium deposits is moving to areas of the basin which are deeper and beyond the detection limits of modern airborne instrumentation. This creates the requirement for a system which can detect conductivity past the detection limits of modern traditional EM systems. This was the motivation behind the field trials of the ZTEM system in the Athabasca Basin. Several areas where known deep conductors (450-600m+) were located were flown. Also, a test survey block in the northern part of the basin was able to trace a deep and plunging conductor to depths that no other airborne EM system has been able to achieve.

ATHABASCA BASIN GEOLOGY

The high-grade uranium deposits within the Athabasca Basin are associated with the unconformity between the essentially flat-lying Proterozoic Athabasca Group sandstones and the underlying Archean-Paleoproterozoic metamorphic and igneous basement rocks. The deposits occupy a range of positions from wholly basement-hosted to wholly sediment-hosted, at structurally favourable sites in the interface between the deeply weathered basement and overlying sediments of the Athabasca Basin (Ruzicka, 1997). The locations of These deposits are lithologically and structurally controlled by the sub-Athabasca unconformity and basement faults and fracture zones, which are localized in graphitic pelitic gneisses that may flank structurally competent Archean granitoid domes (Quirt, 1989).

In general, most of the known important deposits tend to occur within a few tens to a few hundred metres of the unconformity and within 500 m of the current ground surface. This may be more of a limitation of exploration techniques. There is no reason to believe that the distribution of the deposits is dependent on the modern day depth of

[7] Extended abstract submitted to 20TH ASEG International Geophysical Conference & Exhibition, Adelaide, AU, 22-26 Feb, 2009.

burial.
Empirically, the geophysical exploration for unconformity type uranium targets have been to search for large basement structures which post date the sandstone deposition of the basement (Matthews et. al, 1997). All the deposits located so far are associated with fault structures associated with a graphitic conductive basement. An alteration zone of clay silicification and enrichment around the deposits probably leads to magnetite destruction causing the magnetic low observed around the deposits. The clay alteration should give rise to a resistivity low signature about the deposits. The low conductivity of the clay alteration makes it a difficult target for airborne EM if it is buried at significant depth.

ZTEM INSTRUMENTATION AND PRESENTATION

ZTEM is an airborne AFMAG system introduced by Geotech Ltd. of Canada in early 2007 (Lo et al., 2008). In a ZTEM survey, a single vertical dipole air-core coil is flown over the survey area in a grid pattern similar to other airborne electromagnetic surveys. Two orthogonal, air-core, horizontal axis coils placed close to the survey site measures the horizontal EM fields for reference. A GPS array on the airborne coil monitors its attitude for post-flight corrections.

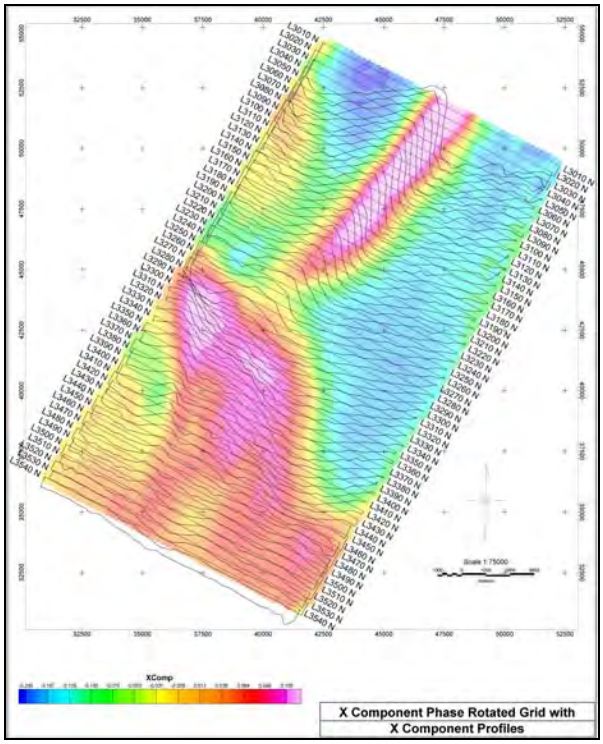

Figure 1 – Stacked profiles of the x-component Tipper over the gridded values of the phase rotated x-component data. Note that the cross-overs in the profiles are now peaks on the image.

As the source field is assumed to be far away, the excitation of the ground is more or less uniform. For large structures, the signal fall-off will be much slower than from a dipole source, such as those energized by traditional airborne systems. With the ZTEM system being less susceptible to terrain clearance, the planned ground clearance height is higher and the terrain drape is looser as compared to standard helicopter EM surveys.

The two Tippers obtained from the relationship between the vertical airborne coil and the two ground coils have a cross-over over a steeply dipping, plate-like body. The cross-overs can be made into local maxima via a 90 degree phase rotation which allows for easier interpretation of the gridded values. Figure 1 is an example of this transformation.

To present the data of both Tippers as one image, we calculate a parameter termed the DT which is the horizontal divergence of the two Tippers, much in the same manner as the "peaker" parameter in VLF (Pedersen, 1998). The DT is typically plotted with an inverted colour bar as it is negative over a steeply dipping thin body.

ZTEM RESULTS – NORTHERN ATHABASCA BASIN

Figure 2 shows gridded values from a number of ZTEM lines over an area where the sedimentary cover is approximately 450-600 metres thick. A number of traditional EM systems have also been flown over this block. While they were able to detect conductors, the resolution of the conductive features is not nearly as detailed as the information provided by ZTEM.

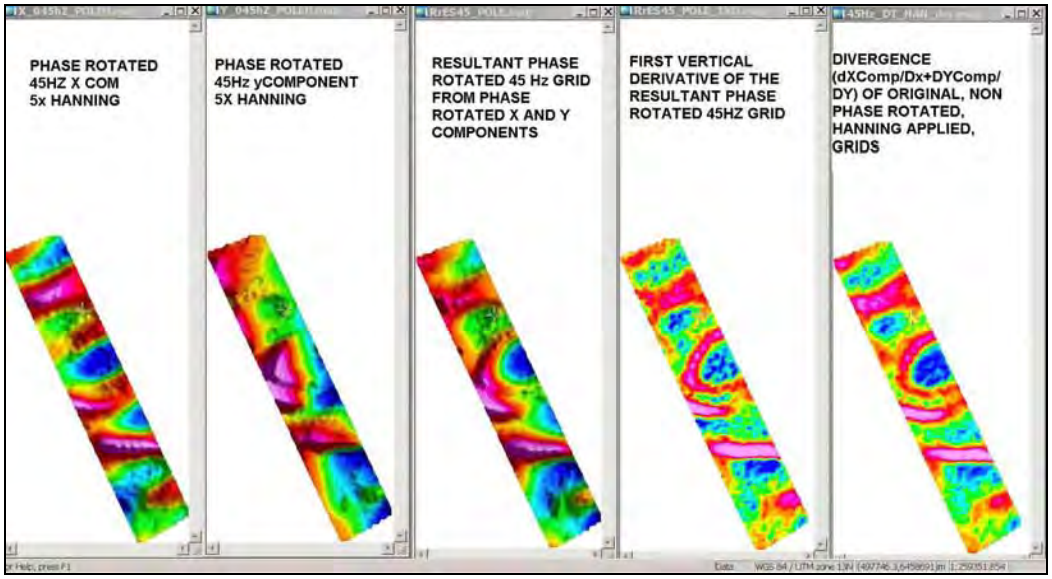

Figure 2 – ZTEM results over an area of 450-600 metre thick sedimentary cover.

Figure 3, from another area, shows the data from one of the larger blocks that was flown. It is a 3D composite image of the DT at various frequencies plotted at the equivalent skin depth assuming a 1,000 ohm-m average resistivity.

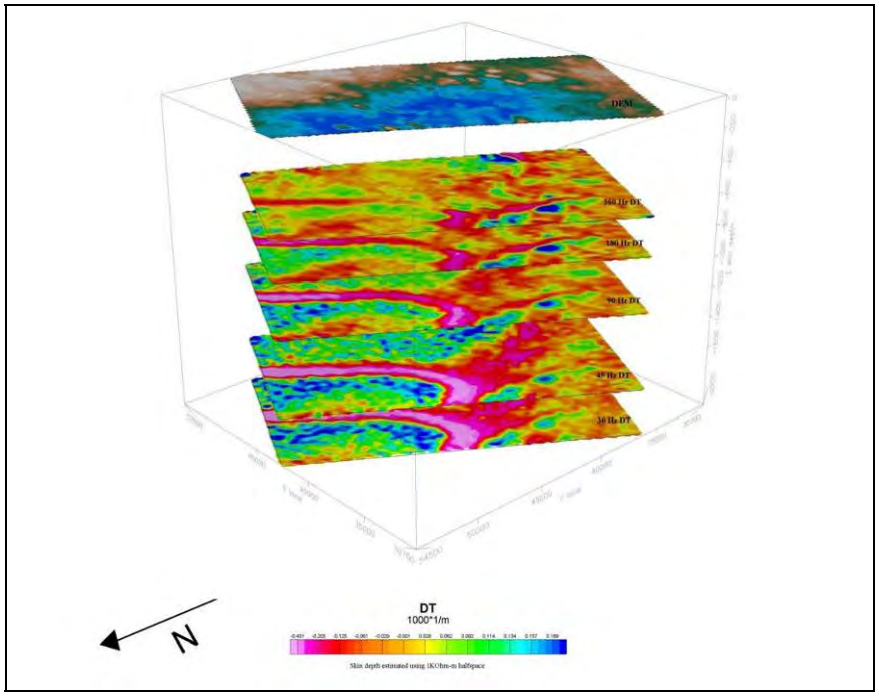

Figure 3 - Perspective view of DT's of different frequencies plotted at the skin depth (using a 1,000 ohm-m Earth.

The data in Figure 3 come from a survey over the north rim of the Athabasca Basin. The sandstone cover is about 500m on the left hand side of the image, and progressively getting deeper to the right. It is about 700m in the middle part of the image and over 800 metres thick on the right middle portion where exploration drilling is concentrated. Starting in the middle left and trending to the right of the image, there is a known graphitic shear.

In the uppermost (600m) "depth slice", Figure 3 shows a linear conductive feature that progressively weakens as one moves to the right until it is no longer seen. This is interpreted to be due to the graphitic shear conductor plunging deeper past the depth of investigation of the 360 Hz data. The lower frequencies penetrate more into the sedimentary cover that is deeper towards the right. DT's of decreasing frequency show the linear conductive feature extending more and more to the right. The feature also strengthens/sharpens into a synformal shape with lower frequencies. This fits with what the known geology of a plunging conductor at depth is doing.

At the nose of the fold, in the right third of the images, we also see another, broader anomalous zone that trends towards the back of the image. At this location, two radioactive springs are situated. These spring waters which are anomalously high in uranium and radon may reflect the upward migration of deep waters along faults, suggesting structural targets in areas where basinal waters may have tapped a radioactive source. This broad DT trend might be the plunge of the fold axis that is aligned away from the front of the image. An anomaly along this trend, at the highest frequency, that steadily grows with each decreasing frequency can be seen. This might represent an alteration zone in the sandstone that is detected at the shallowest depth. By about the 90Hz DT depth slice or so, we are possibly in the deeper basement and into a basement graphitic unit.

CONCLUSIONS

A number of successful ZTEM tests were conducted over the Athabasca Basin. The tests demonstrated that ZTEM can easily detect conductivity to 800 metres beneath relatively resistive sedimentary cover. Assuming a 1,000 ohm-metre

resistivity, the skin depth of the 30 Hz data is approximately 2,000 metres. The 30 Hz data presented have good signal to noise ratios indicating a deep depth of exploration. The observation that ZTEM may be detecting the clay alteration above the crystalline basement is a significant advantage for exploration of unconformity uranium deposits.

More demonstration surveys are planned in the Athabasca Basin later this year. And more target types for testing are also planned.

ACKNOWLEDGEMENTS

The authors thank Geotech Ltd. for allowing them to publish this work and for providing the support required to write this abstract and to present this paper.

MEMORANDUM

To: Bill Wengzyowski **Date:** June 11, 2010

From: Dave Hildes, Leatina Wood

Re: EL showing 2010 Induced Polarization Survey Field Report

FIELD

This memorandum is a field report describing geophysical surveys conducted on the El showing comprising seven lines of induced polarization (IP) surveying using a modified pole-dipole array. The survey was conducted from May 31 to June 10, 2009, based out of the McQuesten camp. A full survey log describing day by day operations is attached to this report.

A total of 7.7 line-km (seven lines) were completed over nine working days on lines put in prior to the arrival of the Aurora IP crew. There was one weather day due to very wet conditions. Production was hampered by very conductive ground causing a poor signal to noise ratio. Consequently many repeats were needed and reliable data was not routinely collected to the farthest offsets.

The crew was originally to conduct mise-a-la-masse IP surveys at the Rau on holes Rau-09-44 and Rau-09-61 but both holes had collapsed. An alternate 2010 was attempted but the hole was blocked by grease which the current electrode could not penetrate so the mise-a-la-masse survey was abandoned.

a. Crew and equipment.

The survey was conducted by the following personnel:

Tim Stewart	Crew chief	May 30th- June 10th 2010
Sam Lemay	Helper	May 30th- June 10th 2010

Christian Vitterlien	Helper	May 30th- June 10th 2010
Jessica Bulmer	Helper	May 30th- June 10th 2010

The crew was equipped with the following instruments and equipment:

IP receiver	1	Iris Elrec Pro (2315-2762498451-166)
IP transmitter	1	GDD TxII 3.6 kW (226)
Generator	1	Honda 5kW generator
IP equipment	1	Repair tools & spare IP parts
	5 km	14 gauge wire
	4	VHF handheld radios
		Georeels & spools ,and stainless steel electrodes
Other	1	Laptop with Geosoft IP package
	1	Truck

b. Survey specifications.

The modified pole-dipole IP surveys were conducted according to the following specifications:

Array	Modified Pole-Dipole Array
Dipole spacing	50 m on all lines
Dipoles Read	N=1 through 10 when possible
Tx	Time domain, 50% duty cycle, reversing polarity, 0.125 Hz.
Stacks	Minimum 15
Rx error	5 mV/V or less, otherwise repeated several times until repeatability assured
Grid registration	Handheld GPS points at line ends and every 200m minimum averaged 60 s or until estimated accuracy

FIELD

< 10 m, whichever was longer. All coordinates in NAD83 UTM Zone 8W.

c. Data Processing.

Data was downloaded nightly from the receiver and imported into Geosoft Oasis Montaj IP package. Every reading was inspected and readings which did not repeat were rejected from the database. Apparent resistivity was recalculated using a four electrode equation assuming a homogeneous earth. Average apparent resistivity and chargeability were calculated using a weighted mean based on the number of stacks and the standard deviation of the chargeability.

GPS points were dumped from the handheld units and the coordinates for the stations determined by linear interpolation between GPS units.

Prior to 2D resistivity modelling, errors in the apparent conductance were assigned to the data. There is no means of directly quantifying these errors because neither the transmitter nor receiver records the error in the current or voltage. Default initial and reference models based on an average of the apparent resistivity were used. After the default run, the data were inverted a second time using initial and reference models of a much higher value than the average in the survey area. The purpose of this second run is to generate a model with a background resistivity greatly different than the average values used in the default run. After the second run, the two models were compared and the area where the models differed by a given factor (see attached table) was removed from the default run model. These points are not sensitive to the field data and there is no reliable subsurface information. Chi factors were adjusted to ensure convergence and an appropriate level of structure to the model.

Prior to 2D chargeability modelling, the observed standard deviation of chargeability was used as a measure of error for apparent chargeability. To avoid zero errors, a minimum of 0.2 mV/V was added to each error measurement. The IP data were first inverted using default values (initial and reference model of a 0 mV/V half-space), with the same mesh as the resistivity modelling, using the default recovered resistivity model. After the first run, the data were inverted a second time using initial and reference models of 500 or 700 mV/V (a much higher value than the average in the survey area). The two models were then compared and regions in the default model which varied more than a given factor (see attached table) were removed in the final models. In these regions, the final model is not sensitive to the field data and there is no reliable subsurface information. Chi factors were adjusted to ensure convergence and an appropriate level of structure to the model.

Pseudosections of apparent resistivity, apparent chargeability, and apparent chargeability error, draped over topography, were produced with Oasis Montaj along with the recovered resistivity and chargeability models plotted at the same scale.

e. **Results**.

In general the results are consistent with a Manto style carbonate replacement model of mineralization. There is a very conductive core (> 1S) running across the grid just north of station 10000, modelled at depths as shallow as 50 m below surface. This is not consistent with unaltered carbonate and could represent massive sulphide mineralization. If further work confirms the target of interest to be this conductive horizon, EM techniques, either frequency-domain (e.g. Maxmin) or time-domain (e.g. Protem) depending on the desired

depth of investigation, are better suited and cheaper techniques to further delineate this target geophysically.

The conductive core tends to be interrupted by a more resistive horizon at station 10100, clearly seen in lines 9700, 9800, 9900, 10100 and 10200. The resistive horizon appears to be absent on L9800. There are indications of a second resistive horizon further south at station 9800 on lines 9800, 10000 and best defined on line 10100.

Although the survey geometry is not particularly sensitive to dip, there are consistent indications in the data and the inversions of a dip to the north. This is best illustrated in L9800 and L10100.

This conductive core manifests itself as low voltage readings which in turn results in chargeability data that is contaminated with significant noise. Nevertheless, the resistivity data indicative of the conductive core is sound and most of the chargeability data, although noisy, has spatial coherence and conclusions can also therefore also be drawn from that data.

Generally there is a chargeable halo around the conductive core, consistent with a halo of disseminated sulphide mineralization around a massive sulphide core. This chargeable layer is often above the conductive core. It should be noted that some of the chargeability inversions, particularly L10200 were difficult to run and many of the extreme values in the data were consequently omitted from the inverted data set to facilitate the execution of the code.

The lines on the eastern part of the grid (line 9900 through 10200) show some indication of a deeper chargeability anomaly

The geophysical results warrant drill testing. There is a shallow, robust chargeability high at station 10200, well defined on lines 9600, 9700 and 9800, this could be tested with a 100 m vertical hole on line 9700, station 10200. Alternatively, an angled hole with a 65 degree dip to grid-south could be collared at station 10200 on line 9700 to test both the shallow chargeability and the deeper conductive target, but would have to be > 400 m to adequately test the deeper conductive feature. A shallower, 200 m vertical hole at station 9960 on line 9800 could test the upper conductivity feature and also test a separate shallow chargeability feature. On line 10100, the resistivity feature comes closer to surface and a 200 m angled hole (65 degree to grid-south) at station 10050 would test the upper part of the conductivity anomaly or a steeper (80 degree) 350 m hole at the same collar would test the deeper conductive target. Both would also test the recovered shallow chargeability from that line.

1. INTRODUCTION

This report describes the analysis of a ZTEM airborne geophysical data over the Rau property, located near Mayo, Yukon, Canada (Figure 1). The survey was flown between June 14-22, 2010 by Geotech Ltd. (Geotech) for ATAC Resources Ltd. (ATAC) and comprised three blocks, Central, NW and SE. The Central block encompasses the Tiger zone, where recent drilling has defined a gold resource, the El zone where drilling has been undertaken and a number of other Au prospects. The SE block encompasses the recently discovered Osiris zone, which has also been drilled.

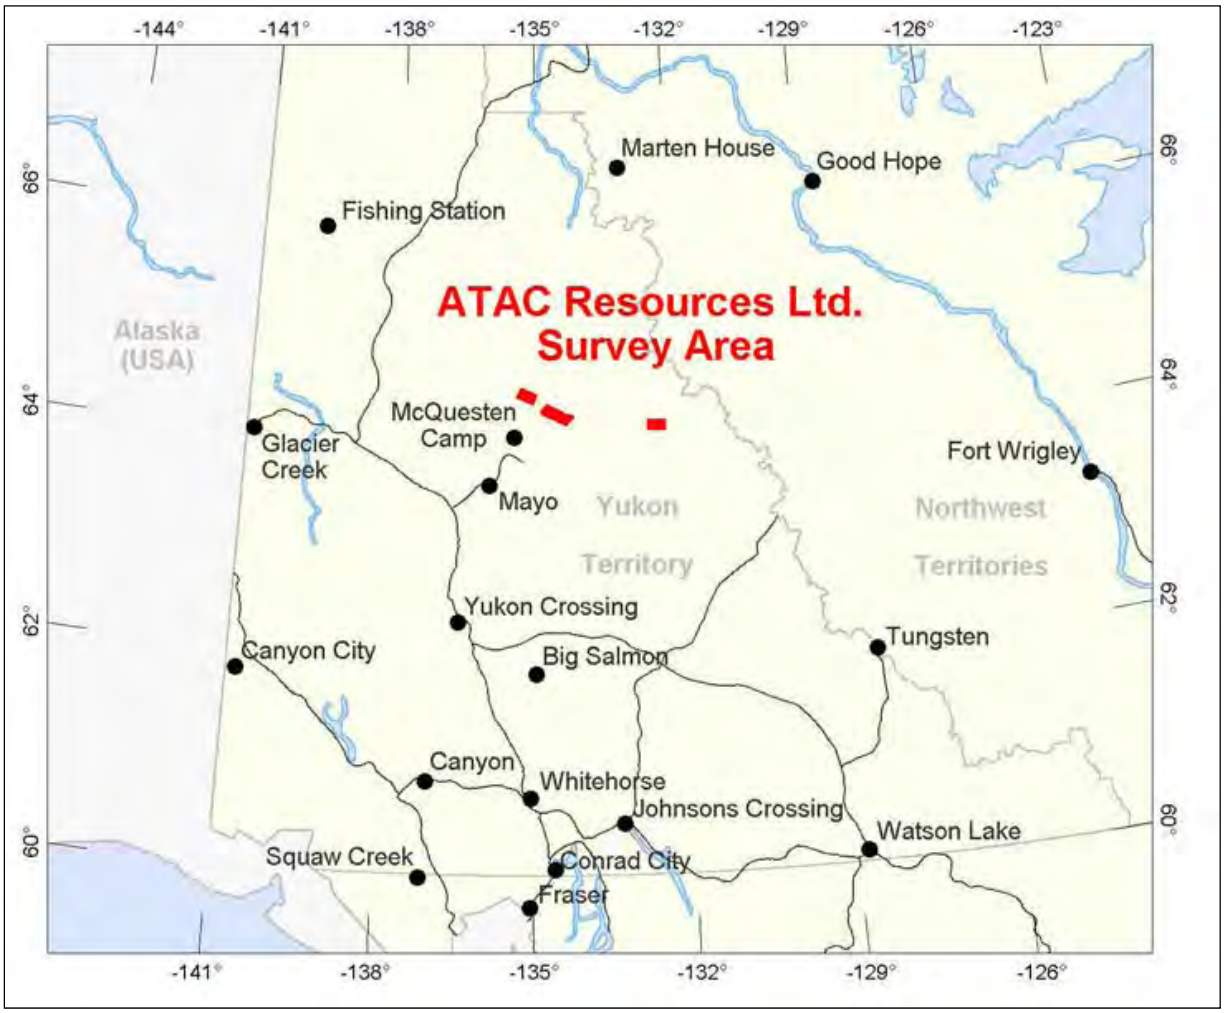

Figure 1: Location of ZTEM surveys.

The aim of the ZTEM survey was to map structures and lithologies controlling gold mineralization and thus generate additional targets.

Previously, in 2007-2008, a VTEM survey was flown over a similar area to the ZTEM Central block. The VTEM data defined relatively modest conductive zones correlating with the Tiger zone and extending northwest across other Au mineralized zones, including the El zone.

In early 2010, ATAC decided to fly additional AEM to assist in defining targets elsewhere in their extensive land package at Rau. Because of the relatively poor conductivity of the Au mineralization and associated alteration, a ZTEM test survey was carried out between May 27-June 6, 2010 over the Tiger zone to evaluate whether ZTEM could define this target style better than VTEM. A well-defined conductive zone was delineated by the ZTEM over the Tiger zone, which extended northwest and correlated with other Au mineralized prospects. Consequently ZTEM was adjudged to be a more effective method for mapping features significant to the gold mineralization in this environment.

Following the positive results from the test survey, additional ZTEM was flown to cover most of the area of the 2007-2008 VTEM survey. The data from the test survey have been merged into the main survey for this report.

Condor Consulting Inc. (Condor) was commissioned to carry out comprehensive processing, analysis and interpretation of the ZTEM and magnetic data. The interpretation had two principal goals:

- Identify the EM and magnetic signatures of the known gold mineralization at a local scale
- Generate additional targets, either extensions of the known mineralization or new zones elsewhere within the three survey blocks.

The principles of the ZTEM system, together with modelling and analysis techniques, are summarized in Condor Technical Note “ZTEM Primer” (Appendix A).

2. SURVEY DETAILS

The ZTEM survey comprised three blocks (Central, NW and SE), as shown in Figure 2. The survey was flown out of ATAC's McQuesten Camp, shown on the figure. The magnetic base station was located close to the camp, while the ZTEM base station was located approximately half way between the camp and the Central block.

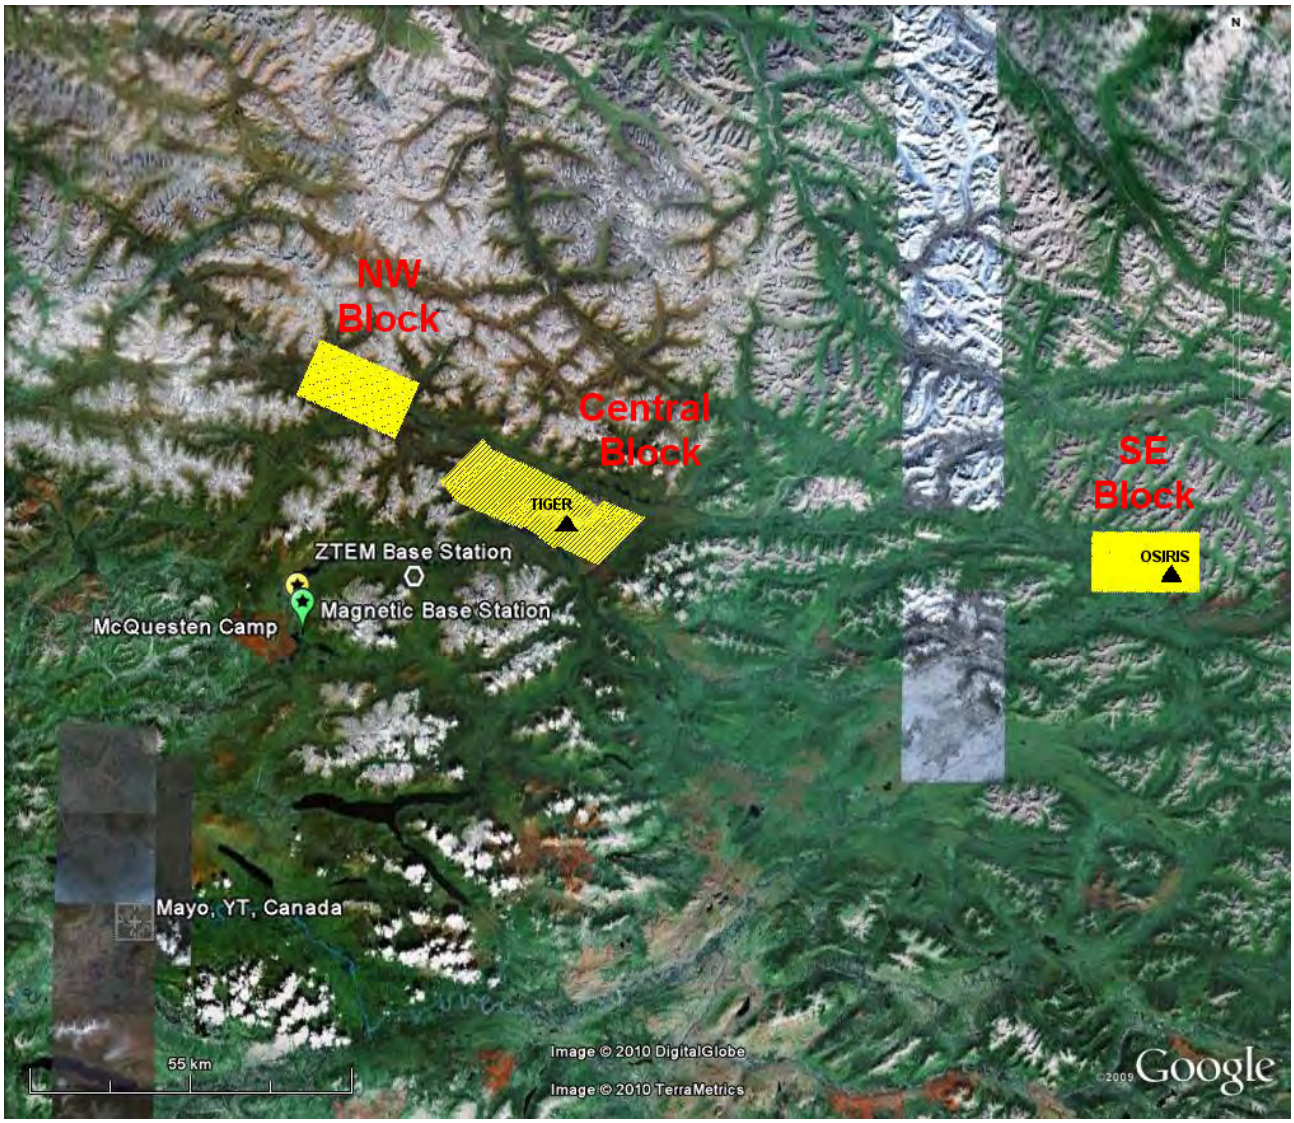

Figure 2: Locations of three survey blocks.

The Central block consisted of 1531.4 line km, of which 322.6 km had been flown during the initial test survey stage (Figure 3).

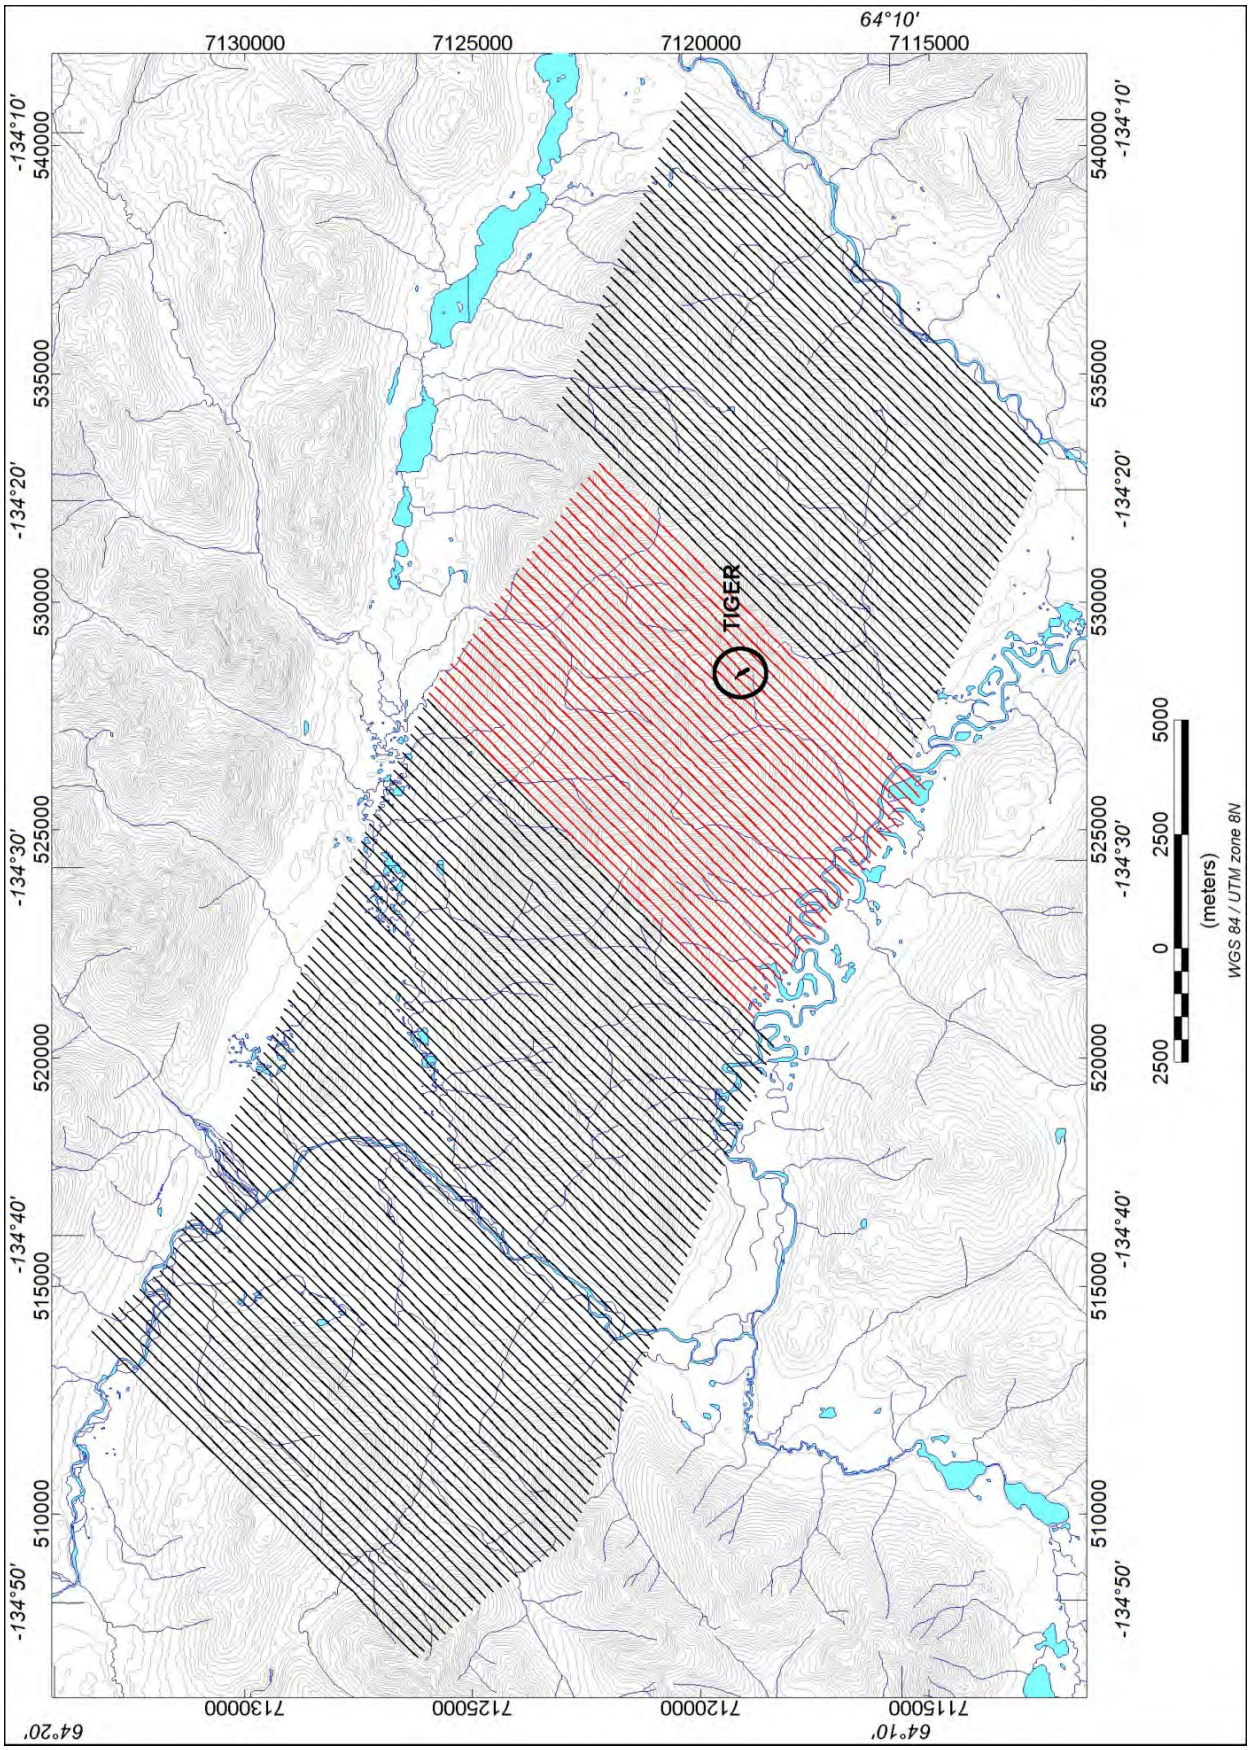

Figure 3: Central block - ZTEM flight path.

The Northwest block comprised 922.5 line km (Figure 4) and the Southeast block 923.1 line km (Figure 5).

The total line Km of ZTEM (including the test survey) was 3 377 km.

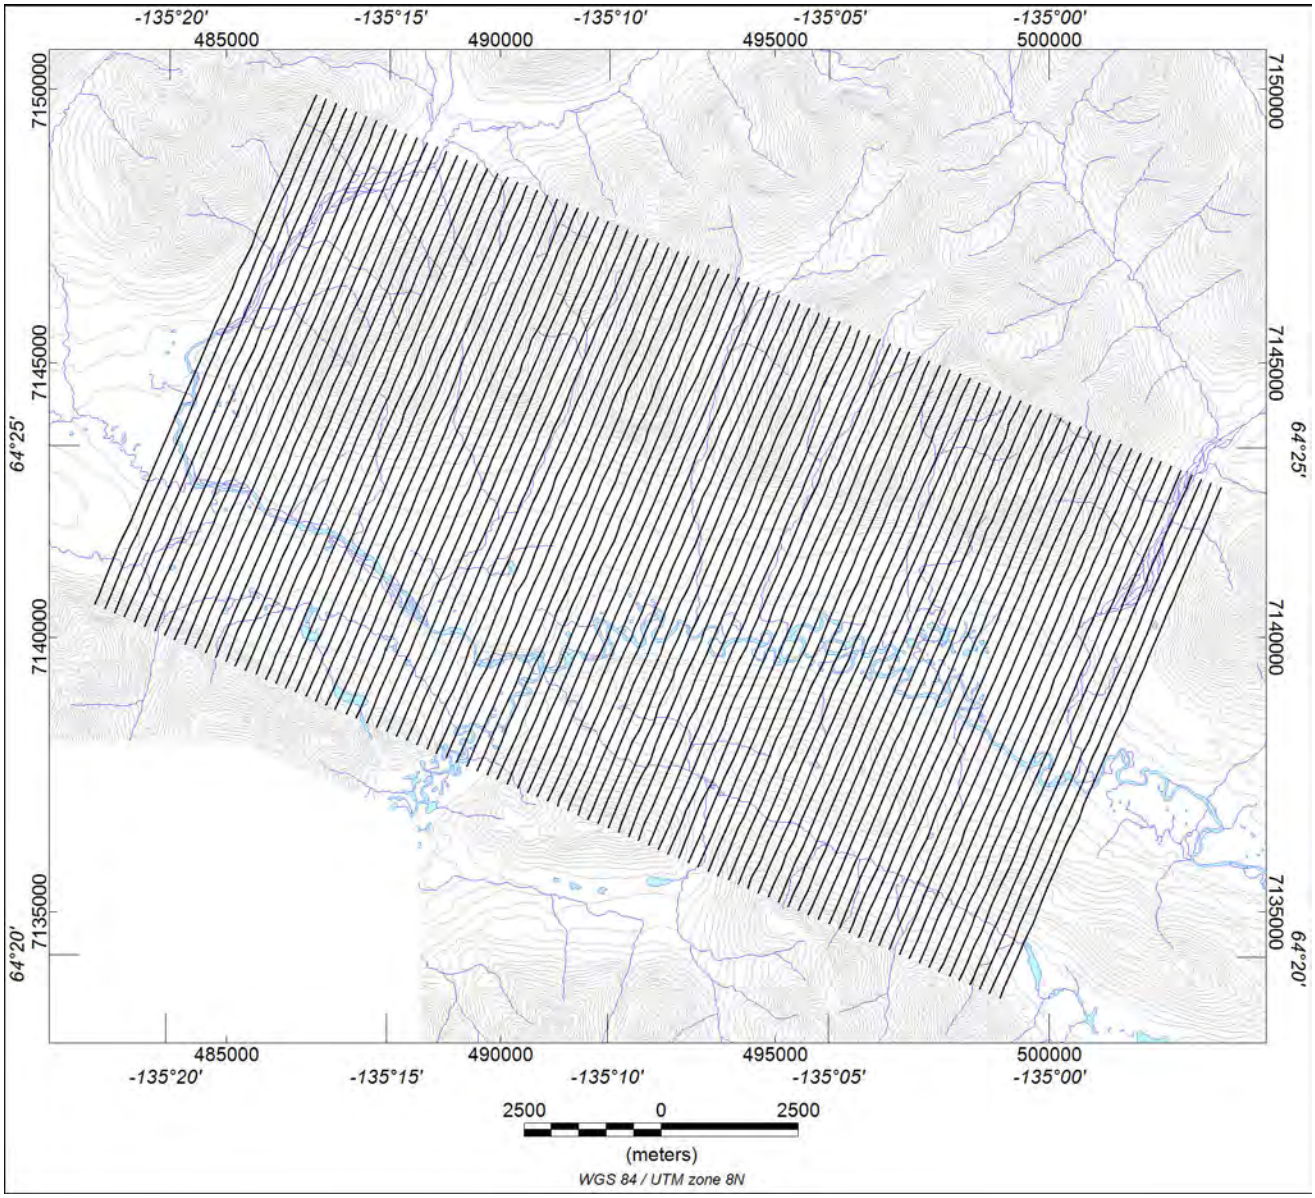

Figure 4: Northwest block - ZTEM flight path.

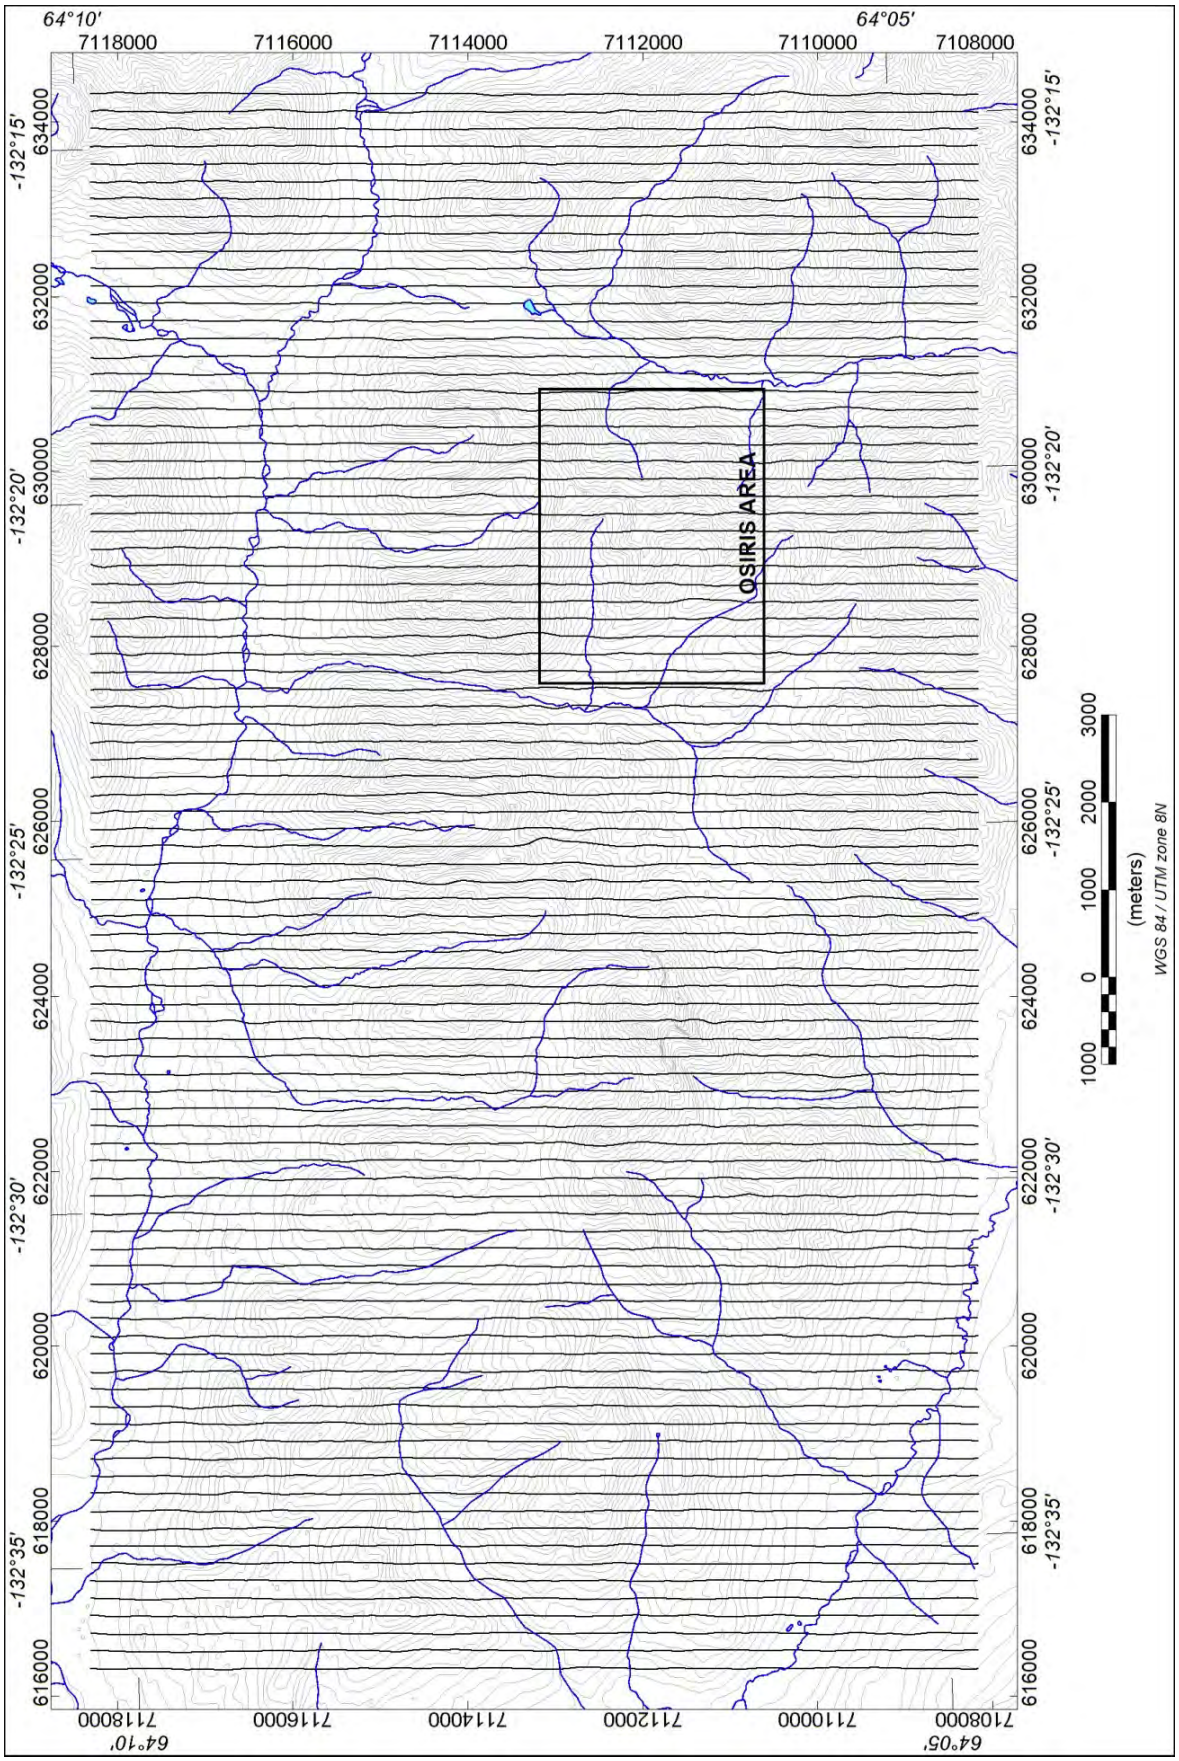

Figure 5: Southeast block - ZTEM flight path.

3. GEOLOGY

The geology of the Central block is shown in Figure 6a and the accompanying legend in Figure 6b. No geologic maps covering the other blocks were available, except for a small area covering the Osiris prospect in the Southeast block, which is shown on the interpretation maps later in this report.

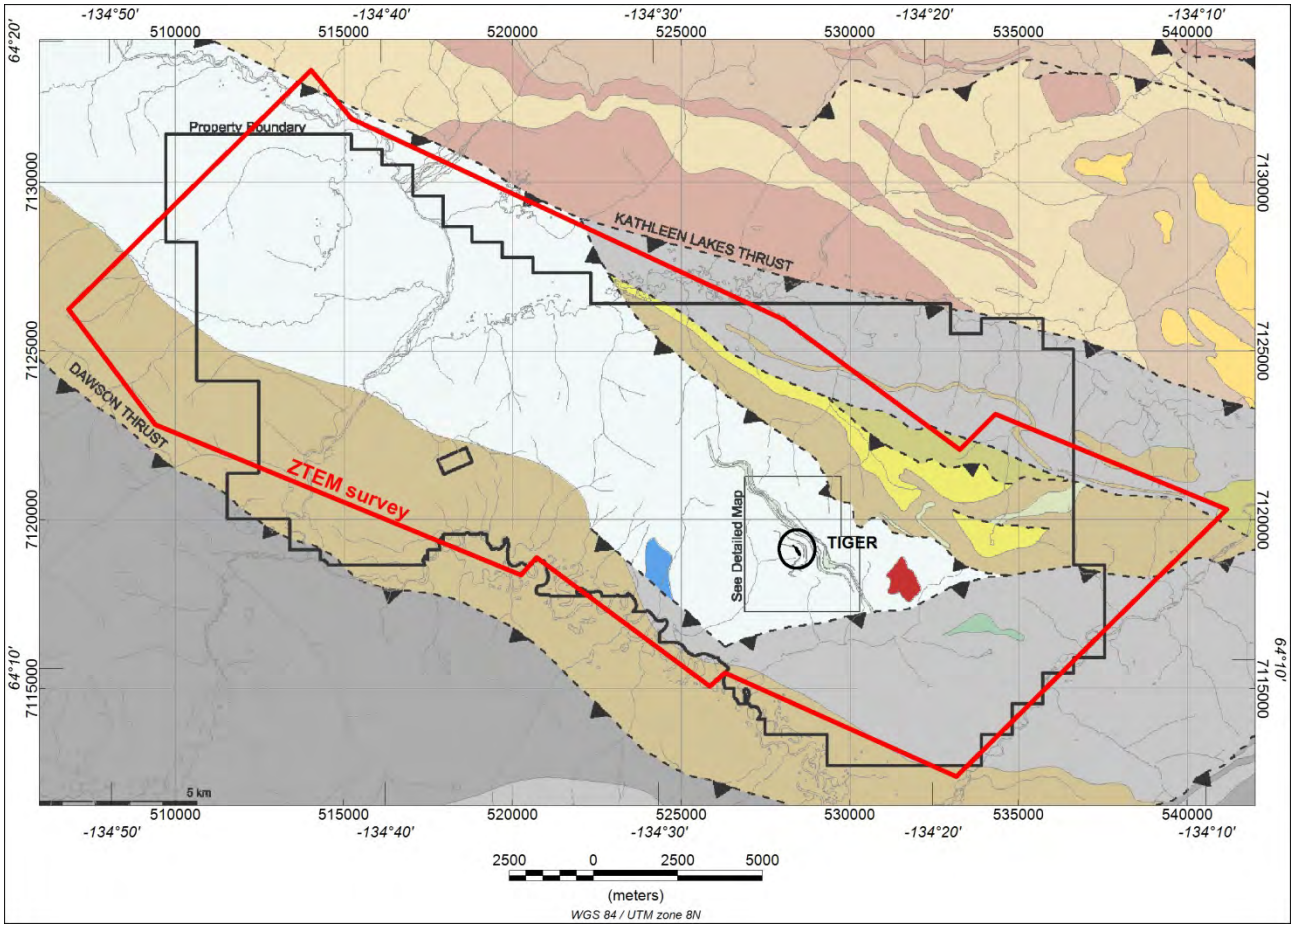

Figure 6a: Geology of Central block, showing boundary of ZTEM survey.

The following description of the geology and mineralization is extracted from ATAC's web site:

http://www.atacresources.com

The Rau Project is located 55 km northeast of Keno City in Central Yukon. The project is over 1300 sq km and is situated between the regional-scale Dawson thrust and Kathleen Lakes fault, within a Paleozoic carbonate inlier of the Selwyn Basin tectonic province. Replacement-style, gold-bearing sulphide and oxide mineralization occurs in Bouvette Formation shallow water limestone, dolomite, and calcareous siltstone of Cambrian to Devonian age. ATAC Resources Ltd. wholly owns the project, which was a grass roots discovery in 2006. Since then, it has acquired by staking over 160 km of potential strike length of favourable structure and stratigraphy, of which only a very small portion has been explored for gold.

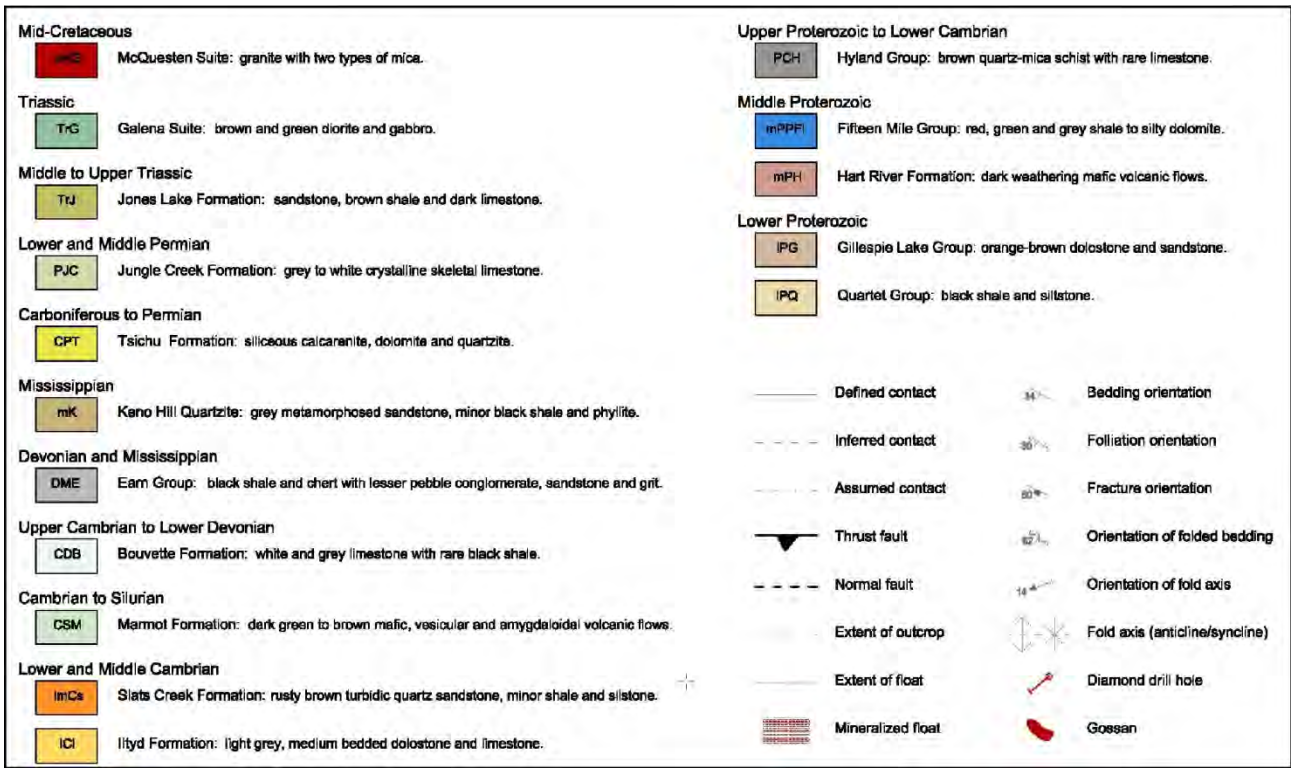

Figure 6b: Legend for geological map shown in Figure 6a.

Exploration conducted by ATAC has focused along a 15 km portion of the Bouvette Formation where it forms a local ridge system bound by the Beaver and Rackla Rivers. Carbonate strata at the southeast end of the ridge system is intruded by a small early Tertiary (62.9+0.5 Ma) granite stock. Work along the 15 km trend comprises widely spaced soil geochemical surveys, airborne VTEM surveys plus limited geological mapping and prospecting. Detailed work conducted in a 3 km by 5 km area at the southeastern end of this trend focused on the Tiger Zone and included detailed grid soil geochemical surveys and diamond drilling of 71 holes.

The Tiger Zone is a stratigraphically-controlled gold deposit that trends northwest and dips moderately northeast and is characterized by replacement of host carbonates. It is currently 650 m long, 100 to 200 m wide, and up to 96 m thick. Mineralization is contained within a 40 m to 150 m wide zone of small-scale folding and shearing, which is itself developed in and adjacent to a regionally extensive corridor of highly strained rocks. The mineralized system is defined by a series of stacked and folded limestone horizons intercalated with locally extensive mafic flows and volcaniclastic units. Most of the exploration has been directed toward the Discovery Horizon, although there is evidence for at least two additional stratabound intervals of gold mineralization

Gold occurs in both sulphide and oxide material. Sulphide mineralization is accompanied by, and developed within, limestone which is replaced by ferruginous dolomite and iron carbonate minerals. Sulphide species consist of disseminated to banded pyrite, with subordinate arsenopyrite and pyrrhotite, and minor bismuthinite and sphalerite. Small amounts of disseminated scheelite are also present. The main sulphide minerals exhibit at least three stages of mineralization. The best intersection from sulphide-bearing mineralization averaged 4.04 g/t gold over 96.01 m from hole Rau-09-66.

Oxide mineralization is completely devoid of sulphide minerals and ranges from very competent, weakly

porous limonitic mud to rubbly porous limonitic grit. The oxide appears texturally amorphous in most intersections but occasionally exhibits residual color banding that may represent relict sulphide textures. Complete oxidation extends up to 150 m from surface. The best oxide grades (e.g., hole Rau-09-19, which assayed 24.07 g/t gold across 28.04 m) and deepest oxidation occur where north-striking extensional faults intersect the regional northwest-striking structure. The nature of the contacts between the oxide and sulphide facies is poorly understood, as is the gold distribution in the mineralized horizon and within individual sulphide species. Mineralization at the Tiger Zone remains open along strike and down dip, as well as at depth across a normal fault that locally defines the southwest margin of the favourable structural corridor.

In addition to the work done at the Tiger Zone, ATAC identified six new surface gold zones by following up high values from grid and widely spaced reconnaissance soil sampling. The best zones are in a 500 m wide belt, which lies 2 to 5 km along strike to the northwest of the Tiger Zone, in and adjacent to the northwest-striking structural corridor. Anomalous soil geochemical values stretch intermittently for about 22 km to the northwest along the projected trace of the structural corridor, which is marked by electromagnetic conductors. Surface rock samples collected from talus or recessively weathered areas assayed between 1.0 and 18.5 g/t gold.

The Osiris Target Area in the SE block was delineated during the 2010 field season. The following description is taken from ATAC's press release dated July 29, 2010.

The Osiris Showing occurs within the Sten claim block that was staked in 2009 to cover a 17 km long mountain range where five of six stream sediment samples in the federal government stream sediment database were highly anomalous for arsenic. Follow up reconnaissance-scale stream sediment sampling in 2009 identified several areas that warranted additional exploration, in particular one 2 km long tributary of one of the anomalous drainages that is characterized by stream sediment gold values ranging from trace to 2 g/t gold. Prospecting in the headwaters of this creek revealed gold mineralization over a widespread area.

Mineralization is hosted by carbonate rocks of uncertain age that are folded into a southerly plunging anticline and occurs in the form of narrow veins, veinlets, stockworks and disseminations of realgar and orpiment (both are arsenic sulphide minerals) accompanied by calcite flooding. The discovery has been traced for a 1 km strike length on both limbs of the fold. The strongest soil geochemical response corresponds to a 40 m wide breccia zone that lies along the fold axis where soils commonly contain in excess of 1 g/t gold, and range from trace to a maximum value of 17.5 g/t gold. The core of the gold and arsenic geochemical anomaly covers an area of approximately 150 by 500 m with 60% of the soil samples grading in excess of 1 g/t gold.

The Osiris mineralization is distinctly different in character from the Tiger Zone mineralization in that realgar and orpiment appear to be the primary gold bearing minerals -- rather than pyrite and arsenopyrite. The Osiris mineralization occurs in limestone debris flows and turbidite deposits characteristic of an offshore sedimentary environment, whereas the Tiger Zone is hosted by shallow water dolomitized limestone. The mineralogy, chemistry and geological setting of the Osiris Showing are more characteristic of Carlin-style mineralization than Tiger Zone. Realgar and orpiment with calcite flooding are common attributes of areas peripheral to, or above, certain gold deposits of the Carlin type.

4. PREVIOUS WORK

Figure 7 shows an image of the regional TMI magnetics. The Central and NW blocks are located within a large area of more complex magnetics, while the SE block lies in a relatively “quiet” area, on the southeast flank of a broad magnetic high.

Figure 8 shows the regional gravity, with the stations marked. The station spacing is too wide to delineate prospect scale features. A broad gravity high loosely correlates with the complex magnetic feature covering the Central and NW blocks, suggesting that more mafic rocks may underlie this area. The SE block is located within a gravity low. A more localized gravity high correlates with the magnetic high northwest of the SE block, but this is defined by a single reading and consequently its size is questionable.

A VTEM airborne EM and magnetic survey was flown for Archer, Cathro and Associates Ltd. between August 2007-September 2008, over an area similar to the ZTEM Central block (the flying was interrupted several times by bad weather). Figure 9 compares the survey boundaries of these surveys. The VTEM survey data was interpreted by Condor (Irvine, 2009).

The VTEM survey defined relatively subtle conductive zones correlating with the Tiger zone and other Au prospects to the northwest. Comparison of the VTEM and ZTEM data is discussed later in this report.

Exploration to date has been concentrated on the Tiger zone in the Central block (Figure 10) and extensions along strike to the northwest. In early 2010 gravity surveys were carried out over the Grid2 (Tiger), ZTEM, Puma and El zone grids and an IP survey was carried out over the El zone (these grids are shown in Figure 10). Correlation of the gravity and IP with the ZTEM results is discussed later in this report.

5. PRODUCTS, PROCESSING AND ANALYSIS TECHNIQUES

ZTEM

Geotech Products

Geotech delivered grids and maps produced from the ZTEM data for each of the three blocks. An explanation of these products is included in their report (Milicevic, B., Legault, J. and Smith, G., 2010). For convenience, their description of Total Divergence and Phase Rotation is included in Appendix B.

The 720Hz data is typically somewhat noisy and less reliable than the lower frequencies.

The ZTEM receiver measures the vertical (Z) component, which is normalized by the horizontal components (X and Y) at the ground base station. X is component in the along-line direction while Y is the component in the across-line direction. In this report, the terminology Z/X and Tzx are equivalent, as are Z/Y and Tzy. In parts of this report, Z/X and Z/Y are abbreviated to X and Y components.

GRIDS (for each frequency 30, 45, 90, 180, 360 and 720Hz):
Z/X In-Phase Component Phase Rotated
Z/X Quadrature component Phase Rotated
Z/Y In-Phase Component Phase Rotated
Z/Y Quadrature component Phase Rotated
Total Divergence grid from In-phase components
Total Divergence grid from Quadrature components
Total Phase Rotated grid from In-phase components
Total Phase Rotated grid from Quadrature components

MAPS @1:20 000 scale in Geosoft MAP format, as follows:
Total Magnetic Intensity (TMI)
Digital Elevation model (DEM)
3D View of In-Phase Total Phase Rotated Grids versus Skin Depth
30Hz Z/X Component In-Phase Phase Rotated
90Hz Z/X Component In-Phase Phase Rotated
360Hz Z/X Component In-Phase Phase Rotated
30Hz In-Phase Total Phase Rotated Grid
90Hz In-Phase Total Phase Rotated Grid
360Hz In-Phase Total Phase Rotated Grid

30Hz Quadrature Total Phase Rotated Grid
90Hz Quadrature Total Phase Rotated Grid
360Hz Quadrature Total Phase Rotated Grid
Z/X (In-line) In-Phase Profiles over 90Hz Phase Rotated In-Phase Grid
Z/X (In-line) Quadrature Profiles over a 90Hz Phase Rotated Quadrature Grid.
Z/Y (Cross-line) In-Phase Profiles over 90Hz Phase Rotated In-Phase Grid
Z/Y (Cross-line) Quadrature Profiles over a 90Hz Phase Rotated Quadrature Grid.

Geotech provides what might be considered an excessive number of grids for the ZTEM survey, likely due to the relative newness of the technique and the lack of controlled case studies to define the likely geological significance of the various grids. Condor has been working on a number of ZTEM case studies to assist in the general better understanding of the technique; these are provided in Appendix A.

The Z/X grids are generated using the Tzx (along line) component and are thus more sensitive to conductive and resistive features generally perpendicular to the flight lines. The Z/Y grids are generated using the Tzy (across line) component and thus are more sensitive to features parallel to the flight lines. The Total Divergence (DT) and Total Phase Rotated (TPR) grids use both components and consequently provide less strike-sensitive maps.

For an individual survey, it is useful to examine the correlation of the various grids with the known geology and empirically the one which best defines the lithologies and structures. For the Central block, the Z/X In-Phase Component Phase Rotated grid for 180Hz best defines the Tiger mineralized zone and its extension through Puma to the northwest, so interpretation has been based principally on this grid. (This grid has the file name XIP_180Hz_PR). In the Southeast block a small area surrounding the newly-discovered Osiris zone has geological mapping, but no mapping covering the Northwest block was available to the author. In view of its application in the Central block, the Z/X In-Phase Component Phase Rotated grid for 180Hz was also used for interpretation in the other two blocks, but since the geology, alteration and style of mineralization is likely different other grids were also used.

Geotech ran 2D inversions on a limited data set in the Central block - two lines over Puma (4050 and 4070) and two lines over El (6680 and 6690). Details of their software and the conductivity depth sections generated from these inversions are contained in their report (Milicevic et al, 2010).

Condor Processing

2D Inversions

Condor carried out 2D Occam inversions of every line of the ZTEM data to produce conductivity depth sections, using open source code (deGroot-Hedlin and Constable, 1990; Wannamaker at al., 1987; deLugao and Wannamaker, 1996), modified for ZTEM data. These inversions use only the Tzx (along-line) component and thus are most sensitive to across-line conductivity variations. Details are contained in Appendix B.

Apparent Resistivity Maps

Apparent conductivity maps were produced for each frequency, using the method of Becken and Pedersen (2003). This product uses both the Tzx and Tzy components and thus maps both across-line and along-line conductivity variations. The higher frequencies map shallow conductivity variations while the lower frequencies respond more to deeper features.

Karous-Hjelt Filter

This filter facilitates data interpretation by turning cross-overs into peaks and troughs. Grids and pseudosections were derived from the Tzx inphase response.

MAGNETICS AND GRAVITY

In addition to the normal filters available in the Geosoft application, additional processing was done on the ZTEM magnetic data using the encompass[1] software and algorithms described by Shi and Butt (2004) – this paper is included in Appendix G (DVD). These enhancements are termed ZS filters. A variety of enhancements were produced, but one is deemed to be particularly useful in the present study, termed Tilt (Verduzco et al, 2004). This grid is provided as one of the TargetMaps (see Section 10).

UBC MAG3D and GRAV3D Inversion

The University of British Columbia (UBC) 3D magnetic data inversion program MAG3DINV, version 4.0, was used to invert the ZTEM magnetic data to a voxel model (Li and Oldenburg, 1996). The similar program GRAV3D (Li and Oldenburg, 1998) was used to invert gravity data acquired in early 2010 on four grids shown in Figure 8. More information on these programs is included in Appendix C.

[1] encompass is the product of Pitney Bowes Business Insight.

INDUCED POLARIZATION

The IP data acquired in early 2010 on the El grid (Aurora Geosciences, 2010) was inverted by Condor using UBC DCIP2D software (Oldenburg and Li, 1994). A description on this software is included in Appendix D.

ANALYSIS TECHNIQUES AND ISSUES

Target Zones

The ZTEM system operates quite differently than traditional airborne EM systems such as VTEM. Condor has provided a short note on these differences in Appendix A.

In this survey Target Zones (TZs) are deemed to be conductive zones and have been prioritized based on their relative conductivity, together with their magnetic association and any other available geoscience data.

6. CENTRAL BLOCK INTERPRETATION

Several grids derived from the ZTEM data are shown in Figure 11 to facilitate comparisons. The images are:

(a) DEM
(b) XIP 180Hz PR
(c) IP 180Hz TPR
(d) YIP 180Hz PR
(e) IP 180Hz DT (reversed color palate)
(f) 180Hz Apparent Conductivity (Condor)

The “warm” colors represent conductors and the “cool” colors represent resistors. The color palate for the IP 180Hz DT image has been reversed to be compatible with this convention.

Significant differences are observed between the XIP_180Hz_PR and YIP_180Hz_PR grids, indicating that the strike direction of the geology is variable and not simply east-west (perpendicular to the flight lines). The IP_180Hz_TPR and 180Hz_Apparent_Conductivity grids, which are generated using both the Tzx and Tzy (along and across line) components, provide a better representation of the overall distribution of conductors in this block. The DT (Total Divergence) grid provides a (somewhat noisy) picture of conductor axes.

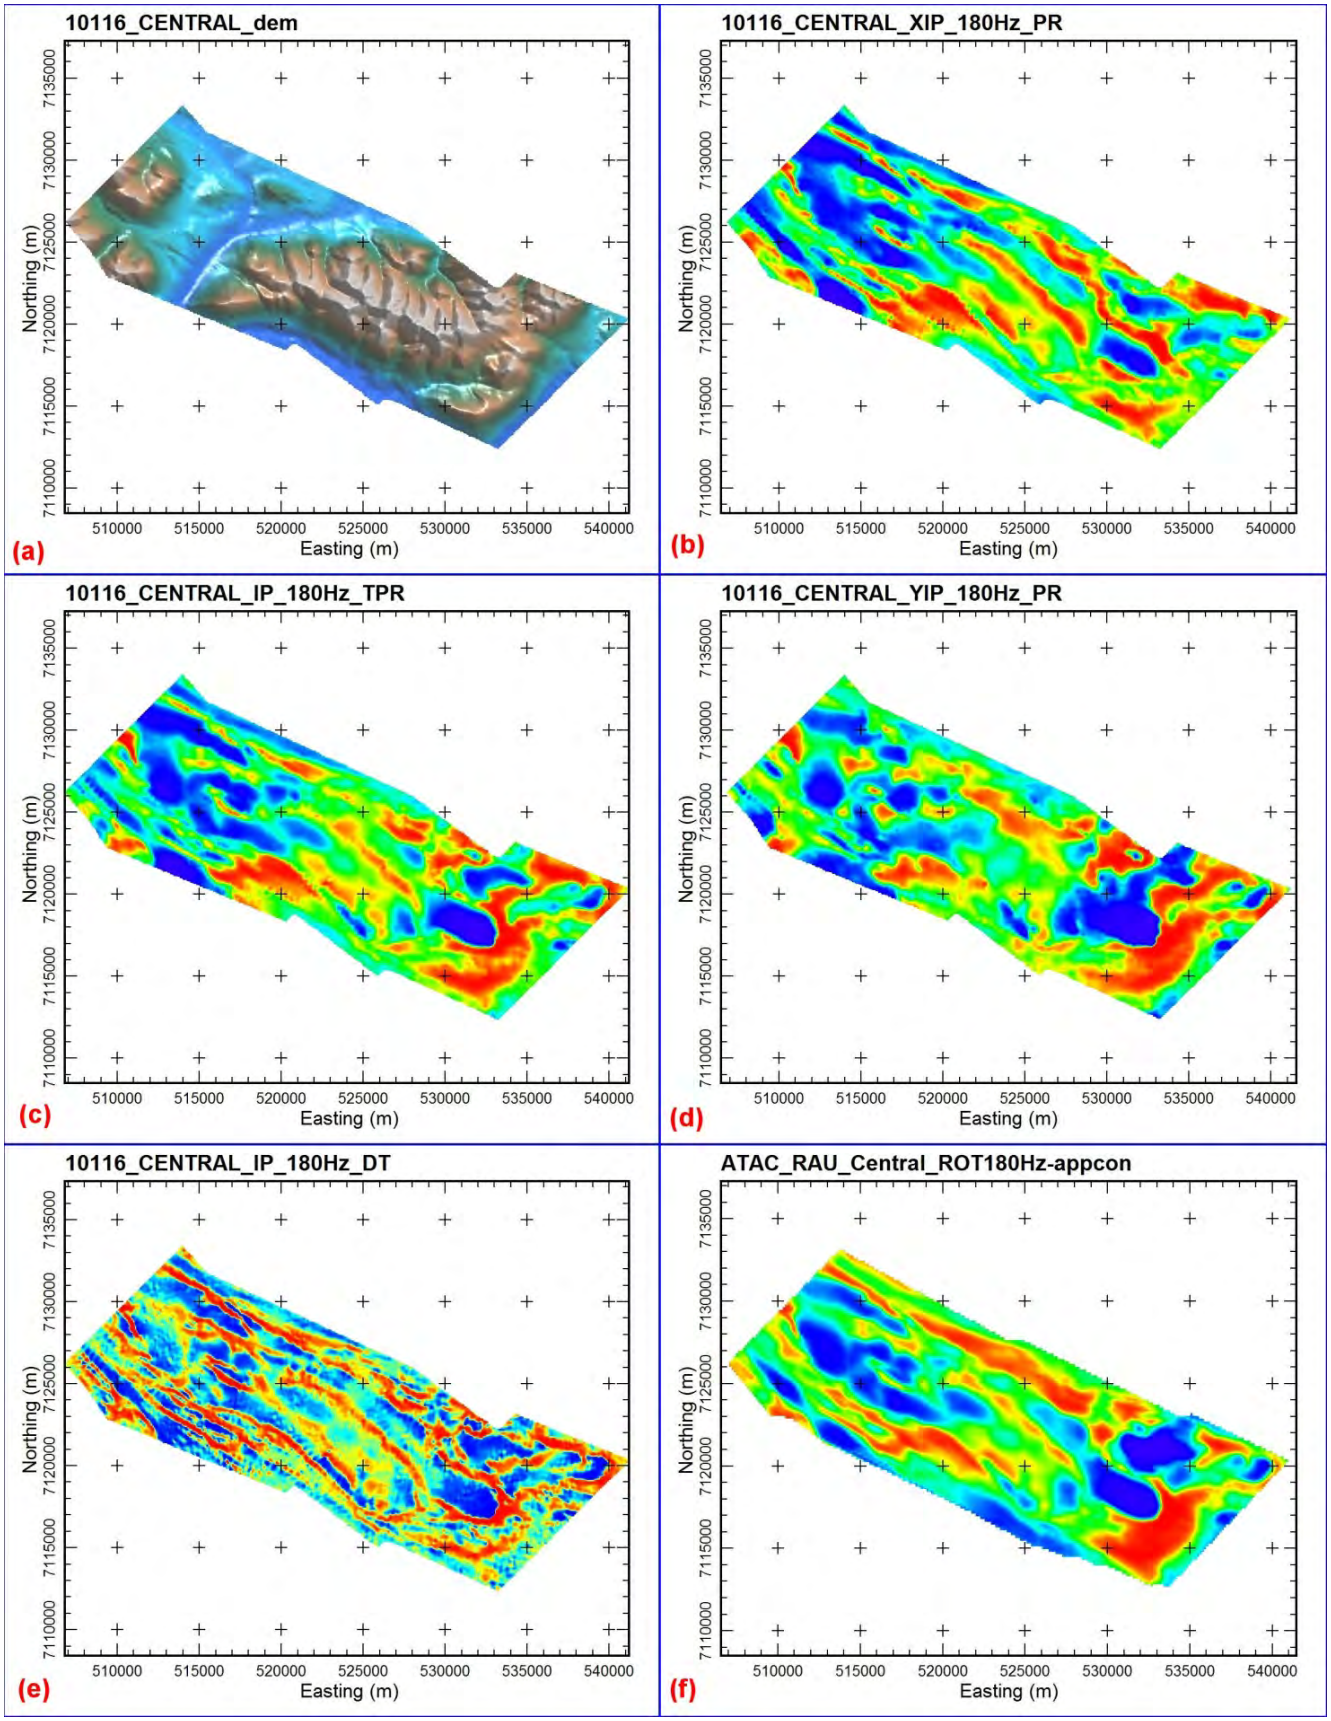

Figure 11: Central block – comparison of grids derived from ZTEM data (see text for details).

Figure 12 shows the Tilt magnetic image from the ZTEM survey, together with the axes of magnetic trends, interpreted faults and the extent of the magnetic unit apparently associated with mineralization. The latter was defined using the VTEM magnetics, which has better resolution than the ZTEM magnetics, as the average sensor height was significantly lower (80 m compared to 166 m). The same features are overlaid on the RTP image in Figure 13.

The favorable sedimentary package containing Tiger and the other mineralized zones has relatively subdued magnetic character. A linear, relatively narrow magnetic unit extends in almost unbroken fashion for approximately 22 km, from southeast of Tiger to beyond El. This unit trends in a NW-SE direction approximately 500 m northeast of Tiger. This suggests that Tiger, El and the prospects between (ZTEM and Puma grids) all lie within the same stratigraphic horizon. To the north and south of this unit the magnetic images show numerous magnetic lows which appear to be due to reversely magnetized intrusive and/or volcanics. These areas do not appear prospective for Au mineralization. Based on these observations, the block has been divided into Prospective and Non-Prospective areas (Figure 14).

Figure 15 shows the XIP 180Hz PR image, with conductor axes highlighted. This appears to be the best image and frequency for tracing conductors in this area. The Tiger mineralization lies at the southeastern end of a well-defined conductor trend approximately 10.0 km long, which extends northwest through the Puma zone. There is a gap of 2.5 km and then another, weaker, conductor trend extends through the El zone. Many other conductor trends have been defined on this image.

The complete interpretation of the magnetic and ZTEM is shown in Figure 16. As this is a crowded figure, the TZs have been isolated in Figure 17.

The TZs are defined as ZTEM conductors which lie within the Prospective sedimentary areas shown in Figure 14. They are labeled A-H, with A-E being 1st Priority and F-H being 2nd Priority (based on the strength of the conductor).

- TZ A is a long conductor encompassing Tiger at the SE end, as well as the ZTEM and Puma gravity grids.
- TZ B contains the El grid.
- TZ C is a relatively long and open to the NW) conductor in the far north of the block, which has no direct magnetic expression. It lies on the opposite side of the magnetic unit associated with mineralization compared to El, but possibly in a similar stratigraphic position if the latter unit has been folded.

- TZ D is a relatively strong conductor in the far west of the Block (and open to the west), that has no obvious magnetic signature.
- TZ E lies southeast of Tiger and appears to lie in a similar stratigraphic position.
- TZ F is located 1 500 m ESE of the El grid in a similar stratigraphic position.
- TZ G comprises possibly two weaker conductors on the western side of El grid and represents possible continuations of the mineralization.
- TZ H is a reasonable conductor located approximately 3 000 m southwest of Puma grid, but still within the Prospective area.

The ZTEM conductors do not appear to significantly correlate with terrain clearance or with the topography. Figure 18 shows the conductor axes superimposed on the DEM image. The conductors shown in the XIP 180Hz PR image in Figure 15 also do not show any significant correlation with topography.

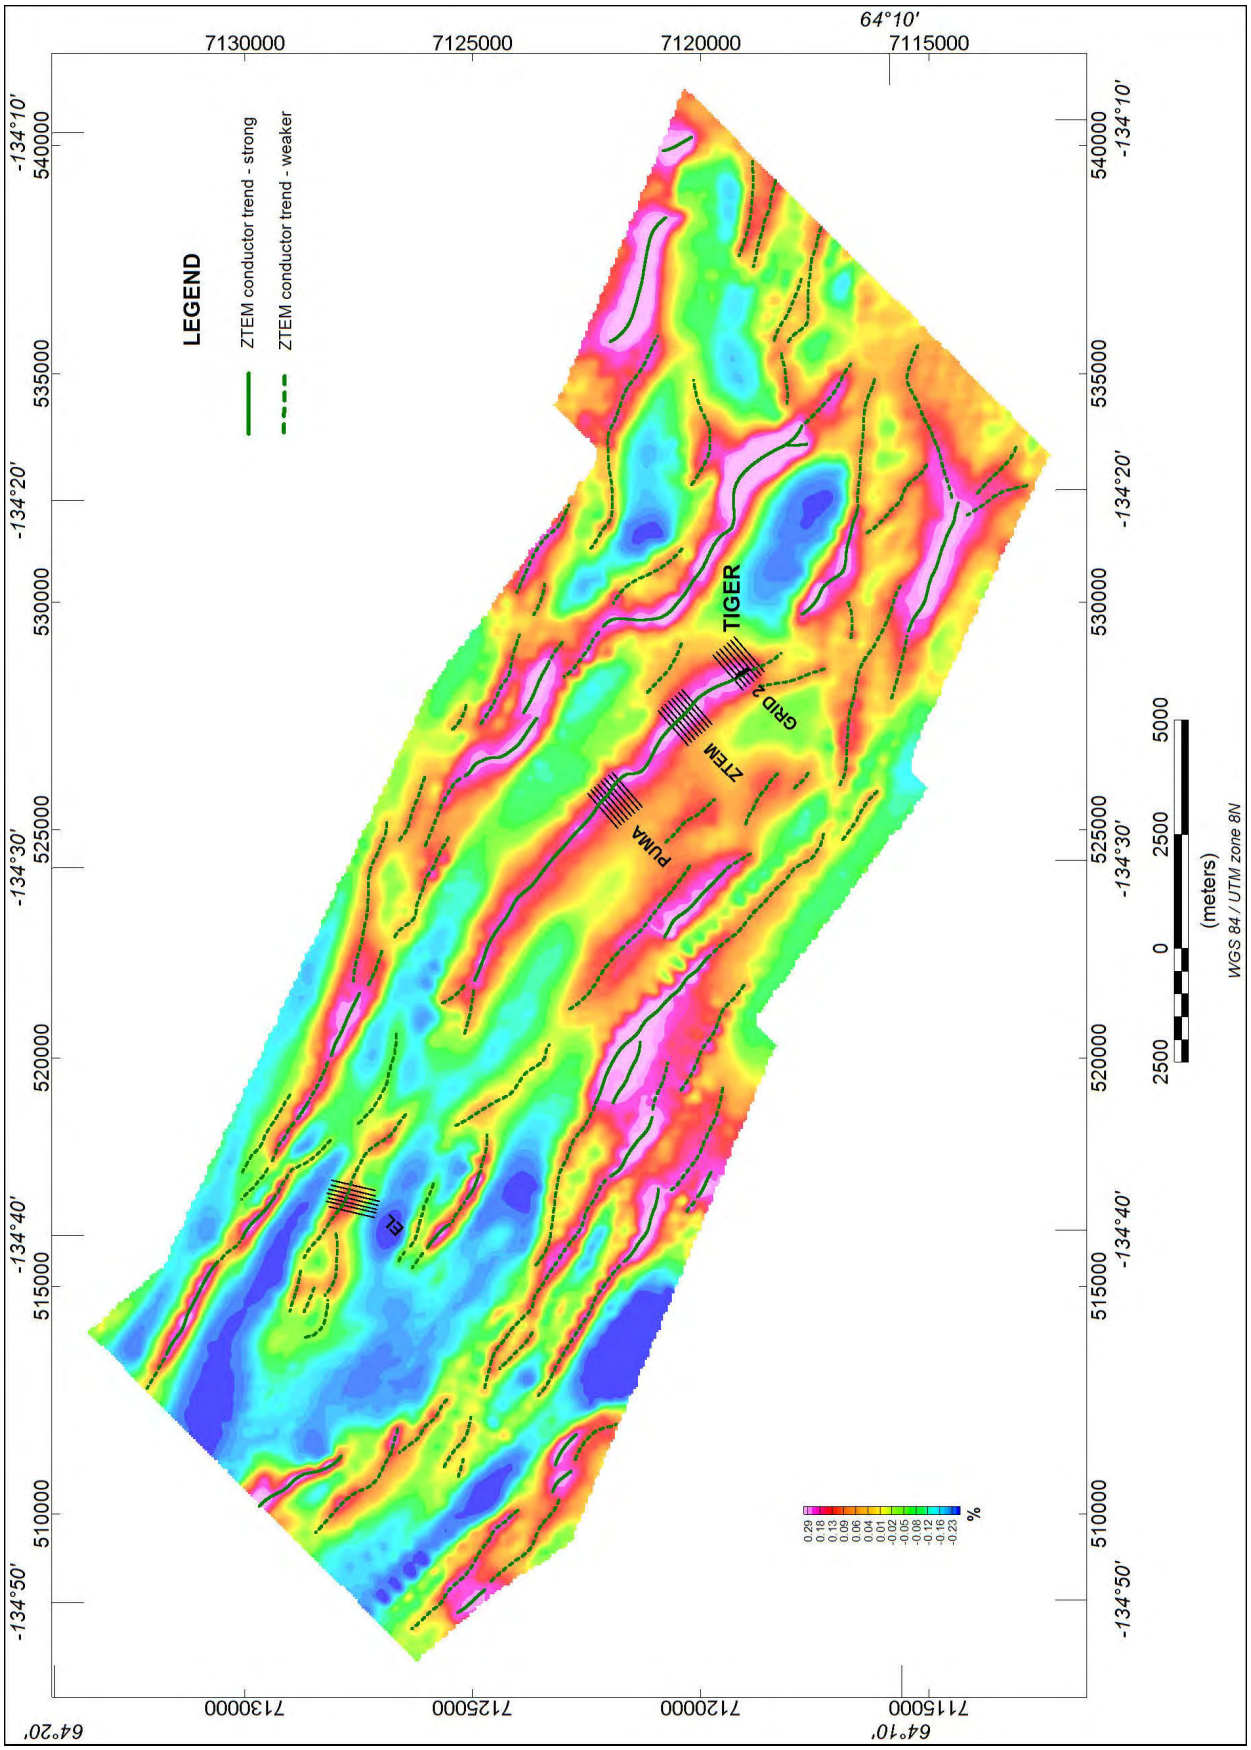

Figure 15: Central block – Conductor trends on XIP 180Hz PR image.

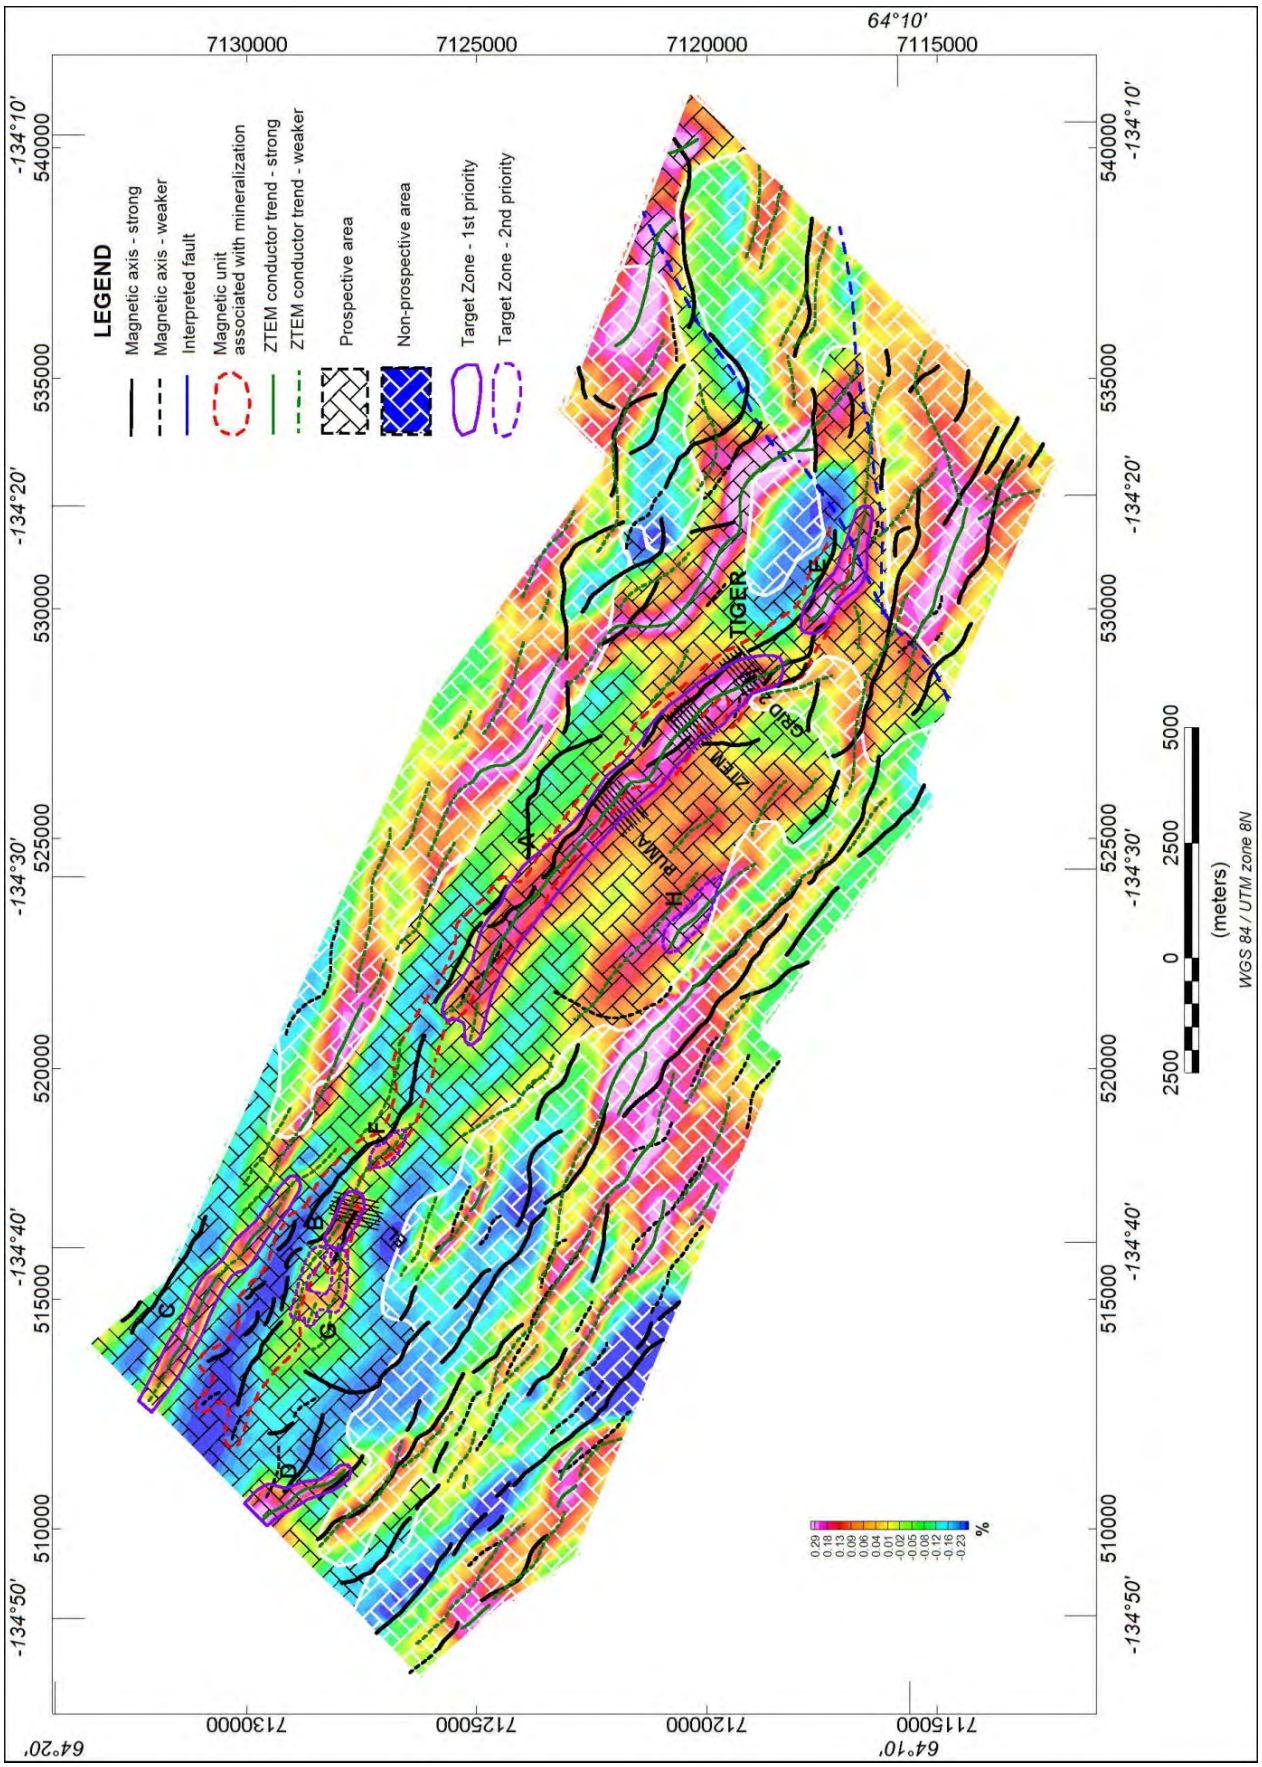

Figure 16: Central block – Complete interpretation XIP 180Hz PR image.

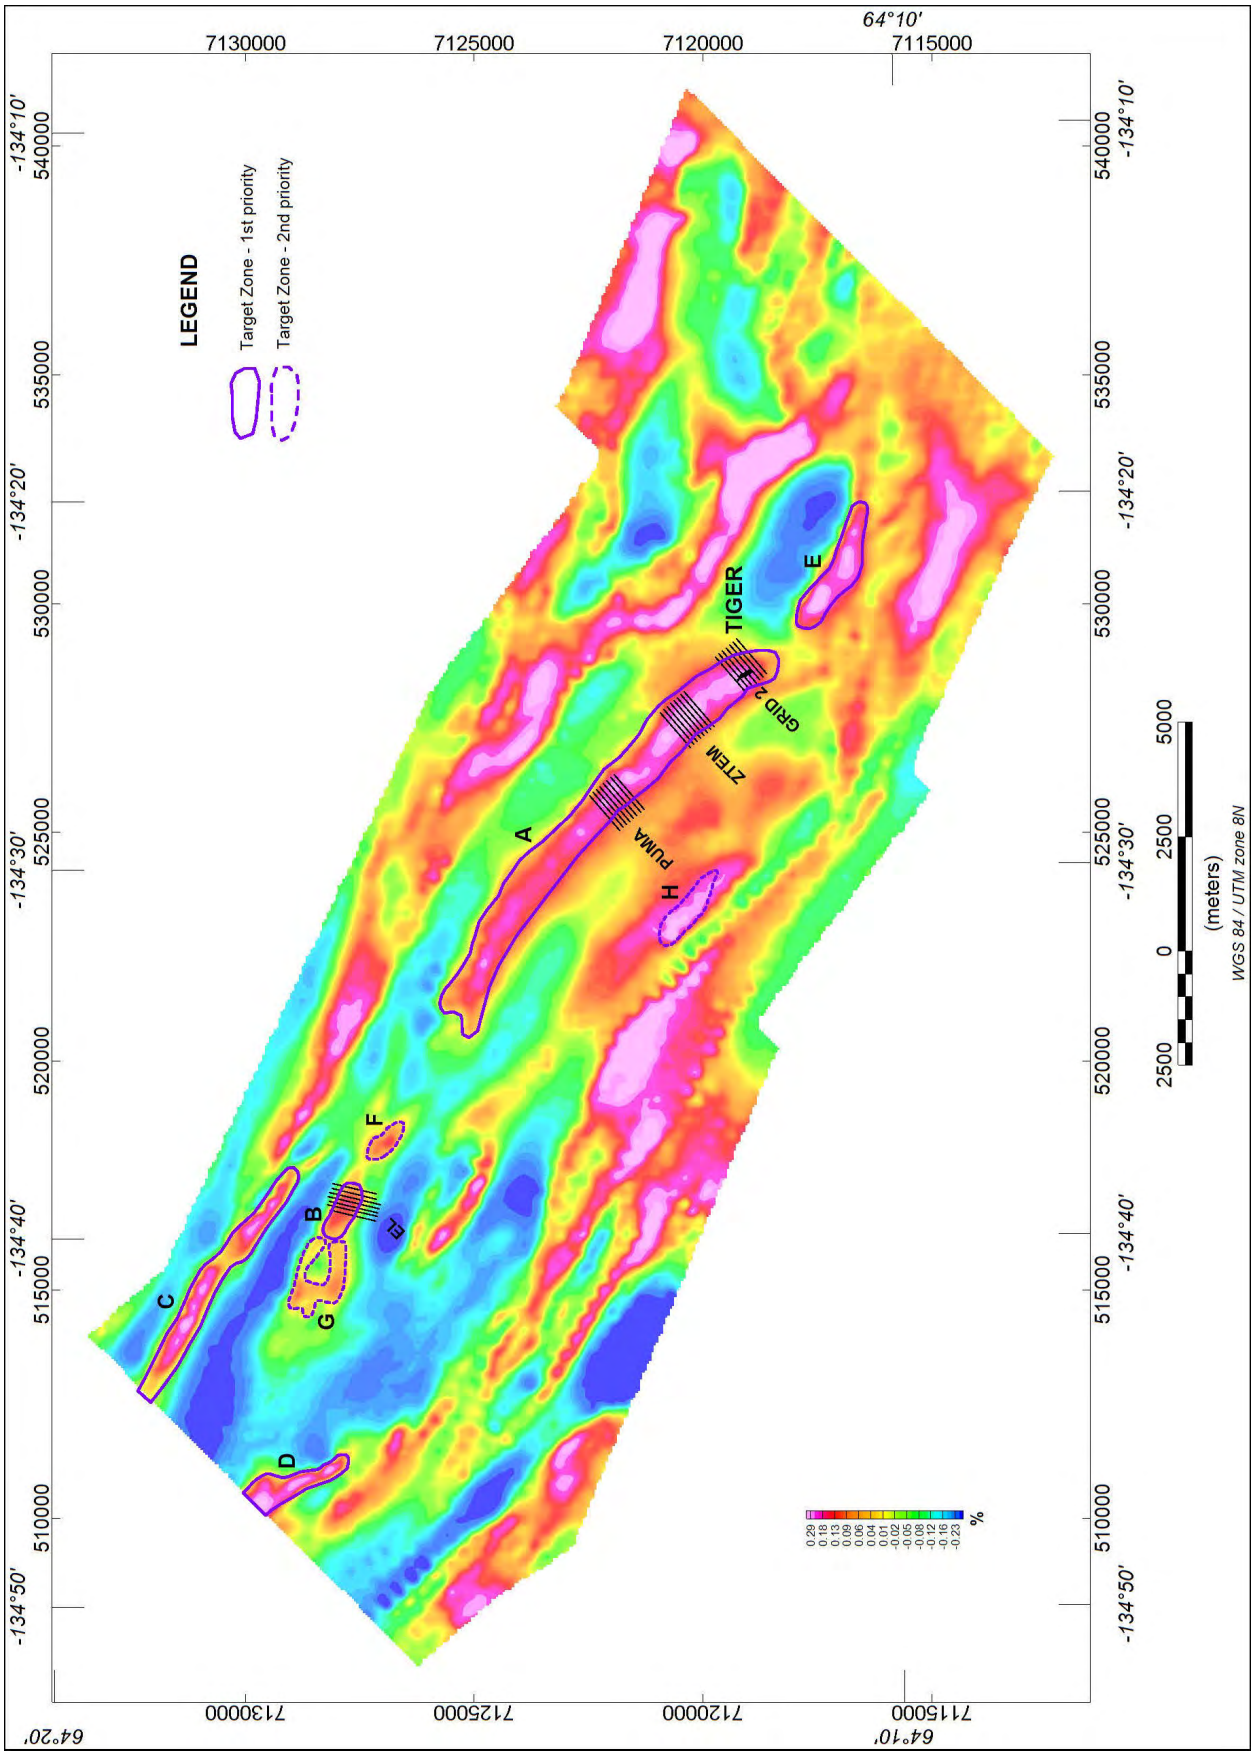

Figure 17: Central block – Target Zones on XIP 180Hz PR image.

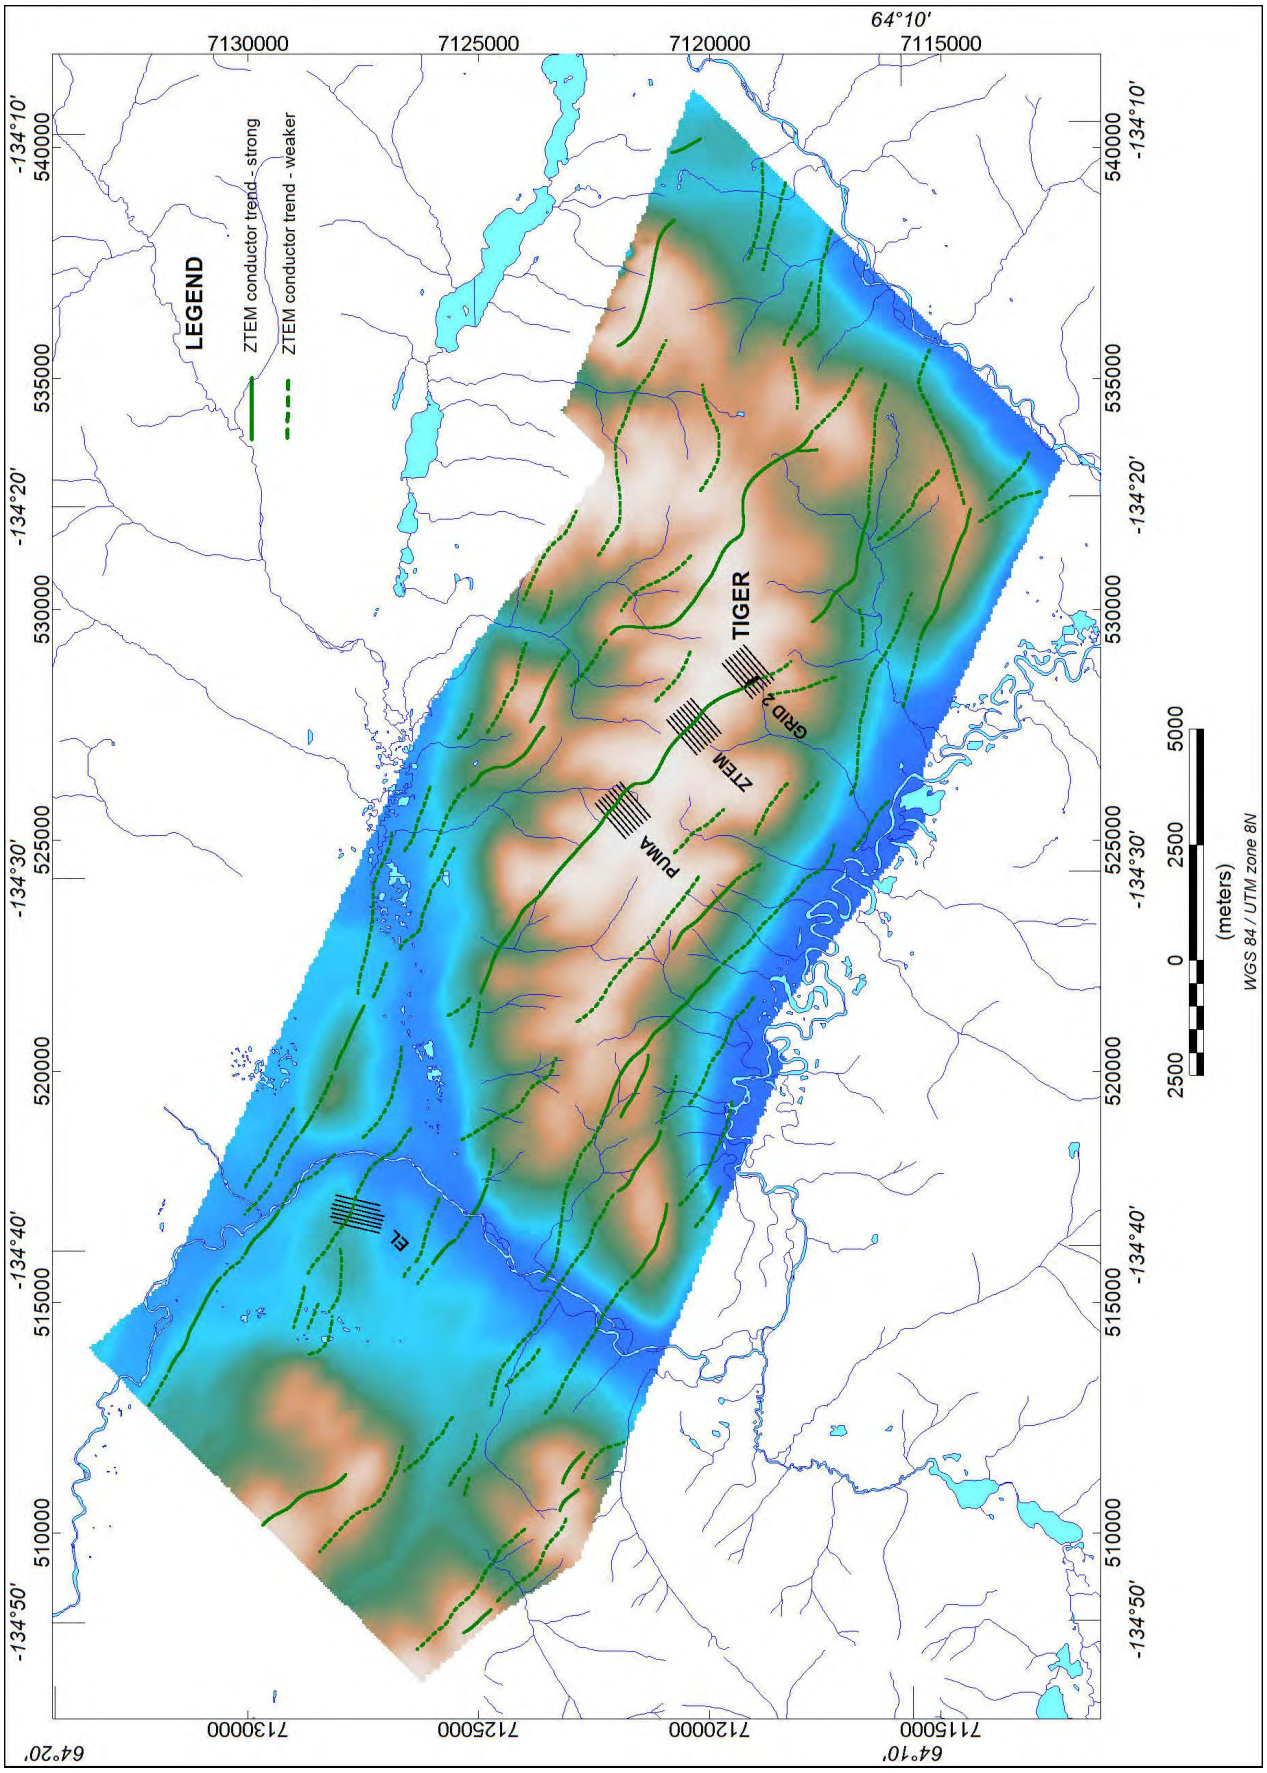

Figure 18: Central block – Conductor trends on DEM image.

7. SE BLOCK INTERPRETATION

To facilitate comparisons, several grids derived from the ZTEM data are shown in Figure 19. The images are:

(a) DEM
(b) XIP 180Hz PR
(c) IP 180Hz TPR
(d) YIP 180Hz PR
(e) IP 180Hz DT (reversed color palate)
(f) 180Hz Apparent Conductivity (Condor)

Differences are observed between the XIP_180Hz_PR and YIP_180Hz_PR grids, indicating that the strike direction of the geology is variable and not simply east-west (perpendicular to the flight lines). The IP_180Hz_TPR and 180Hz_Apparent_Conductivity grids, which are generated using both the Tzx and Tzy (along and across line) components, provide a better representation of the distribution of conductors in this block and indicate that the general strike direction is WNW-ESE. The DT grid provides a (somewhat noisy) picture of conductor axes.

The RTP magnetic image (Figure 20) shows a major, east-west trending magnetic boundary which extends across the entire block, with more magnetic rocks to the north and less magnetic to the south. The Tilt image (Figure 21) shows a variation in magnetic trends – there is a lack of dominant curvilinear features. In the western part of the block, the more obvious trends are WNW-ESE, but elsewhere the trend directions are more random, with one stronger E-W trend in the eastern part, just north of the major magnetic boundary. The Osiris area (outlined by a black rectangle) does not stand out on either of the magnetic images.

Conductor trends based on the XIP_180Hz_PR image are shown in Figure 22.

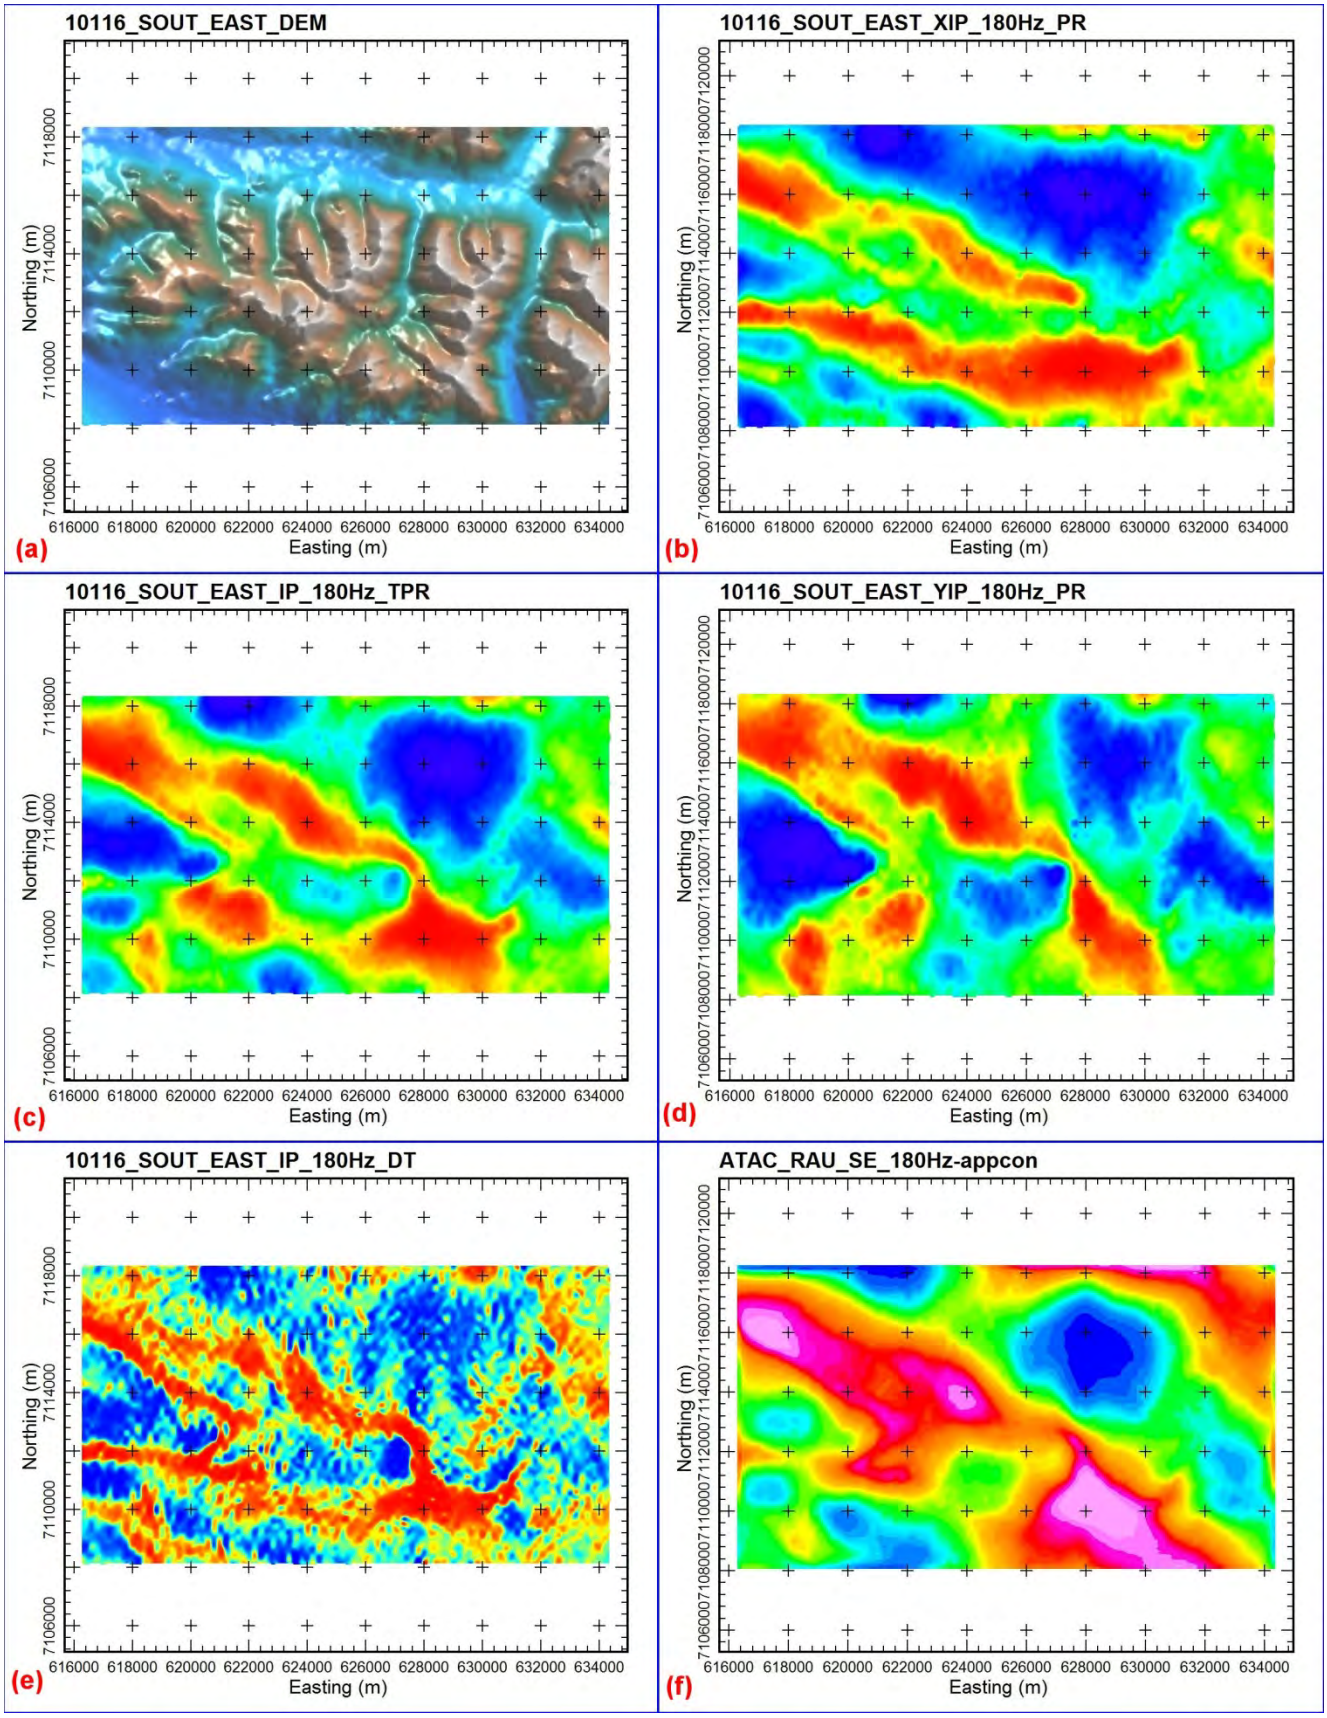

Figure 19: SE block – comparison of grids derived from ZTEM data (see text for details).

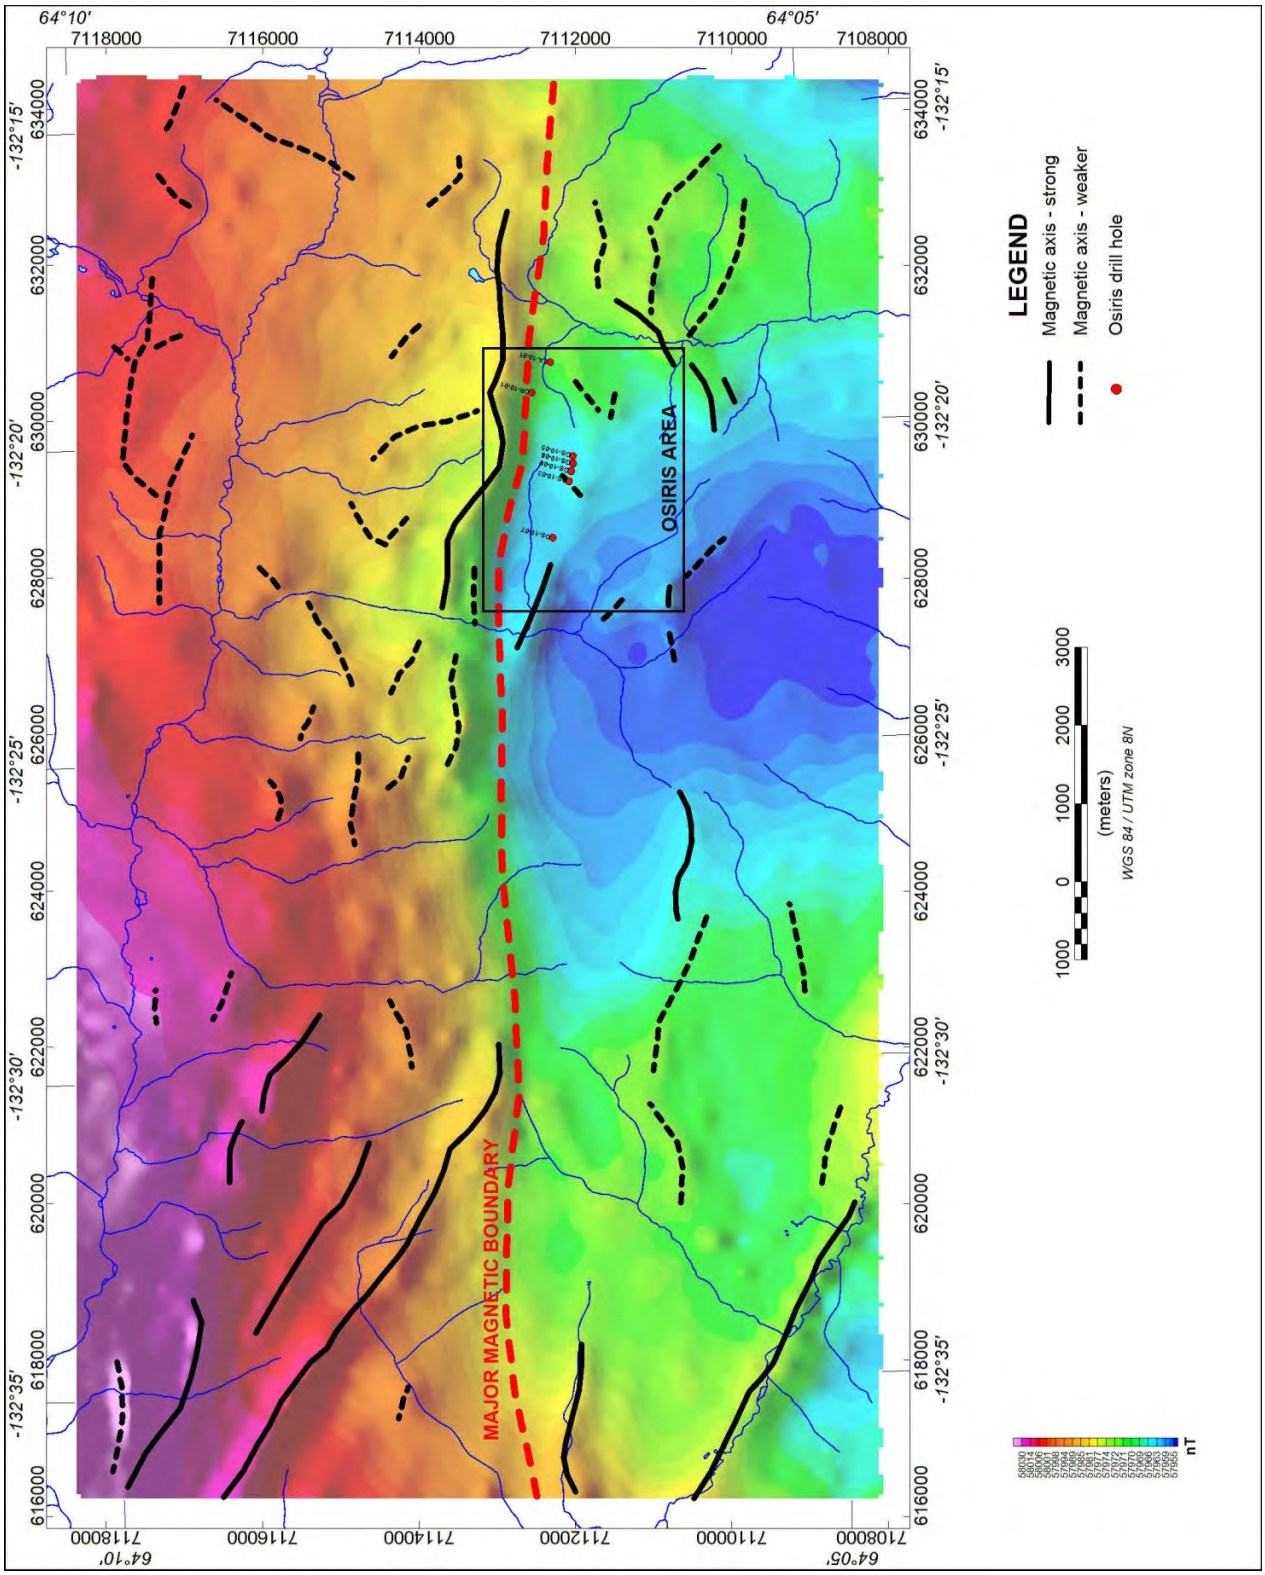

Figure 20: SE block – Magnetic interpretation on RTP image.

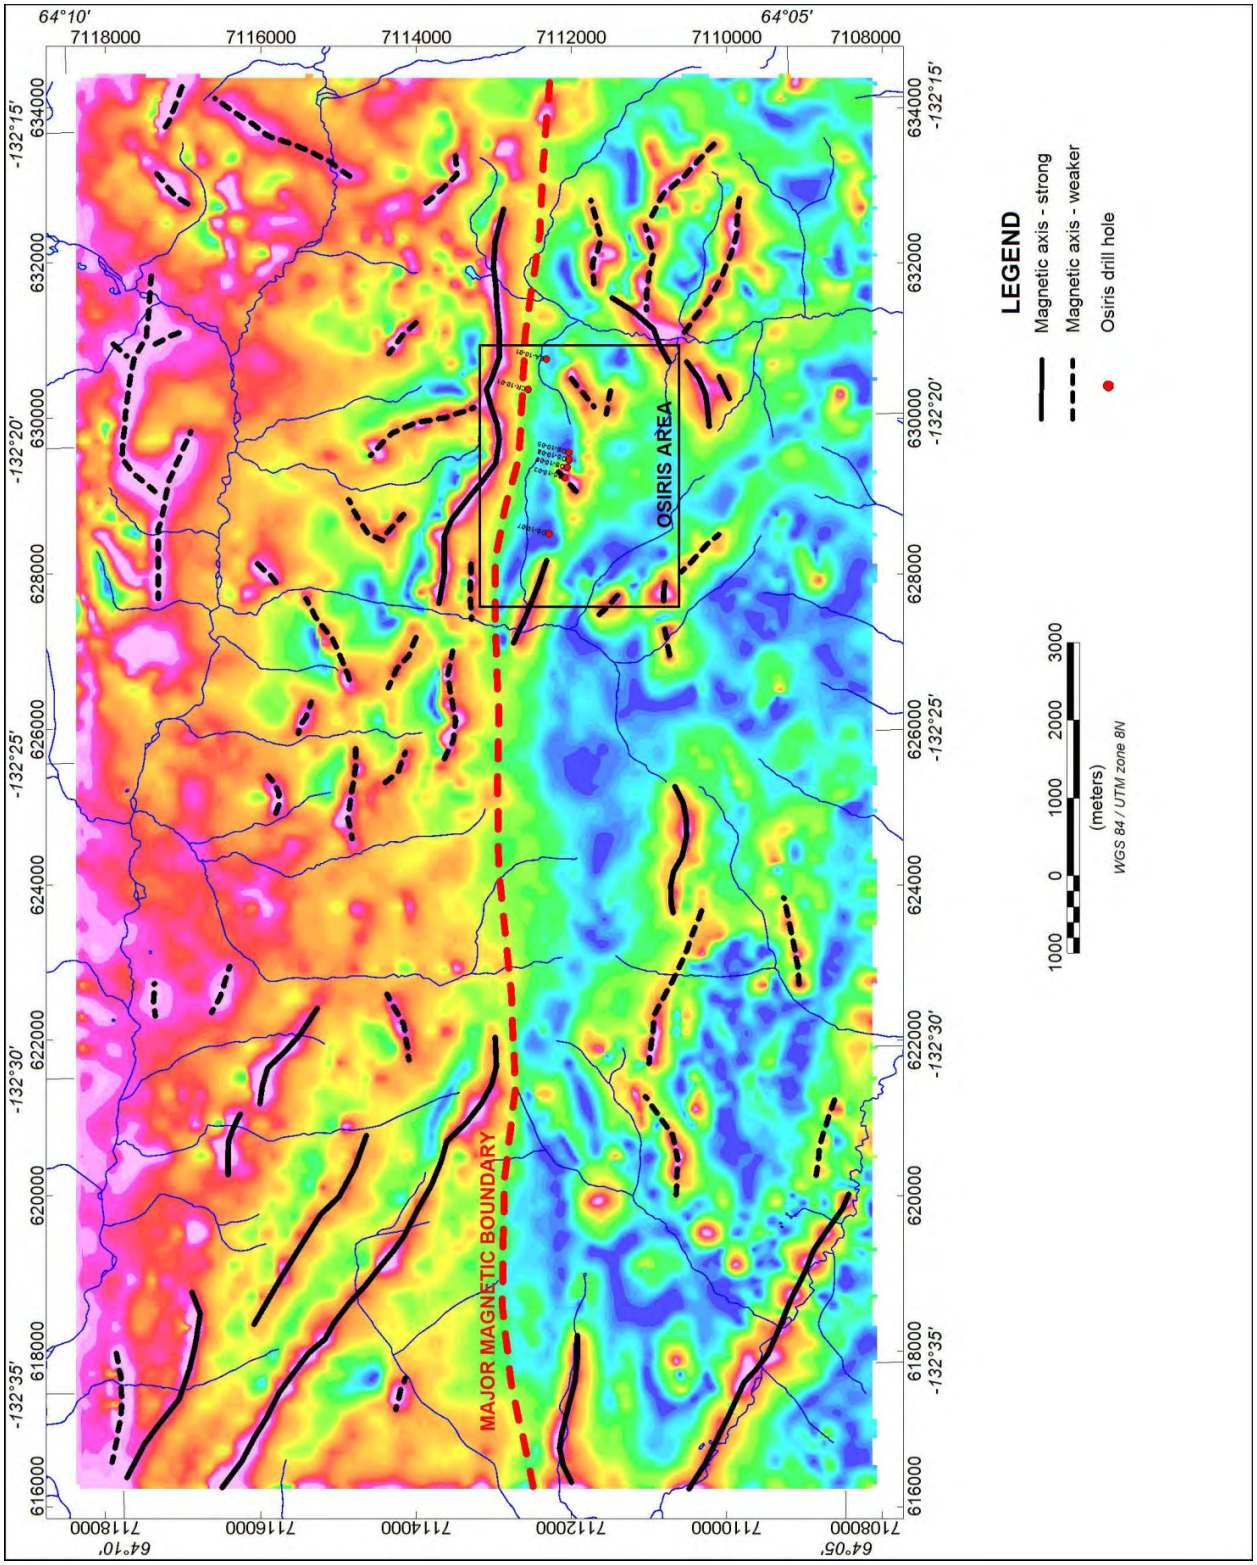

Figure 21: SE block – Magnetic interpretation on Tilt image.

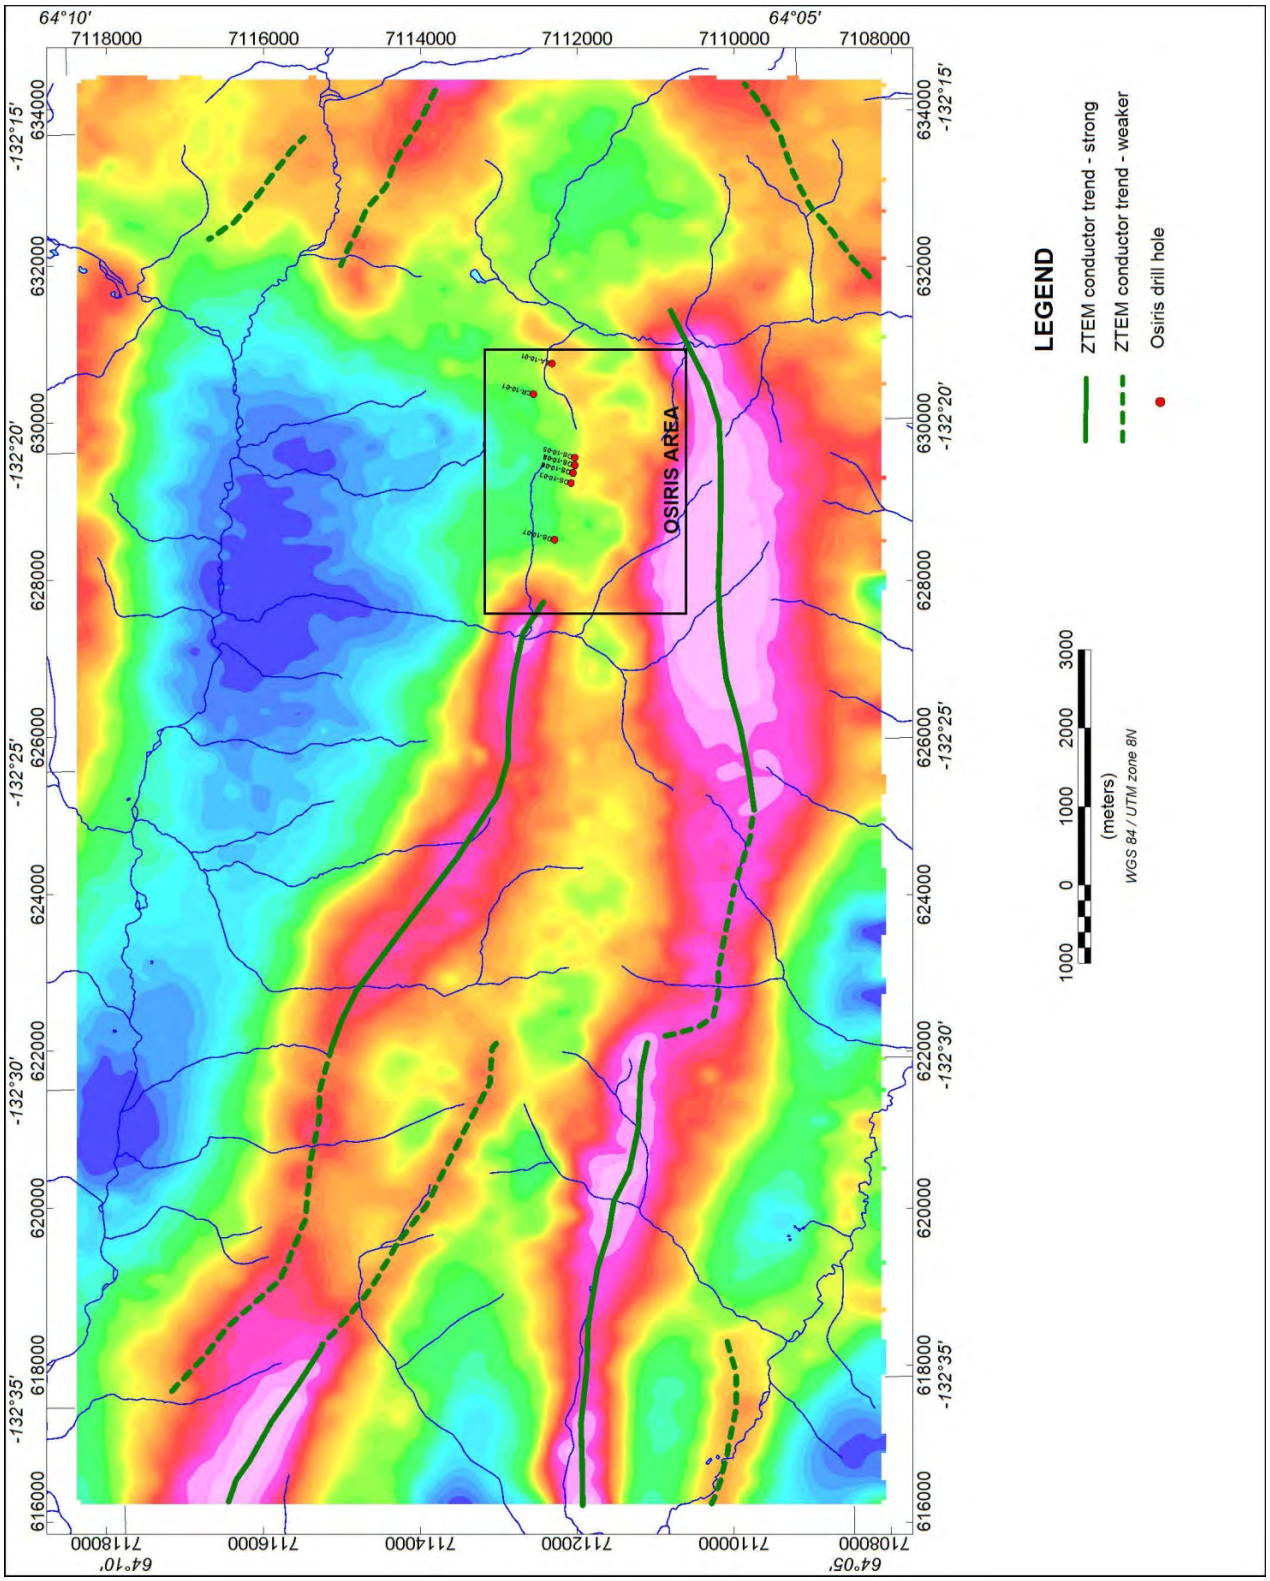

Figure 22: SE block – Conductor trends on XIP 180Hz PR image.

Three relatively strong conductive zones (1st priority) have been defined, labeled as TZ A, B and C, together with three relatively weaker zones (2nd priority) labeled as D, E and F (Figure 23).

- TZ A is relatively wide (up to 2 km), trends approximately E-W and lies south of the major magnetic boundary in less magnetic rocks. Several relatively weak magnetic axes lie within this TZ, but it does not have an obvious magnetic association.
- TZ B trends NW-SE (open to the west) and lies completely north of the major magnetic boundary. It correlates closely with a linear magnetic trend. Both the conductor and the magnetic trend appear to be truncated at the major magnetic boundary.
- TZ C is sub-parallel to TZ B, but has no obvious magnetic association, except at the extreme southeast end. It lies mostly north of the major magnetic boundary, but the southern part extends across this boundary, where the conductor is associated with the magnetic trend.
- TZ D is a weaker conductor located at the northern edge of the block and extending outside it, so it is not fully defined. It has no obvious magnetic signature.
- TZ E is a weaker conductor extending outside the eastern edge of the block, where it is stronger. It has no obvious magnetic signature.
- TZ F is a broad, diffuse, weakly conductive zone at the southeast corner of the block, with no obvious magnetic signature

Figure 24 shows the geophysical interpretation overlain on the DEM image. There is no obvious correlation of the TZ with the topography, other than the TZ mainly occupy the higher ground and none are located in the valleys.

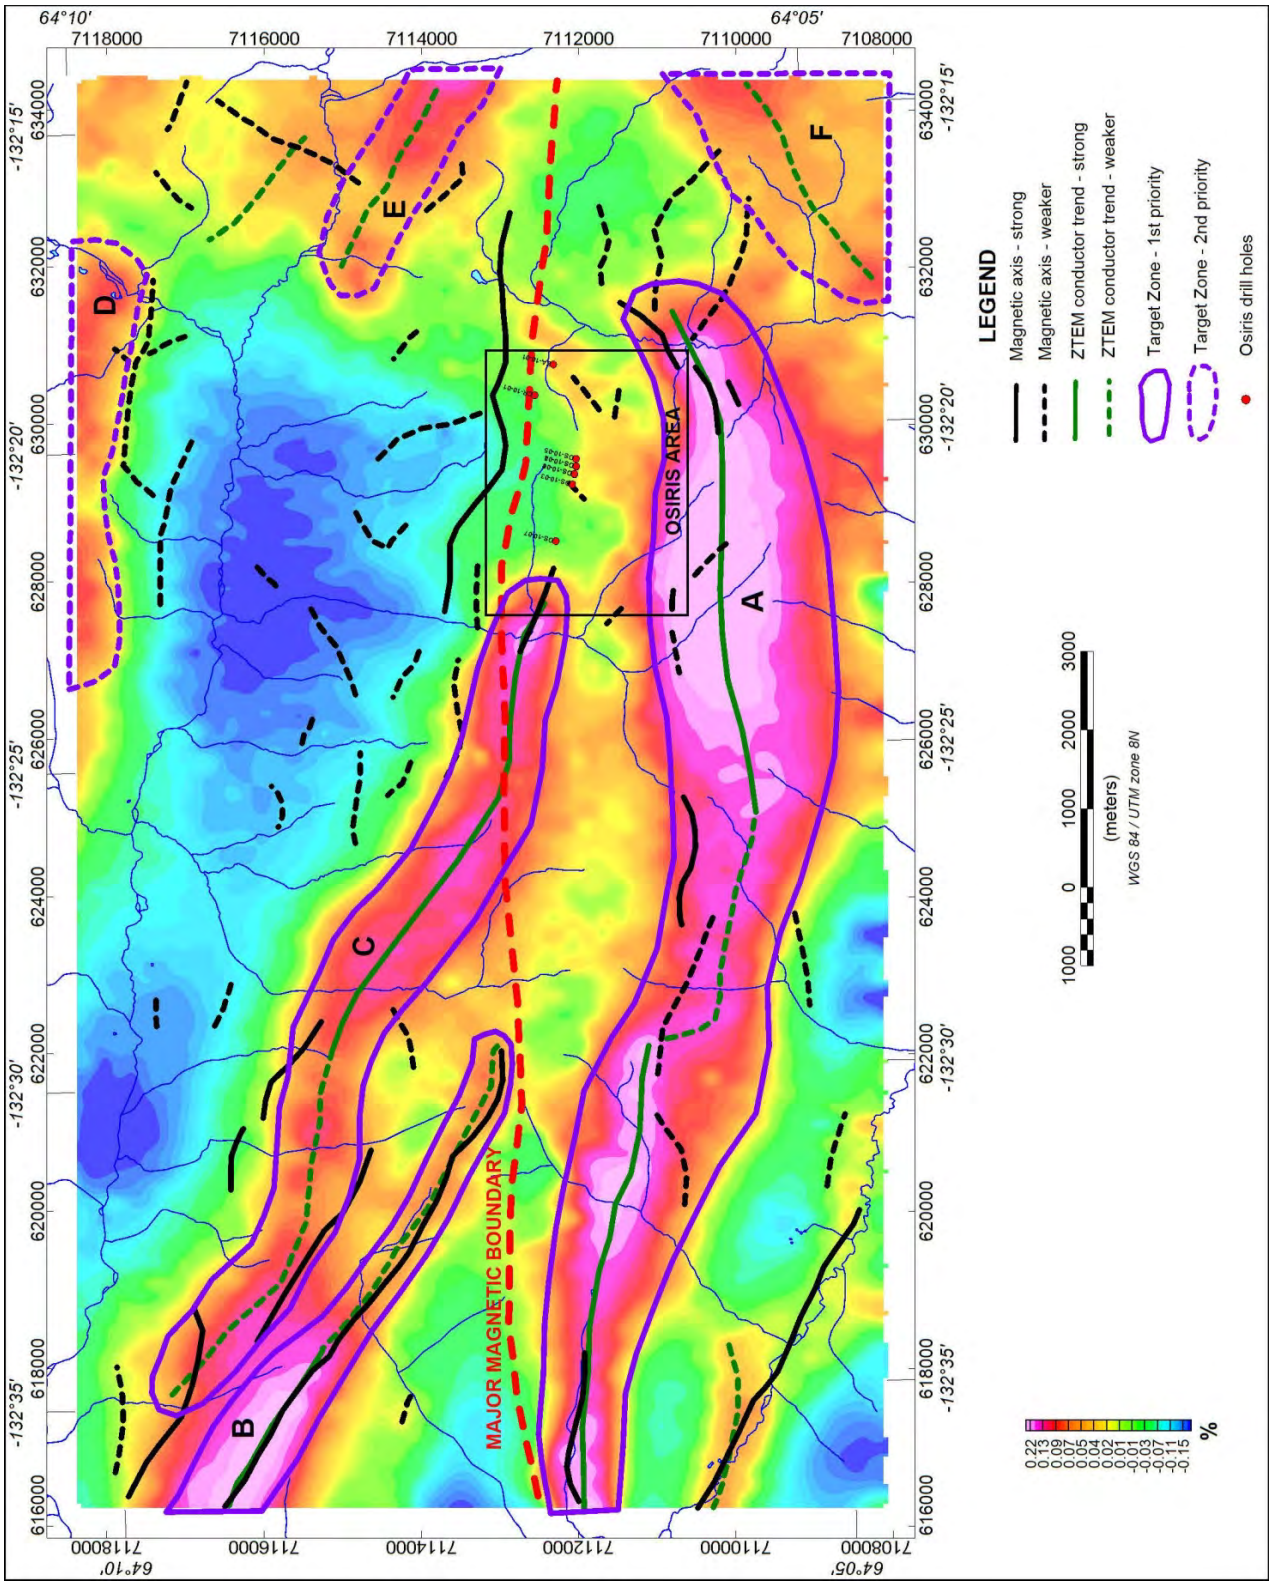

Figure 23: SE block – Interpretation and TZs on XIP 180Hz PR image.

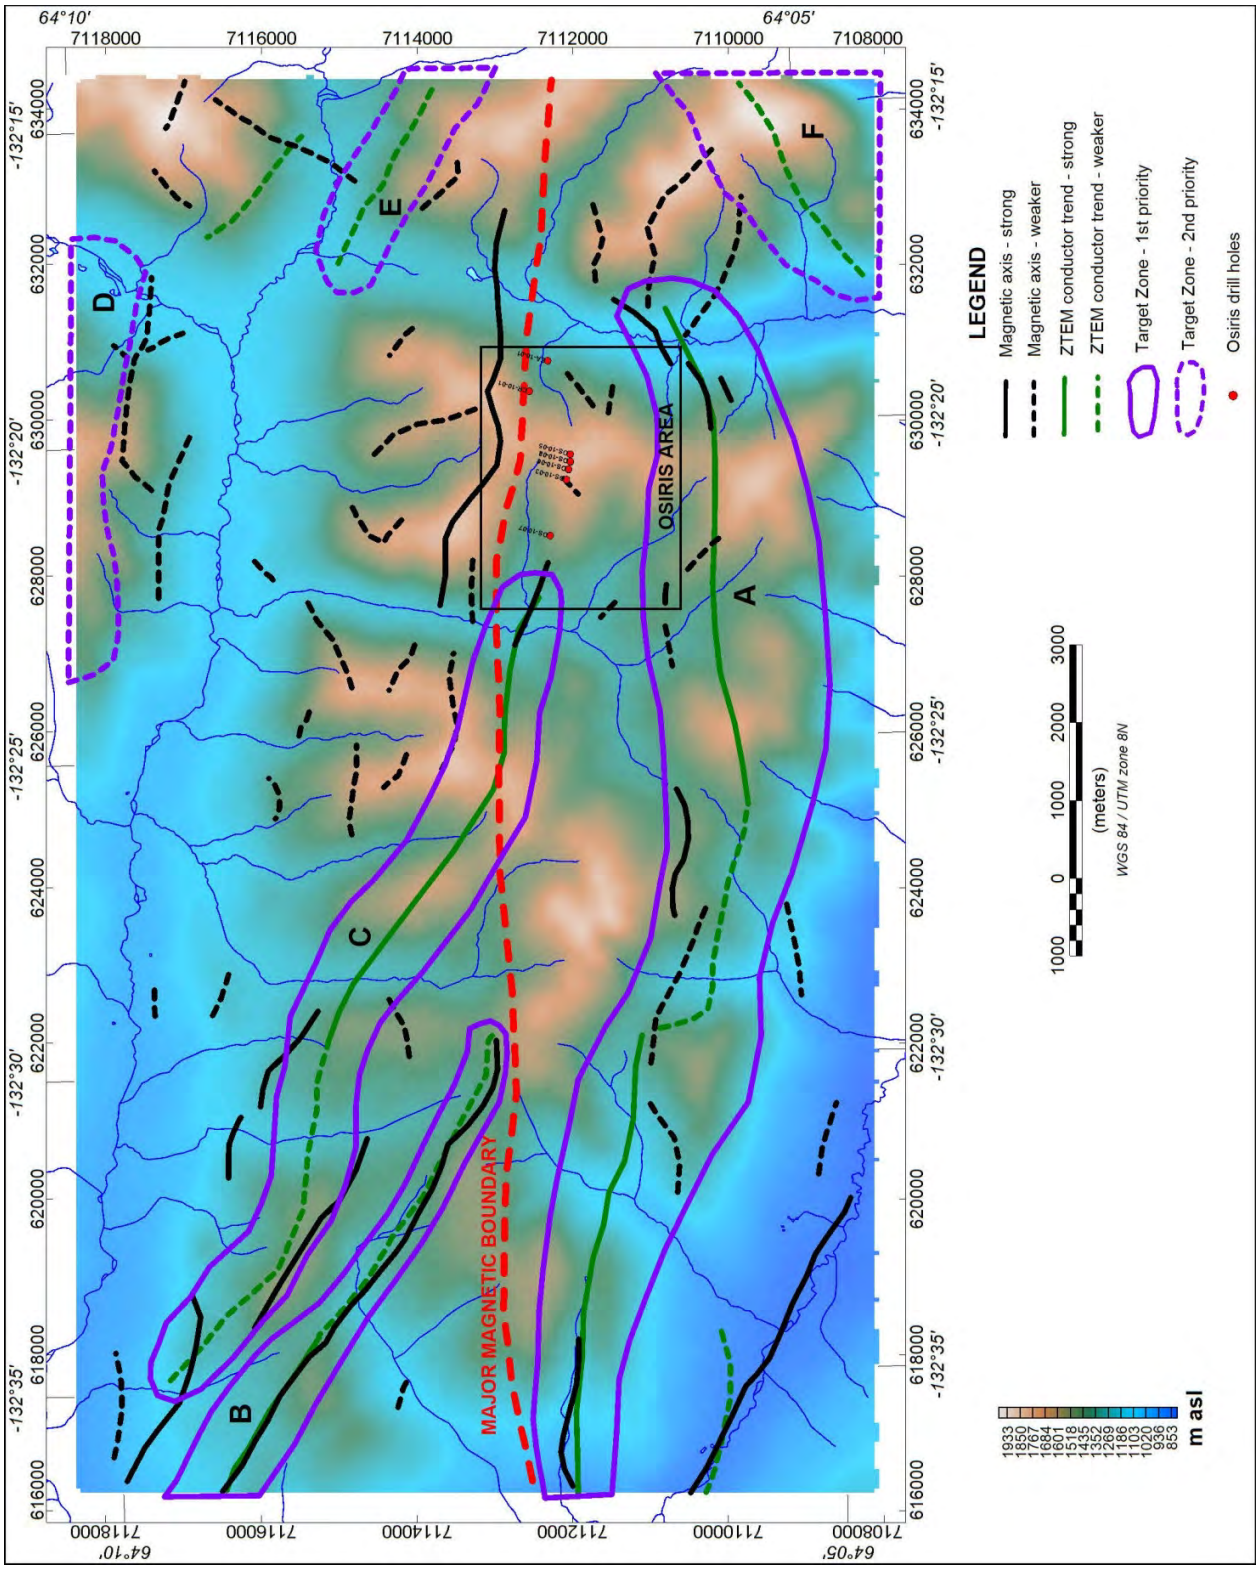

Figure 24: SE block – Magnetic interpretation and conductor trends on DEM image

OSIRIS AREA

The Osiris area is shown in Figures 20 to 24, along with the collar locations of nine holes drilled in mid-late-2010. Significant Au mineralization was delineated in these holes (ATAC news release Sept 15, 2010).

In the Central block, the XIP 180Hz PR image best mapped the mineralized zone at Tiger and the trend to the northwest though Puma and El (Figure 15). However, the comparable grid for the Southeast block (Figure 22) does not show any clear conductivity enhancement associated with the Osiris area. Other grid products were examined to determine if any of these better define this zone.

Figure 25 shows the 180Hz Apparent Conductivity image produced by Condor. This shows a major conductivity boundary extending in a NW-SE direction across the middle of the block, which passes close to the Osiris mineralized zone. This boundary is better defined on this image than on the other images in Figure 19. The significance of this feature is not clear.

The geology of the Osiris area as mapped by ATAC is shown in Figure 26.

To investigate if this mineralized area has a more subtle signature, the mapped geology is shown compared to a number of magnetic enhancements in Figure 27 and compared to several of the ZTEM grid products in Figure 28.

The magnetic enhancements in Figure 27 were produced using the ZS filter discussed in Section 4:

(a) Geology
(b) RTP (Reduced to Pole)
(c) Tilt
(d) AS (Analytic Signal)
(e) Block
(f) Plateau

The outline of the mapped area shown in (a) is replicated in the other boxes for reference. Collar positions of the nine drill holes are also shown. Red areas are more magnetic, green and blue less magnetic.

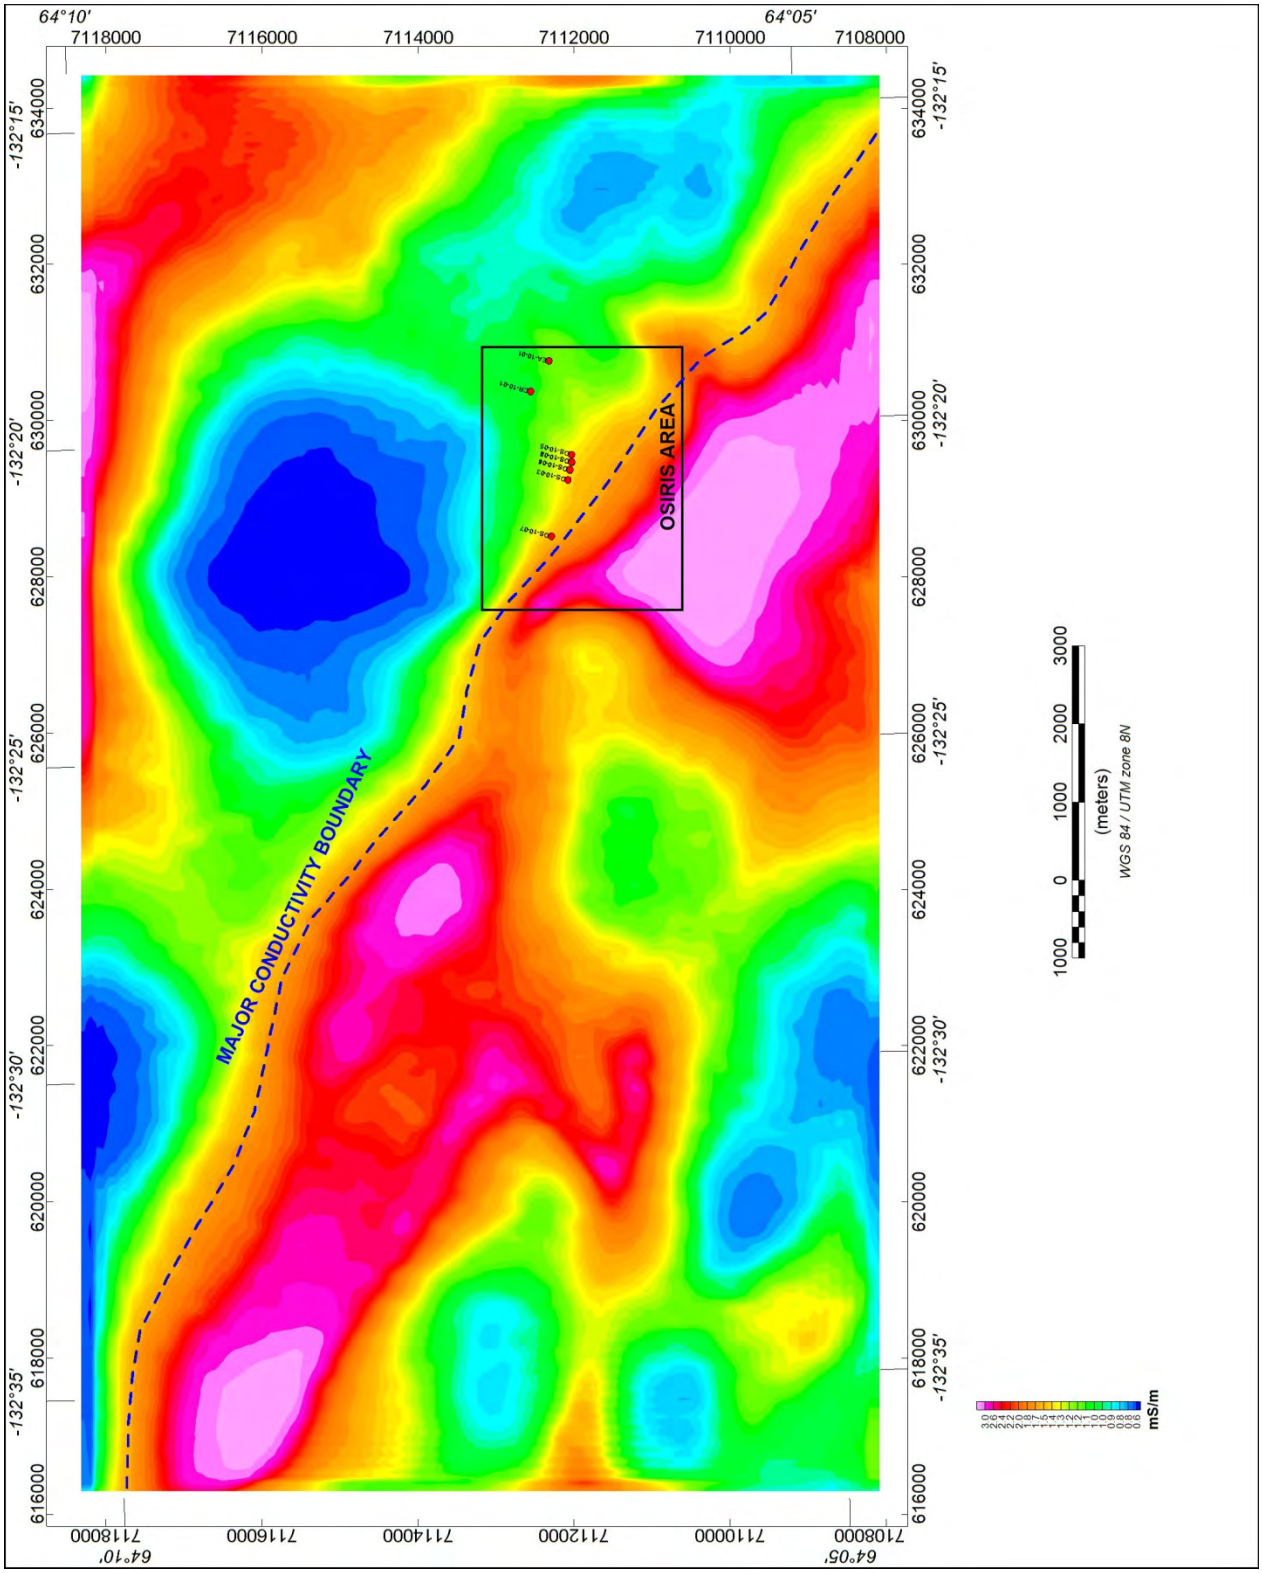

Figure 25: SE block – Condor Apparent Conductivity 180Hz image.

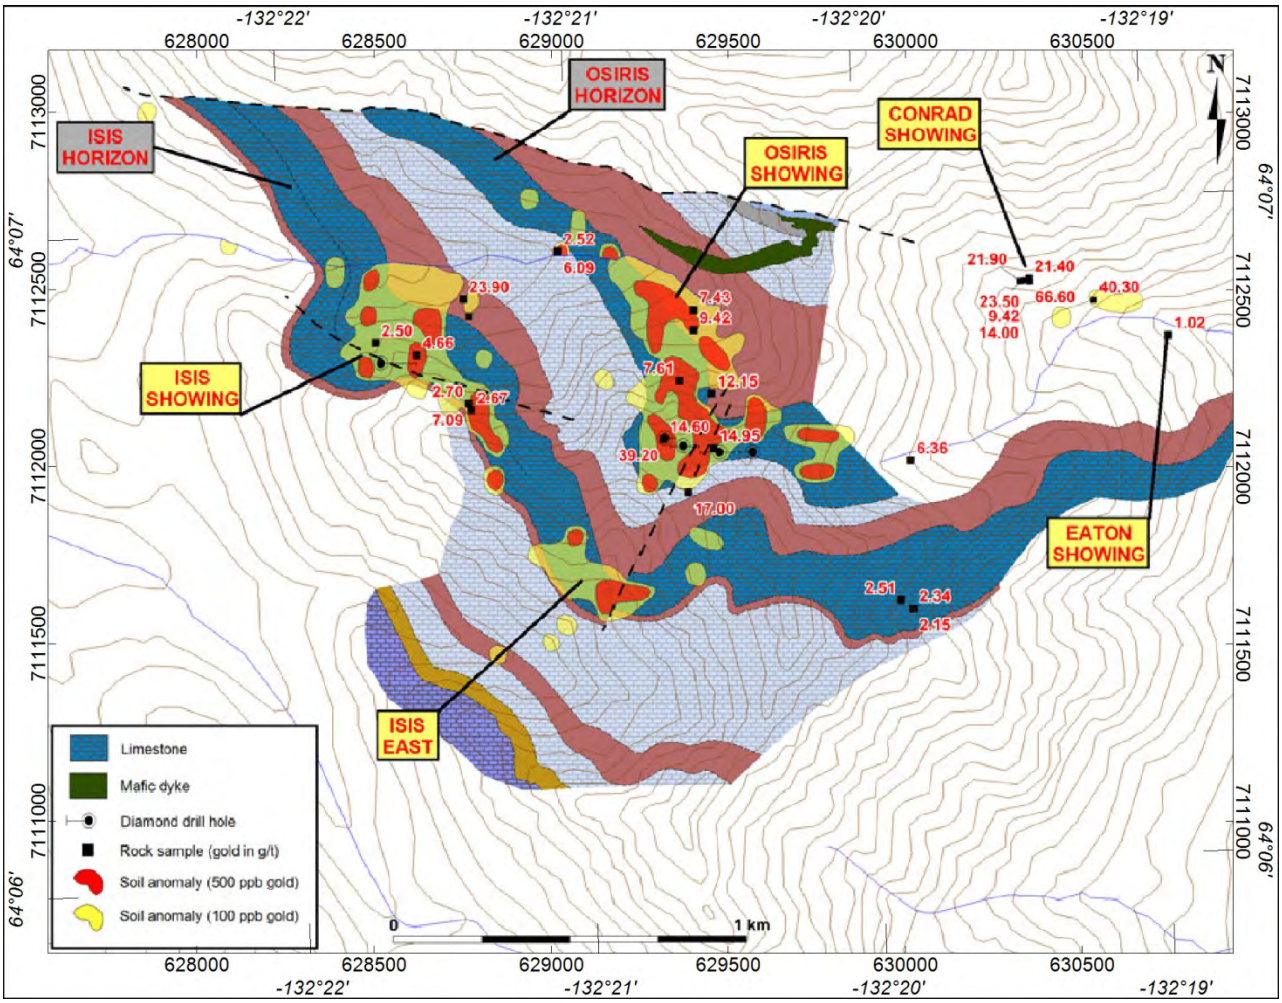

Figure 26: Osiris geology (after ATAC)

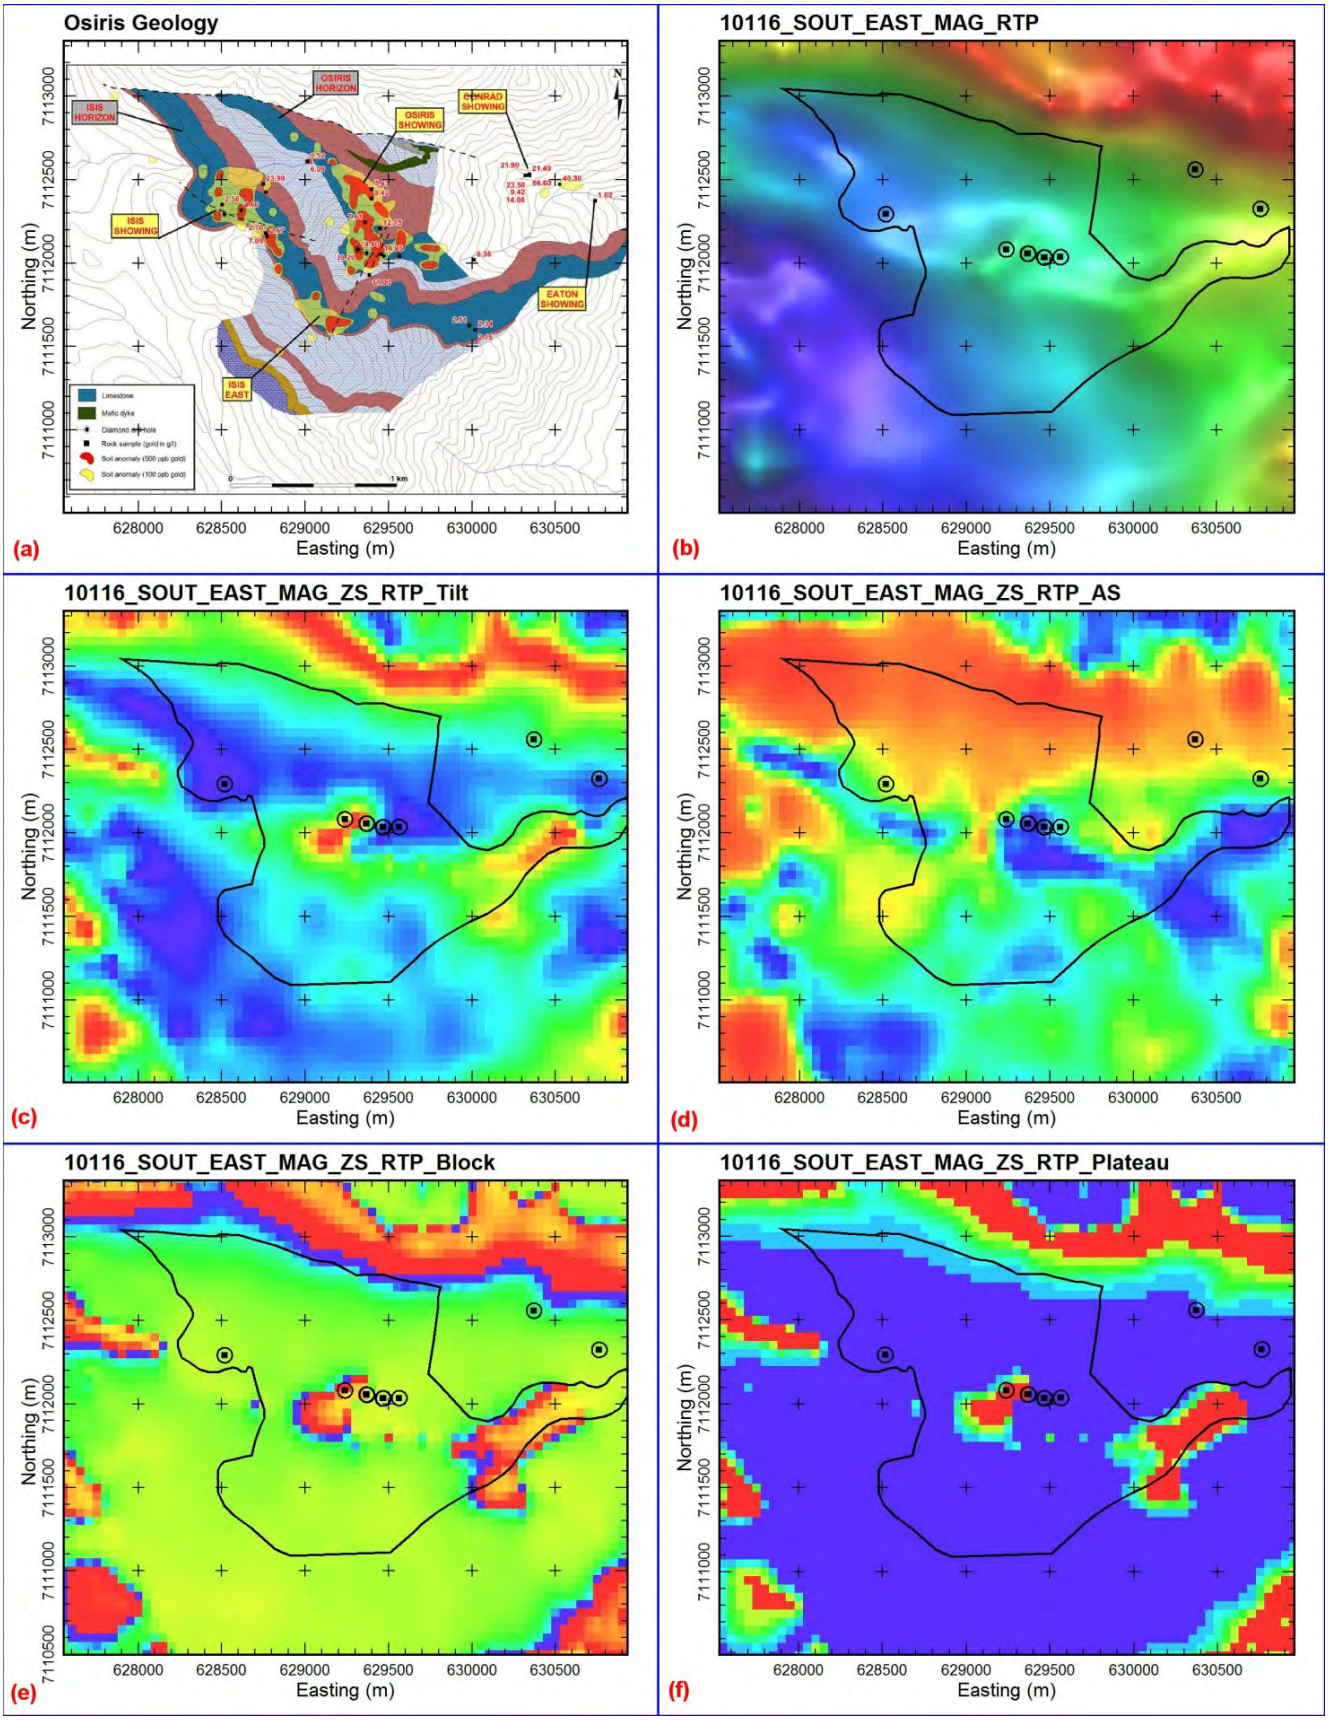

Figure 27: Osiris: Comparison of geology and MAG grids (see text for details).

On the Tilt magnetic image, a magnetic horizon wraps around the anticline axis. It is stronger on the western side and weaker on the southern side, but appears to be continuous. The stronger anomaly on the western side is also apparent on the Block and Plateau images. The E-W trending fault on the north side of the geology map lies close to the major magnetic boundary shown in Figures 20 and 21.

The ZTEM grid products in Figure 28 are:

(a) Geology
(b) XIP 180Hz PR
(c) IP 180Hz TPR
(d) YIP 180Hz PR
(e) IP 180Hz DT (reversed color palate)
(f) 180Hz Appcon (Condor product)

Red areas are more conductive while blue areas are more resistive.

Images (b), (c), (d) and (f) all show a strong conductivity boundary trending NW-SE located on the southwest edge of the Osiris area, but no clear signature for the mineralized area. The IP_180Hz_DT image in (e) shows a subtle, rather amorphous conductor, part of which correlates with four drill holes in the Osiris mineralized zone. However, this weak conductor is not definitive.

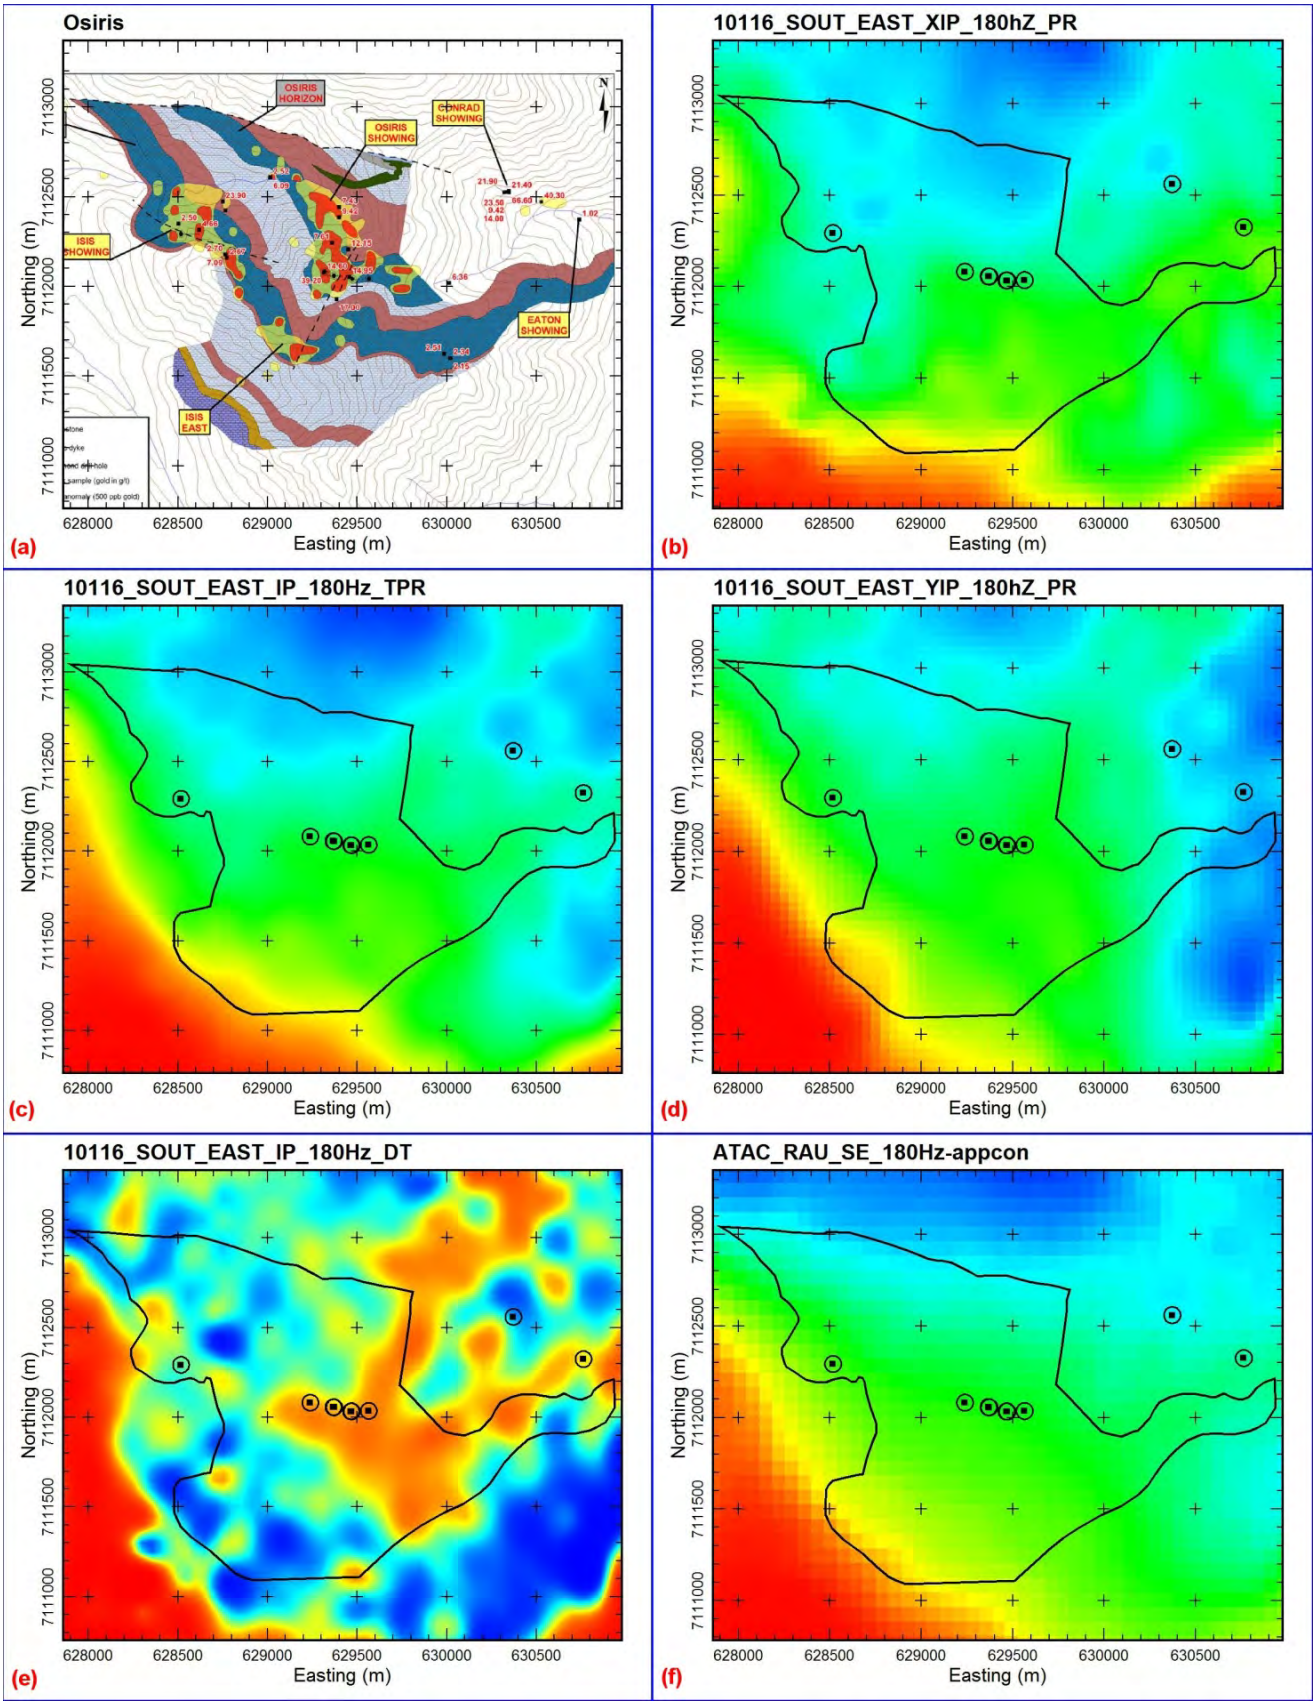

Figure 28: Osiris: Comparison of geology and ZTEM grids (see text for details).

8. NW BLOCK INTERPRETATION

Several grids derived from the ZTEM data are shown in Figure 29, to facilitate comparisons. The images are:

(a) DEM
(b) XIP 180Hz PR
(c) IP 180Hz TPR
(d) YIP 180Hz PR
(e) IP 180Hz DT (reversed color palate)
(f) 180Hz Apparent Conductivity (Condor)

The differences between the XIP_180Hz_PR and YIP_180Hz_PR grids indicate that the strike direction of the geology is variable and not simply east-west (perpendicular to the flight lines). The IP_180Hz_TPR and 180Hz_Apparent_Conductivity grids, which are generated using both the Tzx and Tzy (along and across line) components, provide a better representation of the overall distribution of conductors in this block. The DT (Total Divergence) grid provides a (somewhat noisy) picture of conductor axes.

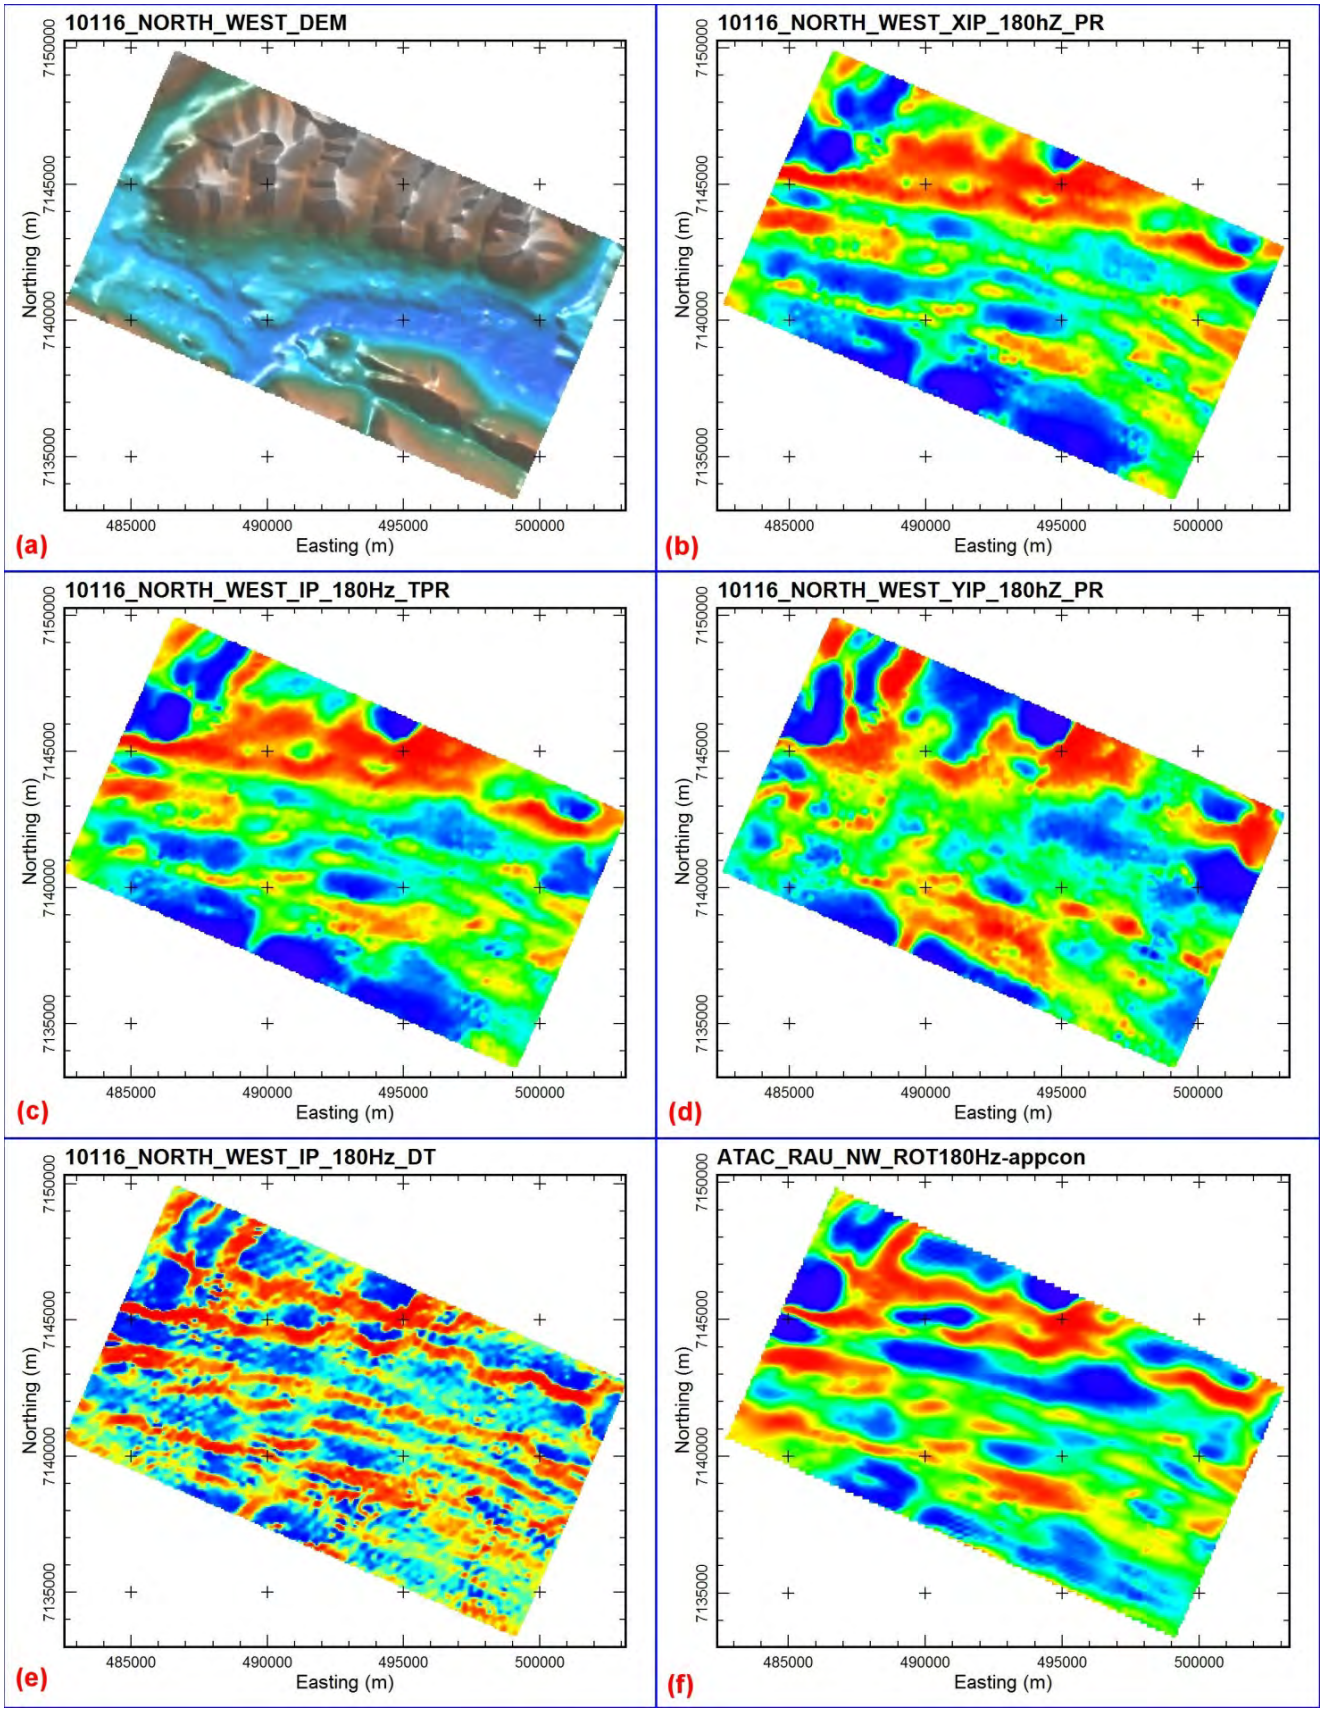

Figure 29: NW block – comparison of grids derived from ZTEM data (see text for details).

The RTP and Tilt images (Figures 30 and 31) highlight a semi-continuous curvi-linear magnetic trend extending in an E-W direction across the northern part of the block. North of this magnetic horizon the trends are more random. South of this horizon most of the magnetic trends are approximately E-W, although the lateral continuity is generally poor. Along most of the southern boundary a relatively strong and continuous magnetic unit is highlighted on the RTP image, but extends outside the boundary and is not defined. This appears to be part of a relatively extensive, magnetic lithology quite different from the rocks to the north.

Conductor trends based on the XIP 180Hz PR image are shown in Figure 32. The relatively strong, extensive magnetic unit along the southern edge of the block has no significant conductivity.

Target Zones are defined in Figure 33. Two bands of relatively good conductors extending across the northern part of the block, named TZ A and TZ B are designated 1st Priority, together with TZ C and TZ D.

- TZ A correlates closely with the curvi-linear magnetic horizon described above.
- TZ B lies sub-parallel to TZ A, about 1200-1500 m north, but without any obvious magnetic signature.
- TZ C has similar conductivity as TZ A and TZ B, and correlates with a magnetic low. It is open to the west.
- TZ D has slightly lower conductivity, but loosely correlates with several linear magnetic highs.

The 2nd Priority TZs consist of:-

- TZ E comprises an enhanced conductive zone east of TZ C. Two weak magnetic trends correlate with the northern part of this TZ.
- TZ F, G and H are similar conductors in the eastern part of the block, open to the east. Although several linear magnetic highs lie within these conductive zones, there is no obvious correlation of the magnetic and conductivity.
- TZ I has anomalous, but lower, conductivity. It loosely correlates with a magnetic low, except at the western end where the northern section overlaps with a magnetic high.
- TZ J and K are conductive zones in the northwestern part of the block. They trend in a more northerly direction and both extend outside the survey area. Neither have any obvious magnetic signature.

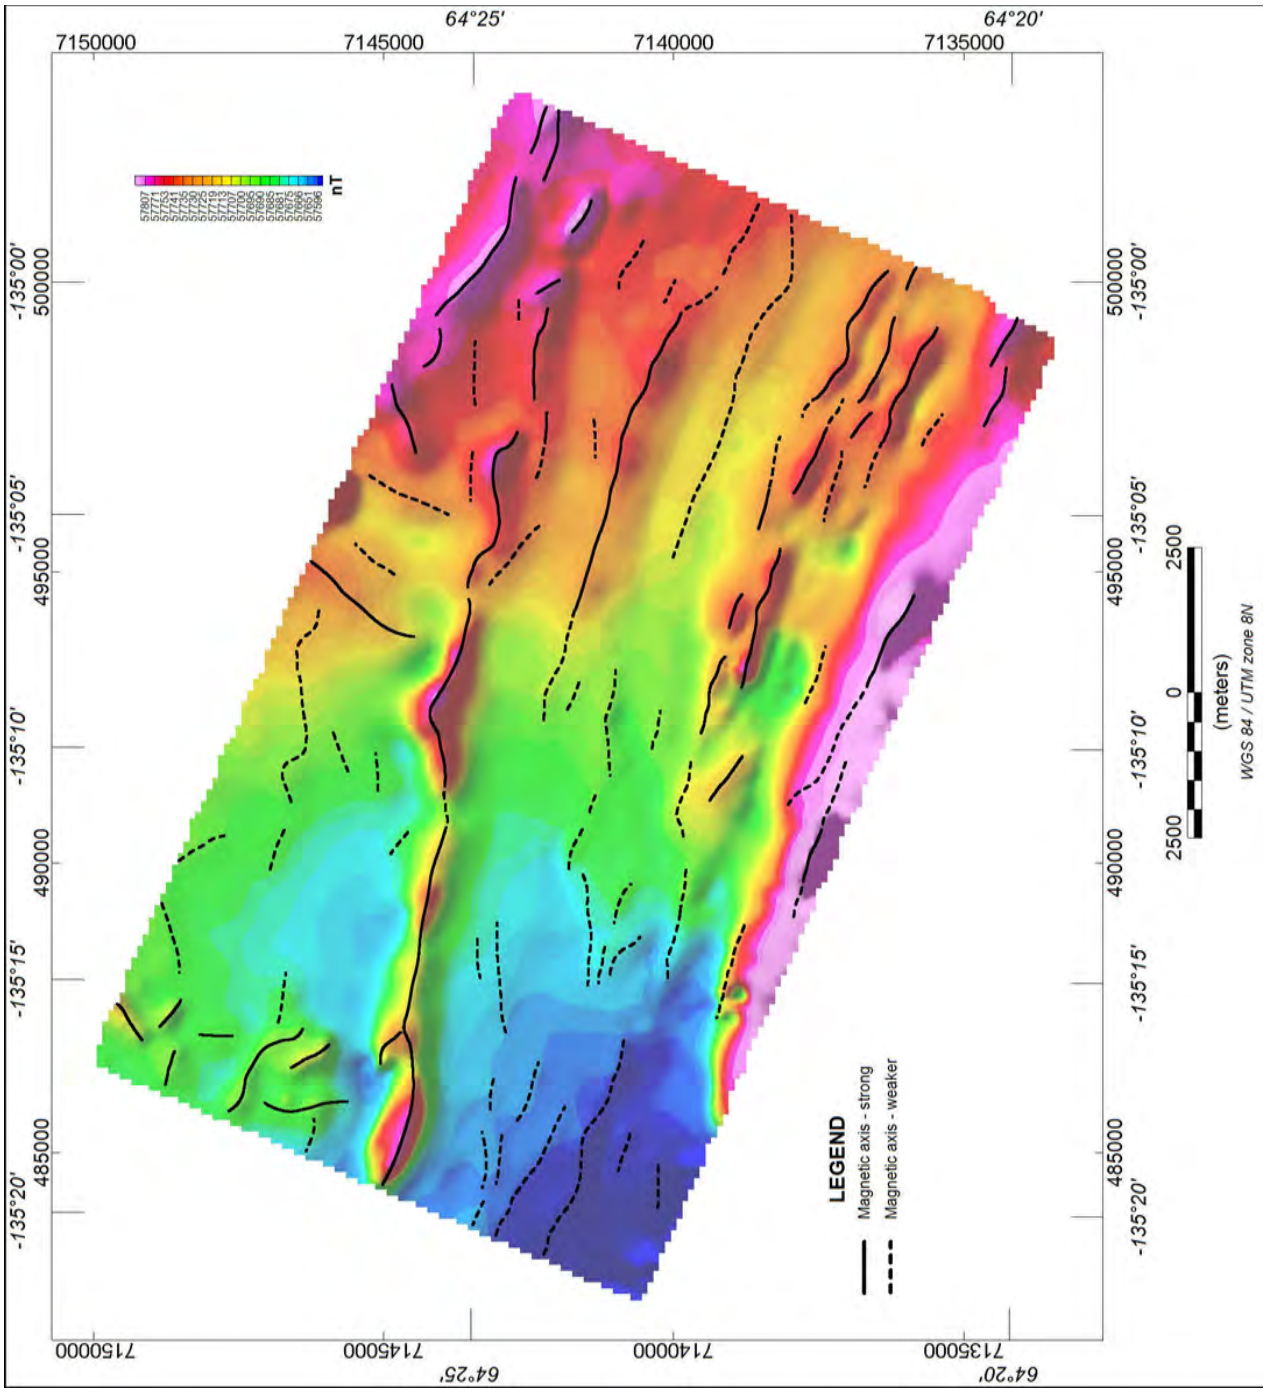

Figure 30: NW block - Magnetic interpretation on RTP image.

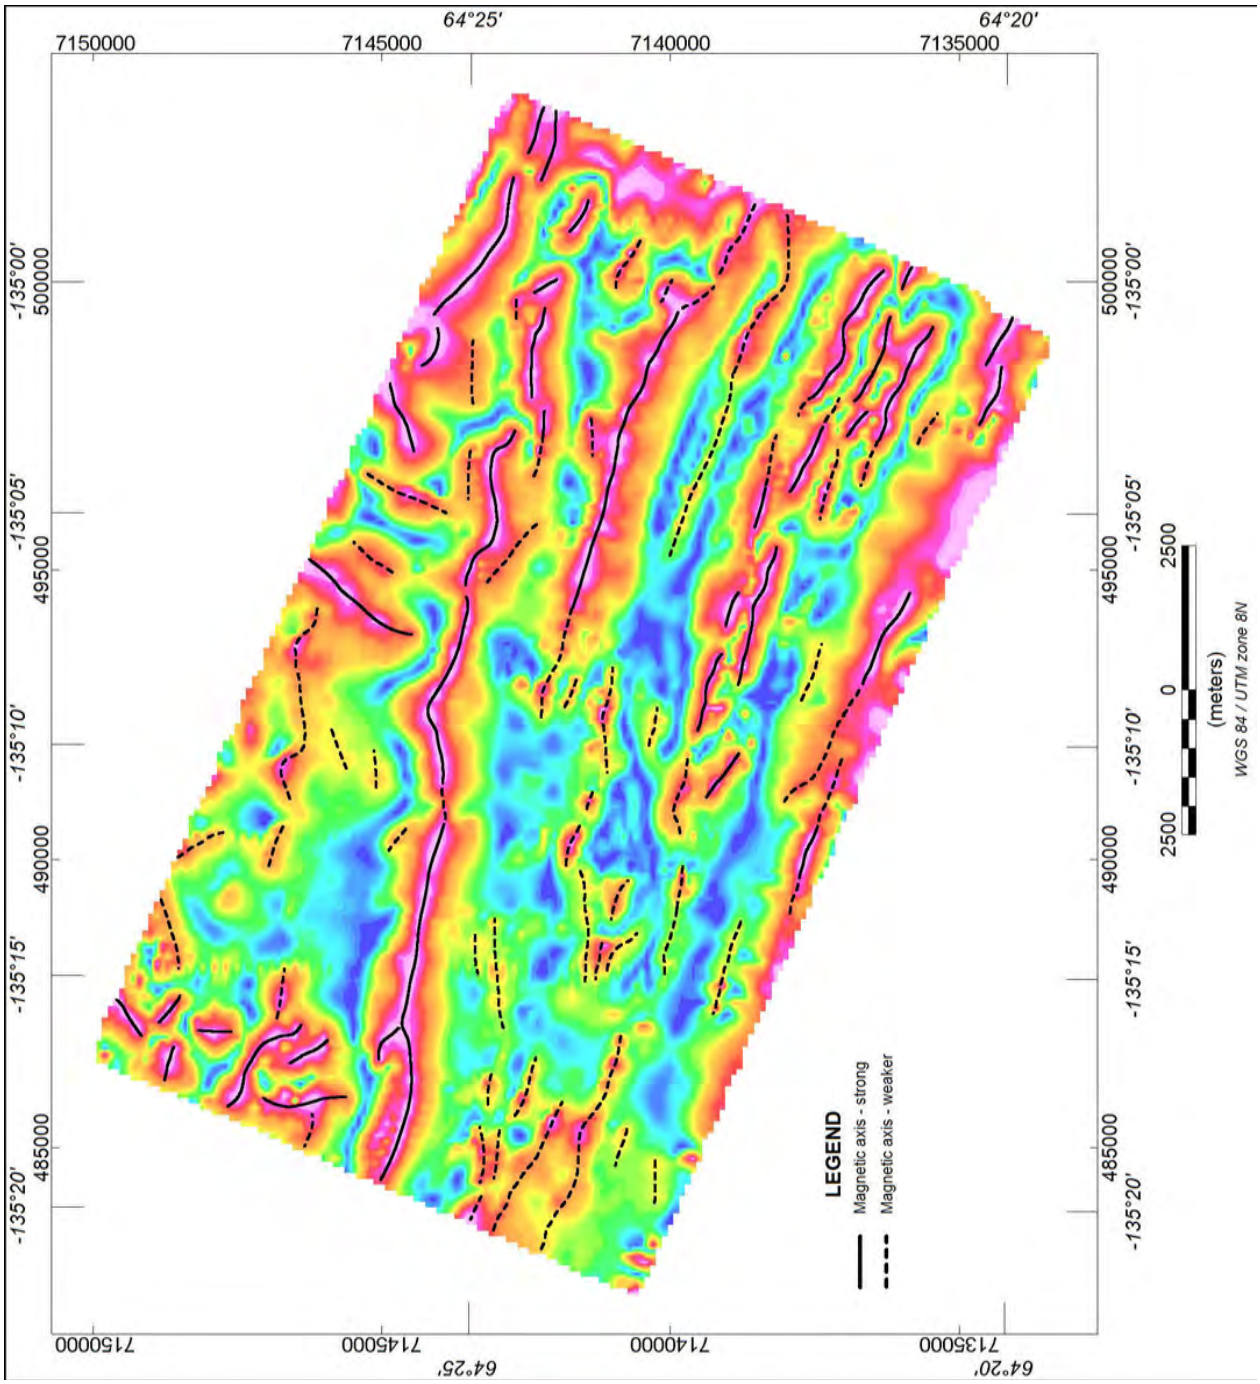

Figure 31: NW block - Magnetic interpretation on Tilt image.

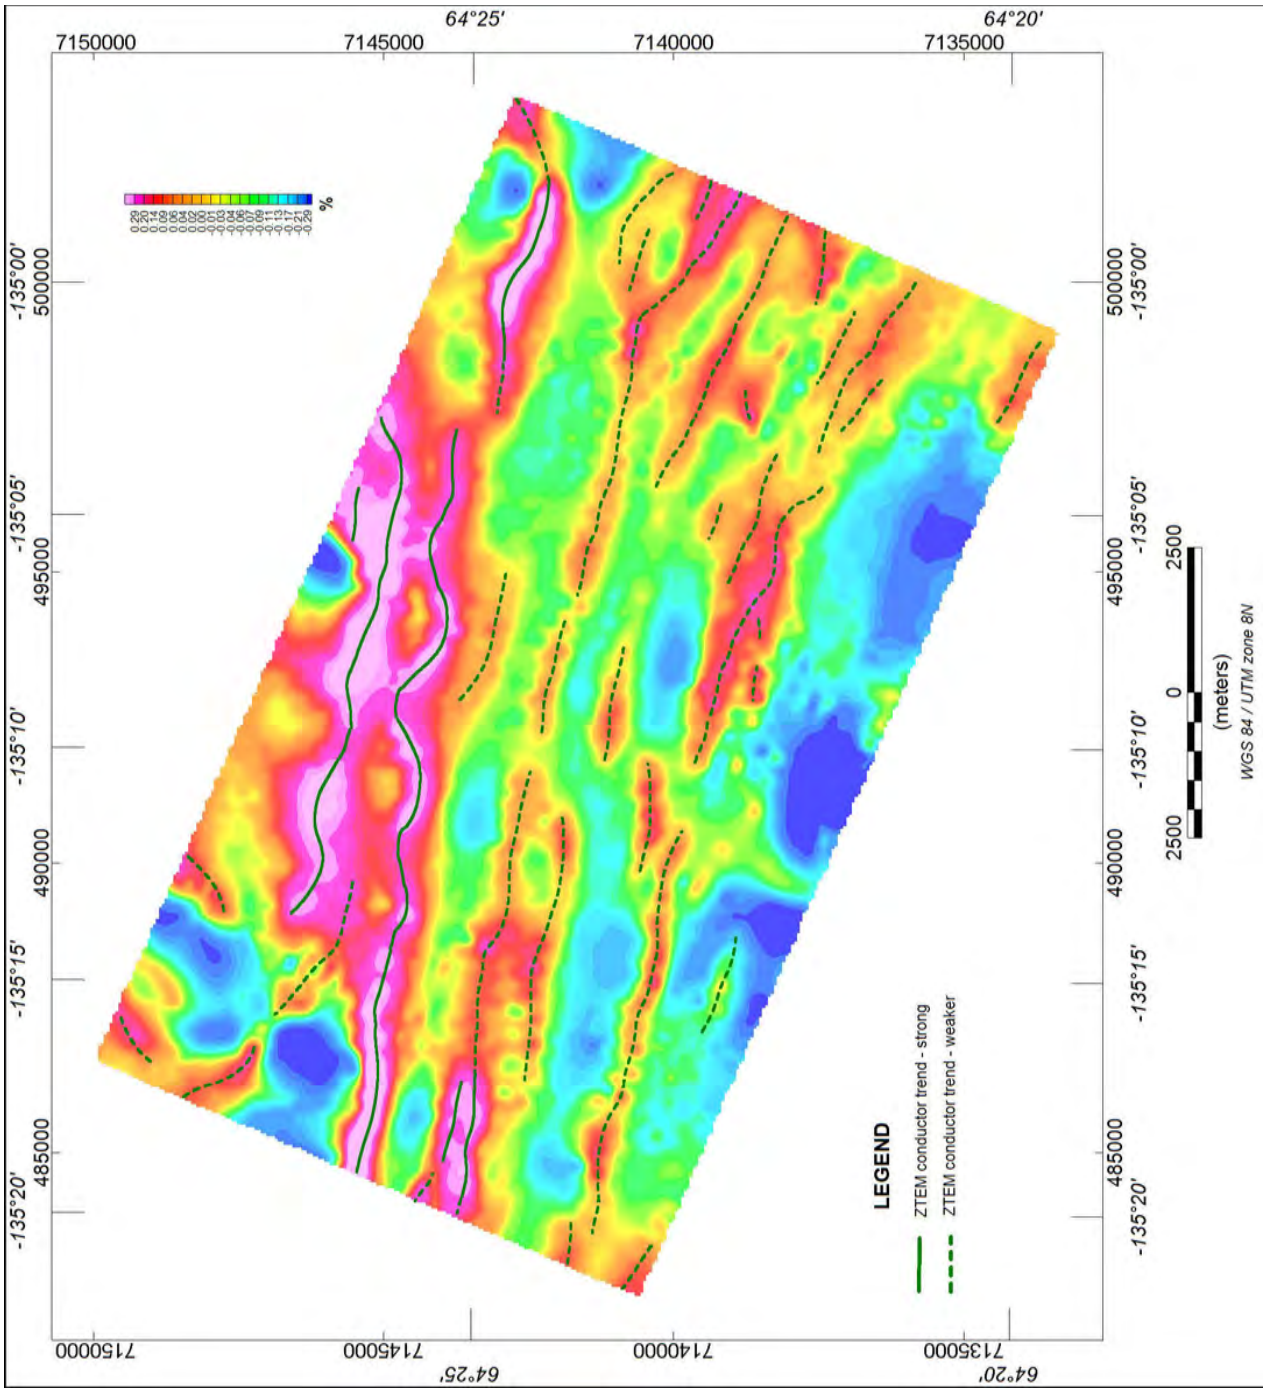

Figure 32: NW block – Conductor trends on XIP 180Hz PR image.

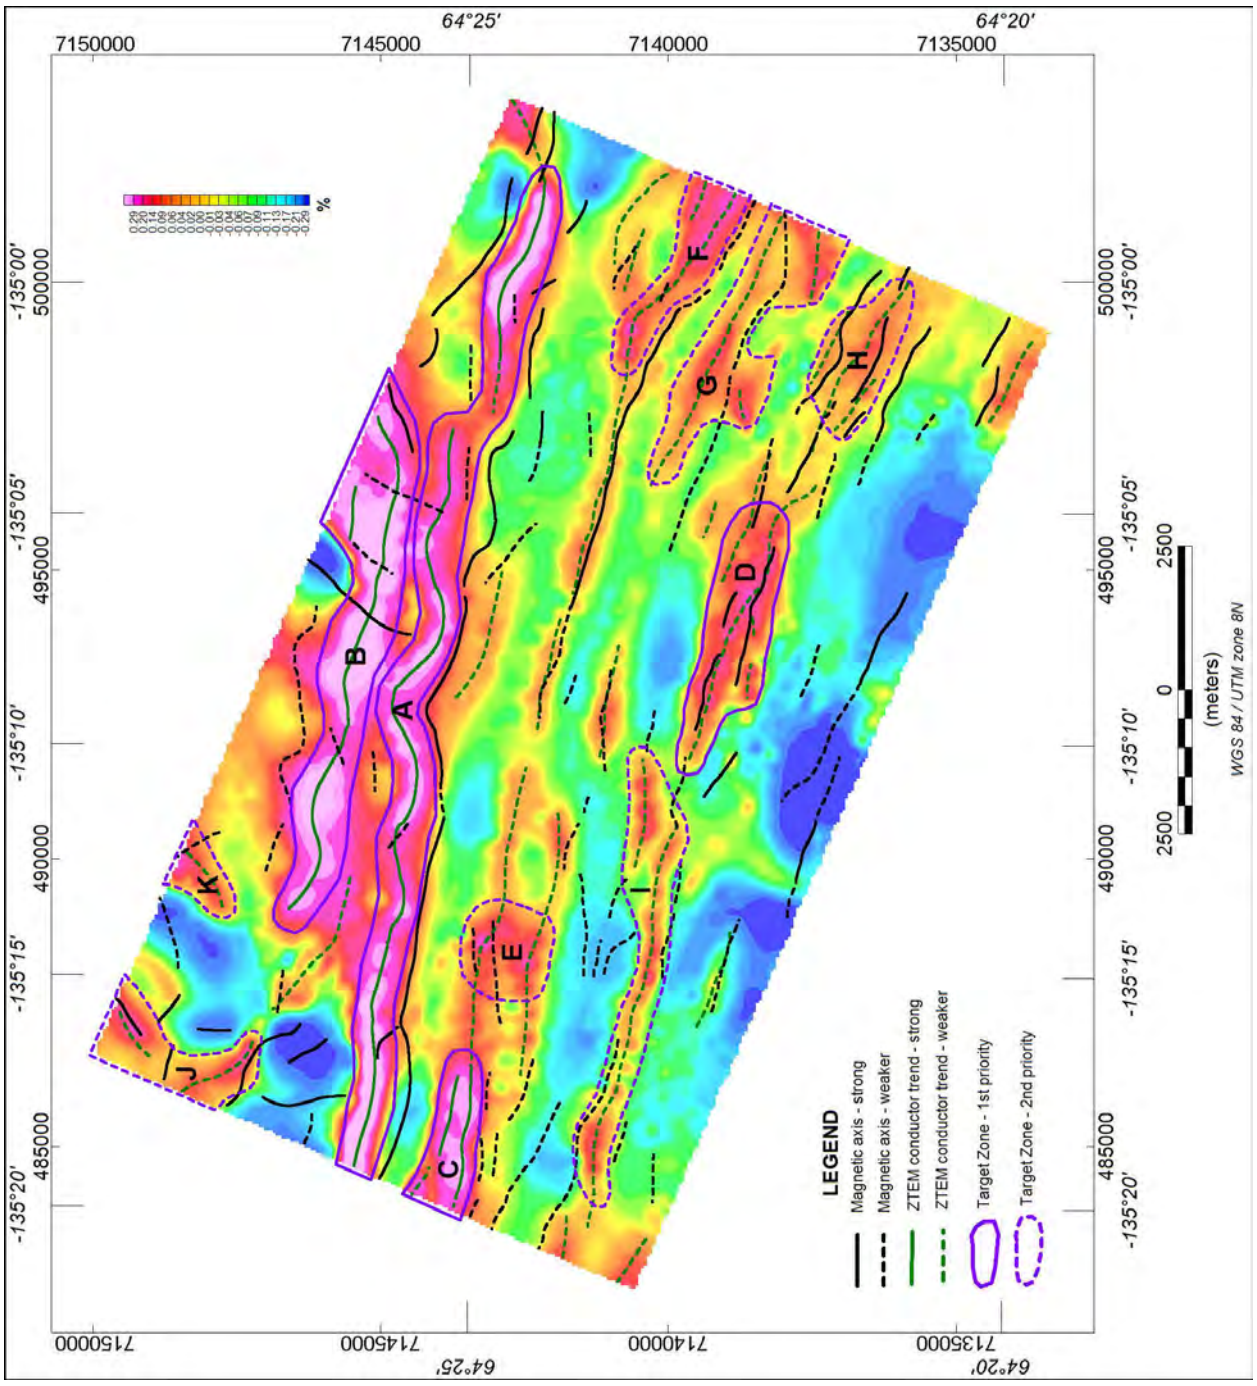

Figure 33: NW block - Interpretation and TZs superimposed on XIP 180Hz PR image.

Figure 34 shows the interpretation and TZs overlain on the DEM image. There is no obvious correlation of ZTEM conductors and topography. Most of TZ A and TZ B are aligned along the E-W trending topographic high in the north of the block, but the west end of TZ A continues uninterrupted across a valley. The other TZs correlate with topographic highs, lows and slopes.

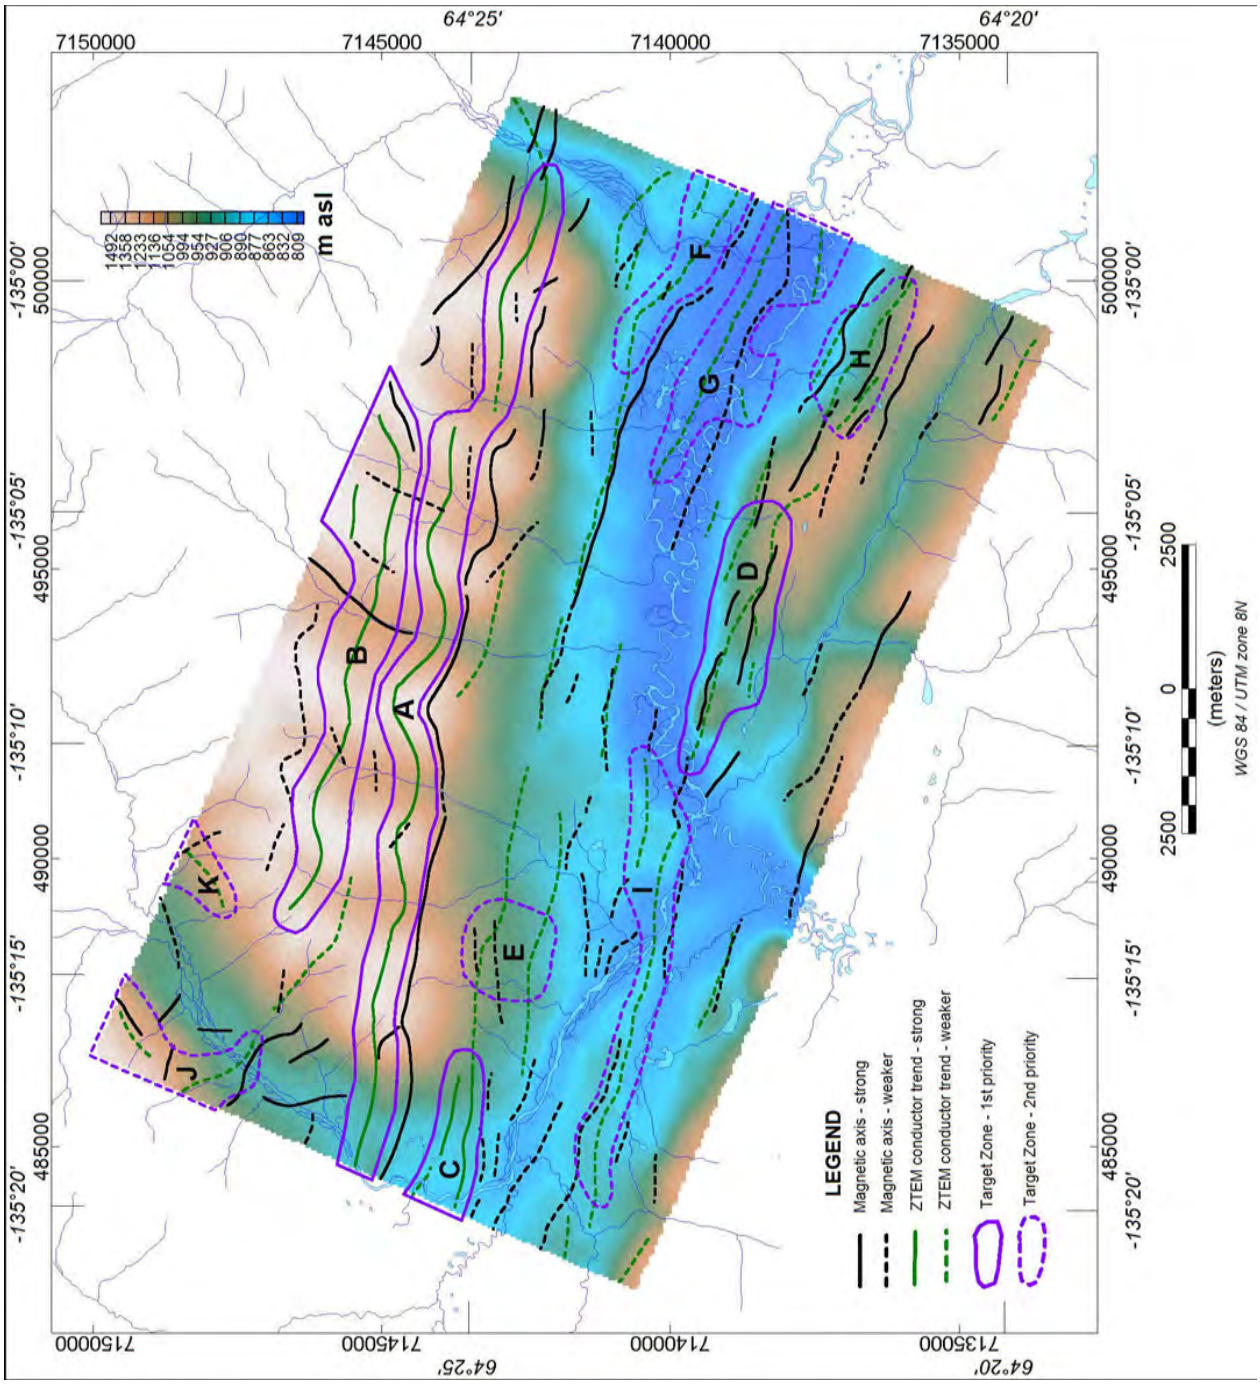

Figure 34: NW block – Magnetic interpretation and conductor trends on DEM image.

9. COMPARISON OF GEOTECH AND CONDOR ZTEM INVERSIONS

Geotech carried out 2D inversions of four ZTEM lines within the Central block, viz. 4050 and 4070 crossing the Puma prospect and 6680 and 6690 crossing the El Gossan prospect. These inversions are compared with Condor's 2D inversions in Figures 35, 36, 37 and 38 respectively.

The observed inphase and quadrature profiles for the five frequencies are shown in black and the modeled profiles in red. The conductivity depth sections are limited in depth to -500 m asl, which is approximately 1 000 m below surface. The Karous-Hjeldt (K-H) pseudosection is included at the bottom of the plots, for comparison with the 2D inversions.

The inversions compare closely, although the Condor inversions exhibit finer detail compared to the Geotech inversions, which appear to have more smoothing. The modeled profiles (red) look similar, but close examination demonstrates that the Condor inversion is fitting the observed profiles more closely. A balance is required between fitting the data more closely, but avoiding fitting noise.

The K-H pseudosection is useful as a check on over-fitting the data. Any conductors in the 2D inversion conductivity depth section which do not correlate with a conductor in the K-H pseudosection are probably produced by noise rather than signal. However, depths on the K-H pseudosection are not reliable and should not be used for any quantitative purposes.

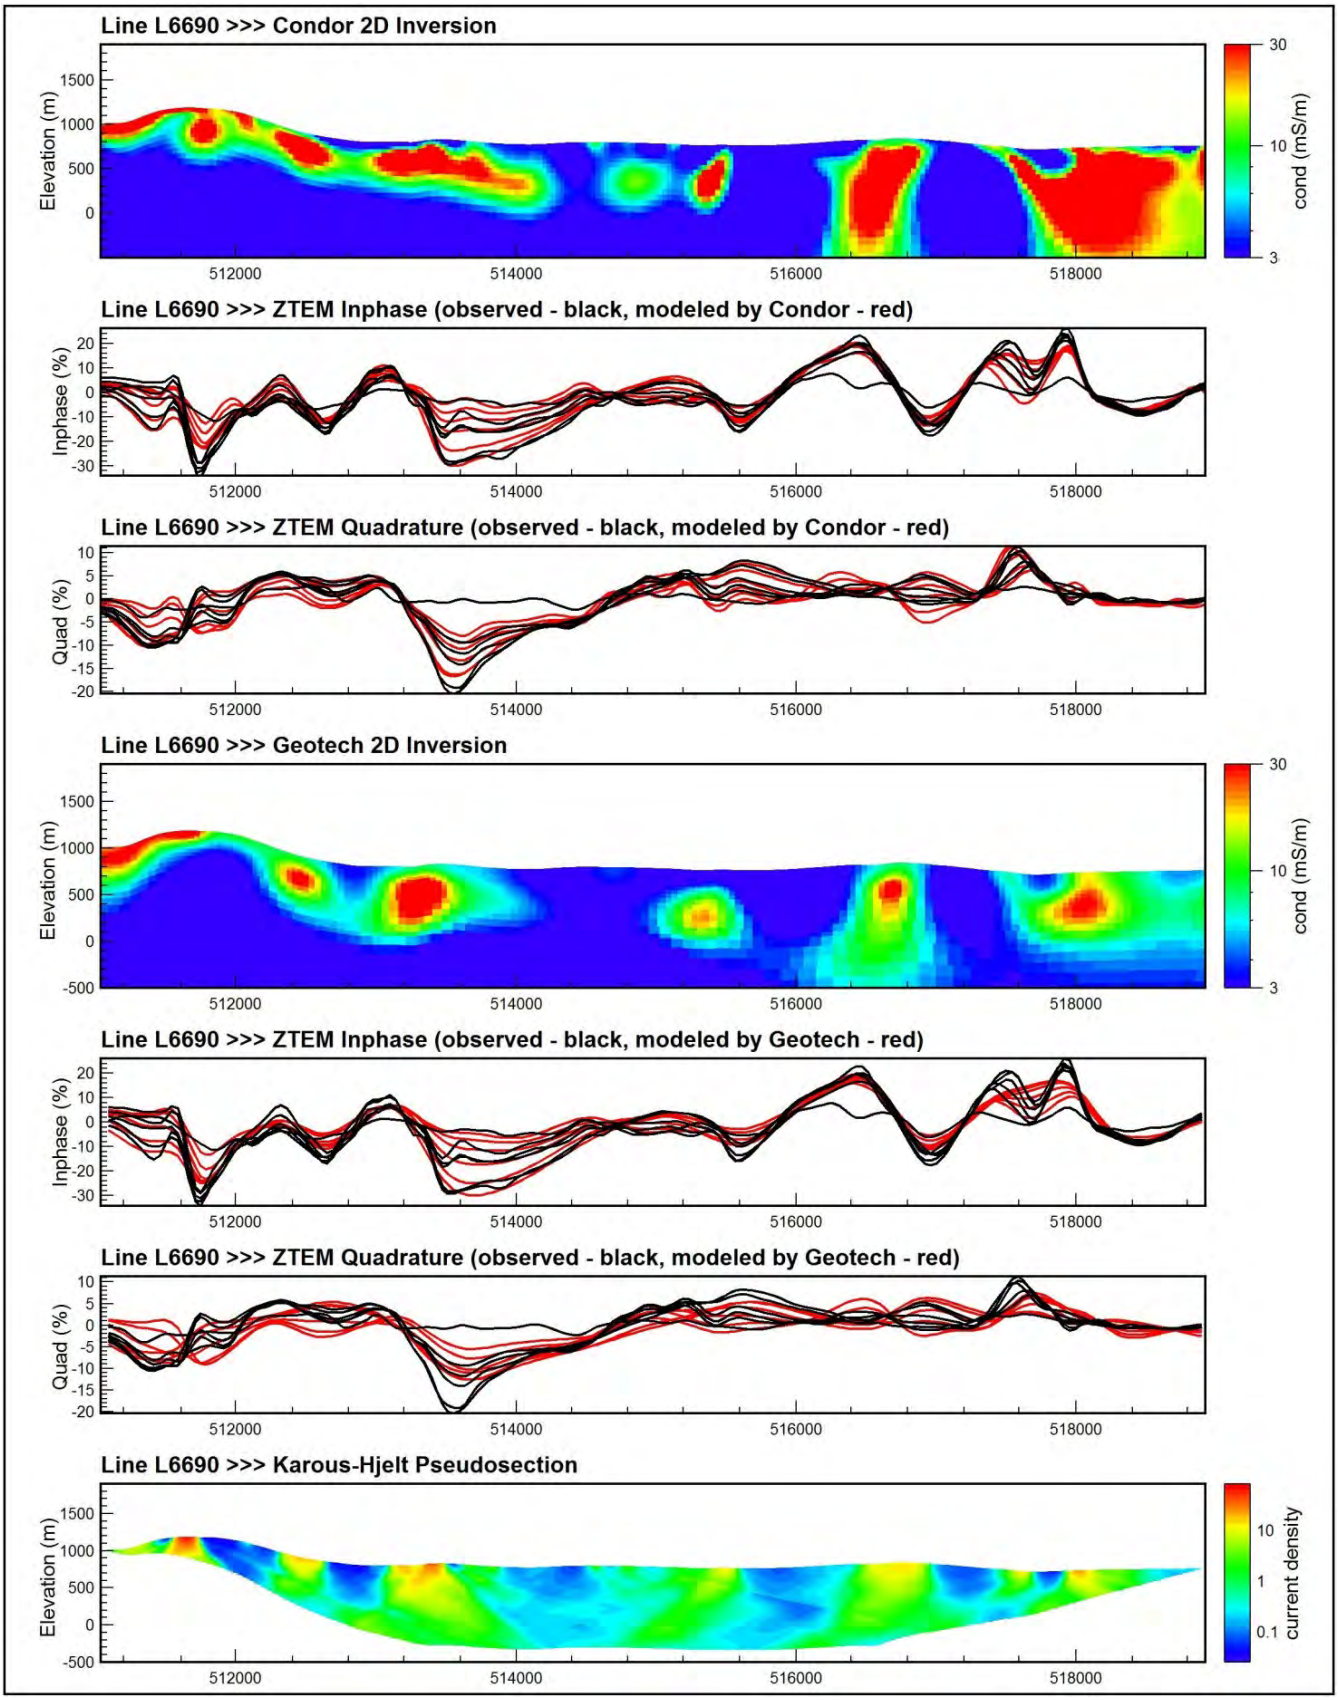

Figure 38: Comparison of Condor and Geotech 2D inversions of ZTEM – Line 6690.

10. COMPARISON OF ZTEM WITH VTEM

The 2008 VTEM survey covered a similar area to that of the ZTEM Central block (Figure 9). A detailed comparison of the VTEM and ZTEM is included in Appendix E, while a summary of the most important conclusions is presented here.

Figure 39 compares images of VTEM conductance from 25-431 m and ZTEM 30Hz Apparent Conductivity. The former is representative of the conductivity from near-surface to moderate depth for the VTEM survey, while the later is the comparable conductivity from the ZTEM survey. Of the numerous products generated from the ZTEM survey, the 30Hz Apparent Conductivity image appears to best map the overall conductivity distribution in plan view (see Appendix E. The conductivity distributions generally correlate well, although the Tiger-Puma mineralized trend is better defined by the ZTEM image. Due to the nature of the system, ZTEM is more suited to defining zones with longer strike length than discrete conductors.

The VTEM TZs defined by Condor in 2009 (Irvine, 2009) are shown in Figure 40, superimposed on the XIP 180Hz PR image, which has been used to define the ZTEM TZs in this report. Both VTEM and ZTEM TZs are shown in Figure 41. The two sets of TZs correlate reasonably well:

- The extensive ZTEM TZ A, which covers the Tiger-Puma trend, correlates with VTEM TZs C, F, G, H and part of M.
- ZTEM TZs B, F and G correlate with the extensive VTEM TZ S.
- ZTEM TZ D correlates with VTEM TZs W and X.
- The west end of ZTEM TZ E correlates with VTEM TZ D.
- ZTEM TZ H partially correlates with VTEM TZ K.
- VTEM TZ O correlates with a ZTEM conductor, but lies within the non-prospective area (Figure 12) and so was not selected as a ZTEM TZ.

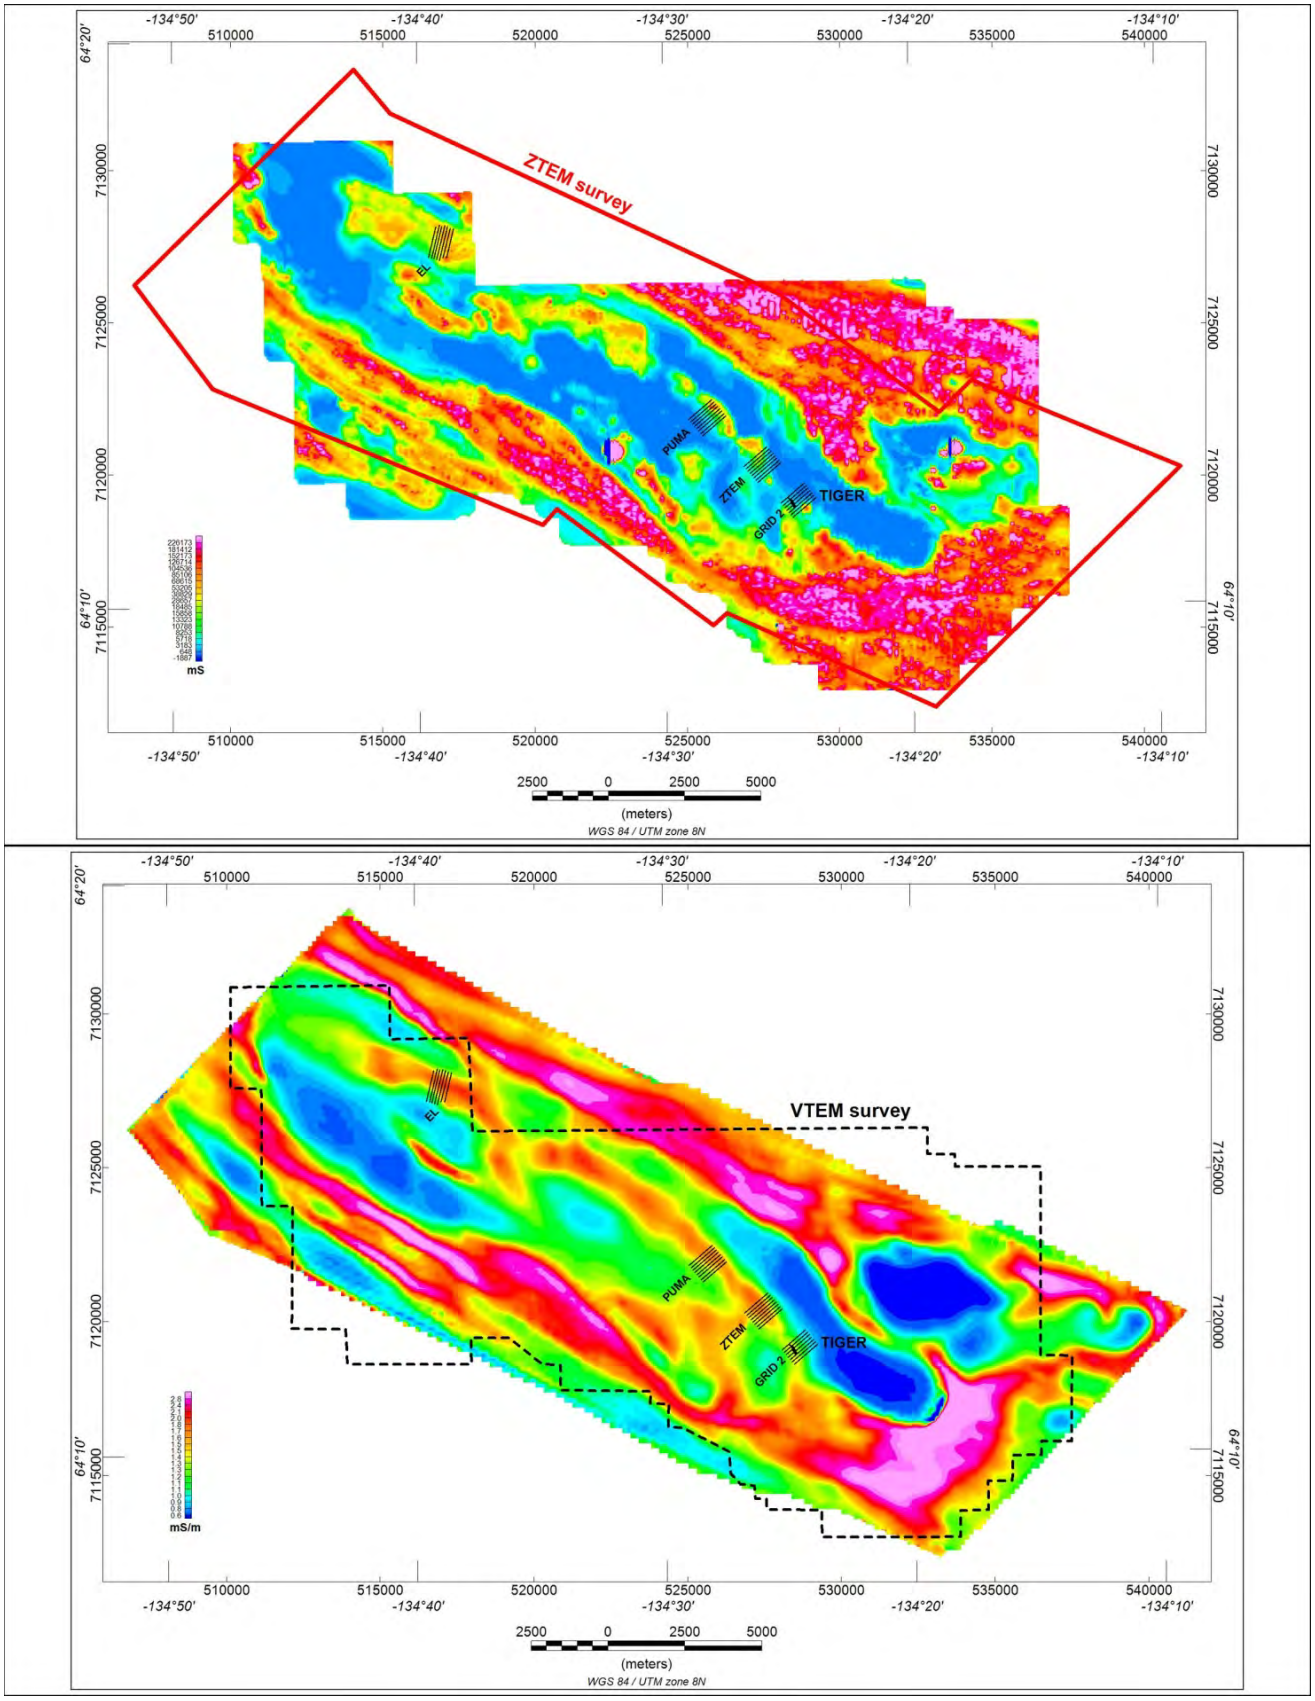

Figure 39: Central block – comparison of VTEM conductance (top) and ZTEM 30Hz Apparent Conductivity (bottom).

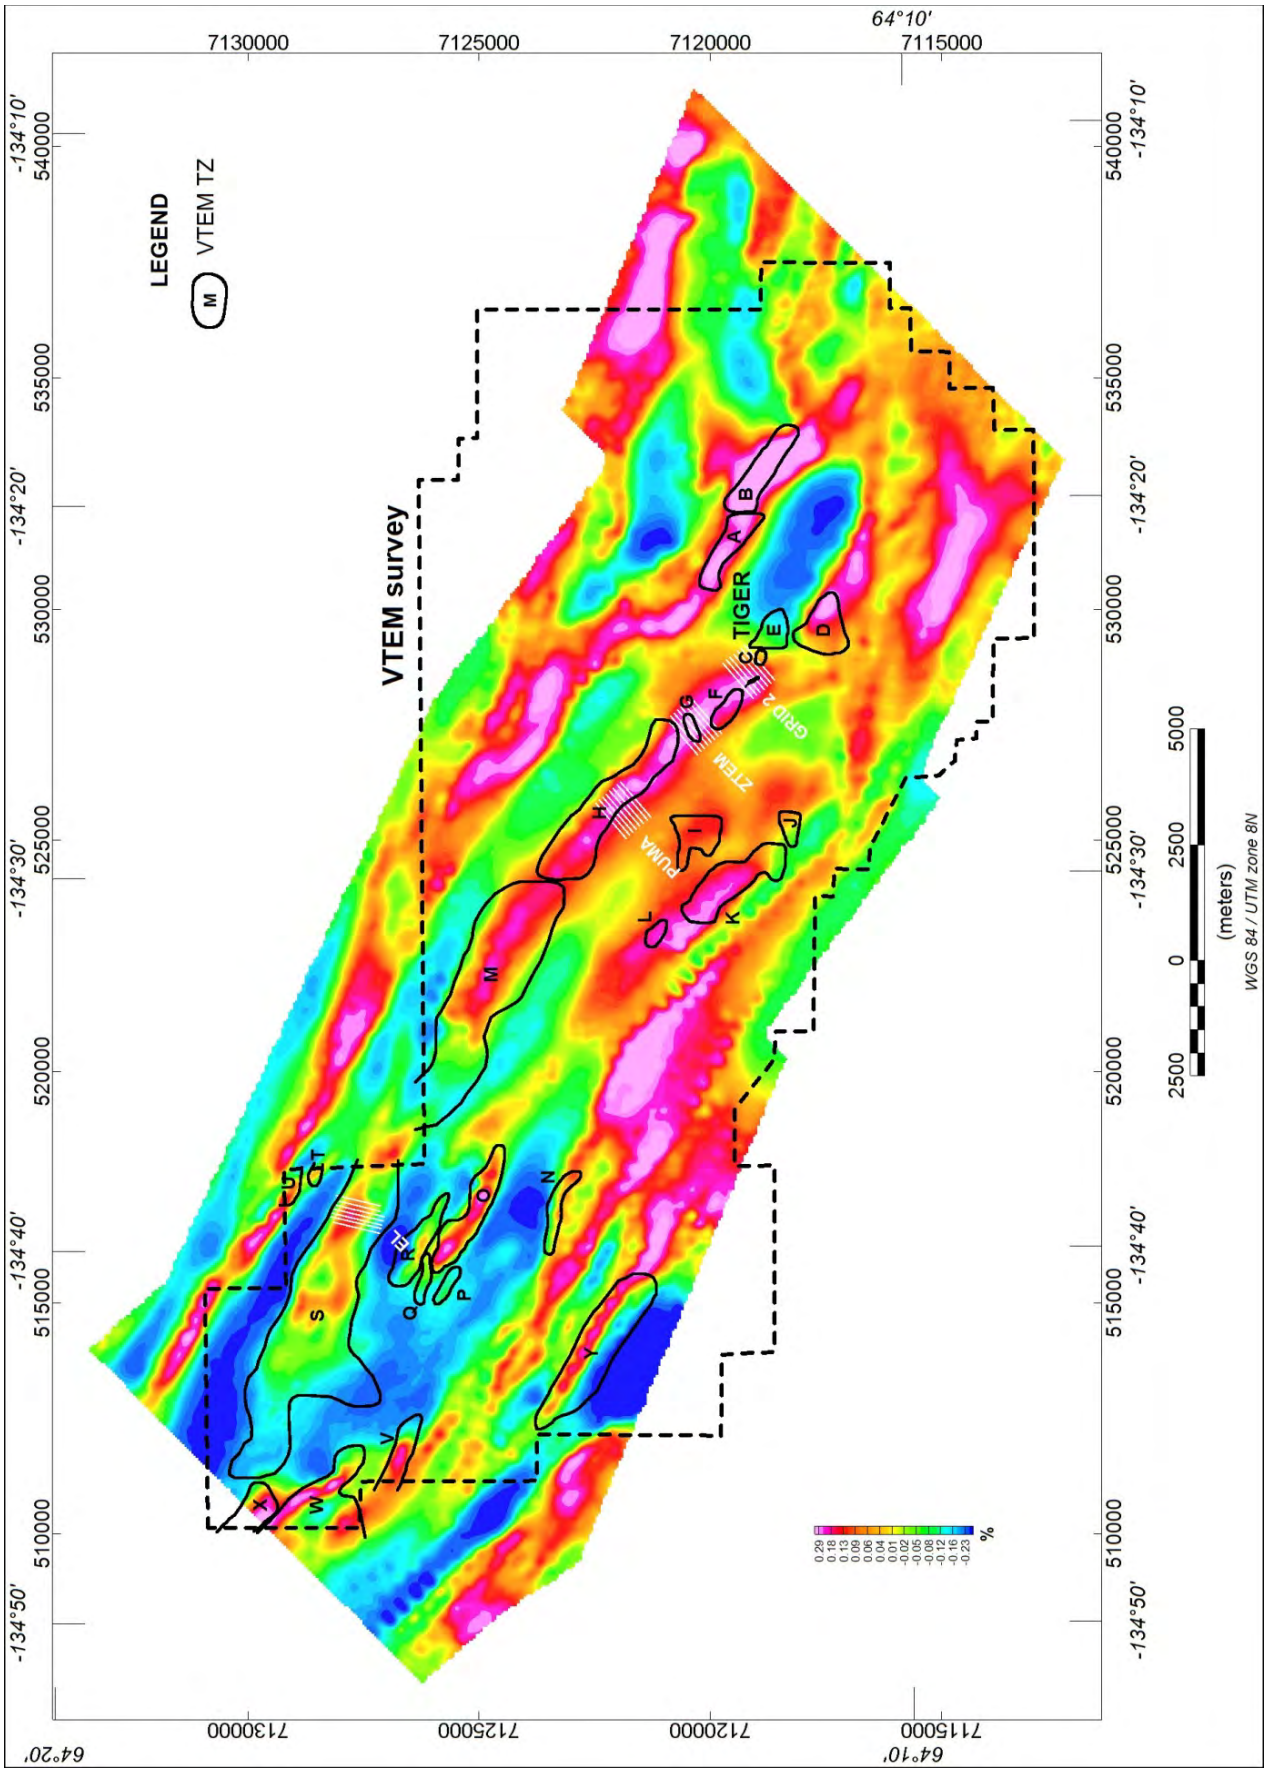

Figure 40: VTEM TZs superimposed on ZTEM XIP 180Hz PR image.

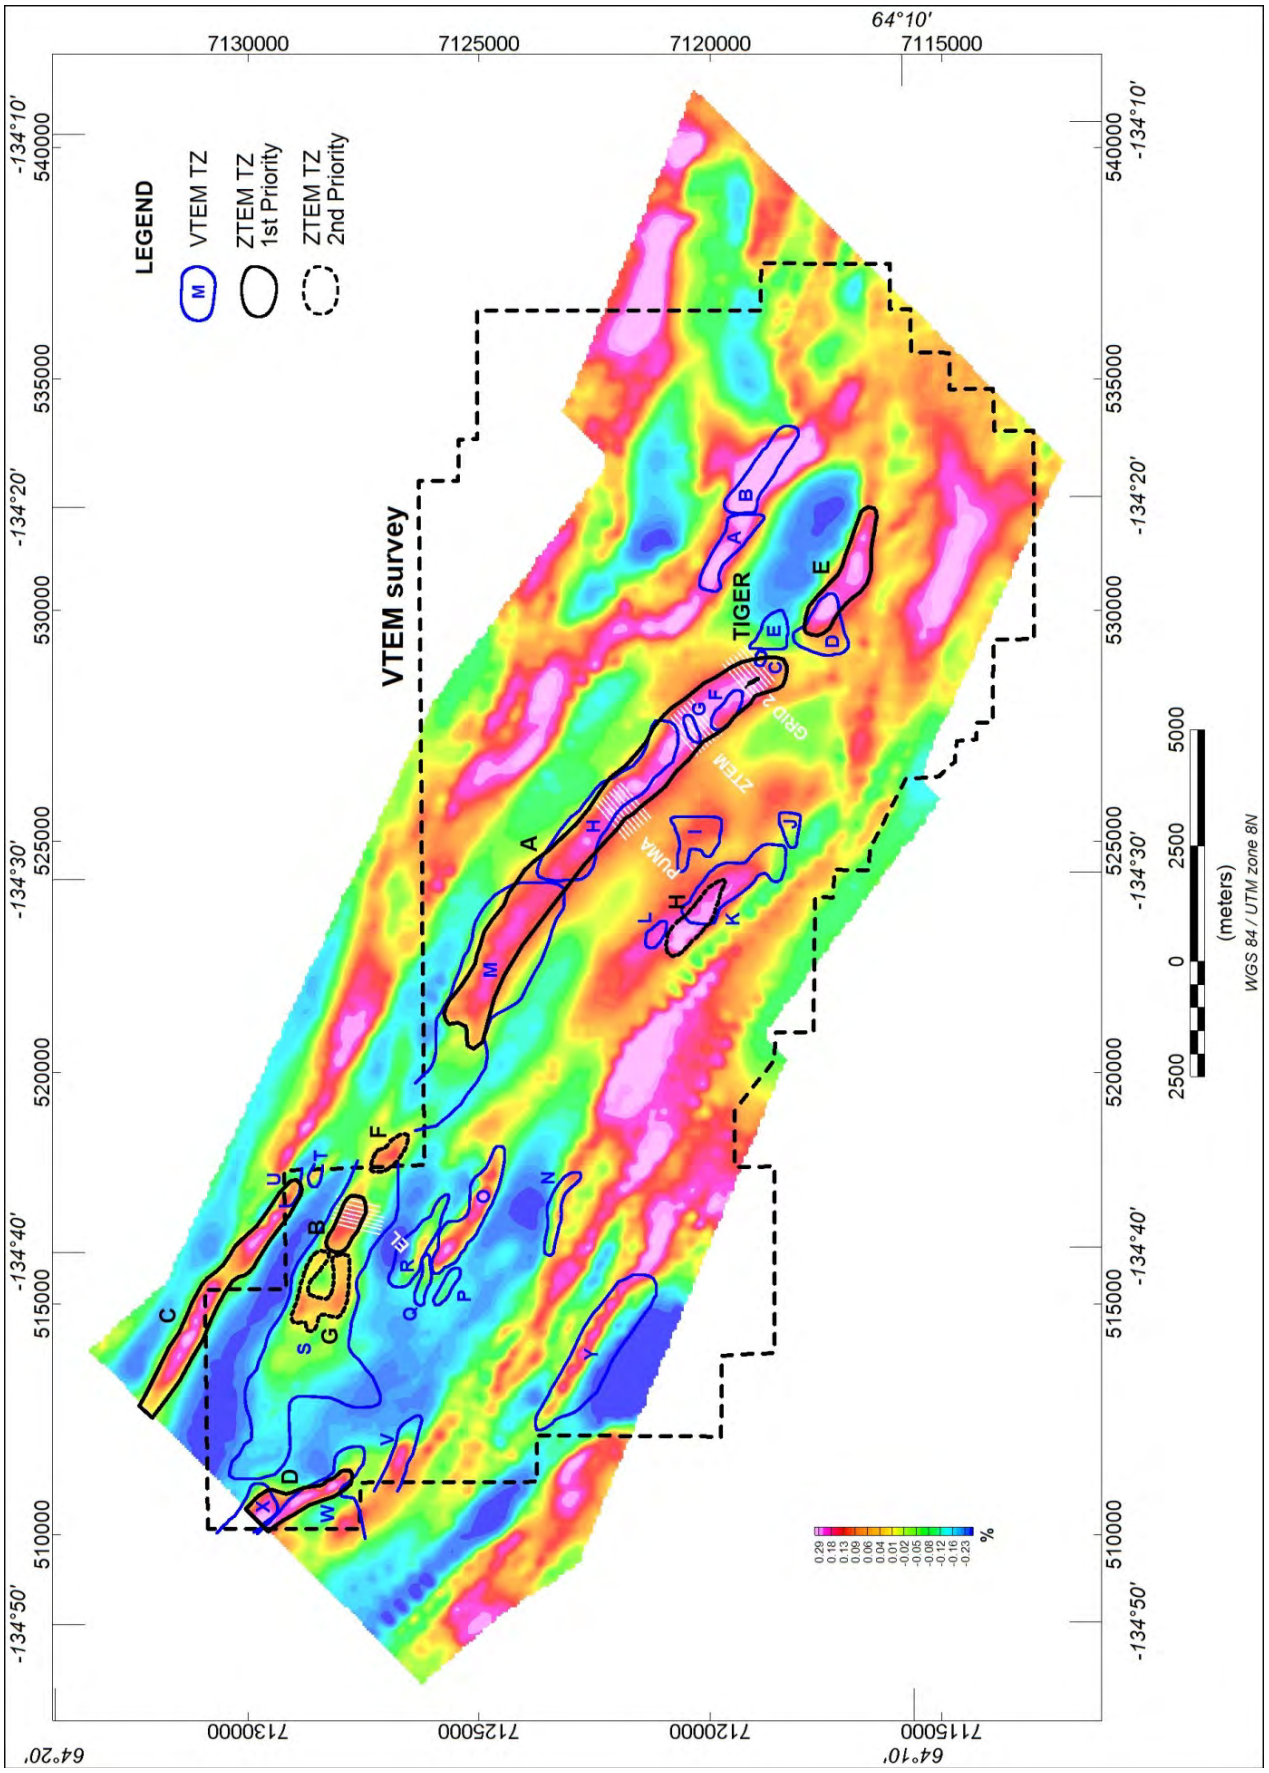

Figure 41: Central block: comparison of VTEM and ZTEM TZs, superimposed on ZTEM XIP 180Hz PR image.

11. COMPARISON OF ZTEM WITH IP AND GRAVITY SURVEYS

As discussed in Section 4, gravity surveys were carried out over the four grids in the Central block - Grid2 (Tiger), ZTEM, Puma and El. Also, an IP survey was carried out over the El grid. The locations of these grids are shown in Figure 10.

GRAVITY SURVEYS

The gravity surveys were carried out for ATAC by MWH Geo-Surveys, Inc. in June 2010. The line spacing was 100 m and the station spacing was 50 m.

These gravity data were inverted by Condor using the GRAV3D software, to produce a voxel model. A brief explanation of the inversion process is included in Appendix C.

IP SURVEY

The IP survey over the El grid was carried out by Aurora Geosciences Ltd. (Aurora) in June 2010. The configuration used was a modified Pole-Dipole array, with dipole spacing of 50 m, reading N=1 through 10 wherever possible.

Aurora carried out 2D inversions of each line to produce resistivity and chargeability depth sections. However, these sections extended to depths over 150 m where, in Condor's opinion, the inversions are unreliable. Also, the inversion errors at depth were large in areas where very low resistivities were observed near the middle of the lines.

Consequently, Condor ran new 2D inversions of all seven lines using DCIP2D software (Appendix D), but constraining the depth extents to reliable data.

PA MULTIPLOTS

Sections along each of the gravity lines were extracted from the voxel models of the inverted gravity, VTEM, ZTEM and magnetic data. To facilitate direct comparison, these sections have been plotted as MultiPlots, using Encom PA software. In the El area, the inverted IP resistivity and chargeability have been included. MiniPlates of the VTEM magnetics, Bouguer gravity and DEM are shown at the top of the MultiPlot, with the gravity stations and drill holes shown on the gravity MiniPlate. Drill holes are also shown on the sections. All the MultiPlots are included in Appendix F.

TIGER (GRID 2) AREA

An example MultiPlot (for Line 4.2) is shown in Figure 42. The gravity shows that the Tiger drill area lies just north of probable fault, which juxtaposes lower densities to the north with higher densities to the south. Small areas of higher density correlate with the mineralized zone on lines 3.2, 4.2 and 5.2.

The magnetic inversion does not indicate any specific signature for the mineralization. A shallow north-dipping magnetic unit is well defined on the middle and southeastern lines of the grid.

The VTEM conductivity depth sections show a conductor south of the mineralized zone, which appears to correlate with higher densities shown on the gravity inversion. This conductor is deeper and may not crop out. A shallow, thin conductor correlates with the mineralized zone on the northwestern lines 7.2, 6.2 and 5.2 but this conductor then trends south and merges with the previously mentioned deeper conductor.

The ZTEM conductivity depth section shows a relatively strong, shallow conductor which directly correlates with the Tiger mineralization. This conductor has limited depth extent – approximately the base of existing drilling. The northern extent of this conductor is located close to the northern limit of drilling, but it extends (possibly dipping flat to the south) several hundred meters south of existing drilling.

ZTEM GRID

An example MultiPlot (Line 5) is shown in Figure 43. The gravity inversions shows a shallow, higher density unit which dips flat to the southwest. This is similar to the denser unit delineated on the Tiger grid. The greatest density contrast is located in the southwestern section of the grid.

The magnetic inversion is relatively featureless, other than defining a more magnetic unit along the northeast edge of the grid.

The VTEM conductivity depth sections show a well-defined conductor, which is strongest in the northwest of the grid area and weakens to the southeast. This conductor does not appear to extend to the surface – possibly it is covered by a non-conductive lithology.

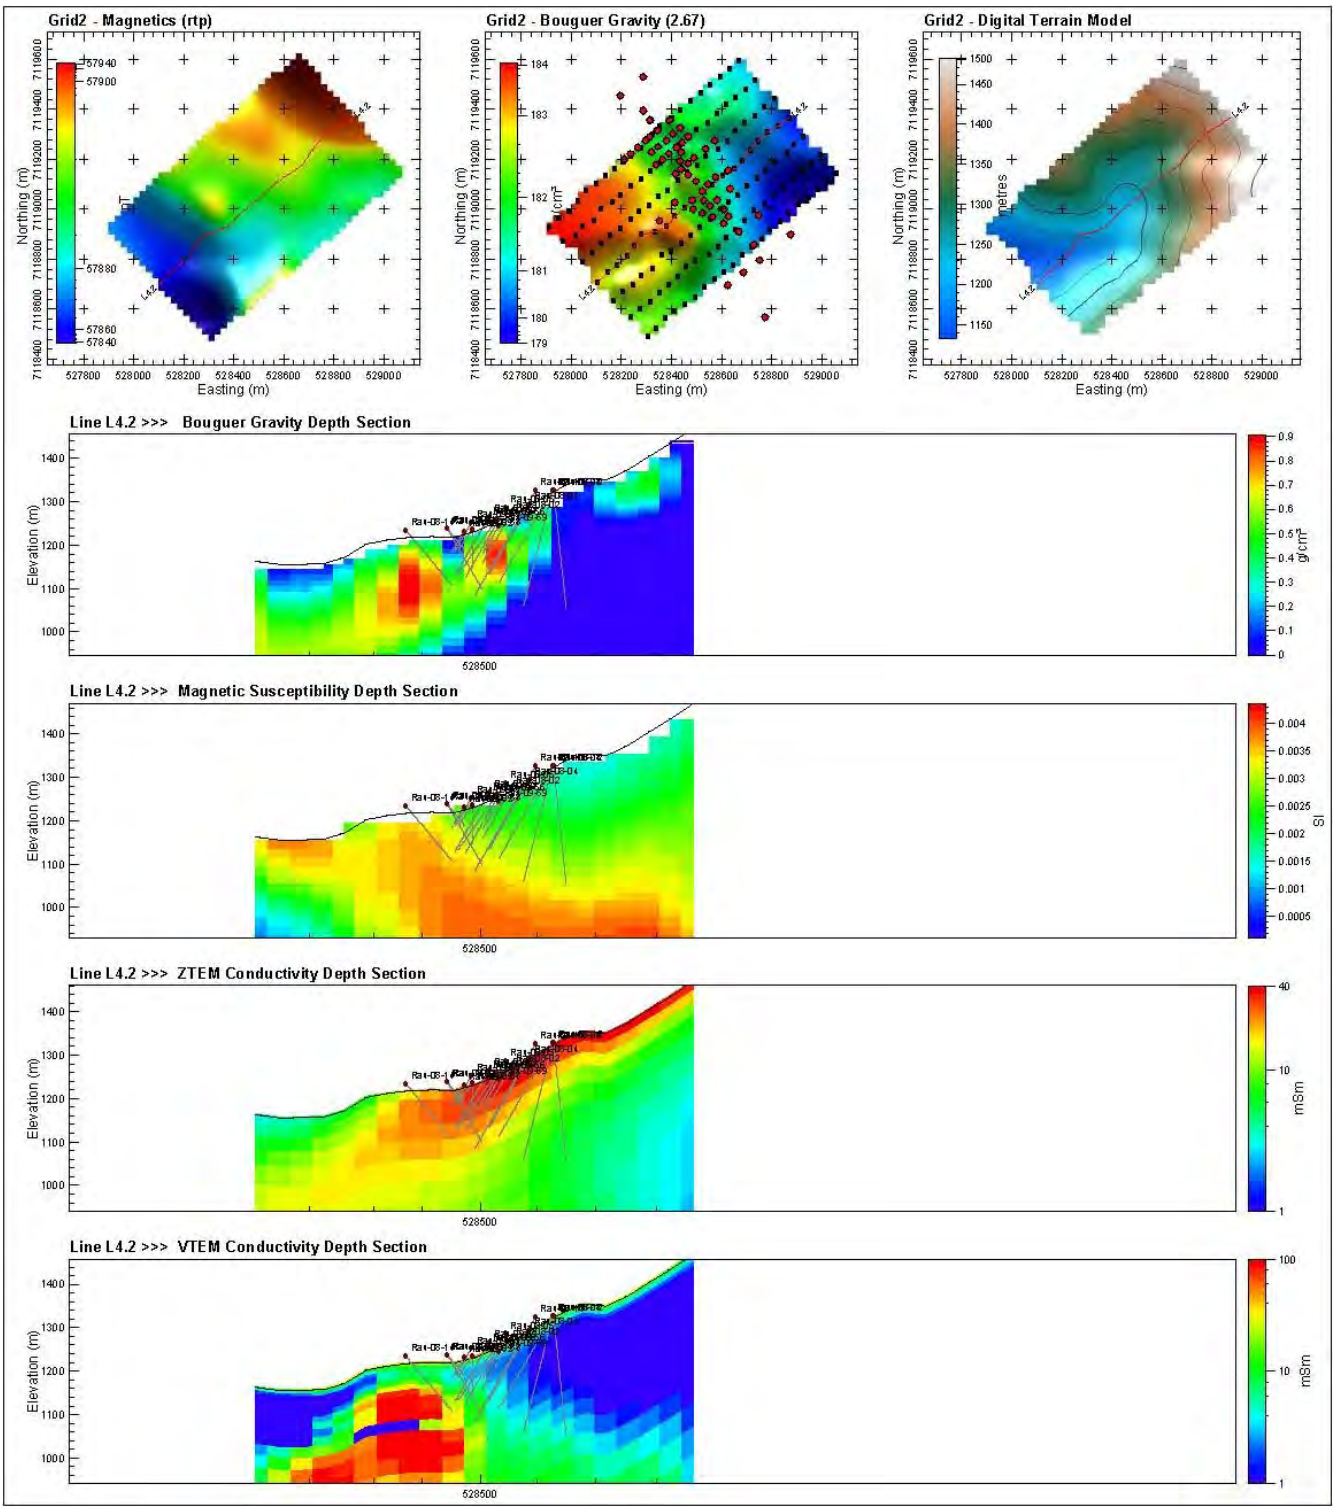

Figure 42: Grid2 (Tiger). Example MultiPlot - Line 4.2.

The ZTEM conductivity depth sections show a strong, localized conductor which extends across all eight lines of this grid (and extends further along strike in both directions). This conductor correlates closely with the VTEM conductor and also does not extend to the surface. As it lies only 1-2 km along

strike from the Tiger mineralization and has similar characteristics, this conductor represents an attractive target for future drill testing.

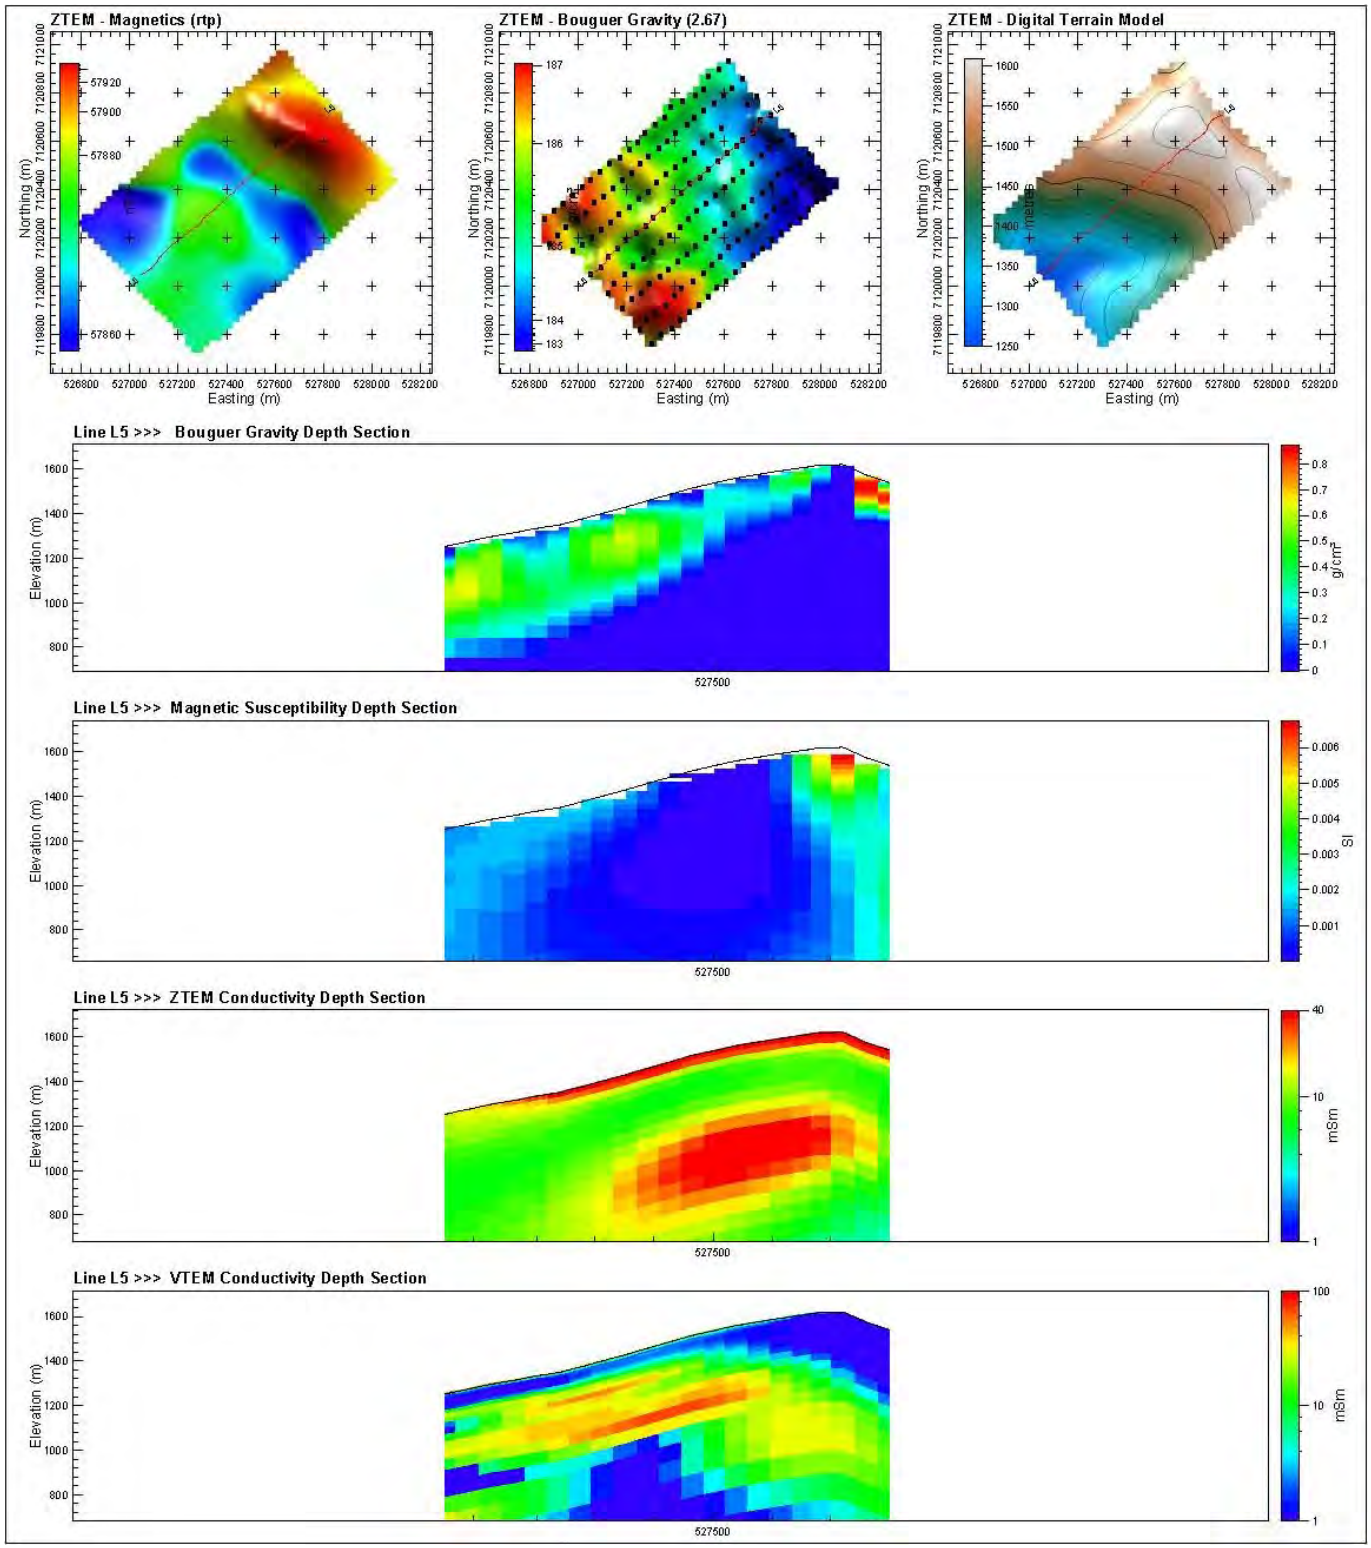

Figure 43: ZTEM grid. Example MultiPlot - Line 5.

PUMA GRID

An example MultiPlot (Line 1.1) is shown in Figure 44. The gravity inversions show a denser unit extending across the western section of the grid. The density within this unit shows considerable variability, with small, isolated highs distributed somewhat randomly.

The magnetic inversion is relatively featureless, other than defining a more magnetic unit along the northeast edge of the grid.

Both VTEM and ZTEM inversions show a very similar conductor which extends across every line at the northeastern edge of the grid and extends beyond the grid area. This conductor is similar to the one defined on the ZTEM grid and may not extend to the surface. It lies approximately 4 km along strike from the Tiger zone and represents another attractive target for drill testing.

EL GRID

An example MultiPlot (for Line 9600) is shown in Figure 45. A local gravity high extends across the western side of the grid and the inversions show discrete density highs on most lines.

The magnetic inversion shows several discrete susceptibility highs corresponding to the magnetic anomalies on the MiniPlate. These susceptibility highs do not correlate exactly with the density highs.

Both VTEM and ZTEM inversions show a broad, very conductive zone extending most of the way across the grid, beneath a relatively resistive surface layer which varies in thickness from 50-100 m.

The Condor inversions of the Aurora IP data also show a similar strong conductor (with resistivities down to 1 ohm-m) beneath a resistive surface layer (resistivities > 1 000 ohm-m) varying in thickness from 50-100 m. A number of discrete chargeability highs are delineated on the inversions-these are relatively small and near-surface and mostly lie within the more resistive surface layer, not within the deeper, strong conductor.

Two drill holes were targeted on the gravity high and susceptibility high on Line 9600 (Figure 45). Geological mapping indicated that the dip was relatively shallow to the north, so the holes were drilled to the south. Hole No 1 was designed to intersect the density high and chargeability high centered just north

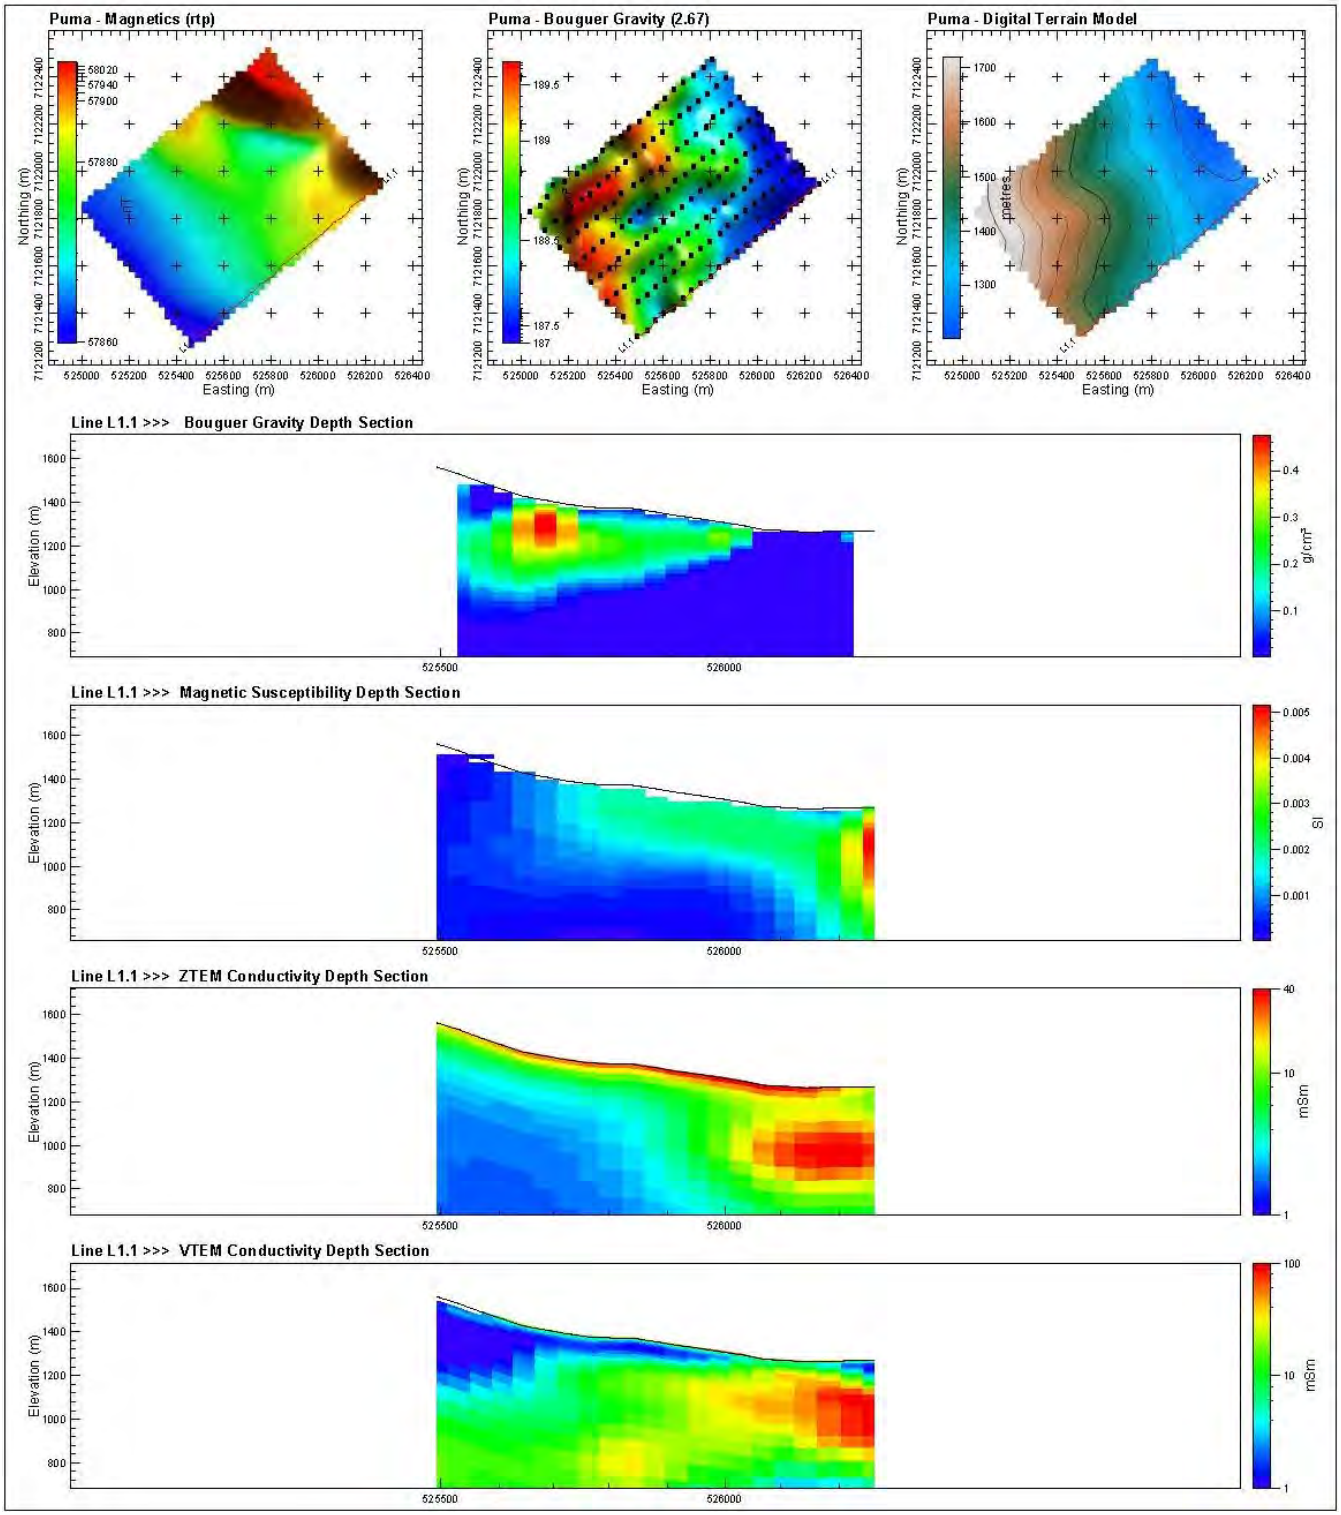

Figure 44: Puma grid. Example MultiPlot - Line 1.1.

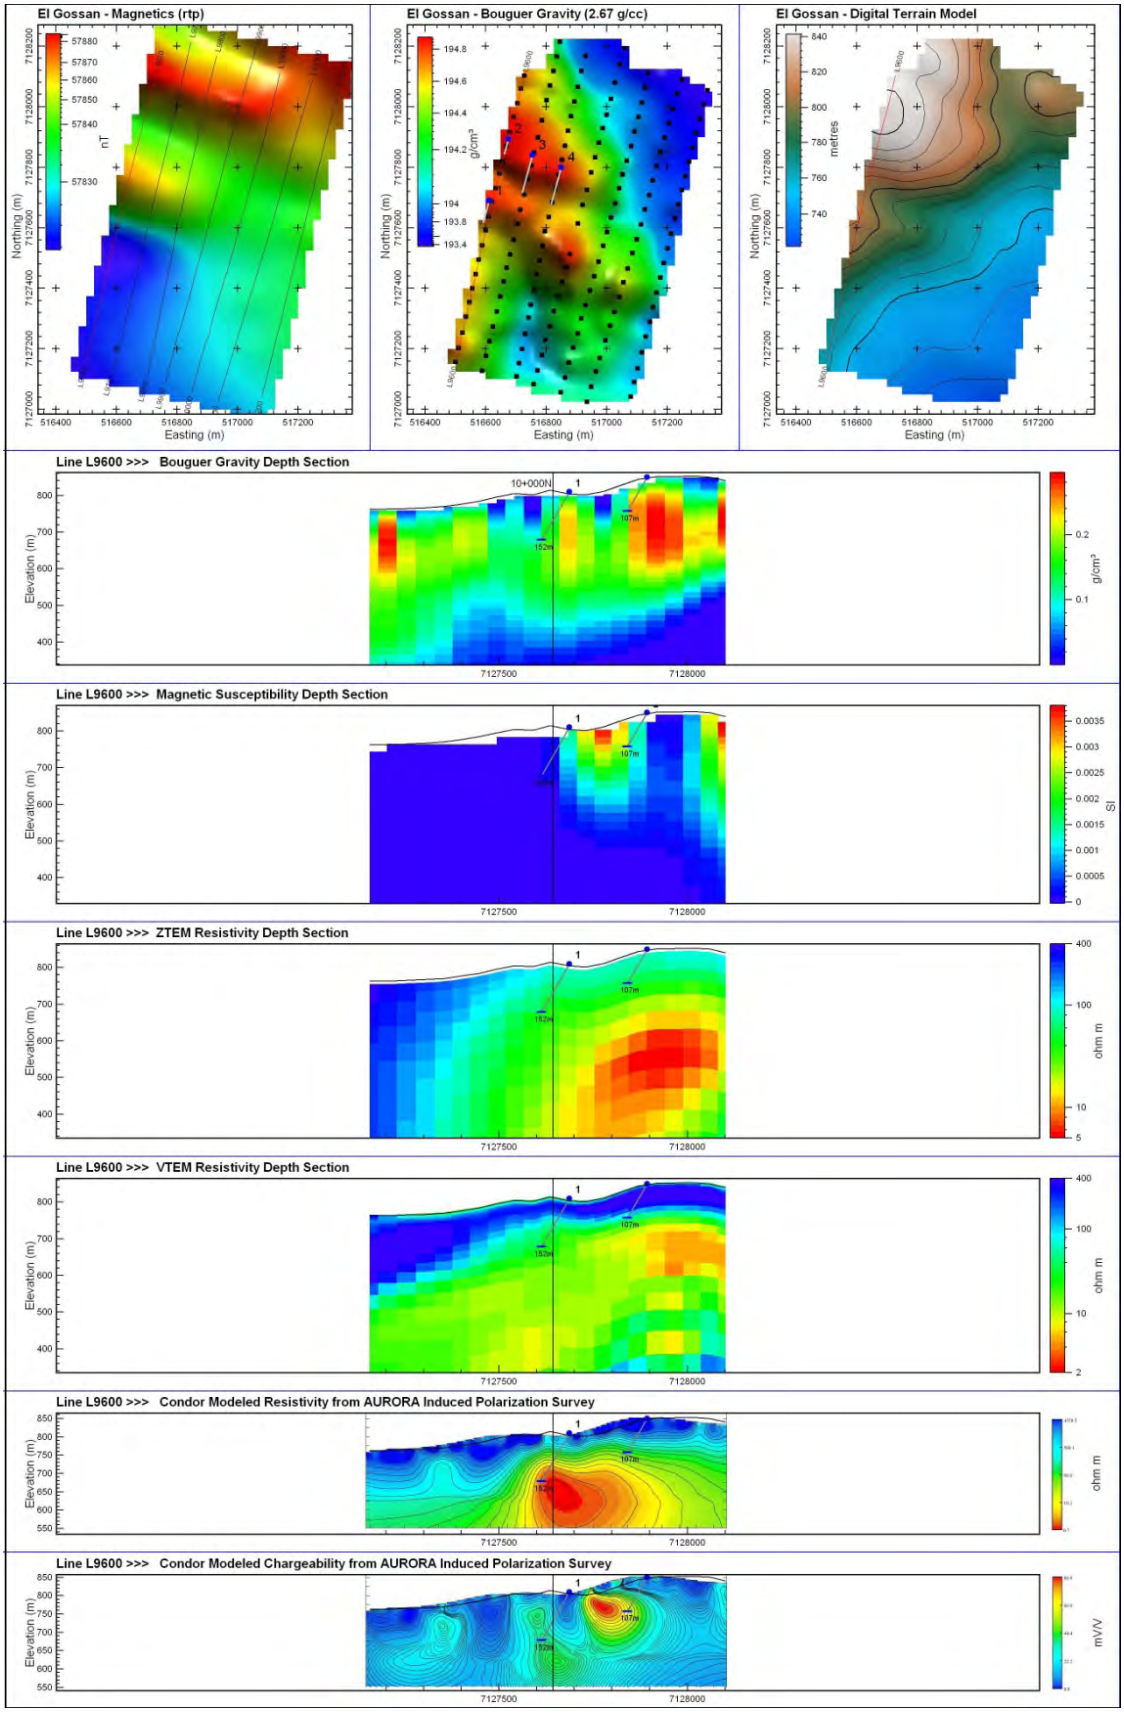

Figure 45: El grid. Example MultiPlot - Line 9600.

of the base line 10 000N. However, in hindsight the collar was located too far south and the hole may have gone over the top of these targets. It intersected a 1 m zone of galena/smithsonite approximately correlating with the density high - however this thin sulphide zone is not sufficient to generate the observed gravity anomaly. Graphite/pyrobitumen was also present within the carbonates

Hole No 2 was drilled under Hole No 1, at a steeper angle. It was designed to test the zone of higher density and higher chargeability. This hole intersected weak mineralization for 70 m down hole in the center of the IP anomaly, which was interpreted as weakly altered, dolomitized karst-filled limestone. Pyrobitumen was also present.

The gravity and chargeability anomalies have not been satisfactorily explained by the two drill holes. The very low resistivities at depth also require an explanation – the holes appear to have barely penetrated this zone. Although graphite/pyrobitumen has been observed in the drill core, graphite does not appear to be the explanation for the low resistivity zone because the observed chargeability highs are localized in the surface resistive zone and do not correlate with this conductor.

12. CONDOR PRODUCTS

TargetMaps

Scale 1:40 000 (Central block) and 1:20 000 (SE and NW blocks) NAD83 / UTM Zone 14N

For each block, eight maps have been generated, with base layer images as follows:

- TMI-RTP
- Magnetic Tilt Angle
- Digital Terrain Model
- XIP_180Hz_PR (Z/X In-phase Component Phase Rotated at 180Hz)
- YIP_180Hz_PR (Z/Y In-phase Component Phase Rotated at 180Hz)
- IP_180Hz_TPR (Total Phase Rotated from In-phase Components at 180Hz)
- IP_180Hz_DT (Total Divergence from In-phase Components at 180Hz)
- 180Hz_Apparent_Conductivity

On each map the following layers are presented:

- Magnetic interpretation
- ZTEM conductor axes
- Target Zones
- Ground grids (in Central block)
- Drainage

MultiPlots

Horizontal scale 1:20 000

MiniPlates: RTP, Tilt Angle, Apparent Conductivity 180 Hz, DTM

Tracks:

- EM X In-phase profiles 30-720 Hz
- EM X Quadrature profiles 30-720 Hz
- TMI, Tilt Angle, 1st vertical derivative
- Conductivity Depth Section showing EM system height and drill holes (where present)
- Magnetic susceptibility model from MAG3D inversion
- Trackmap of Tilt Angle, with flight path

Stacked CDS

Horizontal scale 1:20 000 Vertical scale 1:40 000

Central block – 11 sheets

SE block – 7 sheets

NW block – 7 sheets

Processing and Analysis Report (2 hard copies)

Archive DVD contains the following files:

- PDF files and Geosoft Map files of all **TargetMaps**
- DXF files of interpretation
- Geotiff images of ZTEM magnetic grids (TMI, RTP, 1st vertical derivative and Tilt)
- Geotiff images of ZTEM EM grids (IP_180Hz_TPR, IP_180Hz_DT, XIP_180Hz_PR, YIP_180Hz_PR, 180Hz_AppCon)
- PDF MultiPlots for Central, SE and NW blocks
- PDF stacked CDS for Central, SE and NW blocks
- PDF MultiPlots comparing ground and airborne geophysics over Grid2 (Tiger), ZTEM, Puma and El grids within Central block
- PDF copy of this report

- Geotech report and products for ZTEM Main survey (August 2010)
- ZTEM Primer
- Interim Interpretations June-Aug 2010

13. CONCLUSIONS AND RECOMMENDATIONS

The ZTEM survey has delineated conductive zones in all three blocks which may be caused by lithologies and/or alteration associated with Au (and possibly base metal) mineralization. Due to the nature of the system, ZTEM is more suited to defining zones with longer strike length than discrete conductors. Because ZTEM responds to conductivity contrasts rather than absolute conductivity, it is suited to geological mapping and delineation of structures and alteration associated with precious metal deposition.

In the Central block, a ZTEM conductor correlates with the Tiger zone and extends northwest for a total strike length of approximately 10 km, encompassing a number of Au prospects including Puma. A similar, but separated, conductor correlates with the El zone. These were partially defined by the previous VTEM survey as relatively weak and discontinuous conductors, but the ZTEM conductors are stronger, more continuous and better resolved from other conductors.

Standard products from the ZTEM include maps of various parameters, some of which are based on either the X (along line) or Y (across line) components and some are based on the combined responses. In the Central block the image of the XIP_180Hz_PR (180Hz inphase z/x component phase-rotated) best defined the Tiger zone and its extension to the northwest. Consequently, this parameter was chosen as the primary data for initial interpretation of the other two blocks. The 180Hz data is a mid-frequency which provides suitable depth penetration – images of the same parameter at other frequencies do not differ markedly.

The Z/X measurement is most sensitive to conductors approximately perpendicular to the flight lines, while the Z/Y measurement is most sensitive to conductors sub-parallel to the lines. Examination of both sets of images suggests that in the Central block the majority of conductors are oriented across the flight lines and so the X component data is most useful for mapping conductors. However, in parts of the SE and NW blocks, significant differences are noted between the grids generated using the X component and those generated using the Y component, indicating that the conductors are not perpendicular to the flight line direction. In these areas the TPR (Total Phase Rotated), DT (Total Divergence) and Apparent Conductivity (Condor) which combine the X and Y components have also been utilized in the interpretation.

The Osiris mineralized zone in the SE block does not show any clear ZTEM signature, although it does lie close to a major conductor boundary extending in a NW-SE direction across most of the block. Con-

sequently, this style of mineralization appears to be different from that of the Tiger zone in the Central block.

The Target Zones generated during the interpretation are based on the Tiger zone model – strike extensive, relatively narrow, weak-moderate conductors oriented close to the magnetic strike direction. These TZs are usually relatively large and no viable method has been identified to utilize other geophysical parameters to focus within these zones. Consequently, other techniques including geochemistry and geological mapping will be required in conjunction with the ZTEM conductivity and magnetic data to generate specific drill targets.

THE ZTEM SYSTEM
PRINCIPLES, MODELING AND ANALYSIS TECHNIQUES

GENERAL BACKGROUND

The ZTEM system was developed over the first part of the last decade (Kuzman et al 2005) and has been flying commercially since 2006. This technical note was written so as to provide Condor's clients with a basic background on the system, how the data is processed and interpreted. Additional information on the system and data processing is included with all of Geotech's ZTEM survey reports. As the system is quite new to the exploration industry, this document will most likely be modified from time to time.

The ZTEM system operates quite differently from traditional airborne EM systems such as VTEM. For VTEM and other what are sometimes referred to as active source EM systems, EM signals are transmitted into the earth and return signals received as the system moves over the ground in a fashion analogous to a towed marine sonar 'pinger'. Unlike sonar however, the transmitted EM field interacts with the underlying conductivity in the earth and the received signal (or secondary signal) gives a response that with suitable processing and analysis can define the location and quality of conductors within the earth. The image below shows the transmit and receive modes of an active source EM system.

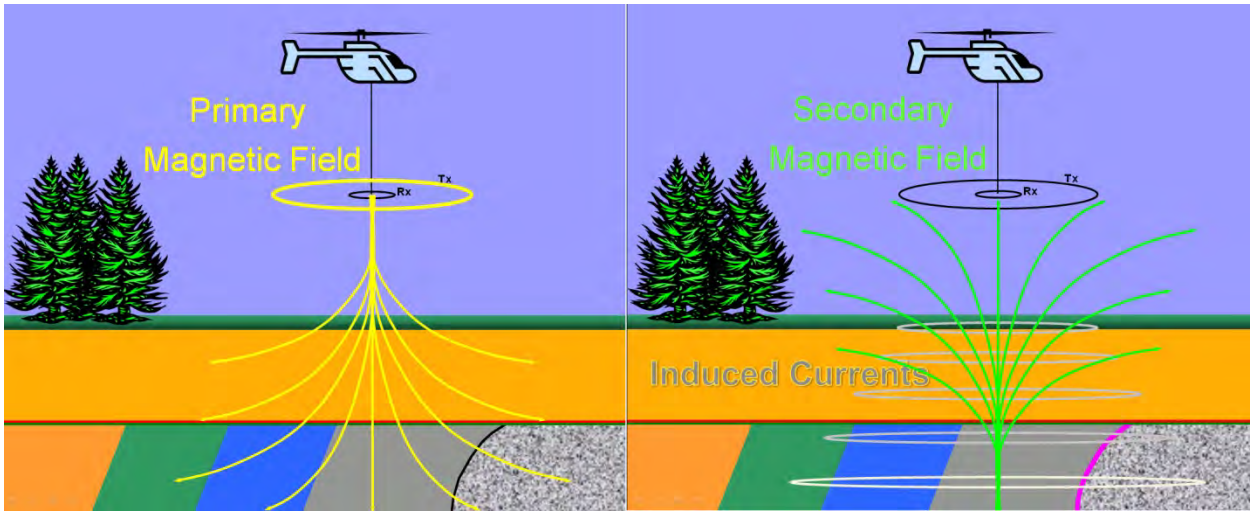

Figure 1

Rather than relying on a signal generated by the equipment on board the aircraft, ZTEM measures naturally occurring magnetic fields in the earth in a fashion similar to the Magnetotelluric (MT) technique. Fig. 2 shows the power spectrum and bandwidth of EM responses that the ZTEM operates in. ZTEM typically operates between 30-720 Hz.

Unlike conventional AEM methods which are designed to map confined conductors (targets of limited sizes) the ZTEM technique responds best to conductivity contrasts or resistivity gradients most often associated with large geological features such as shown in Fig. 3 below.

The ZTEM system measures the vertical MT field (referred to as Hz) in a loop carried below the helicopter. The other two components Hx and Hy are measured on

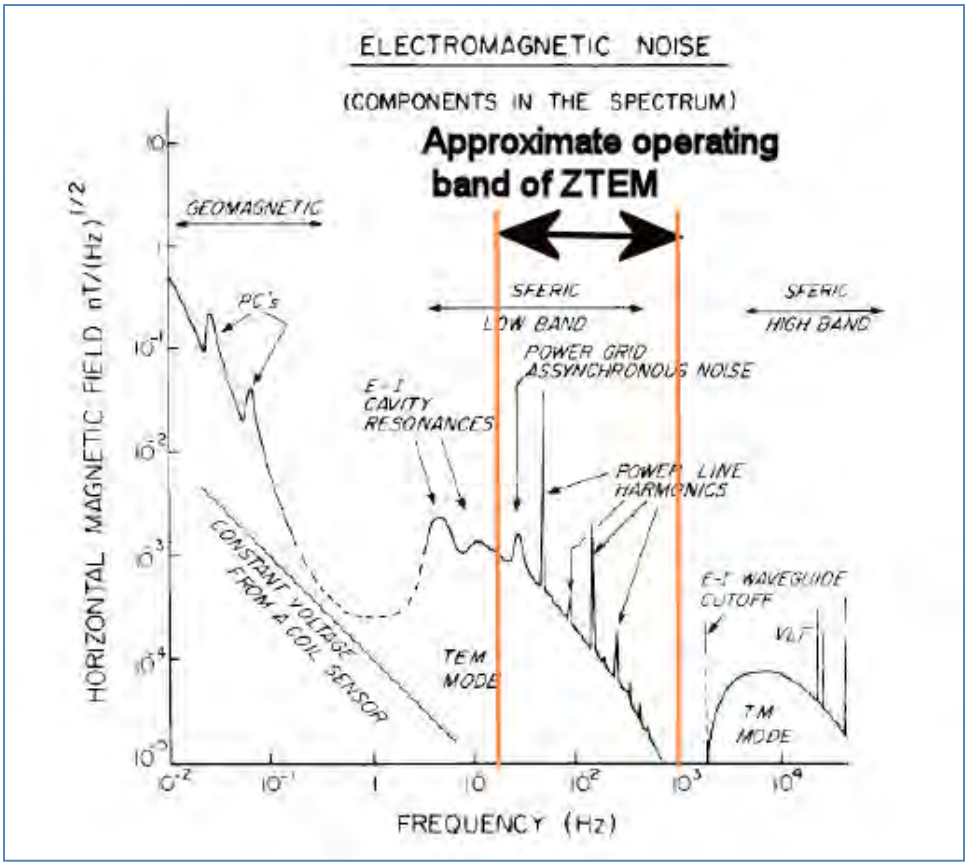

Figure 2

the ground with two fixed coils. The primary delivered data is the ratio of the Hz/Hy and Hz/Hx, commonly referred to as the tipper ratios and expressed in the form Tzx and Tzy. Geotech routinely delivers information (in-phase and quadrature data as a fraction) at the frequencies 30, 45, 90, 180, 360 and sometimes 720 Hz. As can be seen in the naturally occurring EM spectrum plot)Fig 2), the ZTEM signal strength drops as the frequency increases and the 720 Hz signal can sometimes not be obtained. Fig. 4 shows what the various parts of the ZTEM system look like.

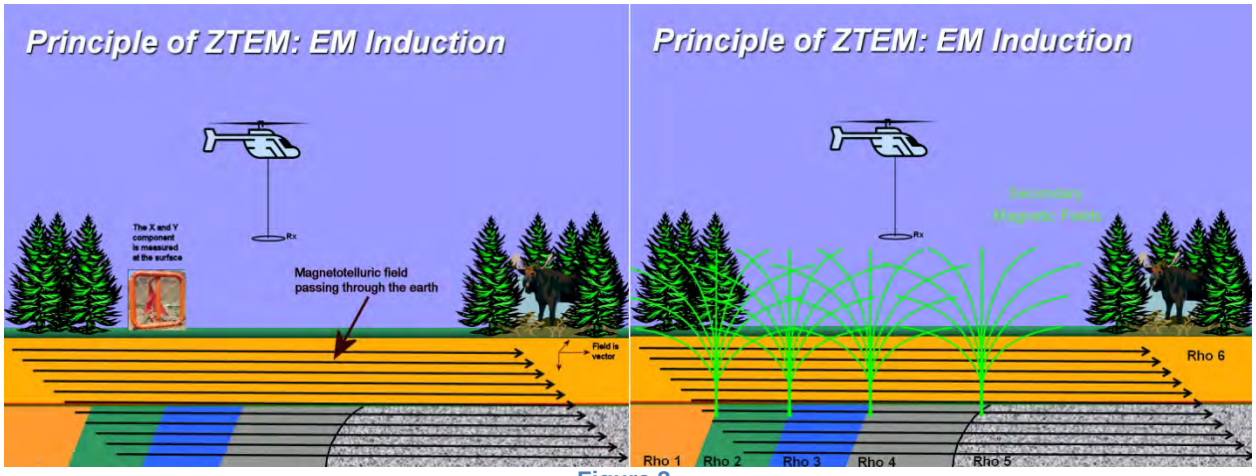

Figure 3

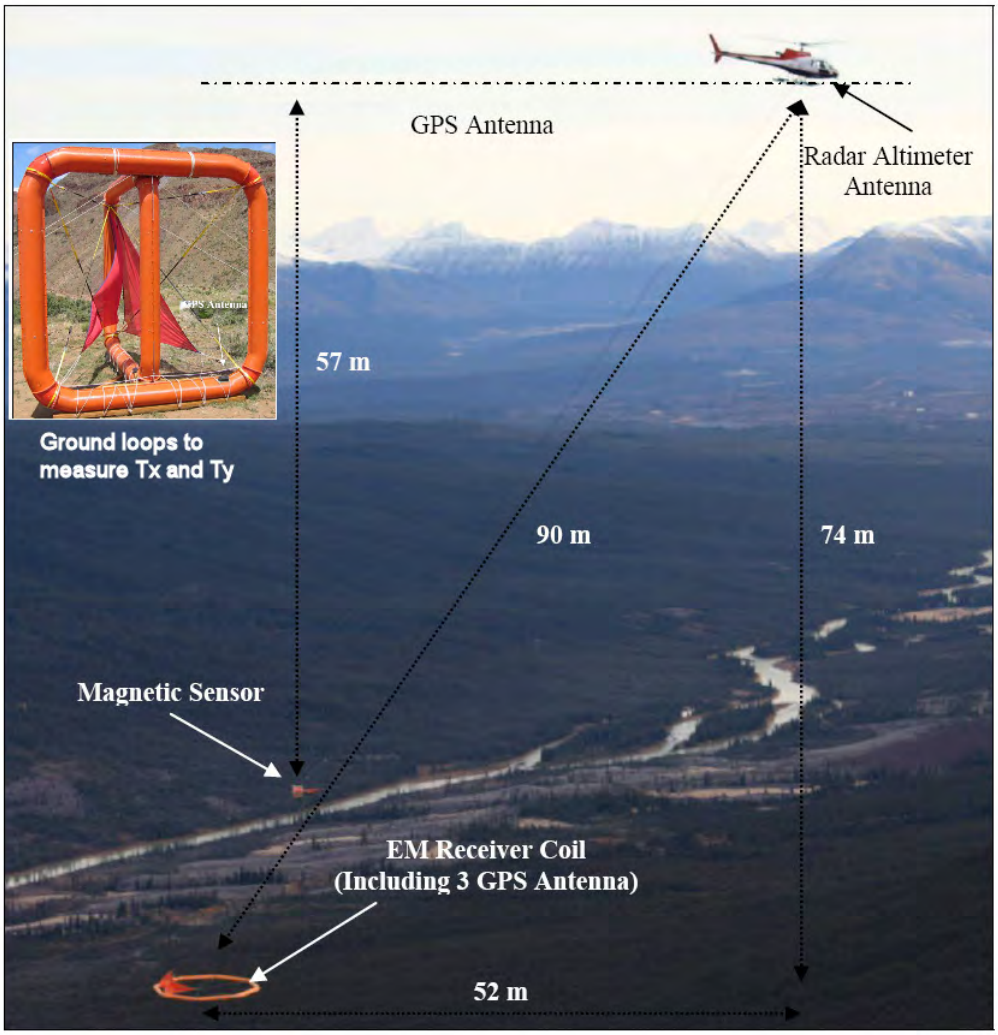

Figure 4

The Geotech standard field report discusses important issues about how the data is processed and presented to clients. A copy of a recent version is attached with this Technical Note (November 2010).

Even though ZTEM data are sensitive to lateral variations conductivity contrasts, the system can't resolve absolute earth conductivities. While calibration of the ZTEM responses using external information is theoretically possible, we have not achieved generally better outcomes of our ZTEM processing using a priori resistivity information.

The setting up of a ZTEM survey is fairly normal compared with other airborne techniques. Flight lines should be normal to the likely geological strike. As to line spacing however, due the more slowly changing primary field strength, little additional information is gained by going to line spacings closer than 100 m. For the primary processing Geotech performs to the raw ZTEM data, Geotech requires a minimum line length of 10 km to be used.

The strength of the natural EM field drops off slower with height than the primary field generated by active-source EM systems. For this reason ZTEM can operate in more rugged terrain (flying higher) and still obtain a useful signal. Condor believes that while this aspect of ZTEM is beneficial to getting good quality data in rugged areas, the system should still be operated as close to the ground as can be safely accommodated in the specific survey conditions.

ZTEM is more sensitive to power line noise than active source EM techniques and in some instances, Geotech will decline to undertake a ZTEM survey if they feel the data will be sub-standard due to excessive power line interference.

SYSTEM RESPONSES

This section shows the ZTEM response to some basic geological scenarios. These results were generated using the 2D finite element code developed by Phil Wannamaker (Wannamaker et al 1987). The first plot (Fig. 5) shows the response across a layered earth. Since Hz is zero above a 1D (layered) earth, the ZTEM Tzx response is also zero.

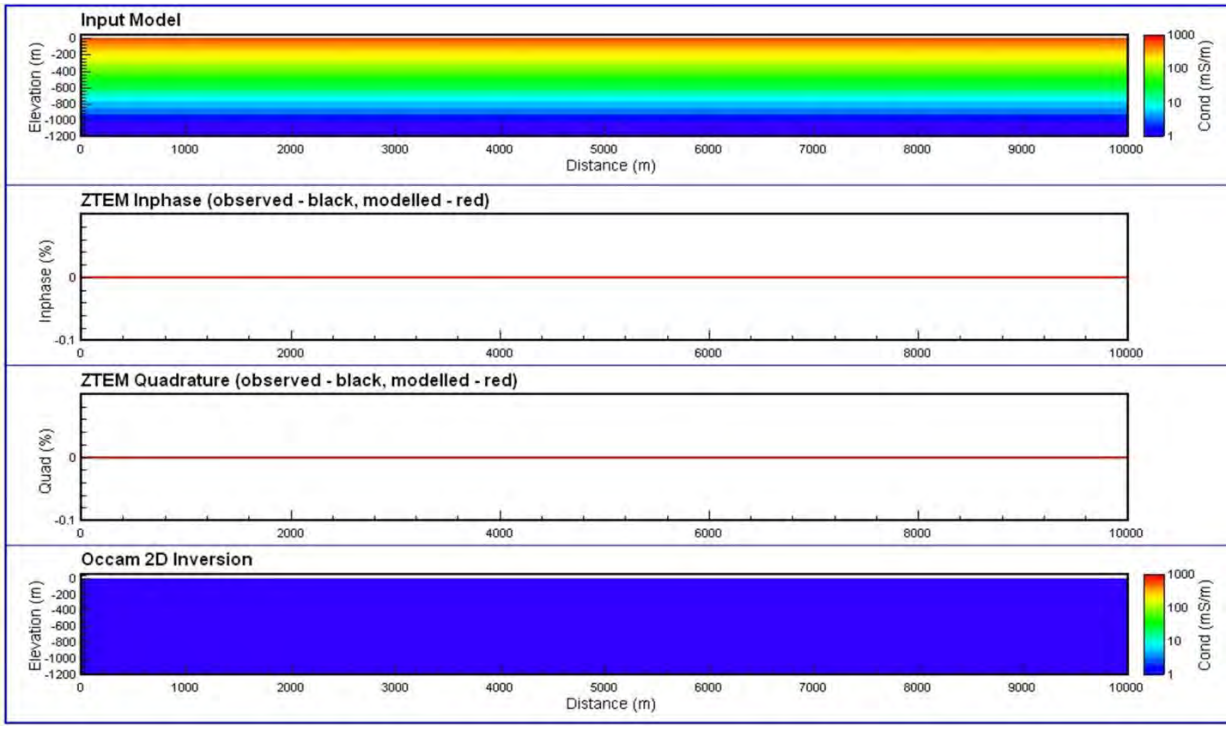

Figure 5

In the next figure (Fig. 6) the response over a contact with a fixed ratio between the two sides (1:100) but with the absolute resistivity values allowed to vary. This shows the basic shape of the ZTEM responses, a peak overtop of the contact. Note the slope of the response is steep on the conductive side and broad on the resistive side. There is also a change in amplitude with absolute value of the resistivity; higher resistivities produce slightly higher peak responses.

The next set of models (Fig. 7) shows the response for a variable contrast contact; 1:2 at the top of the figure and 1:1000 at the bottom. The higher the contrast the higher the amplitude of the response; lower contrasts also produce broader, more symmetric responses.

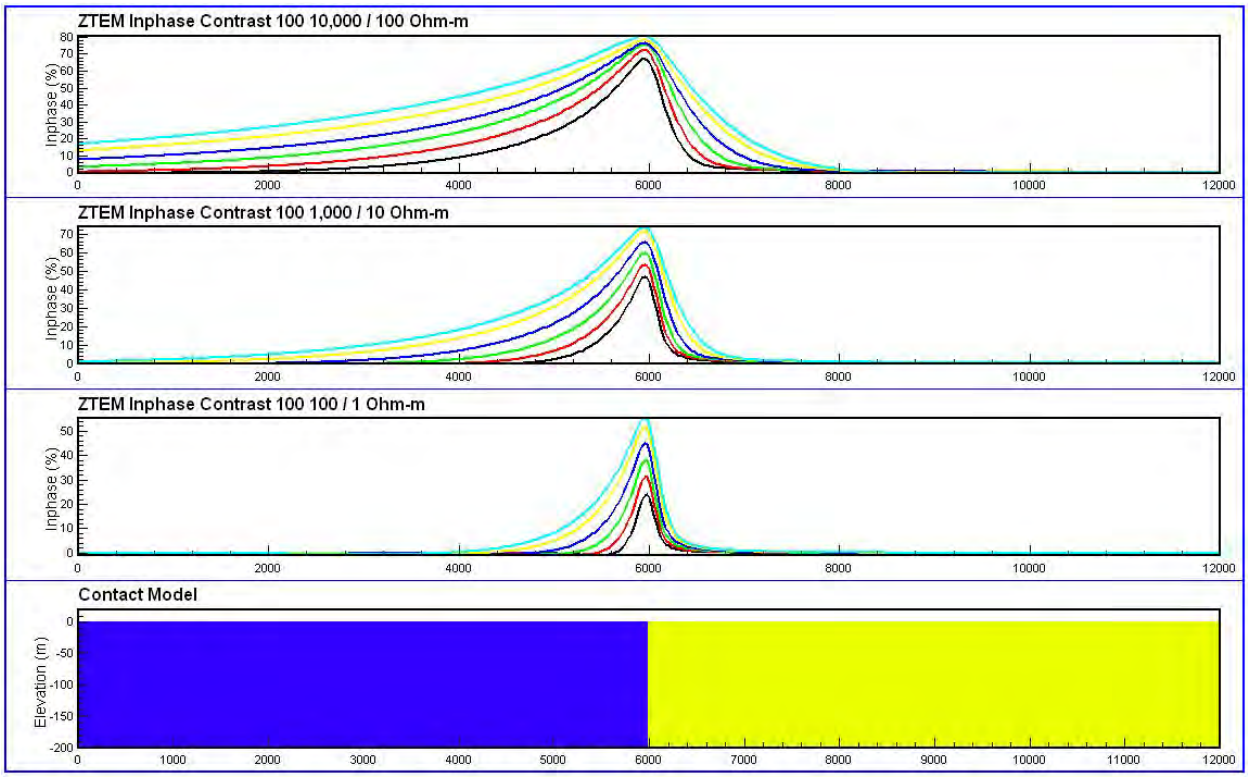

Figure 6

The next model (Fig. 8) shows the 1:100 ratio contact model that has been processed with Condor's 2D Occam code (Sattel and Witherly 2010). The observed and model fits to the data are shown in profile form and the resulting conductivity depth section at the bottom of the image. Note the resistive part of the model is well recovered but the conductive section is over-estimated in conductivity value. As well a minor contact 'artifact' appears at the contact.

A conductive body is added in the next figure (Fig. 9). In the modeling this then produces a strong conductor that is slightly shallower than the actual target depth. The resistivity of conductive unit (on right) is also better recovered in this situation.

The response over a conductive slab is shown in the next figure (Fig. 10). This highlights that ZTEM responds primarily to resistivity gradients at contacts or edges. At both edges, a strong response is observed but over the conductive slab proper, there is no response observed.

The final figure (Fig. 11) shows the response of a target under a conductive slab. Note this discrete response also allows the inversion program to achieve some definition of the surface layer as well.

In terms of anomaly shapes, over contacts (example in Figs. 6-7-8) the anomaly shapes are peaks whereas for discrete targets, the responses are more cross-over's (examples in Figs 9 & 11). This means that contact-type responses will be displaced if a phase-rotated product is used for interpretation.

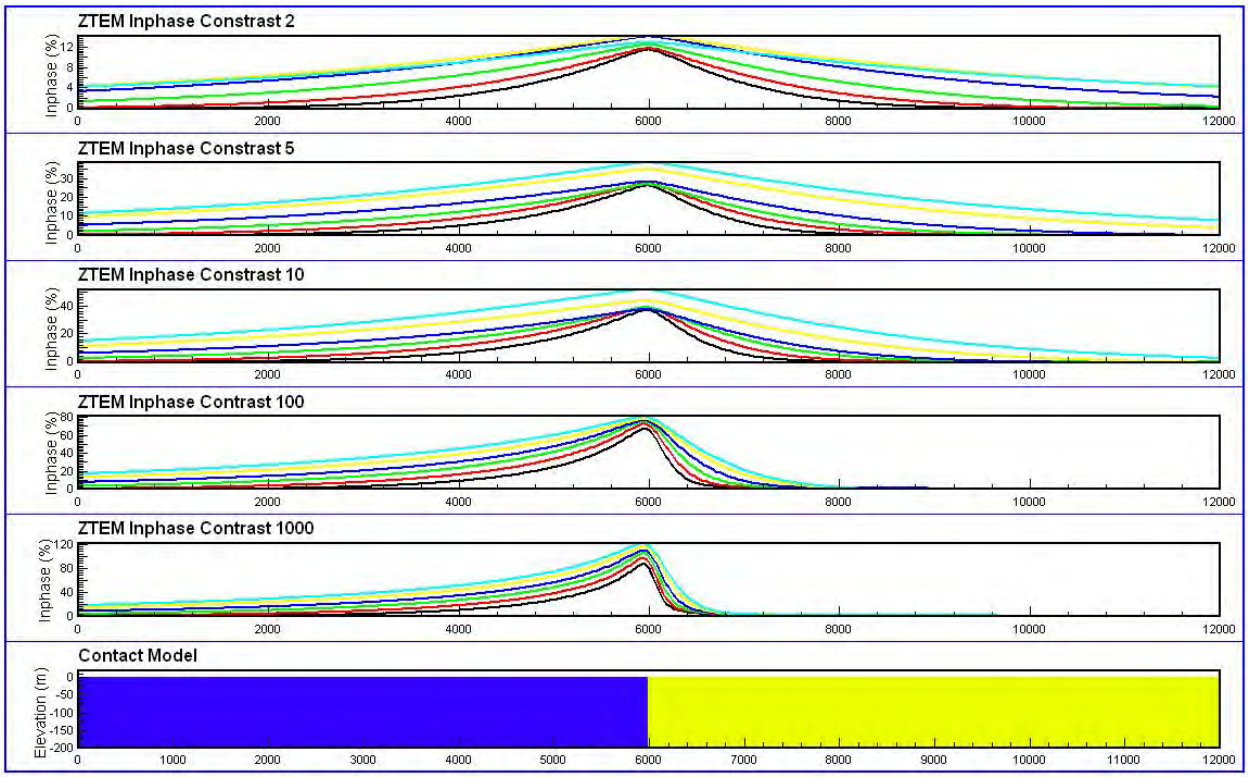

Figure 7

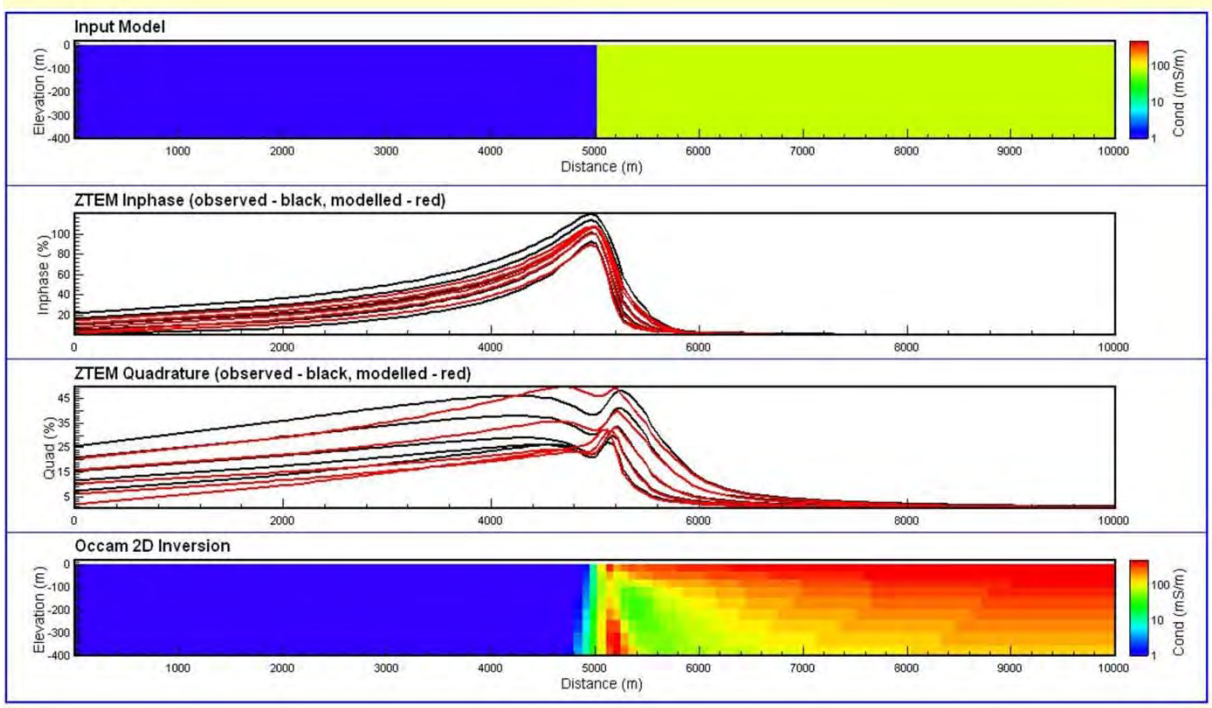

Figure 8

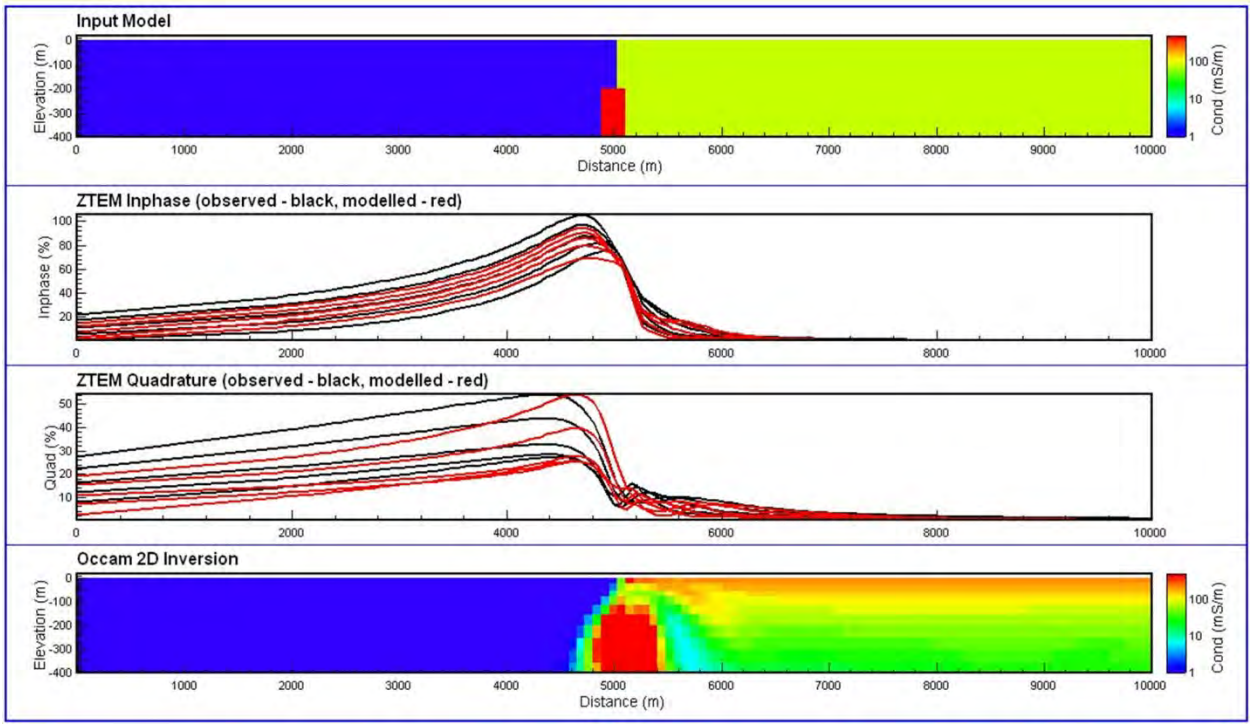

Figure 9

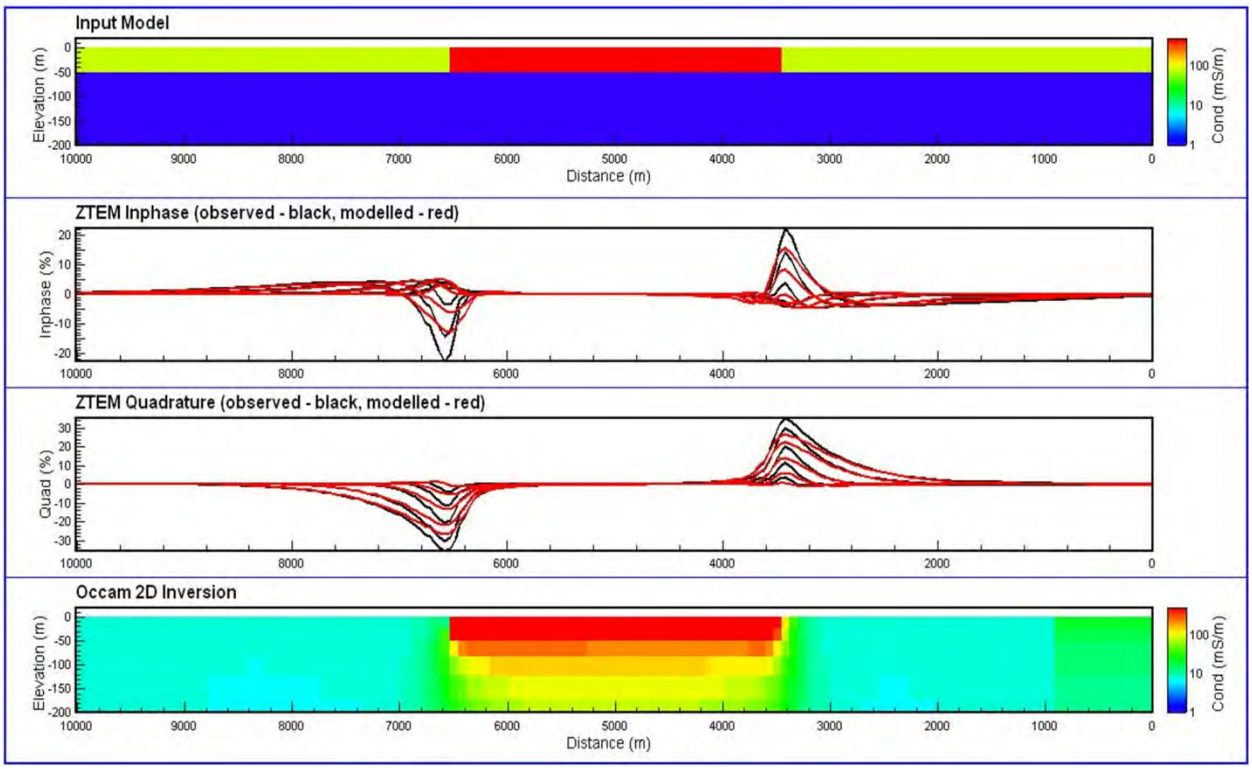

Figure 10

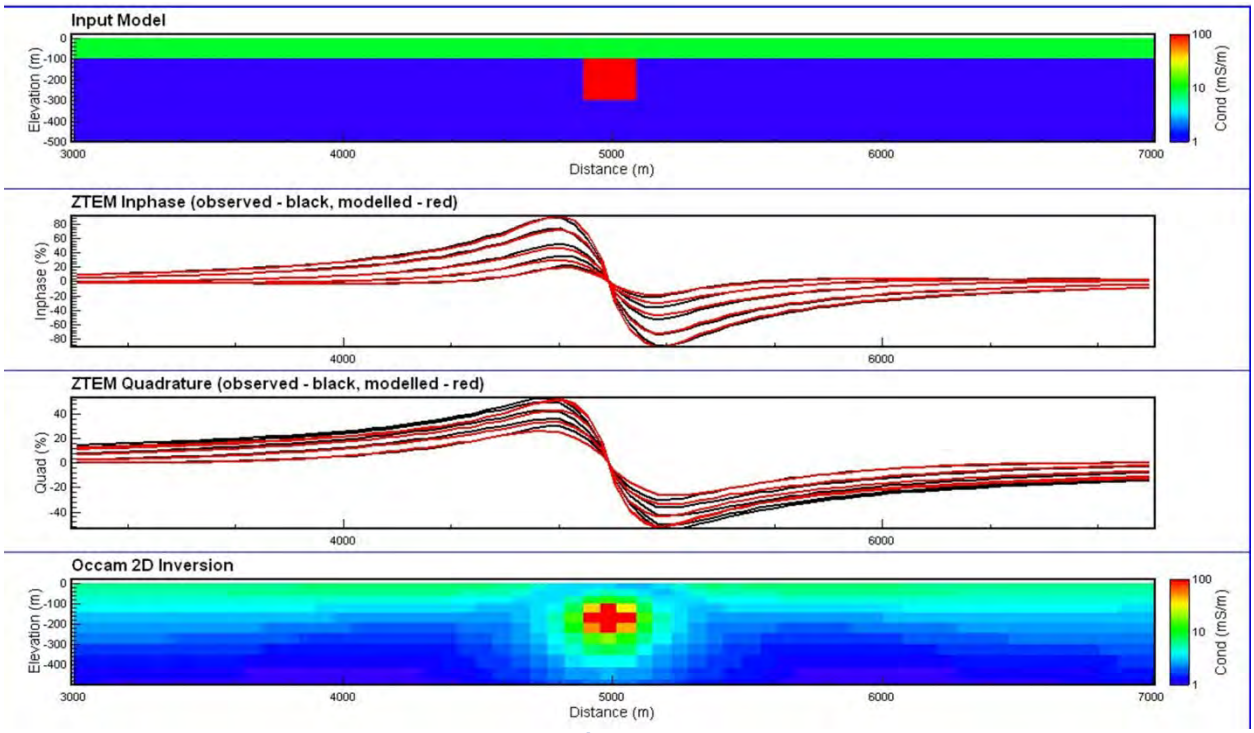

Figure 11

PROCESSING & PRODUCTS

The three main forms of products that are currently generated from the ZTEM data are:

1) Profiles of the tipper ratios (for each of the acquired frequencies, each with an in-phase and quadrature component.

2) Grids of original and phase-rotated in-phase and quadrature information of the Tzx and Tzy components. The phase-rotation produces positive peaks over discrete conductive features. The same filtering over formational contacts (examples in Fig 6-7-8) will produce a slightly displaced peak since the primary anomaly shape is a positive peak (rather than a cross-over as is present over a discrete conductor (examples Fig. 9 & 11)). A further grid set is also generated from the merging of the Tzx and Tzy grids and the peaker (sum of the horizontal derivatives). The derivation of these products is discussed in more detail in the Geotech field survey report.

3) 2D conductivity inversions.

The application of 3D inversions, such as described by Holtham and Oldenburg (2010), for the modeling of large scale ZTEM surveys is still considered impractical due computing time to perform 3D inversions over large areas.

Examples of these products are shown below from ZTEM surveys Condor has worked on over the last six months.

Profiles
Typically the in-phase and quadrature information for the various frequencies is what is commonly displayed.

Grids-Geotech
The definitions of the Geotech-derived grids are provided below. The DT and TPR grids are generated from the peaker and phase-rotated, merged Tzx and Tzy component data respectively.

DT (Total Divergence): The DT gives a clearer image of conductor's location and shape but, as a derivative, it does not preserve some of the long wavelength information and is also sensitive to noise.

TPR (Total Phase Rotation): As an alternative, a 90 degree Phase Rotation (PR) technique is also applied to the grids of each individual component (Tzx and Tzy). It transforms bipolar (cross over) anomalies into single pole anomalies with a maximum over conductors, while preserving long wavelength information (Lo et al., 2009). The two orthogonal grids are then usually added to obtain a Total Phase Rotated grid for the in-phase and quadrature.

The major purpose of various grid displays is try and provide an optimal means to show the contained geological content. On a component basis, the Tzx component contains the most information about the geology normal to the survey line and the Tzy about across-line conductivity. Together (in the form of the DT or TPR products), a more 3D-view of the geology is conveyed.

Fig 12 shows all of the Geotech-generated grids for the Pebble 45 Hz signal. As noted above, some of the products are unique and some are the merged product of the Tzx and Tzy component data; this is indicated in the figure. There is a suite of such grids for each frequency being provided by Geotech.

Currently, there are likely more choices in grid-based products than are effective for most exploration situations; i.e. too many choices. Geotech has likely pursued this approach given the nascent state of ZTEM interpretation and a fear they might 'miss something' if they did not provide what they felt were all the products that might show useful information. At this stage, Condor has usually performed 'quick looks' using the Tx-in-phase data at one of the lower frequencies.

Condor also produces a set of products defined below. Some have similarity to what Geotech provides and some considered different. As noted above, there are likely too many derived products currently being produced for ZTEM surveys and with experience, we'll know the best suite of products to employ in most situations.

1) AppCon grid

2) 2D Occam conductivity depth model

3) Karous-Hjelt depth section & grids

AppCon: The apparent conductivities and phases are derived using both the Tzx and Tzy Tipper information for each frequency. This approach uses an approach first developed for VLF data by Becken and Peterson (2003) and is believed to derive a superior estimate of the conductivities being mapped.

The AppCon outcomes for Pebble are shown in Fig. 13.

2D Occam: This uses a modified version of a 2D MT inversion program developed over a number of years by Constable and Wannamaker (deGroot-Hedlin and Constable, 1990; Wannamaker at al., 1987; deLugao and Wannamaker, 1996). The primary output of the inversion is a conductivity depth section such as shown in Figs. 8-11. In addition, grids can then be created showing the conductivity at a particular depth below surface.

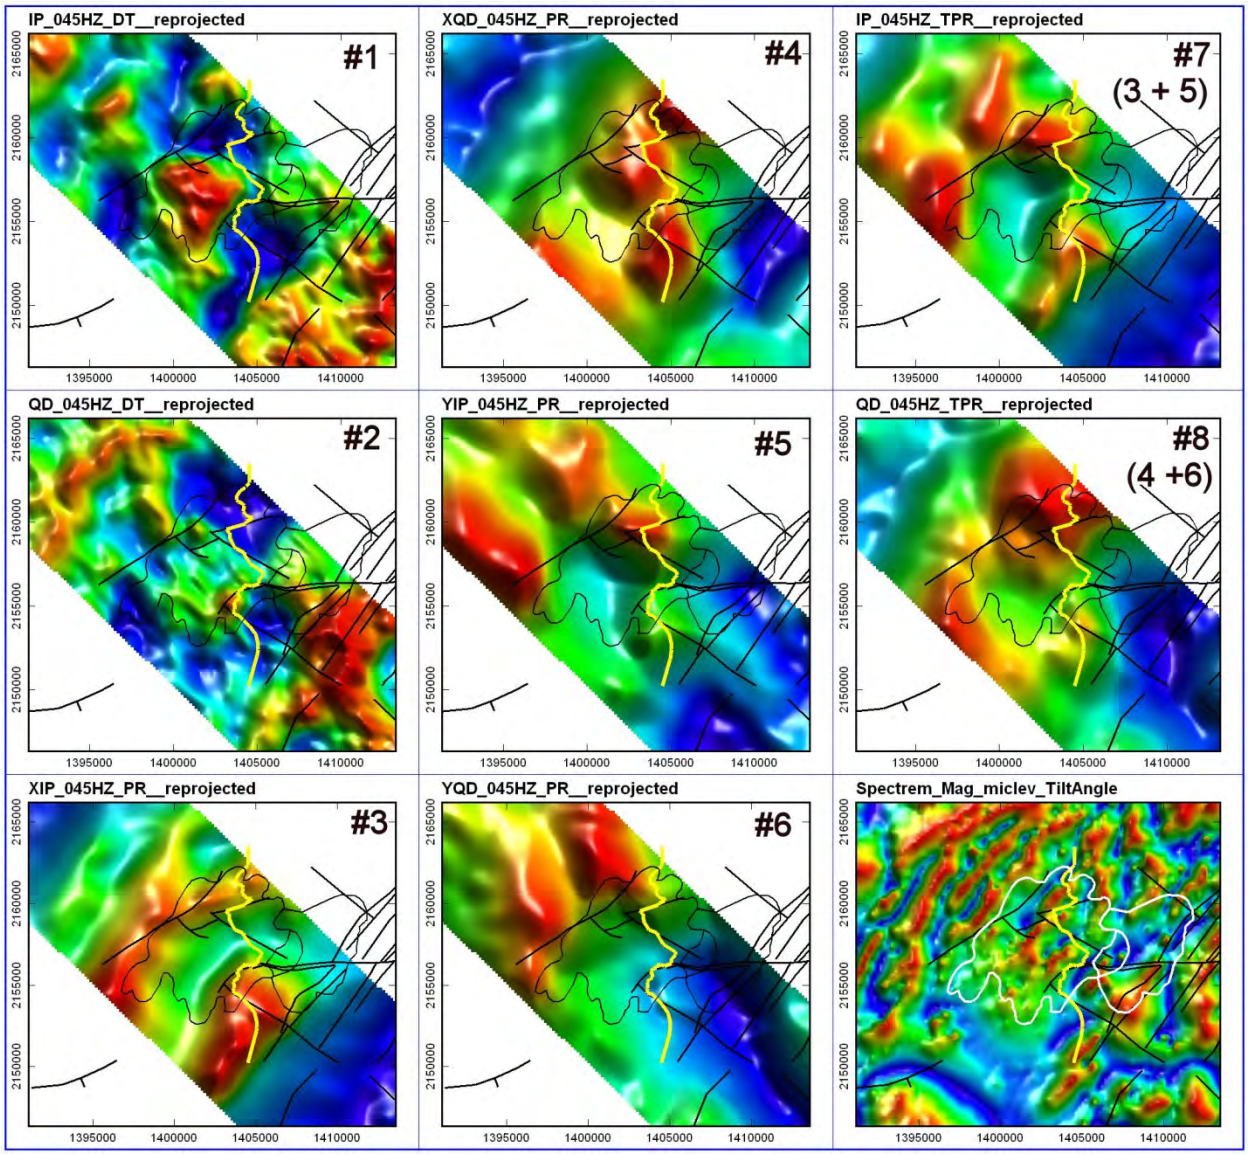

Figure 12

The result of a 2D Occam inversion for Pebble is shown in Fig. 14; the result of an inverted line of Spectrem data (active-source time domain EM system) is shown as well for comparison.

Fig. 15 shows a series of depth slices through a block of models derived with 2D Occam inversions from ZTEM data acquired across the Pozo Seco deposit (Witherly 2010). The depth slices from a VTEM-derived conductivity model over the same area are also shown. This example shows that the ZTEM results provide considerably more detail about the conductivity structure of the earth than the VTEM. This is considered a good example of ZTEM being more sensitive to high resistivity zones and contacts within these zones.

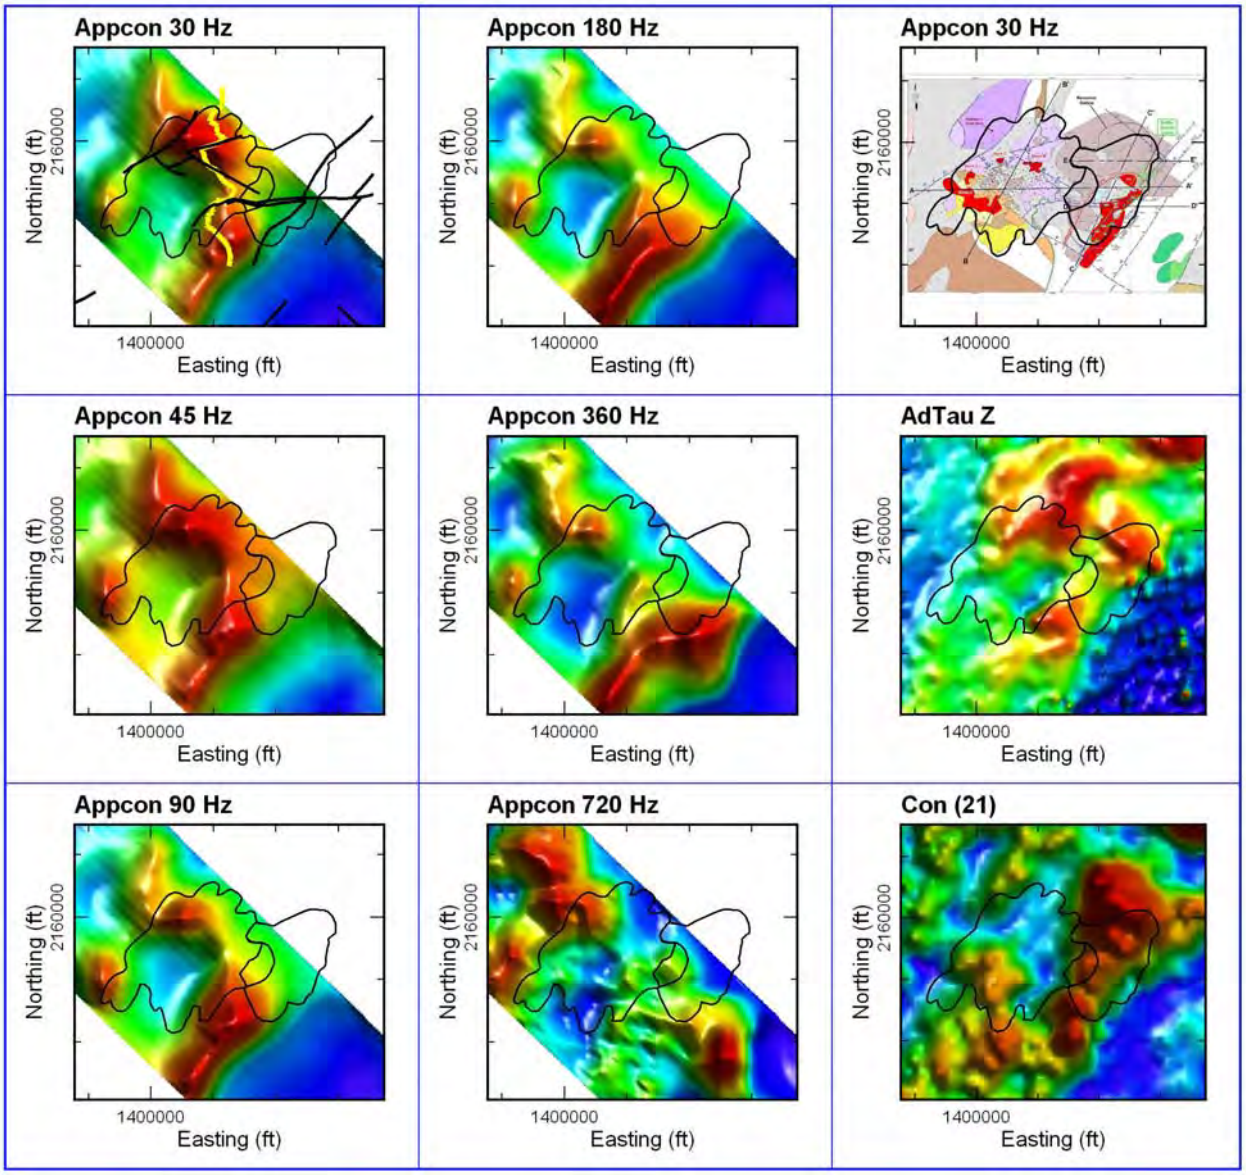

Figure 13

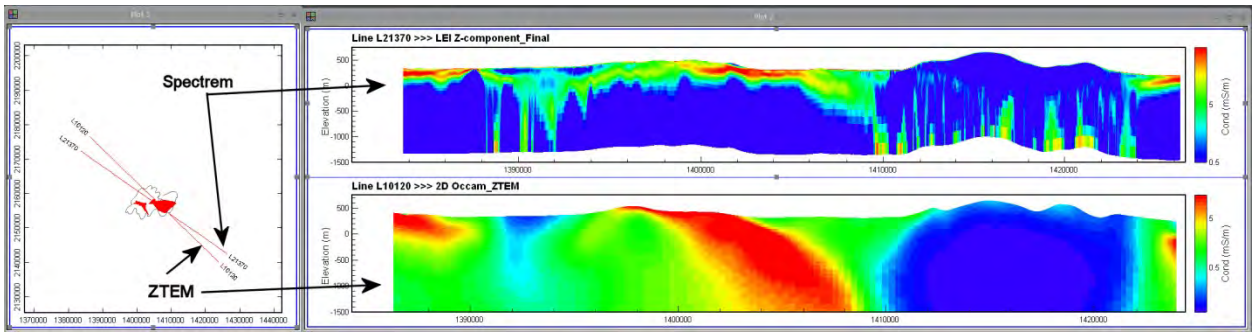

Figure 14

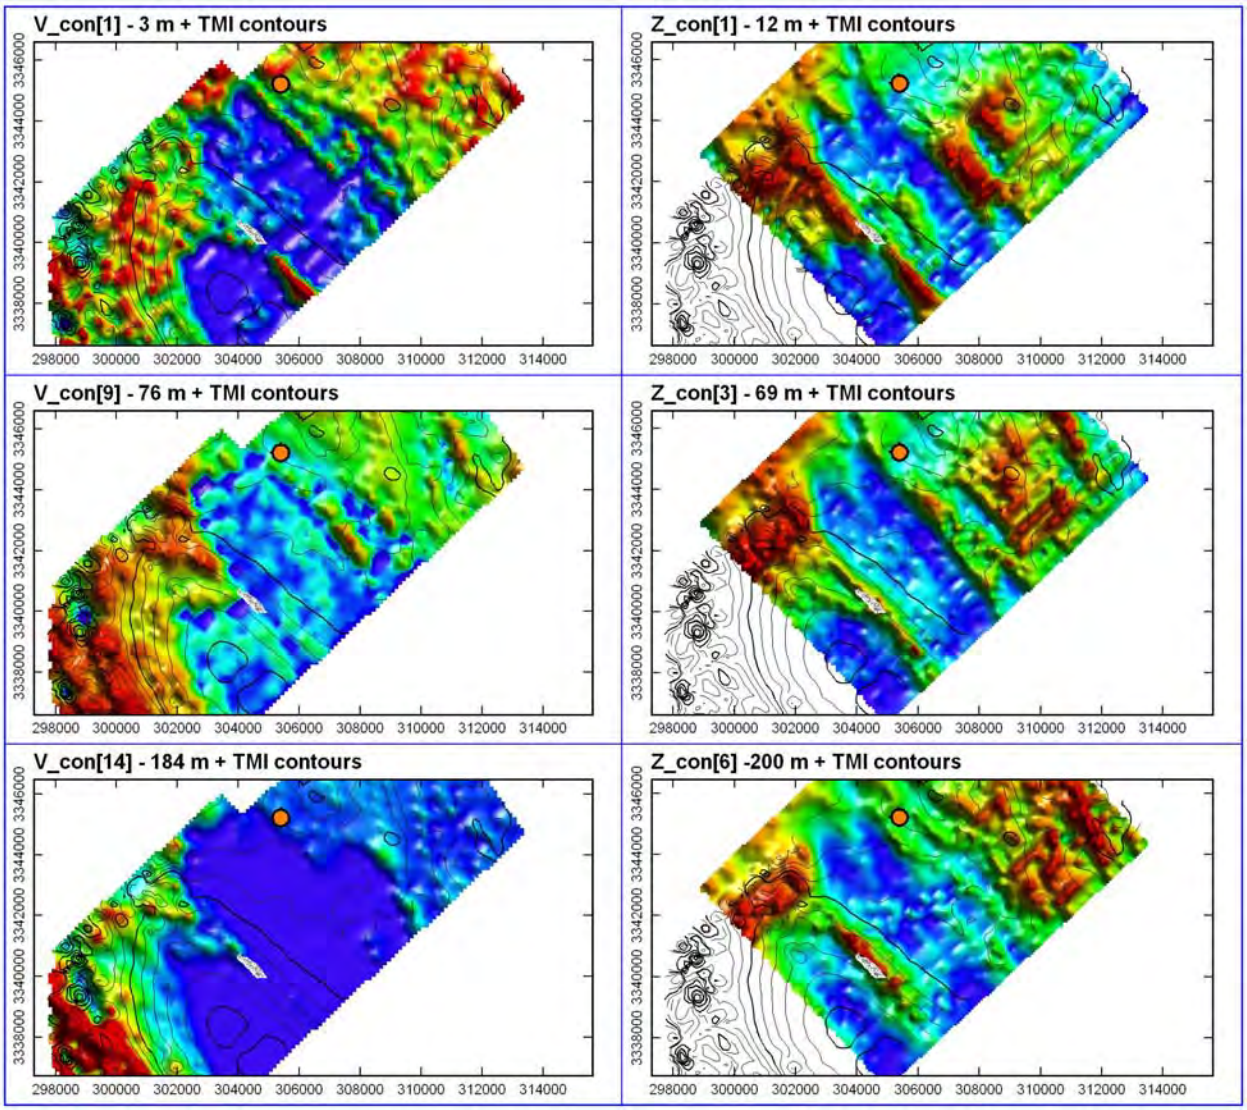

Figure 15

Karous-Hjelt depth section & grids: Pseudo-sections derived with the Karous-Hjelt filter (Karous and Hjelt, 1983) can be useful to extract subtle conductors from the ZTEM profiles. The main property of the Karous-Hjelt filter is to turn cross-

over's into peaks. **G**rids can as well be generated from the Karous-Hjelt processing. These grids are similar to divergence grids generated by Geotech that are based on the VLF peaker derivation (Pedersen et al., 1994). The latter however, makes use of the spatial derivatives of the Tzx and Tzy tippers, whereas the Karous-Hjelt-filtered grids shown are derived from either the Tzx or Tzy data.

Fig. 16 shows the Karous-Hjelt pseudosections for a line of ZTEM over the Forrestania deposit (Sattel and Witherly 2010). Also shown is the 2D Occam inversion as well.

Depth of Investigation of ZTEM

A theoretical assessment of the ZTEM frequency group using a skin depth assumption is shown in Fig. 17 (Lo et al 2008). While this concept has merit, it over simplifies the understanding of where the ZTEM signals are being generated. The VTEM system has a base frequency of 30 Hz (same as lowest frequency available with ZTEM) but the deepest useable signal Condor has observed is over conductors in the Athabasca Basin that have been drilled to a depth ~825 m depth. This is believed to be close to the effective depth of investigation of VTEM and is the result of both the skin depth of the primary signal as well as the signal/noise characteristics of the actual acquired data.

An examination of the modeling examples presented there and field results such as from Pebble (Fig. 14) show that the ZTEM results when modeled can produce a smeared result that is wider and deeper than the actual geological sources are most likely coming from.

CONCLUSIONS

ZTEM is one of the most exciting developments in airborne geophysics in the past decade. However, Condor advises caution when trying to interpret ZTEM outcomes as geological information whether profiles, grids or conductivity depth products are being used. More than most EM techniques, ZTEM is a somewhat paradoxical technique in that it is seen as both very sensitive to subtle changes in the earth's conductivity structure but then in some cases will only allow us to view these features as fairly unsatisfactory blurry images. In other instances, ZTEM can produce high resolution images that appear to capture very subtle geological features that no other technique is likely capable of. It is therefore deemed very important to make every effort to calibrate ZTEM outcomes with ground truth (geological or constrained geophysical results) before embracing the ZTEM results 'geo-truth'.

APPENDIX B: DETAILS OF ZTEM PROCESSING

GEOTECH TOTAL DIVERGENCE AND PHASE ROTATION PROCESSING

Extracted from Geotech report - Milicevic, B., Legault, J. and Smith, G. (2010)

In a final processing step DT (Total Divergence) and PR (Phase Rotation) processing are applied to the multi-frequency In-phase and Quadrature ZTEM data. This is due to the crossover nature of the Tipper Responses; these additional processing steps are applied to convert them into local maxima for easier interpretation.

To present the data from both tipper components into one image, the Total Divergence parameter, termed the DT is calculated from the horizontal derivatives of the Z/X and Z/Y tippers (Lo and Zang, 2008). It is analogous to the "Peaker" parameter in VLF (Pedersen, 1998).

Total Divergence DT: *DT = DIV (Z/X, Z/Y)*
= d(Z/X)/dx+d(Z/Y)/dy

This DT parameter was introduced by Petr Kuzmin (Milicevic, 2007, p. 13) and is derived for each of the In Phase and Quadrature components at individual frequencies. These in turn allow for minima over conductors and maxima over resistive zones. DT grids for each of the extracted frequencies were generated accordingly, using a reverse colour scheme with warm colours over conductors and cool colours over resistors.

The DT gives a clearer image of conductor's location and shape but, as a derivative, it does not preserve some of the long wavelength information and is also sensitive to noise. As an alternative, a 90 degree Phase Rotation (PR) technique is also applied to the grids of each individual component (Z/X and Z/Y). It transforms bipolar (cross over) anomalies into single pole anomalies with a maximum over conductors, while preserving long wavelength information (Lo et al., 2009). The two orthogonal grids are then usually added to obtain a Total Phase Rotated grid for the In-Phase and Quadrature.

Total Phase-Rotation: *= PR (Z/X) + PR (Z/Y)*

CONDOR PROCESSING OF ZTEM DATA

2D Inversion Algorithm

The recorded ZTEM data were inverted using a 2D MT algorithm, developed by Constable and Wannamaker (deGroot-Hedlin and Constable, 1990; Wannamaker at al., 1987; deLugao and Wannamaker, 1996). The algorithm models the along-line tipper data Tzx (loosely called the X component), taking into account that the vertical component is airborne and the horizontal component sits on a uniform ground. The responses of all frequencies (30 - 720Hz) were included in the inversion.

Model specifications

The cell widths are 15 m, and the cell thicknesses increase with increasing depth, as listed in the following table:

Layer	Depth to bottom (m)	Thickness (m)		Layer (cont.)	Depth to bottom (m)	Thickness (m)		Layer (cont.)	Depth to bottom (m)	Thickness (m)
1	12	12		15	639	66		29	1897	116
2	24	12		16	707	68		30	2018	121
3	38	14		17	778	71		31	2145	127
4	52	14		18	852	74		32	2278	133
5	85	33		19	929	77		33	2428	150
6	125	40		20	1009	80		34	2608	180
7	174	49		21	1092	83		35	2828	220
8	225	51		22	1179	87		36	3088	260
9	278	53		23	1269	90		37	3388	300
10	333	55		24	1363	94		38	3728	340
11	390	57		25	1461	98		39	4148	420
12	449	59		26	1563	102		40	4568	420
13	510	61		27	1670	107		41	5108	540
14	573	63		28	1781	111		42	5648	540

Padding was added in symmetric fashion to the left and right of each section. The padding cells to the right have the following widths: 60, 60, 80, 200, 200, 200, 400, 400, 400, 800, 800, 800, 2 700, 8 100, 24 300 m.

A 1 000 ohm-m halfspace was used as a start model, and a reference resistivity of 10 000 ohm-m was used for depths beneath 4 568 m.

Noise and target fit

After testing a range of noise levels, the final noise level, specified for the inversion, was the maximum of 7% of the ZTEM response (relative noise level) and 0.7% (absolute noise level). The noise level for the high-frequency responses at 360 and 720Hz were set twice and five times those values, respectively. These noise estimates resulted in a stringent target data fit that was hardly ever met by the inversion, due to the actual noise level exceeding the noise estimates and the occasional inappropriateness of the 2D algorithm in a 3D conductivity scenario. As a result, the algorithm has occasionally over-fitted the data, i.e. fitted noise rather signal. However, using this approach, as much information as possible is extracted from the data.

Apparent Conductivity and phase

The derivation of apparent conductivity and phase from VLF data is discussed by Becken and Pedersen (2003). The method has been applied to the ZTEM data, making joint use of the Tzx and Tzy tipper data (loosely called the X and Y components).

Karous-Hjelt Filter

The application of the Karous-Hjelt filter to VLF data is described by Karous and Hjelt (1983). This filter facilitates data interpretation by turning cross-overs into peaks and troughs. Grids and pseudo-sections were derived from the Tzx inphase response.

APPENDIX C: UBC MAGNETIC AND GRAVITY INVERSION SOFTWARE

Condor uses the UBC (University of British Columbia, Canada) magnetic and gravity inversion software, MAG3D and GRAV3D.

Summary

The earth is divided into cubes, or prisms starting at surface and extending to approximately 1 km in depth. These cubes are called VOXELS. The aim of the software is to determine a relatively smooth susceptibility or density distribution within the voxels which produces a response closest to the observed data. This process is called inversion and is an iterative (trial and error) approach where the susceptibility or density of each voxel is systematically varied, a new calculation of the response is performed and this model result is compared to the observed data. The susceptibility or density is then modified to produce a better match of model and observed data and the process is repeated until a good match is achieved. This iterative method is computer intensive and takes a considerable amount of time, minutes to hours for small data sets and days for larger data sets. The susceptibility or density distribution across the voxels may then be displayed either as a 3D voxel model, or in vertical or horizontal slices through this model.

Smooth Model Inversion

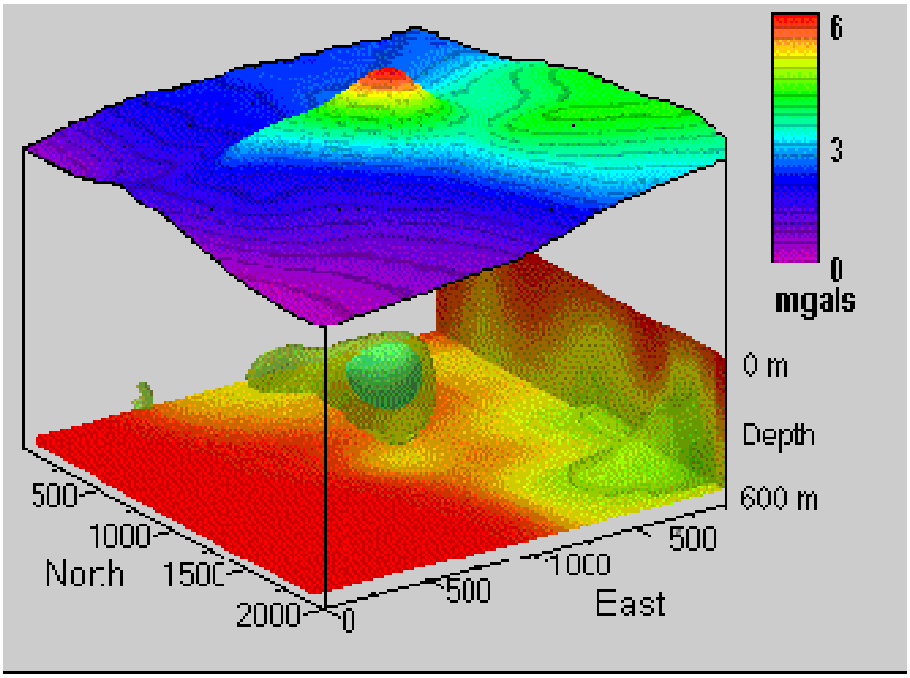
The UBC 3D magnetic inversion is a smooth model inversion, producing fuzzy objects in the resulting block model. This can be mitigated to some extent by sharpening techniques and by constraints. However, the model will still contain a large spatial uncertainty, which manifests as indistinct boundaries. Therefore, the magnetic susceptibility or density values in this model in general underestimate the actual susceptibility/density of the magnetic objects being imaged, since the susceptibility/density is smeared over a greater volume than the actual object.

Depth Weighting

It is a well known fact that magnetic and gravity data have no inherent depth resolution. A numerical consequence of this is that when an inversion is performed the constructed susceptibility/density is concentrated close to the observation locations. In order to overcome this, the inversion introduces a depth weighting to counteract this natural decay. The weighting approximately cancels the sensitivity decay and gives cells at different locations equal probability to enter into the solution with a non-zero susceptibility/density. This weighting is approximately the depth of the finite element cell to the 3rd power, to counter a sensitivity drop of that is approximately $1/z^3$.

Example

An example of a UBC GRAV3D inversion of gravity data over the Voisey Bay Ni deposit is shown below. The measured gravity data in color is displayed draped onto the topographic surface at the top (red=high, blue=low values). The density distribution generated by the inversion is shown below, with the green and yellow "blob" corresponding to the Ovoid Ni zone.



3D inversion of gravity: Voisey's Bay Ovoid Ore Body

- Observed gravity data on top of recovered density contrast.
- Isosurfaces at 0.8 g/cc (inside) and 0.4 g/cc.

APPENDIX D: UBC DCIP2D SOFTWARE

IP/resistivity data are usually initially presented as pseudo-sections. The pseudo-section is the traditional method of plotting the IP and resistivity data, but it is not a true geological cross-section. The vertical axis is based upon electrode separation rather than depth.

A formal 2D or 3D inversion is increasingly being used to quantify IP/resistivity data, because it generates a cross-section which is close to a “true” geological section. However, the non-uniqueness of applying an inversion to geophysical data must be appreciated; i.e. a single data asset may yield multiple interpretations. Only by applying some independent constraints derived from other surveys, or from geological insights, can the inherent non-uniqueness problem be mitigated.

The IP/resistivity inversions performed by Condor utilized the DCIP2D software developed by the University of British Columbia (UBC) Geophysical Inversion Facility (Oldenburg and Li, 1994). The earth is divided into rectangular prisms and the resistivity and chargeability are assumed to be constant in each cell. DCIP2D is an example of a geophysical inverse modeling program that estimates the distribution of resistivity and/or chargeability in the subsurface based on a numerical solution to an over-parameterized, constrained optimization problem. Such problems are intrinsically non-linear and require iterative solutions, as well as some form of regularization to stabilize the solution and yield models that are realistic in a geological sense. The DCIP2D modeling code uses finite difference approximations to the relevant differential equations. The 2D limitation means that the physical property distributions and topography are assumed to not vary in the direction that is perpendicular to the survey profile.

APPENDIX E: COMPARISON OF VTEM AND ZTEM – CENTRAL BLOCK

The layered earth inversion (LEI) of the 2007-2008 VTEM data used a 28-layer earth model, increasing in thickness from the surface to depth in an approximately logarithmic fashion. The first layer was 5 m thick while the deepest was 232 m thick. To show an overall conductor distribution, the conductance (conductivity x thickness) has been calculated for two depth ranges, (a) 25-143 m and (b) 25-431 m (Figure E1). The former shows shallower features and the latter shows the conductance down to close to the depth of investigation of the VTEM survey. The conductances of the layers down to 25 m have not been included because these sometimes contains “glitches” in the inversions. The major conductivity boundaries on the 25-431 m image are highlighted with black lines, which are replicated on the upper image.

The two images are quite similar indicating that most of the conductivity is near-surface. The Tiger-El mineralization is enclosed in a relatively resistive unit approximately 5 km wide. Northeast and south of this unit relatively high conductivities are seen. The Tiger-El mineralized trend itself produces a relatively narrow (approximately 500 m wide) zone of moderate conductivity, which is intermittent along strike.

Figure E2 compares the VTEM conductance from 25-431 m with the ZTEM conductance from 24-449 m. The major conductivity boundaries from the VTEM are replicated on the ZTEM image for reference. The principal features of the ZTEM conductance correlate closely with the VTEM, but significant differences can be seen. For wide conductors, the ZTEM conductance tends to be concentrated at the edges of the conductor, while the VTEM conductance is more uniform. For narrower conductors, the ZTEM response is more similar to the VTEM. The conductive trend correlating with the Tiger to El mineralized trend is better resolved on the ZTEM conductance image.

Figure E3 compares the VTEM conductance with the ZTEM IP 30Hz TPR image. The major conductivity boundaries are very similar to those on the VTEM. On the latter, the conductivity highs (hot colors) are more evenly distributed across wide conductors compared to the ZTEM conductance image in Figure E2.

Figure E4 compares the VTEM conductance with the ZTEM 30 Hz DT image. As the latter is similar to a gradient filter, conductor edges are highlighted and the conductivity is generally not extended across wide conductors. However, narrow conductors are well defined, including the Tiger to El mineralized trend.

Figure E5 compares the VTEM conductance with the ZTEM 30 Hz Apparent Conductivity image. The latter exhibits the closest correlation with the VTEM conductance of all of the ZTEM image products. Both the wide conductors and narrow conductors are well defined, including the Tiger to El mineralized trend.

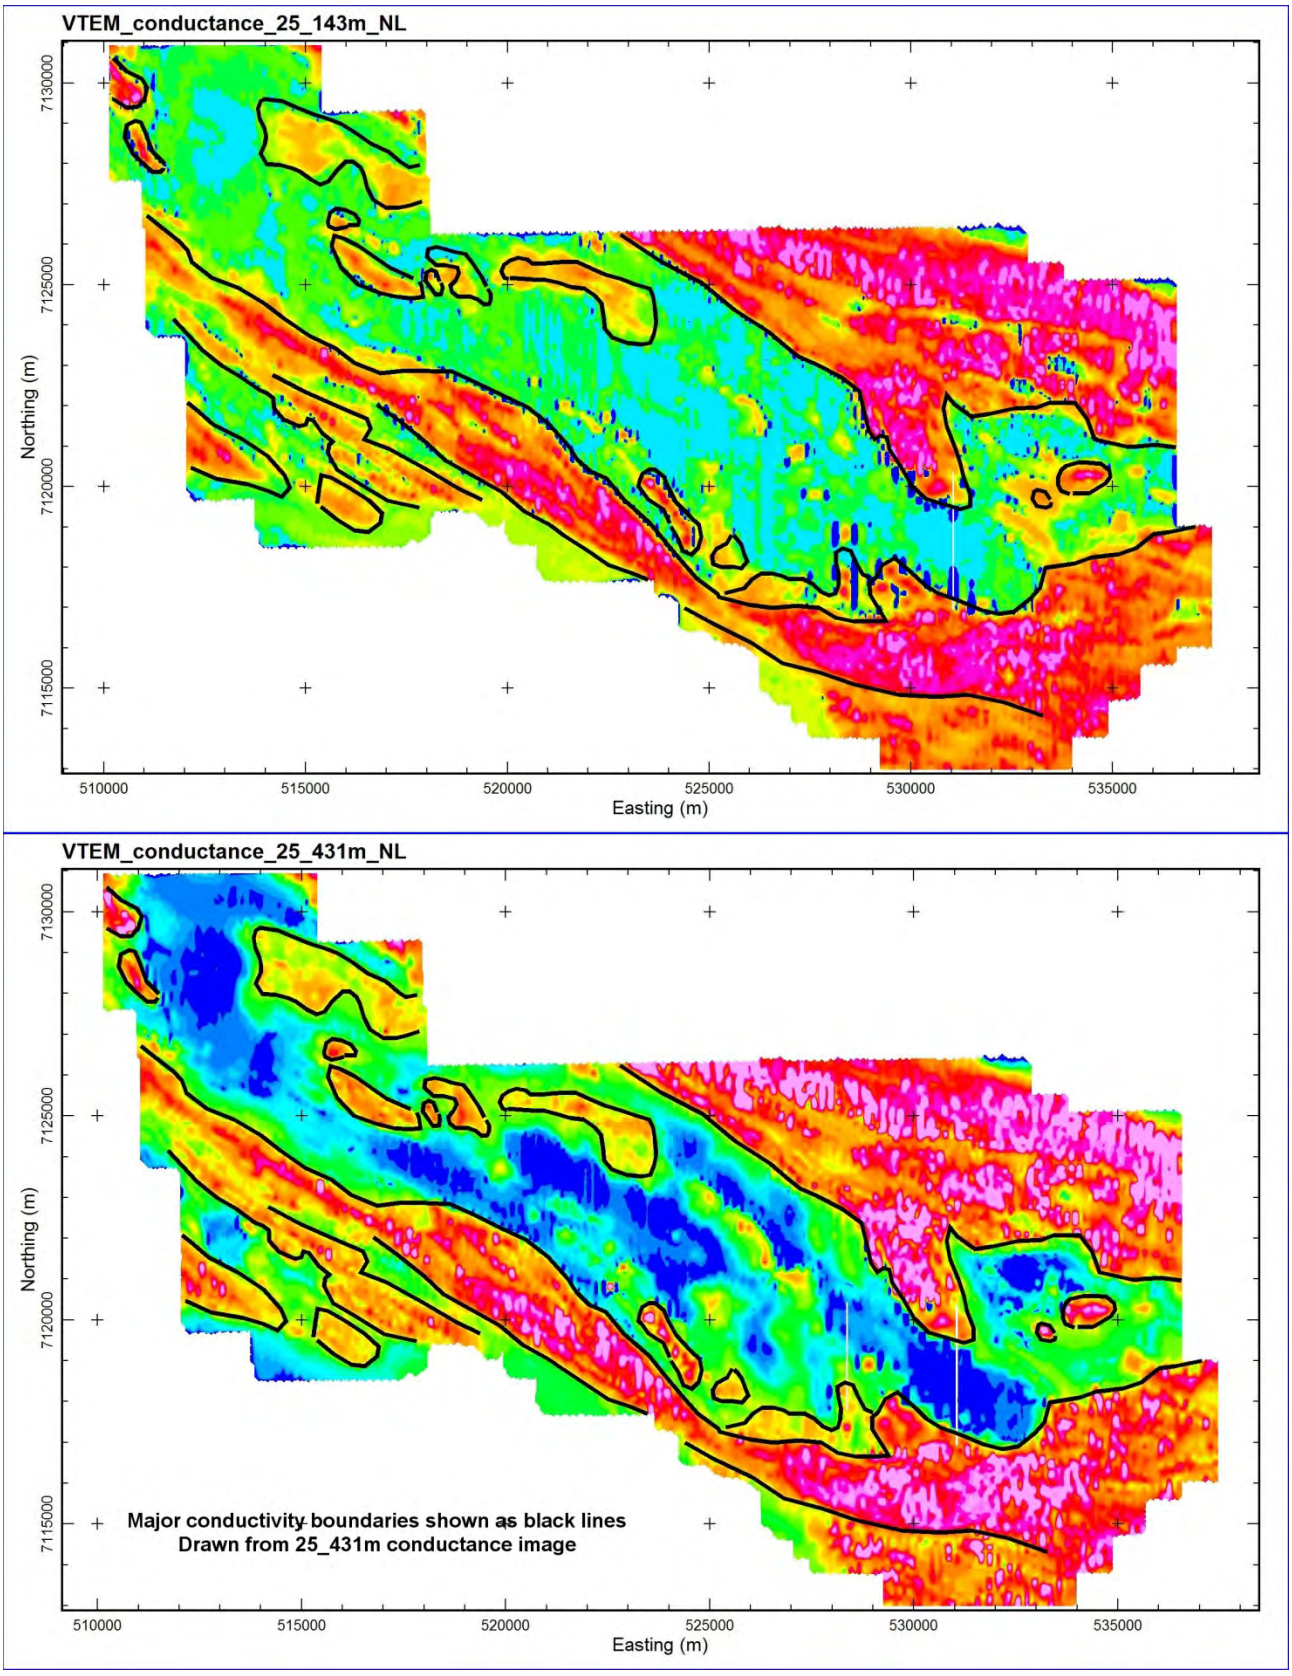


Figure E1: VTEM conductance 25-143m (top) and 25-431m (bottom).

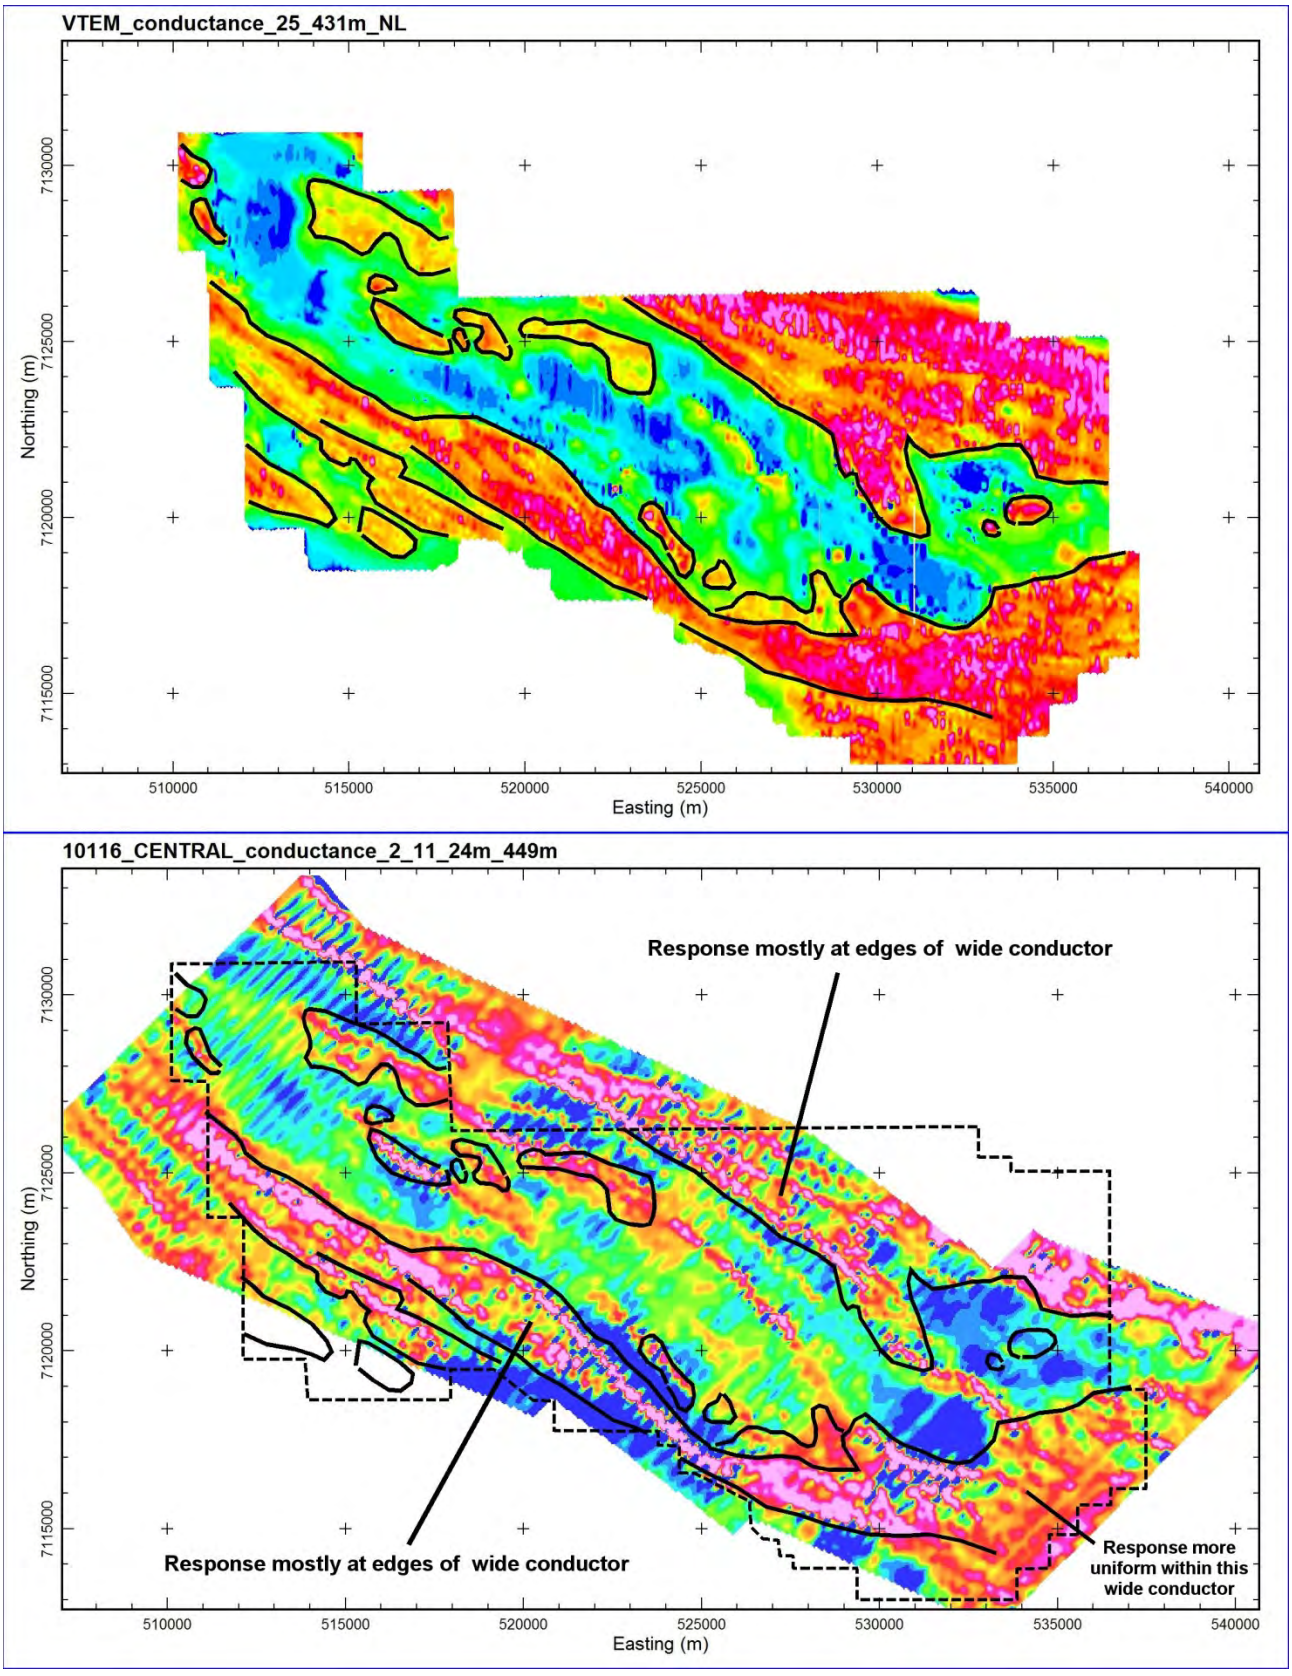

Figure E2: VTEM conductance 25-143m (top) and ZTEM conductance 24-449m (bottom).

1 Survey overview

In 2010, Archer, Cathro and Associates contracted Scintrex Limited to conduct a multi-hole Borehole Gravity Meter (BHGM) survey in the Rau Trend Prospect, Yukon, Canada. The survey was designed to detect gravity and bulk density anomalies arising from gold-hosting oxide and sulphide mineralization. Scintrex acquired BHGM data in eight boreholes in September, 2010. The BHGM data was processed by MicrogLaCoste (MGL), Scintrex' sister company.

2 The Gravilog system

Scintrex has developed the Gravilog borehole gravity system (Nind et al., 2007) for mining and geotechnical applications. The gravity sensor is based on the fused quartz technology proven to be rugged and accurate in Scintrex land exploration gravity meters (most recently the CG-5). This basic sensor technology has been miniaturized and equipped with self-leveling capabilities. The associated electronics modules have been packaged to fit into a narrow-diameter borehole sonde. Gravilog has been designed to log inside NQ (57 mm I.D.) drill rods to 2,000 m depth, using standard 4 conductor wireline cable, with a sensitivity of better than 5 μGals, and operable in boreholes inclined from vertical to 60° off of vertical. Gravilog has undergone extensive laboratory testing, followed by several successful mining-industry-sponsored downhole tests.

2.1 Field operation procedure

At each station, the cable is clamped using the winch brake to secure the probe. The gravity sensor is leveled, and repeated 60 second gravity measurements (usually 3-5) are taken until the readings stabilize. The winch brake is then disengaged and the probe is moved to the next station location using the winch counter for a depth reference. This procedure requires about 5 minutes at each station, plus the time required for moving between stations.

3 Survey operations

The four-person Scintrex crew was initially mobilized for the survey on August 8th, 2010. After arrival at the first borehole, the Gravilog probe failed pre-survey checks. On-site diagnosis indicated a problem with the senor module itself, possibly due to shock/vibration during the rough

road transport to the drillsite. At this time, Scintrex had only one Gravilog probe available, so the survey had to be put on hold until the problem was fixed. The gravity module was returned to Scintrex for repair, and the crew was demobilized on August 15th.

After repair at Scintrex and completion of a second, backup Gravilog probe, the Scintrex crew (again four persons) re-mobilized on September 7th, 2010. The crew was divided into two two-man teams, which operated 24/7. The Gravilog probe was flown by fixed-wing aircraft and helicopter to the survey site to avoid transportation over rough roads, and then shifted from drillsite to drillsite via helicopter long-line. The Gravilog sensor was kept on heat being transported to avoid excessive drift due to thermal cycling. The survey crew was demobilized on September 15th, 2010.

Each borehole was tested with a dummy sonde before logging: two boreholes were found to be blocked and were not logged. Hole 10-96 was first surveyed with an incorrect maximum depth supplied. This caused the sonde to bottom out, tangling the winch cable. The hole was re-logged, and the relogging run is referred to as 10-96R.

Overall, the extremely rugged terrain in the survey area (see Figure 1 for an example) produced difficult and hazardous working conditions for the survey crew. This survey was conducted in, quite likely, the most rugged terrain ever to host a BHGM survey.

4 Data processing

The BHGM survey data processing was done by MicrogLaCoste (MGL). MGL and Scintrex are divisions of LaCoste-Romberg-Scintrex (LRS). MGL has been involved with BHGM data acquisition and processing for several years, using both LaCoste & Romberg metal-spring and Scintrex Quartz spring systems. MGL has developed an extensive suite of software for processing and interpretation of BHGM data, which was used in the processing of this survey. A good general introduction to BHGM survey data processing can be found in Beyer (1983).

The processing workflow consisted of three main steps:

1. Deterministic corrections, which can be calculated independent of the observed gravity data. These include depth corrections and Earth tide corrections.

2. Least-squares correction, which are determined using the observed gravity data.

3. Manual editing, which allows the processor to visually edit out gravity readings which are obvious outliers.

Figure 1: Survey area terrain

SCINTREX LIMITED
222 Snidercroft Road, Concord, Ontario, Canada, L4K 2K1
Telephone: +1 905 669 2280 Fax: +1 905 669 6403
e-mail: scintrex@scintrexltd.com

These steps were applied in multiple iterative passes through the data until there were no obvious outliers or systematic repeat stations errors remaining in the dataset.

4.1 Least-squares corrections

In addition to the deterministic corrections, which have known functional forms and are independent of the observed gravity values, there are other corrections which can be applied to the BHGM data which are empirical in nature. The major corrections of this type are time-based meter drift corrections and sensor temperature corrections. The drift is modeled as a linear function of time, and the sensor temperature response is modeled as directly proportional to the deviations of the logged temperature about the mean temperature. The coefficients of these models are determined by least squares techniques, with the objective being to minimize the scatter of readings at repeat stations.

4.2 Manual editing

An example of a manual edit run is shown in Figure 2. The point marked with a red 'x' is selected as an obvious outlier, and will be flagged for removal from the dataset.

5 Terrain corrections

Due to the steep terrain of the survey area and the shallow depth of the boreholes, terrain corrections were critical in the processing of the gravity data. Scintrex subcontracted the terrain correction calculations to Geoaviation LLC. An example of the calculated densities from Borehole 10-104 is shown both with (Figure 3) and without (Figure 4) terrain corrections applied.

5.1 Terrain correction data sources

The terrain corrections for the RAU Prospect were based on the following data sets:

1. Well collar locations provided by Matt Dumala of Archer, Cathro and Associates Ltd. in an Excel file.
2. 2 meter contours of the extended well site area provided by Matt Dumala of Archer, Cathro and Associates Ltd. in AutoCAD files.
3. Gravilog survey station wire line depths from MGL in an Excel file.
4. Hole locations and directions from Alex Milanovic, Scintrex in an Excel file.
5. GPS-RTK survey data from Alex Milanovic, Scintrex in AutoCAD and Excel files.
6. 30m and 90m Yukon DEM data from Environment Yukon.

5.2 Terrain correction processing steps

The Gravilog survey station depths were measured relative to the well collar elevations, measured by RTK-GPS at ground level after establishing the drill pads. The UTM horizontal coordinates and elevations of each survey station were calculated using the hole directions and wire line depths.

The 2m contour line coordinates and elevations were extracted from the AutoCAD dxf file and triangulated to a regular 1 meter grid over an area within a radius of 4500 m from the approximate center of the well pattern.

A discrepancy was noted between the well collar elevations and the surface elevations at the collar locations derived from this 1 meter grid. The most likely source of this discrepancy is that the Ortho Photo survey elevations are calculated relative to orthometric heights whereas the RTK-GPS surveyed well collars are ellipsoidal heights. The vertical distance between the geoid and the ellipse at the prospect location calculated from the Canadian Spatial Reference System program GPS-H, is 7.044 meters. The ellipsoidal elevations of 7400 points from the GPS-RTK survey were compared to elevations at the same locations from the Ortho Photo survey. The mean elevation difference was 7.866 meters with a standard deviation of 2.241 meters.

The terrain calculations were made using the well collar GPS-RTK elevations decreased by 7.87 meters to match the orthometric elevation surface.

Ortho photo elevations from the station location to a radius of 3,740 meters were used in the terrain correction calculation.

The 30 meter Yukon DEM data was converted from the Yukon Albers projection to UTM zone 8N and gridded within a radius of 20,000 meters of the well pattern center. 30 meter data from 3,740 m to 18,200 m station radius were used in the terrain correction calculation.

The 90 meter Yukon DEM data was converted from the Yukon Albers projection to UTM zone 8N and gridded within a 125,000 meter radius of the well pattern center. 90 meter data from 18,200 meters to 121,500 meters station radius were used in the terrain correction calculation.

The Geoaviation software program, DEMaster, calculated terrain corrections for each Gravilog station using a traditional ring and compartment pattern of elevations centered on each station position. The ring radii are finely spaced near the stations to account for the steep terrain. The terrain density assumed for each terrain compartment was 1.00 g/cm^3. The final processing application of the terrain corrections used a density of 2.85 g/cm^3, as communicated by Archer Cathro. This density is an average core sample density.

6 Processing results

6.1 Repeat statistics

The repeatability of the gravity data in each borehole is reported in Table 1. Overall, the data quality of this survey may have been impacted by any or all of the following factors:

1. The boreholes were generally dry or partially water-filled. Water-filled boreholes produce smoother sonde travel, which improves the gravity meter performance.

2. Transitions from air to water in the boreholes can create abrupt temperature changes, which may hinder thermal stabilization of the Gravilog sensor and increased reading time.

3. Shallow BHGM gravity readings are generally noisier than deeper readings, due to increased seismic near the surface.

4. The field crew reported active drilling operations in the area, at times within 50 meters of BHGM logging. This may have increased the overall seismic noise level.

Table 1: Borehole gravity repeatability

Borehole	Gravity repeatability (μGals)
10-79	11.1
10-82	24.6
10-85	15.3
10-86	14.9
10-90	17.6
10-96R	10.7
10-104	10.8
10-116	25.2

6.2 Bouguer gravity residuals

The overall trend of gravity versus depth in a BHGM survey is dominated by the Earth's normal free-air gradient and the effect of the density of the rocks surrounding the borehole. The strong linear gravity-depth trend makes it very difficult to recognize anomalous zones in the BHGM data. The free-air gradient can easily be removed using the standard second-order free-air formula (equation (1)).

$$F = -\left(0.3087691 + 0.0004398\sin^2\varphi\right)h + 7.2125\times10^{-8}h^2 \tag{1}$$

where φ is the latitude of the borehole, and h is the depth in meters. In order to aid in visual recognition of anomalous density zones in the area around the borehole, the effect of a constant rock density can be removed from the free-air corrected gravity to produce the borehole equivalent of the Bouguer anomaly. After free-air correction, the standard equation relating gravity gradient in the borehole to density is

$$\frac{dG}{dz} = -\frac{1}{4\pi G}\rho\left(z\right) \tag{2}$$

If we assume a constant density $\rho\left(z\right) = \rho_{BG}$ and integrate equation (2) with respect to z, we find that the gravity effect of a constant density is a linear gravity/depth trend.

$$G\left(z\right) = G_0 - \frac{1}{4\pi G}\rho_{BG}\,z \tag{3}$$

G_0 is an arbitrary integration constant, which can be ignored since BHGM surveys are relative surveys.

For this survey, the Bouguer anomalies were calculated using a density $\rho_{BG} = 2.85\,\text{g/cm}^3$ (same as the terrain correction density), supplied by the client.

Inspection of the Bouguer anomaly curves for the boreholes suggests that the supplied density is too high, possibly due to sample bias. The drillhole locations may be preferentially located in mineralized zones, with higher rock densities which do not reflect the overall density of the local geology. It may be worthwhile to reprocess the dataset using a density for both terrain corrections and Bouguer corrections which will produce Bouguer anomaly curves having minimum trend.

6.3 Density logs

Apparent density logs can be calculated from BHGM data in several ways. The methods used by MGL assume a horizontally-layered earth, under which assumption the vertical gradient of gravity over the BHGM-logged section of the borehole is determined solely by the density variations within the logged section.

6.3.1 Conventional density

The standard equation for calculating interval density from BHGM data is equation (4):

$$\rho_{12} = \frac{1}{4\pi G}\left(F - \frac{g_2 - g_1}{z_2 - z_1}\right) \tag{4}$$

where the interval density is ρ_{12}, G is the universal gravitational constant, F is the free-air gravity gradient, and g_1 and g_2 are the gravity measurements at depths z_1 and z_2, respectively.

6.3.2 Inversion density

The MicrogLaCoste BHGM inversion method allows stable calculation of interval densities over much closer station spacings than are feasible using the traditional method. The damped least-squares techniques used in the inversion stabilize the density calculations in three ways:

1. The observed gravity data, which we know contain some amount of error, are not fit exactly, but only to within a tolerance determined by the noise level of the data.

2. The inherent redundancy of borehole gravity data further stabilizes the calculations. Each interval density influences the measured value at all the borehole gravity stations, so that each gravity value helps to constrain all the interval densities in the logged interval. The rocks in a given interval will increase the gravity for all stations above the interval, and decrease the gravity for all stations below the interval. The inversion algorithm uses all the gravity data to help estimate the density in a given interval, not just the data from the two stations immediately above and below the interval. An example might make this redundancy more obvious. Assume we have eleven stations at 10 foot intervals, spanning 100 feet of the borehole. The traditional method of calculating densities would use only the two gravity stations immediately above and below each interval. The inversion uses all 11 gravity stations simultaneously to determine each interval density.

3. Given the inherent non-uniqueness of gravity inversions, there are an infinite number of density models which reproduce the observed gravity data to within a specified tolerance. Out of this infinite number of models, the inversion algorithm calculates the one having the smallest deviation (in a least-squares sense) from a constant density. This has been called ”the principle of least astonishment”.

A more detailed summary of the BHGM inversion method can be found in MacQueen (2007)

A Gravity data file format

The processed gravity data is delivered in Microsoft Excel .xls spreadsheet format. The file header fields are:

Well name The well name.

Wellhead elevation The wellhead elevation, in the well file units (see below).

Wellhead latitude The wellhead latitude in decimal degrees.

Wellhead longitude The wellhead longitude in decimal degrees.

Well units The well file units, 'f' for feet, 'm' for meters.

The data channels follow, with one row for each BHGM reading. All gravity values are in milliGals, and all depth values are in the well file units. The data channels are:

SCIN wld The Scintrex wireline depth.

Logged grav The logged gravity value.

Raw grav The logged gravity value with the in-field drift and tide corrections removed.

Field drift The in-field calculated drift correction.

SD The mean standard deviation of the individual 1-minute gravity readings averaged into the reported reading.

Tiltx The sensor x-axis tiltmeter reading, in arcseconds.

Tilty The sensor y-axis tiltmeter reading, in arcseconds.

BHGM temp The Gravilog sensor temperature, in milliKelvin, relative to a reference temperature.

Elec temp The electronics module temperature, in degrees C.

Ambient temp The probe ambient temperature, in degrees C.

Incl The BHGM sonde inclination off vertical, in degrees.

PRB pres The probe pressure, in PSI.

SURF pres The atmospheric pressure at the surface, in PSI.

Tide corr The in-field calculated tidal correction (Longman's algorithm).

Reading timestamp The averaged time of the 1-minute gravity readings, in days relative to midnight, January 1, year 0 (MATLAB time).

Inc x The BHGM sonde inclination off vertical along the x-axis, in degrees.

Inc y The BHGM sonde inclination off vertical along the y-axis, in degrees.

Inner ht volts The Gravilog sensor inner heater voltage, in volts.

Num rpts The number of 1-minute gravity readings averaged into the reported reading.

SCIN incl tvd The Scintrex true vertical depth, calculated from the Scintrex wireline depth and the inclination data.

Station wld The wireline depth assigned to this reading after averaging all readings at that station depth.

Station tvd The true vertical depth corresponding to the station wireline depth.

Station number The serial number of the depth station assigned to each reading, where 1 is the shallowest station in the survey.

Station depth shift The depth shift applied to each reading to bring it to its station depth.

Station depth corr The combined free-air and Bouguer slab correction applied to each station based on the station depth shift.

Drift corr The linear time-based drift correction, based on the least-squares solution (see Section 4.1).

BHGM Temp corr The correction for the BHGM temperature, based on the least-square solution (see Section 4.1).

Total corr The total correction applied to the raw gravity reading.

Corrected grav The final corrected gravity reading. Since the BHGM survey is a relative survey, the corrected gravity values are set relative to the first raw gravity value in the file for convenience.

FA corr The free-air correction for the gravity reading, calculated using Equation (1).

Bouguer Anomaly The constant-density Bouguer anomaly (see Section 6.2).

B Density data file format

The calculated density data is delivered in Microsoft Excel .xls spreadsheet format. The file header fields are:

Well name The well name.

Wellhead elevation The wellhead elevation, in the well file units (see below).

Wellhead latitude The wellhead latitude in decimal degrees.

Wellhead longitude The wellhead longitude in decimal degrees.

Well units The well file units, 'f' for feet, 'm' for meters.

Density type The density calculation method used, conventional (Section 6.3.1) or inversion (Section 6.3.2)

The depth values are in the well file units. The density and uncertainty values are g/cm^3. The density and uncertainty values for row 'n' apply to the interval spanning the depths in row 'n' to row 'n+1'. The density model fields are:

Depth The start(shallow) of the true vertical depth interval used for the density calculations.

Wireline The wireline depth corresponding to the true vertical depth.

Density The interval density.

Sigma density The formal $1-\sigma$ uncertainty of the interval density.
