SUMMARY

The Oro Property, containing the historic Neve-Brick Minfile (105O/032) occurrence, is located 25 kilometres west of the MacMillan Pass Airstrip and the North Canol Highway, in eastern Yukon. Located on the eastern margin of the Selwyn Basin, the property is underlain by Ordovician to Triassic sedimentary strata which are intruded by variably altered Cretaceous felsic sills and dykes. Cretaceous compressional tectonics have isoclinally folded and faulted the sedimentary strata.

Prior to Colorado Resources Ltd. ("Colorado") acquiring the Oro Property, it had been worked by AGIP Canada Ltd. from 1979 to 1989. No work had been done on the property from 1989 until Colorado acquired it by optioning and staking in late 2010 and early 2011. Previous work on the property included geology, geochemistry, geophysics, trenching and diamond drilling. Prior drilling concentrated on the Neve-Brick Minfile area which includes the J.O., Saddle and Canol Zones. Between 1977 and 1984, on the eastern portion of the claim block, Hudson Bay Exploration and Mining and Cominco Ltd. conducted geochemical programs targeting sedex Pb-Zn-Ba mineralization.

After property acquisition, in 2011, Colorado conducted an airborne geophysical survey, a soil, silt and rock sampling program, prospecting, geological mapping and mini-excavator trenching. This exploration program was conducted with the intent of expanding previously reported mineralization and continuing exploration to discover new mineralized zones.

The 2011 exploration program in significantly expanded the J.O.- Saddle –Canal zone anomaly and identiefied a number of new areas of mineralization including Area 51, Golden Hinge, Golden Ridge, North Steel, Repeater and Limey Ridge.
There are also a number of small scattered geochemical and geophysical targets that require preliminary follow up work.

The Neve area (J.O.-Saddle-Canol Zones) remains the primary target area for 2012 exploration. A strong multi-element, zoned geochemical anomaly trends through this area and extends southeast to the Repeater Zone, for a distance of approximately four kilometres. Geological/structural mapping identified Cretaceous intrusive dykes which may indicate an intrusive-style gold mineralizing system, as seen throughout the Tombstone Suite intrusions. However, this dyke system and nearby significant fault structures are also interpreted to intersect limey potential Carlin host lithologies at depth in this same area. A diamond drilling program is required in order to test this target.

Due to the success of the exploration program on the Oro Property in 2011, an expanded program is recommended for 2012. The 2012 exploration program should consist of continued infill soil geochemical sampling and geological mapping in key target areas. Up to 10,000 soil samples should be collected. Excavator trenching is recommended to follow up soil geochemical anomalies, along with 5000 metres of diamond drilling.

While the soil sampling, trenching and mapping is planned to be conducted over several anomalous zones, diamond drilling should at initially target the Neve occurrence area where structural mapping, geophysics and geochemical indicators all suggest a strong possibility of locating a buried Carlin gold target. Estimated cost for the 2012 exploration program is $4.5 million.

1) INTRODUCTION

The Oro Property, containing the historic Neve-Brick minfile occurrence (105O 032), is located in the MacMillan Pass area of northeastern Yukon. The central portion of the property was acquired by Colorado Resources Ltd. ("Colorado") in late 2010 and expanded by staking in early 2011.

Colorado acquired this property after studying the regional geological trends and examining historic minfile records and prior company assessment reports documenting Carlin style gold mineralization potential on the property. After property acquisition, in 2011, Colorado conducted an airborne geophysical survey, ASTER image analysis, a soil, silt and rock sampling program, prospecting, geological mapping and mini-excavator trenching. This exploration program was conducted with the intent of expanding previously reported mineralization and continuing exploration to discover new mineralized zones. The 2011 exploration program is the subject of this report.

2) LOCATION AND ACCESS

The eastern end of the Oro Property is located 25 kilometres west of the MacMillan Pass Airstrip and the North Canol Highway in eastern Yukon (Figure 1). The claims cover an area of approximately 37,515 hectares and are centred at UTM coordinates 7020000 North, 402500 East in Zone 9, within mapsheets 105O 02, 03, 06 and 07.

Access to the Oro Property is via helicopter from the MacMillan Pass Airstrip or Colorado's camp located 8 kilometres south of the airstrip along the North Canol Highway. The camp is road accessible from the community of Ross River, located approximately 210 kilometres to the southwest.

A secondary road (the Nidd Road) branches westerly off the North Canol Highway 2 kilometres south of the MacMillan Pass airstrip and travels for 25 kilometres to the Oro Property border. This road has not been used in several years and both the road and the bridge crossing the South MacMillan River require rehabilitation. Additionally, the winter road to Mayo traverses the valley along the southern border of the Oro Property. This road has also not been used for many years and is somewhat overgrown.

3) PHYSIOGRAPHY AND CLIMATE

Situated in the Hess Mountains, topography is moderate to rugged with elevations ranging from 950 to 1800 metres, yielding a maximum relief of 850 metres. The mountain and ridge slopes of shale felsenmeer and scree are generally steep. A resistive weathering, chert pebble conglomerate unit forms more rugged ridges.

Vegetation is typical of eastern Yukon with treeline at about 1350 metres. Vegetation in the valleys is characterized by spruce and balsam with shrubs, alpine grasses and moss at lower elevations.

Water on the property is restricted to the larger creeks in late July and early August. Sufficient water sources are available for any exploration or mining requirements.

The climate in the area of the Oro Property is variable with cool summers and long, cold winters. During the summer (mid June to early August), temperatures range from 5 to 20^{o}C, with 20 to 22 hours of daylight. Winter weather in this region may commence after August 15th with snow, high winds, cooler temperatures, and decreasing daylight.

4) CLAIM INFORMATION

The Oro Property is located within the Mayo Mining District and consists of 1799 quartz claims totaling 37,515 hectares (Figure 2). The claims have been consolidated into three groups. Full claim information, including grouping lists, expiry dates and claim ownership, is listed in Appendix II.

TABLE I
QUARTZ CLAIM NAMES AND TENURE NUMBERS

CLAIM NAME	TENURE #
ORO 1 – ORO 48	YD31351 – YD31397
ORO 49 – ORO 318	YD104903 – YD105172

HS 243 – HS 250	YE39287 – YE39294
HS 251 – HS 256	YE39281 – YE39286

The claims are all owned 100% by Colorado Resources Ltd., except for the Oro 1 to 330 claims which are owned by Cathro Resources Ltd. Colorado has an option to acquire 100% of the Oro 1 to 330 claims.

5) HISTORY

Neve-Brick Area

The majority of historic work conducted on the Oro Property was done by AGIP Canada Ltd. in the area of the Neve-Brick minfile occurrence (105O 032). The first documented work by AGIPconsisted of a stream sediment sampling program in 1980. This work was targeting sedex

lead-zinc-silver mineralization as found on HudBay's Tom Property. Gold was not analysed during this program, however they did find a few anomalous values of zinc and barium (Beauchamp, 1980).

Despite the disappointing stream sediment results, AGIP returned in 1981 with a mapping and sampling program (Garagan, 1981). Along with preliminary geological mapping, AGIP located two outcrop occurrences of realgar-orpiment +/- stibnite veining associated with intrusive dykes. A small soil geochemical survey indicated anomalous areas of gold, silver, arsenic and antimony.

In 1982, two concurrent exploration programs were carried out on the Neve and Brick claims by AGIP. On the Neve claims soil samples and talus fines were collected in three areas, with the conclusion that only a few weak anomalies were found which could probably be explained by local veining. On the Brick claims a trench was dug across a precious metal soil geochemical anomaly. Elevated values in gold, silver, arsenic, antimony and mercury in the trench samples relate to enrichment in veins cutting highly altered quartz-feldspar porphyry dykes. Some enrichment may also be due to low grade precious metal content disseminated within the intrusives (Garagan, 1982).

Also in 1982, AGIP used a small pack-sack drill to put in 117 overburden holes to sample bedrock chips +/or soil at the bedrock-soil interface. Samples were drilled at 5 metre centres in 3 anomalous zones within the Brick claims. In most cases the deeper values were higher than the surface samples, but were also much more variable due possibly to the erratic nature of the mineralization (Garagan, 1983).

In 1983, AGIP conducted a soil sampling and trenching program. Soil sampling of the new 1983 grid located a new zone ("J.O. Zone") of highly anomalous gold values in soil and talus across a steep slope facing northwest. The J.O. Zone soil anomaly is an extension of the Saddle Zone geochemical anomaly, although the zones seem to be geologically distinct. The soil anomalies are defined by the 100 ppb gold contour; the main part of the J.O. Zone anomaly consists of two distinct anomalies exceeding 1000 ppb gold in soil (these anomalies are 150 metres and 70 metres long, respectively). Some soil samples within the J.O. Zone exceed 5000 ppb gold. Maximum gold values in grab samples of rock in the J.O. Zone reached 1.44 g/t. Gold mineralization seems related to the degree of fracturing (Robertson, 1984).

Three trenches were excavated across the strongest parts of the J.O. Zone soil anomaly. Results of gold analyses of soil and rock samples from the trenches confirm the gold values found in surface soil samples of the J.O. Zone. The best gold grades and the most difficult trenching conditions are associated with strongly fractured sooty carbonaceous shales. The best results were from trench 83-1, where soil and rock composite grab samples were collected at 3 metre intervals over its 44 metre length. All but two soil samples contained greater than 1000 ppb gold, with the best result being 4.74 g/t gold. The rock sample results were lower, with the best result being 655 ppb gold. All samples contained greater than 100 ppb gold and 5000 ppb mercury.

AGIP followed up these early soil sampling and trenching programs with diamond drilling programs in 1985 and 1988. In 1985, a total of 1257.3 metres was drilled in 9 BQ size holes, with 5 of these holes being abandoned before reaching their target depths. Drilling results indicate the weighted average for all anomalous gold and silver values is 0.31 g/t Au and 2.59 g/t Ag over an

average true width of 30.4 metres. The anomalous Au-Ag values correspond to intense fracturing, clay altered fault gouge and veining within black carbonaceous shales and siliceous graphitic-carbonaceous shales. The higher gold-silver values generally correlate with increased structural disruption, lost core and/or increased veining (Aupperle, 1985).

In 1988, 10 NQ and HQ sized diamond drill holes totalling 1229.8 metres, were drilled by AGIP. Results of this drill program have been summarized by Hulstein and Keyser (1989):

"Gold mineralization has been identified at two areas: (1) the Canol Zone and (2) the J.O. - Saddle Zone. Mineralization and alteration appear to be related to faulting, fracturing and quartz-carbonate veinlets and stockworks temporally and spatially related to Cretaceous dykes and sills. Disseminated pyrite, realgar, orpiment, stibnite, arsenopyrite and proustite-pyrargyrite are found in narrow quartz veinlets hosted by altered quartz monzonite sills and dykes and adjacent hornfelsed and bleached sediments.

The Canol Zone, approximately one kilometre long by 50-60 metres wide, is underlain by silty limestone and shales. It was drill tested for the first time in 1988. Although no significant anomalous gold values were intersected in the silty limestone unit, anomalous gold values (up to 0.488 g/t over 2.70 metres) were intersected in faulted and sheared shales.

The J.O. - Saddle Zone, approximately 850 by 300-475 metres in area, is underlain by variably hornfelsed and bleached shales and altered quartz monzonite sills and dykes. The Zone is bounded and cut by faults which are locally anomalous in gold. Even though the 1988 drilling had better core recoveries than the 1985 drilling, gold values and widths were similar. The best 1988 results were 5.30 metres of 0.699 g/t gold in a quartz-feldspar porphyry, including 1.108 g/t over 1.20 metres. Another interval returned 0.574 g/t gold over 30.10 metres."

After 1988, until Colorado acquired the property in 2010, no exploration was conducted in this area.

SOL Claims

Between 1977 and 1984, Hudson Bay Mining and Exploration and Cominco Ltd. put in a series of small soil grids over what is now the eastern half of the Oro Property, in the area currently covered by the SOL claims. Both companies were exploring for Sedex style Pb-Zn-Ag +/or Ba mineralization and obtained localized high soil values for each of these elements. Hudson Bay's exploration work was located on the northern portion of Colorado's SOL claims, and interestingly showed some high areas of mercury values in soil (the only other element for which they analysed). They also obtained some significant silver values in soil which correlate well with Colorado's newly identified Golden Ridge/North Steel Zone.

Other Minfile Occurrences

Four additional minfile occurrences have been documented on the Oro Property. Three of these are sedex style bedded barite occurrences (Gow 105O 029, Minorco 105O 046 and Stroshein 105O 045) and one unknown deposit type (Fal 105O 042).

6) WORK DONE BY COLORADO RESOURCES LTD IN 2011

Work completed on the Oro Property between June 25 and September 21, 2011 consisted of airborne geophysics, ASTER image analysis, silt and soil sampling, prospecting and rock sampling, geological mapping and trenching.

Between July 15 and August 2, 2011, Fugro Airborne Surveys conducted a 2114 line kilometre heli-borne magnetic and electromagnetic (Dighem) survey. Survey lines were spaced 200 metre apart with perpendicular tie lies at 2000 metre spacings.

A large soil sampling program was completed, with a total of 13,808 soil samples collected. Grid lines were run north-south and depending on importance of the area were spaced between 100 to 900 metres apart. Samples were generally collected at 50 metre spacings along the lines, with occasional infill sampling at 25 metres.

A total of 339 silt samples were collected from most of the major drainages on the property.

Prospecting and rock grab sampling was carried out over much of the property, most notably in areas with significant colour anomalies (gossans). During the course of the prospecting program, rock samples were collected from mineralized, stockworked and altered outcrops. At total of 746 rock grab samples were collected.

Detailed geological mapping was undertaken by Dr. Paul Metcalfe in the Neve-Brick showing area in order to interpret structural controls that may be important for mineralization conduits. Also, in this area, a series of 15 trenches totalling 1548 metres were excavated with a Can-Dig type mini-excavator. Trenches were geologically mapped and sampled along 3 metre contiguous intervals for their entire lengths. A total of 525 rock chip and talus samples were collected from the trenches.

Work was conducted by a 10 person field crew working out of a camp along the North Canol Highway. Daily access to the property was via helicopter. Field crew were largely under contract to Colorado from Meridian Mapping Ltd. All field work was directly supervised by the author.

7) GEOLOGY

REGIONAL GEOLOGY (Extracted from Yukon Geological Survey, Selwyn Basin Metallogeny, compiled by Daniele Heon.)

Tectonic Evolution of Selwyn Basin (Figure 3)

Selwyn Basin was the locus of deep-water sedimentation that lay southwest of a major carbonate platform from Late Precambrian to Devonian time. The dominantly thin-bedded siliciclastic rocks grade to the northeast into the thick-bedded carbonate sediments of the variably subsiding Mackenzie Platform. From at least late Silurian to early Devonian, shallow-water clastic, volcanic and carbonate rocks of Cassiar Platform marked the southwestern margin of the basin.

Local episodes of igneous activity occurred throughout the sedimentary sequence. The association of widespread local accumulations of alkaline mafic rocks with Cambrian to Devonian unconformities or disconformities and the local presence of coarse clastics are interpreted to be the result of several short-lived pulses of rifting. Volcanism is interpreted to be the result of extension accompanying thermal subsidence and contraction of the lower crust following thermal uplift due to rifting.

From Cambrian to Silurian time, migration of the shelf edge caused interstratification of basinal and platformal facies, the progradation of basinal rocks into the platform and the formation of a series of satellite sub-basins that occur mostly on the N.W.T. side of Selwyn Basin and deep-water troughs (Richardson and Blackstone troughs) extending into, or enclosed within, the carbonate platform. Dominantly mafic and alkaline volcanic rocks are associated with the sub-Late Cambrian unconformity and also occur in Ordovician, Silurian and Devonian times. Rifting events are inferred in each case. Mid-Devonian rifting and/or wrench faulting resulted in a regional marine transgression that abruptly terminated the Selwyn Basin phase of passive margin sedimentation. Coarse grained clastic and siliceous sediments were deposited across the former shelf edge, locally accompanied by mafic and less abundant felsic volcanism.

Selwyn Basin - Passive Margin Phase

The coarse clastic turbidites of the Upper Precambrian to Lower Cambrian Hyland Group are the oldest exposed rocks of Selwyn Basin. They represent thick accumulations of sediments in submarine fans that were fed from an unidentified, rapidly uplifted source area and deposited in a deepening basin. Marginal uplift and sedimentation are interpreted as manifestations of the onset of a major rifting event. The overlying Lower Cambrian Gull Lake Formation marks off-shelf quiet water setting with some clastic input from the Mackenzie Platform. Local mafic volcanic rocks at the base of the Gull Lake Formation and the possibility of a disconformity at that stratigraphic level suggest a less pronounced rift event in late Early Cambrian time.

The sub-Rabbitkettle or sub-Late Cambrian unconformity is a basin-wide feature thought to result from thermal uplift and erosion caused by a Mid to Late Cambrian rifting event. Subsequent widespread Cambrian mafic volcanism lasted into the Ordovician. The SEDEX deposits of the Anvil district occur during this time interval, at the transition between the Mt Mye and Vangorda Formations, which have been respectively correlated to the Gull Lake and Rabbitkettle Formations.

From Late Cambrian-Ordovician to Silurian time, the Road River Group was deposited in euxinic deep-water conditions. The Lower Ordovician to Silurian Duo Lake Formation hosts the large Howards Pass zinc-lead deposit in east-central Selwyn Basin. The Upper Silurian Steel Formation was deposited in a deep but oxygenated environment. Some local tectonic instability is manifested by the sporadic eruption of Cambrian to Ordovician mafic alkaline volcanics and the migration of the shelf edge. The shelf edge was broken by a series of embayments, basins and troughs within which deeper water facies extended from the main part of Selwyn Basin into the platform. Several arches (Mackenzie, Ogilvie) exerted a degree of influence on the distribution of sedimentary facies. To the south, Selwyn Basin was connected to the Kechika Trough of the southern miogeocline (northern BC).

The Misty Creek Embayment formed during Middle Cambrian and younger extension. The Hess River flysch sequence records uplift and erosion of the flanks of the embayment. Deposition of the Rabbitkettle Formation was followed by the eruption of the Middle Ordovician to Middle Devonian volcanic rocks of the Marmot Formation that were deposited along the Duo Lake Formation (Road River Group). The Meilleur River Embayment was a large semi-circular embayment of Selwyn Basin that extended into the southern Mackenzie Platform from Ordovician to Silurian time. The Prairie Creek Embayment developed in Late Silurian as an eastern satellite depression in the Meilleur River Embayment and was the focus of carbonate sedimentation while deposition of Road River shale continued in the rest of the Meilleur River Embayment. Both the Meilleur River Embayment and the Prairie Creek Embayment were located in the central part of the Liard Depression, a long-lived depocentre that developed in the Ordovician and continued in to Devonian time.

Earn Group - Turbidite Basin Phase

The final and most widespread rifting event in the miogeocline occurred in Devono-Mississippian time. Rifting or wrench faulting along the outer miogeocline caused a dramatic change in pattern of sedimentation. Tectonism may have been associated with a back-arc setting, inboard to a pericratonic Devono-Mississippian arc (Yukon Tanana Terrane) that formed on the western margin of North America; the change in sedimentation is coincident to the age of magmatism on the arc. Widespread Middle to Late Devonian and early Mississippian transgression created a deep marine basin. Shale was deposited across the pre-existing platform-basin transition and well into the Mackenzie Platform to the east. At the same time, to the west, the basin was broken by rift zones that controlled deposition in submarine fan complexes of coarse clastics of the Earn Group. Exhalative barite and sulphides were deposited in this setting, forming significant SEDEX deposits in the Macmillan Pass area, at Clear Lake and in the Kechika Trough.

The deposition of coarse-grained clastic sediments was locally interbedded with volcanic assemblages that include mafic and felsic flows and tuffs. Less abundant felsic volcanism occurred on Cassiar Platform and near the Marg VMS deposit. Shale-hosted nickel sulphide mineralization was also deposited during this time interval, as seen at the Nick occurrence.

Structure

Deformation of Selwyn Basin rocks is dominated by Mesozoic structures. Although less obvious, pre-Mesozoic synsedimentary faults are significant as they control the development of secondary sedimentary basins and focus volcanism and SEDEX mineralization. Where preserved, these structures can be recognized from contact relationships. In other cases, these older structures may be cryptic, as they are often been overprinted by younger structures. Other brittle structures, both pre- and post-Mesozoic, control the NNE to ENE steeply dipping veins and faults.

Mesozoic deformation style is controlled by the incompetent nature of the dominant basinal shaly facies. The rocks deformed internally as a homogeneous mass forming the thrust and fold belt called the Selwyn Fold Belt. The Yukon portion of the Selwyn Fold Belt is bounded to the northeast by the carbonate platform edge and the coincident Mackenzie Fold Belt and to the southwest by the leading edge of accreted terranes and by the dextral transcurrent Tintina fault.

Mesozoic deformation reflects response to largely northeasterly-directed compression. Timing of deformation is constrained: it is younger than the age of the youngest rocks cut by thrust faulting and folding (Jurassic) and is older than the age of non-foliated intrusions that cut the deformed strata as well as thrust faults (mid- and Late Cretaceous). Slight variations in these ages occur throughout the belt with variation in age of intrusive activity and age of deformed strata.

The fold belt is characterized by large-scale thrust faulting, open to tight similar folds, imbricate fault zones, and the development of axial planar slaty cleavage. Competent cherts deformed as Chevron folds or isoclinal folds, accommodating significant shortening, with detachment surfaces in less competent strata. In contrast, the thick sequence of competent carbonate rocks of the Mackenzie Platform buckled as large concentric folds and thrust faults, and lacks the slaty cleavage.

Structural trends parallel the arcuate Paleozoic shale-carbonate facies boundary. In some areas complex internal crumpling and faulting may have doubled or tripled stratigraphic thickness without destroying gross stratigraphic integrity.

Faults within Selwyn fold belt have two main orientations: north to northeast trending faults are oblique to the fold trend (<10 kilometres strike length, <400 metres stratigraphic separation), with mostly dip-slope movement; and northwest trending faults are parallel to the trend of folds. Some of these are interpreted as thrusts; most are with dip slip movement. Thrust faults have long strike length, are parallel with fold trends, juxtapose older strata above younger, and cut into stratigraphy along strike.

In western and central Selwyn Fold Belt, strata are folded and imbricated by a series of moderately south-dipping northerly-directed thrust faults. Three principal thrust faults are, from south to north and from older to younger: the Robert Service Thrust, the Tombstone Thrust and the Dawson Thrust. These faults are more than 200 kilometres long and are inferred to root in a single detachment in the Yusezyu Formation of the Hyland Group, with faults cutting progressively deeper in the section from north to south. The intensity of deformation, amount of shortening, and grade of metamorphism all increase from north to south.

The Robert Service Thrust extends from the Dawson map sheet to the northern end of the Mayo map area. In Mayo map area, the Robert Service Thrust sheet gets deformed within the Tombstone Strain Zone.

The Tombstone Thrust parallels the Robert Service Thrust and is characterized by the development of a thick highly strained ductile shear zone in its hanging wall, called the Tombstone Strain Zone ("TSZ") that gradually grades upward into non-strained rocks and juxtaposes progressively older rocks towards the east in both hanging and footwalls, with metamorphic grade increasing toward the east. The thrust probably links into west-northwest striking dextral strike-slip faults of the Macmillan Pass area.

The Tombstone Strain Zone is characterized by prominent foliations and lineations, lenticular compositional layering, shear bands, folding and higher metamorphic grade than rocks outside the zone. TSZ structures and fabrics deform earlier folds and structures resulting in the folding and

imbrication of the earlier Robert Service Thrust. Many kinematic indicators suggest top to the northwest displacement, supported by vergence of asymmetrical folds. The TSZ is itself folded by open regional-scale folds.

The Dawson Thrust fault is a linear Mesozoic thrust more than 200 kilometres long, that sharply juxtaposes basinal rocks on its south side to shallow water platformal sequence on the north side. It forms the southern boundary of Lower Paleozoic shelf-carbonate sequence and the northern boundary of Selwyn Basin. The Ancestral Dawson fault strongly influenced the emplacement of mafic volcanic and intrusive rocks through much of the Paleozoic, Late Proterozoic and possibly earlier. These rocks are in much greater abundance near the Dawson Thrust fault than in equivalent sequences elsewhere. Even though the Dawson thrust marks a significant and sharp boundary between contrasting sedimentary environments, it is interpreted to represent a moderate amount of shortening, with displacement being no greater than displacement on other thrust faults. Offset across the fault could be as little as two to four kilometres. The Dawson Thrust is interpreted to be an ancient underlying basement structure, which repeatedly influenced patterns of sedimentation, igneous activity and faulting, at least since later Proterozoic time.

In the Anvil Range and to the northwest, structure is dominated by moderate southwest dipping or flat-lying strata imbricated by several large northwest trending, northeast directed thrust faults. Detachment surfaces are the base of Devono-Mississippian chert pebble conglomerate or at the base of thick Ordovician volcanics.

In Eastern Selwyn Basin, strike-slip and normal faulting mark the contact with the underlying Proterozoic assemblages. In the Nahanni map area, Devono-Mississippian steep-dipping normal or reverse syn-depositional faults, exhalative barite and Ag-Pb-Zn mineralization suggest an extensional or transtensional regime. Mesozoic deformation is pre Late-Cretaceous and post mid-Triassic. Further north, folding is Early Cretaceous. Some faults are truncated by mid-Cretaceous plutons; others postdate plutonism.

In the Macmillan Pass area (Figure 4), the Macmillan fold belt has a westerly trend and is thought to reflect a deep-seated Devonian fault zone. Folding is tight and a narrow imbricate fault zone of southerly directed east-west trending thrust faults repeats Lower Cambrian to Devonian stratigraphy. South of the imbricate belt, open to closed folds and steep faults are the dominant structures. Some of the steep faults may have been active in the Devonian, forming grabens, and later exerted control on development of the Mesozoic imbricate belt. Northeast from the imbricate belt, structural trend bends northerly to a northwest-southeast orientation. In southwest Macmillan Pass area, the structure is dominated by small to intermediate scale chevron folds in thin-bedded chert of early Paleozoic age. The chert succession has been shortened and thickened but not tilted or imbricated. Displacement was accommodated in the bounding incompetent shales.

Several short-lived pulses of rifting are marked by Cambrian to Devonian unconformities and volcanism. Cretaceous brittle structures control the NNE to ENE steeply dipping veins and faults such as those of the of the Elsa-Keno Hill mining camp silver-lead mineralization. These post-date Tombstone Strain Zone fabrics as well as Cretaceous intrusions but control the emplacement of late dykes.

MacMillan Pass Stratigraphy (Figure 4)

Stratiform deposits of the Macmillan Pass district are hosted by carbonaceous and siliciclastic rocks of the Earn Group that overlie the eastern edge of the Selwyn Basin. In the Macmillan Pass area, the Earn Group ranges in age from Early to Latest Devonian. It is locally subdivided into the Portrait Lake Formation and an alkalic basaltic volcanic suite. Locally, the Portrait Lake Formation is principally divided into the basal Macmillan Pass Member, the informal Tom Member or sequence and the Itsi Member. The Macmillan Pass Member is composed of brown weathering westerly derived shale, conglomerate and sandstone turbidites sandwiching a central chert pebble conglomerate unit; the Tom Sequence consists of blue grey weathering, carbonaceous, radiolarian-rich cherty mudstone and chert; and the Itsi member comprises brown weathering, northerly derived, resistant, micaceous quartz sandstone, siltstone and shale of shallow marine origin. The deposits are confined to a small basin outlined by the outcrop pattern of chert-pebble conglomerates of the Macmillan Pass member and a thickened isopach of the Tom sequence.

Devonian volcanic rocks and related intrusions occur mostly at the base of the Earn Group but in the area of the Boundary Creek prospect, are interbedded with the coarse clastics of the Macmillan Pass Member and have been remobilized into fault scarp proximal diamictites. Conodonts in limestone lens in the volcanics give a Middle Devonian age. Alkalic basaltic volcanism predated and continued up to the time of formation of Zn-Pb deposits and is spatially associated with them, therefore supporting a link between sediment-hosted stratiform deposits and volcanic processes. The volcanics throughout the belt are carbonatized except in the Boundary Creek deposit where complete sideritization is evident.

MacMillan Pass Structure and Tectonic Setting

The host rocks are part of the west-trending Macmillan Fold Belt, which is discordant to the regional northwest structural grain. This fold belt is interpreted to reflect a deep-seated Devonian fault zone that localized facies changes within the Earn Group and also responded differently to Mesozoic deformation. It is divided into three structural blocks based on contrasts in stratigraphy and style of Mesozoic structure: the North, Central and South Blocks.

The ancestral Central block is interpreted as a Devonian graben, a second order basin that was infilled by early coarse clastic turbidites and chert pebble conglomerates, succeeded by thick carbonaceous, cherty and baritic mudstones. The sediments are considerably thicker within the graben and grade laterally into thinner facies on the bounding north and south "horst" blocks. Secondary north-trending syndepositional faults produced localized pull apart, third order basins where they interacted with the major east-trending, graben bounding faults. The complex syndepositional faulting resulted in the deposition of boulder diamictite as debris flows were shed off fault scarps; it also localized early Devonian volcanic centres and the subsequent hydrothermal vents that deposited the base metals.

Late Jurassic and Cretaceous deformation produced three phases of folding and faulting; the second phase of deformation was associated with low-angle thrust faults. Broad open folding and normal faulting characterize the Central block while tighter folding and thrusting is evident in the North and South blocks. The structure of mineralized areas is further complicated by early syndepositional deformation.

PROPERTY GEOLOGY (Metcalfe, 2011)

The only portion of the property mapped in detail by Colorado is the area hosting the historic Neve-Brick minfile occurrence where prior work was done by AGIP. This section describes the lithologies encountered in this area and discusses the structures which possibly control or modify the mineralization.

The following summary and conclusions are excerpts from Colorado's consultant Dr. Paul Metcalfe's report, which can be found in its entirety in Appendix III. Figure 5 shows the geology and a cross-section through the Neve area (J.O.-Saddle-Canol Zones).

Summary

The area mapped during 2011 fieldwork is underlain by a homoclinal sequence of Palæozoic clastic sedimentary rocks with minor limestone and exhalative units. This homoclinal sequence is north-facing, presented in the axis and overturned limb of a north-vergent syncline. The syncline is overthrust from the south by a panel containing Lower Palæozoic Road River Group and is open to the north to the limit of outcrop. Its axial plane dips moderately to the south and its axial plunge appears near-horizontal, but was not determined accurately during 2011 fieldwork.

Rocks exposed in the syncline compose a near-complete paraconformable sequence ranging in age from Ordovician to Mississippian. At the base of this sequence is the Road River Group, comprising siltstone of the Steel Formation overlain by argillaceous limestone of the Sapper Formation. The overlying Devonian Earn Group (Portrait Lake Formation) comprises siliceous shale, argillaceous chert and minor bedded barite of the Niddery Lake member at is base, overlain by siliciclastic rocks of the MacMillan Pass member, in turn overlain by siliceous and carbonaceous shale of the Fuller Lake member. The MacMillan Pass member exhibits a facies variation, fining from chert cobble conglomerate in the east to siltstone in the west. With the exception of a sandy limestone unit near the top of the Fuller Lake member, the Portrait Lake Formation lithologies are non-calcareous. This limestone unit returned conodonts of Late Frasnian age.

Grey shale, siltstone and sandstone overlying the Portrait Lake Formation were identified as the Itsi Formation. This unit is exposed on the south side of the mountain's peak and has a true thickness of roughly 150 metres. The Itsi Formation is overlain by argillaceous chert and siliceous shale grading up into carbonaceous shale and siltstone. A limestone unit near its base returned conodonts of Tournaisian age; lithologies north of the peak are therefore assigned to the basal part of the Tischu Group.

An inferred subvertical fault (the "Secondary Fault") with a strike of 130^{o} repeats the basal Tischu Group section on its north side. The fault is interpreted as downthrown to the north, setting the upright beds to the south against the overturned limb of the fold to the north. The Tischu Group succession north of this fault passes upsection through siliciclastic strata with calcareous cement and a non-calcareous shale unit to the thick Caribou Pass limestone and overlying shale and quartzite units at the limit of exposure.

The sedimentary section has been intruded by numerous irregular subvertical dykes with strikes between 290^o and 310^o. The dykes are peraluminous, with minor garnet as a phenocryst phase and are identified as microgranodiorite porphyry (garnet-bearing, quartz+biotite+plagioclase phyric) in an independent study (Dunne, 2011). The dykes have undergone moderate patchy to intense pervasive phyllic alteration with replacement of all phenocrysts with fine grained dioctahedral mica. The dykes are weakly mineralized with pyrite and arsenopyrite, with late-stage, fracture hosted realgar, orpiment and, less commonly, stibnite. The dykes carry a shear fabric with apparent dextral and minor north side down movement, but their relationship to the Secondary Fault is not known. A second subvertical fault with a strike of 070^o passes to the south of the drill area and offsets the dyke swarm and the Secondary Fault with sinistral sense; displacement is estimated to be 85 metres.

The Oro gold occurrence is hosted by the above stratigraphy, in proximity to the quartz-phyric dykes. It is probable that more consistent grade occurs at the conjunction of the sheared dykes and the reactive argillaceous and silty limestone of the Sapper Formation. It is necessary that any future drill program test the mineralized zone beginning at the shallower, known mineralization, but it is recommended that testing continue to depths where the contact between the Sapper Formation and the overlying Niddery Lake member is predicted by the geometry of the fold. Shallower drilling preceding this deeper testing should take careful note of the limestone units at the base of the Tischu Group and at the top of the Fuller Lake member as aids to refining the fold geometry.

<u>Conclusions</u>
Mapping in 2011 and subsequent analysis indicates that the area is underlain by a homoclinal sequence of Palæozoic clastic sedimentary rocks with minor limestone and exhalative units. This homoclinal sequence is north-facing, presented in the axis and overturned limb of a north-vergent syncline. The syncline is overthrust from the south by a panel containing Lower Palæozoic Road River Group and is open to the north to the limit of outcrop. Its axial plane dips moderately to the south and its axial plunge appears near-horizontal, but was not determined accurately during 2011 fieldwork.

Rocks exposed in the syncline present a near-complete paraconformable sequence ranging in age from Lower Palæozoic Road River Group to Devono-Mississippian Tischu Group. At the base of this sequence is the Road River Group comprising siltstone of the Steel Formation overlain by argillaceous to silty limestone of the Sapper Formation. The overlying Devonian Earn Group (Portrait Lake Formation) includes basal siliceous shale and argillaceous chert of the Niddery Lake member, siliciclastic rocks of the MacMillan Pass member and siliceous and carbonaceous shale of the Fuller Lake member. North of the peak and extending to the Saddle, are basal argillaceous cherts and siliceous shale and siltstone of the Devono-Mississippian Tischu Group. Replication of the basal Tischu section on the other side of the Saddle confirms the presence of the Secondary Fault, but requires vertical rather than strike-slip movement, downthrowing that part of the syncline on the north side of the fault.

The sedimentary sequence is intruded, in the vicinity of the peak by a number of irregular, subvertical dykes with sheared margins, possibly with dextral sense. This sense of movement is inconsistent with the movement of the Secondary Fault and may predate the latter. The shearing,

combined with previous bedding-parallel movement and parasitic folding associated with development of the syncline, will have optimised permeability for hydrothermal fluids. It is suggested here that elongation of the elevated gold zone subparallel to bedding and its coincidence with the location of the dykes implies involvement of the dykes as a heat source for the mineralizing system. A phyllic alteration halo occurs around the dykes and the formation of graphite on bedding and cleavage surfaces in the carbonaceous, siliceous shales is interpreted as a composition-specific response to this phyllic alteration. This might fulfil one requirement of a Carlin-type system, if calcareous units are in proximity. The limestone unit at the base of the Tischu Group is thin but may be responsible for locally elevated gold grades at or near surface in the area drill-tested by AGIP.

Not one but two large calcareous units are available, excluding the Caribou Pass Limestone on the basis of its distance from the dykes. The Squirrel Pass calcareous member within the Tischu Group is much shallower and moreover explicitly in contact with a dyke of the quartz phyric suite on the north side of the Secondary Fault. There is little alteration or mineralization in the vicinity, but the potential of this unit should be noted.

A far more prospective unit is the 150 metre thick argillaceous limestone of the Sapper Formation, overlain by the siliceous and carbonaceous shale of the Niddery Lake member. Indeed the coincidence of the mineralization at surface with this contact on the southern slope of the mountain (the "Canol Zone") was noted by Hulstein and Keyser (1989). Garagan (1983) noted that the syncline's geometry required that the contact between the Sapper argillaceous limestone and the overlying siliceous and carbonaceous shale of the Niddery Lake member be present at between 300 and 500 metres beneath the Saddle Zone. This author suggests a somewhat greater depth of 600 metres or more beneath the peak of the mountain.

This author submits, with respect, that the encouragement encountered in the 1980s drilling records only the tip of the system and that the zone of more regular gold values lies at greater depth. It is recommended that deeper drilling be contemplated and that a closer study made of existing information on gold:silver ratios in the system. Exploration should make use of oriented core with particular attention to core-bedding angles and the location of the two limestone units above and below the Itsi Formation. The target zone for the gold mineralization should be tested from surface to the intersection of the dykes with the Sapper/Niddery Lake contact.

Coincident with the geological mapping of the showing area, Dr. Metcalfe also submitted nine samples for independent petrographic analysis. The petrographic report by Kathryn P.E. Dunne, P.Geo. can be found in Appendix IV. Results of the petrography assisted in interpretation of some of the geological units, most notably the dykes.

8) GEOCHEMISTRY

Lithogeochemistry

In 2011, during the course of geological mapping and prospecting, 746 rock chip and grab samples were collected. Also, a total of 525 three metre contiguous rock chip samples were collected from 15 trenches (for results and discussion – see Trenching section below). Figure 6

shows the rock chip and grab sample numbers and locations. Appendix V is a full listing of all rock sample locations (UTM coordinates), descriptions and results. ACME Labs Certificates of Analyses for rock and trench samples can be found in Appendix VI.

Rock chip samples were collected as continuous rock chips of about golf ball size collected across the true width (wherever possible) of mineralized zones or structures. Grab samples consist of 2 or 3 fist size rock pieces indicative of a certain lithology or mineralization type. Sample sites were marked in the field with spray paint or numbered flagging tape. Samples were put into correspondingly labelled plastic bags with matching bar-coded assay tags inserted and shipped to the laboratory for analyses.

Rock samples were shipped from site via airplane or truck to ACME Laboratory Ltd.'s preparation lab in Whitehorse for sample preparation then shipped on by the laboratory to ACME's Vancouver facility for analyses. All sample preparation was done at the laboratory by their staff. In the laboratory, samples were crushed to minus 200 mesh and fire assayed for gold, plus geochemically analyzed for 36 additional elements by the ICP-MS method.

Statistical analyses were completed for rock and trench sample results. Table II shows percentile breakdowns for select elements which were used for plotting of results.

TABLE II
PERCENTILE VALUES OF ROCK AND TRENCH SAMPLES

percentiles	Au (ppb)	Ag (ppm)	As (ppm)	Sb (ppm)	Hg (ppm)	Bi (ppm)	Tl (ppm)	Zn (ppm)	Ba (ppm)
98%	342.46	4.72	772.30	59.88	40.45	3.60	2.50	1328.60	2974.00
95%	195.00	3.00	499.00	31.75	17.84	1.70	2.00	386.00	2321.00
90%	104.20	1.90	300.50	16.30	9.09	1.10	1.10	217.00	1432.00
75%	18.00	0.90	121.30	6.50	2.27	0.30	0.50	118.00	647.00
50%	4.00	0.20	28.20	1.80	0.32	0.10	0.10	54.00	281.00

Percentile values in this table are somewhat skewed by combining the trench and rock samples, as trench samples overall contain higher gold and indicator element values. It is also interesting to note the relatively high zinc and barium numbers, showing that the property also has sedex mineral association, such as those seen on the nearby Tom (Pb-Zn) and Nidd (Ba) Properties.

Figures 8 to 15 show rock, silt and soil sample results for gold, silver, arsenic, antimony, mercury, bismuth, thallium and zinc, respectively. Results of the rock sampling program will be discussed, along with the soil and silt results, at the end of this geochemistry section.

Soil and Silt Geochemistry

During the 2011 exploration program, a total of 13,808 soil samples and 388 silt samples were collected. Soil sample lines were initially spaced 900 metres apart (to correspond with claim lines), and infilled as results warranted. In the J.O.-Saddle-Canol area, soil lines were spaced much closer, with infill lines in some locations being at 50 metre spacings. Soil samples were

collected at 50 metre intervals along the lines with infill done in key locations at 25 metre sample spacings.

Soil samples were taken from the 'B' soil horizon whenever possible, and were collected using a mattock, shovel or auger. In many instances, samples consisted of talus and scree fines on steeper slopes, and of 'A' horizon soils (sometimes with permafrost) on north facing gentle slopes and in valley bottoms. Three test lines were also put in with a power auger and samples collected near surface and at 90 and 180 centimetre depths along these lines.

Silt samples of stream fines were collected from most of the drainages on the property by manually scooping fine material into labeled cloth stream sediment bags. In areas of talus, coarse particles were screened out of the silt samples at site, in order to ensure sufficient fine material was collected.

Soil and silt sample sites were labelled with fluorescent flagging with the station number recorded on it. Soil was placed in correspondingly labelled Kraft soil bags, while silt samples were placed in cloth silt bags. The soil and silt bags were tagged with bar-coded sample tags, one section of which was stapled to the outside of the bag and a second section inserted into the bag.

At camp, soil and silt samples were dried and sieved to -20 mesh. The -20 mesh fraction was analysed on site utilizing a Niton desk mounted XRF unit. Although gold values do not report accurately by XRF analyses, some pathfinder elements, notably arsenic, were utilized to direct infill and expansion of the soil survey grid. This allowed for daily examination of the XRF data to help direct the exploration program, while awaiting the actual laboratory analyses.

All soil samples were shipped to ACME Laboratory Ltd.'s preparation facility in Whitehorse. The samples were dried, then soil samples were sieved to -230 mesh, while silt samples were sieved to -80 mesh. The prepared samples were then shipped by ACME to their Vancouver laboratory for analyses. The samples were analysed for 36 elements (including gold) by the ICP-MS method.

Appendix VII (in digital version) has a complete database of soil sample locations, descriptions and results. ACME Laboratory Ltd.'s Certificates of Analyses for the soil samples can be seen found in Appendix VIII. Appendix IX (in digital version) has a complete database of silt sample locations, descriptions and results. ACME Laboratory Ltd.'s Certificates of Analyses for the silt samples can be found in Appendix X. Figures 7A to 7D show the soil and silt sample numbers and locations.

Statistical analyses were completed for the soil sample results. Table III shows statistical percentile breakdowns for select elements which were used for plotting of results.

INSERT TABLE III
PERCENTILE VALUES OF SOIL SAMPLES

percentiles	Au (ppb)	Ag (ppm)	As (ppm)	Sb (ppm)	Hg (ppm)	Bi (ppm)	Tl (ppm)	Zn (ppm)	Ba (ppm)
98%	42.7	4.6	307.9	44.7	6.4	0.7	3.3	1551	2497
95%	19.6	3.0	146.9	25.4	2.3	0.5	1.8	881	1877
90%	11.3	2.1	85.4	15.2	1.2	0.4	1.1	508	1333

Discussion of Results

Figures 8 through 15 show the property-wide gold, silver, arsenic, antimony, mercury, bismuth, thallium and zinc soil, silt and rock sample values, respectively. Red and pink dots represent the 95th and 98th percentile values for these elements and have their associated values posted. The J.O-Saddle-Canol Zones, Area 51 and the Golden Ridge-North Steel areas have been plotted in more detail on Figures 16, 17, 20 and 21.

J.O.-Saddle-Canol Zones (Neve occurrence)

The Neve occurrence area (J.O.-Saddle-Canol Zones) shows up as a geochemical high for all elements, defining the strong mineralizing system in that vicinity. The correlation between gold (and indictor elements) mineralization with limey sediments, fault and fold structures and intrusive dyke swarms allows for interpretation of two deposit model types.

Throughout the Selwyn trend, Cretaceous aged Tombstone plutonic rocks are responsible for gold occurrences such as at Brewery Bay and Dublin Gulch, where strong Au-As associations occur. These associations are also apparent in the J.O.-Saddle Zones where Cretaceous dykes produce elevations in gold-arsenic and other indicator elements. Of course, these same dykes and nearby fault structures have been interpreted by Metcalfe (2011) to potentially intersect limey Carlin host units at depth below the J.O.-Saddle-Canol Zones. The gold-arsenic mineralization therefore, could also be interpreted to be an indicator of a buried Carlin deposit.

Figure 16 shows the gold values posted on arsenic contours outlining the significant geochemical signatures, with Au soil values as high as 1490 ppb. The gold and arsenic values have a very strong spatial correlation in this area. Figure 17 shows the thallium values plotted on the same arsenic contours for reference. Thallium is considered a key indicator element for Carlin style mineralization in the Yukon and at the Carlin Trend in Nevada. A strong trend of thallium values lies to the southwest of the main arsenic-gold anomaly, along the Canol Zone trend. The Canol Zone does not contain Cretaceous dyke swarms, but does have a much closer association with the limey sedimentary units and is a very important Carlin gold target area.

Silver (Figure 9), antimony (Figure 11) and zinc (Figure 15) also show strong geochemically anomalous trends in the Canol Zone. Mercury (Figure 12) and bismuth (Figure 13) show strong anomalies in the J.O.-Saddle Zone, likely correlating with the intrusive dykes. Additional interpretive work with the geochemical, geological and geophysical data is required in order to fully understand the deposit model signatures and economic potential of this area.

The original geochemical anomaly defined by AGIP in the 1980s covered about one square kilometre. Colorado's 2011 sampling program has expanded this anomalous area over the J.O.-Saddle-Canol Zone to approximately 2.5 kilometres in length, with several of the key indicator elements extending for another 1.5 kilometres to the southeast to join up with the Repeater Zone.

Repeater Zone

The Repeater Zone lies 1.5 kilometres southeast of the J.O.-Saddle-Canol Zones (in fact, along direct trend from the Canol Zone). Although gold geochemistry for soils and rocks is low in this area, it is highly anomalous for most other elements, notably arsenic, antimony, mercury, thallium and zinc. These elements continuously extend along the lithological trend from the Canol Zone, expanding that mineralized trend to 4 kilometres in strike length. Lithologically, the Repeater Zone is underlain by a strongly carbonatized Devonian volcanoclastic unit. Geological/structural mapping is recommended in order to fully understand the significance of the Repeater Zone mineralization and its association to the Canol Zone.

Area 51

In the southeast corner of the Oro Property is another strong geochemically anomalous zone called Area 51. Arsenic and antimony (Figures 10 and 11) values are elevated in this area, associated with spotty high gold geochemical values (up to 1530 ppb). Figure 20 shows in more detail, the gold values plotted on the arsenic contour map. The arsenic-antimony anomaly is approximately 1300 x 250 metres in size.

Unlike the J.O.-Saddle-Canol Zones, Area 51 is associated with a Devonian gabbroic dyke which exhibits strong arsenic alteration and pyrite-arsenopyrite mineralization. This dyke intrudes the Carlin favourable limey siltstones of the Sapper Formation. Geological/structural mapping and detailed soil geochemistry is required in Area 51 in order to determine the significance of this mineralization.

Golden Hinge-Golden Ridge-North Steel Area

Late in the 2011 exploration program, soil samples were collected from a broad east-west trending area hosting the newly termed Golden Hinge, Golden Ridge and North Steel Zones. The Golden

Hinge area lies to the northwest of the J.O.-Saddle-Canol Zones in an area with significant folding of the limey lithologies.

Golden Ridge is probably the most geochemically significant part of the area, with a broad silver signature containing scattered elevated gold values. The silver anomaly trends for 10 kilometres, with an inset gold anomaly extending through the western 6 kilometres (see Figure 21). This trend lines up with a strong regional structure, the Hess River thrust fault, and the adjacent siliceous conglomerate unit. The silver-gold mineralization may represent "leakage" of a buried mineralized body associated with the thrust fault.

The North Steel zone lies in an area of strong structural deformation marked by repetitive northeast-southwest faults. As in the Golden Ridge area, soil sampling has been done only at relatively wide line spacings of 900 or 450 metres. Infill soil sampling, mapping and prospecting is required in this target area in order to better define the core of the mineralized zone.

Limey Ridge

To the east of the J.O.-Saddle-Canol Zones is the newly identified Limey Ridge Zone, consisting of a gold, silver, arsenic and mercury soil geochemical anomaly. The arsenic anomaly extends across 6 grid lines for a distance of 1350 metres. The gold anomaly occurs central to the arsenic anomaly, with gold soil geochemical values up to 1112 ppb.

Thallium Zone

Approximately 6 kilometres west of the J.O.-Saddle-Canol Zones lie two sub-parallel, three kilometre long, east-west trending thallium anomalies of unknown origin (Figure 14). Weak silver and antimony values are associated with these anomalies (Figures 9 and 11).

Conclusion

In general, gold-arsenic-antimony-mercury values occur together, however arsenic is often more widespread and mercury-antimony is less consistent although can return comparatively high values. Bismuth and thallium also often occur with gold, but can also be found in zones independent of gold or other indicators.

9) TRENCHING

In 2011, fifteen trenches, totalling 1548 linear metres, were excavated on the Oro Property. Thirteen of the trenches were located on the mountain hosting the Neve mineralization, while one was located to the northwest and one on the Repeater Zone to the south. Trenches T2011-01 and T2011-02 reopened and expanded historic trenches put in by AGIP in 1982 and 1983. The trenches were designed to test soil geochemical anomalies, contacts and structures believed to be associated with Carlin style gold mineralization.

Trench locations and sample numbers are shown Figure 18. A database with trench sample descriptions and select results can be found in Appendix V and ACME Labs Certificates of Analyses for rock and trench assays can be found in Appendix VI.

Sample Collection, Preparation and Analyses

Sample preparation procedures used by Colorado follow standard industry practice and professional guidelines. After the trenches were mapped, three metre continuous chip samples were collected from the base of the trench wall for the length of the trench. Occasionally a duplicate trench sample was collected from the same site as the original. The trench sample intervals are marked with aluminum tagged pickets labelled with the assay tag number. The chip samples were placed in poly sample bags correspondingly labelled and with a bar coded assay tag inserted into the bag. Standards and blanks were inserted into the sample sequence prior to shipping.

The trench chip samples were shipped by airplane or truck from camp directly to ACME Laboratory Ltd.'s preparation lab in Whitehorse for sample preparation then shipped on by the laboratory to ACME's Vancouver facility for analyses. All sample preparation was done at the laboratory by their staff. In the laboratory, samples were crushed to minus 200 mesh and fire assayed for gold, plus geochemically analyzed for 36 additional elements by the ICP-MS method.

Trench Results

A summary of select trench results has been listed in Table V.

TABLE V
TRENCH SAMPLE RESULTS

TRENCH #	COMMENT	WIDTH (m)	Au (ppb)	Ag (ppm)	As (ppm)	Sb (ppm)	Zn (ppm)	Ba (ppm)

Figure 19A shows the gold assay values from the trenching program and Figure 19B shows arsenic values. Results from the trenching program are somewhat consistent with previous results from AGIP for the bedrock chip samples. Also, AGIP sampled the talus fines material separately from bedrock and received more highly elevated gold values from this material. Sampling by Colorado included bedrock where exposed and/or talus plus talus fines where bedrock was not exposed. Gold values similar to AGIP's talus fines values were not obtained by Colorado from the media sampled.

However, broad zones of elevated gold grades were obtained, such as 446.3 ppb Au over 36 metres from Trench T2011-02, representing the entire trench length. These elevated gold values, combined with the surrounding large, consistent multi-element soil geochemical anomaly suggest that the trench material may lie distal (above?) to a better mineralized, structurally controlled lithological horizon as suggested by Metcalfe (2011). A substantial diamond drilling program is required to better evaluate the Carlin-style gold mineralization in the Neve area.

10) GEOPHYSICS

Airborne Geophysical Survey

From July 15 to August 2, 2011, a DIGHEM electromagnetic/resistivity/magnetic survey was flown over the Oro Property for Colorado by Fugro Airborne Surveys ("Fugro"). Survey coverage consisted of 2114 line kilometres including 192 line kilometres of tie lines. Flight lines were flown with a line separation of 200 metres. Tie lines were flown perpendicular to the flight direction, with a line spacing of 2000 metres. Flight lines were oriented at 27°/207° and tie lines at 117°/297° (Figure 22).

The survey employed the DIGHEM electromagnetic ("EM") system. Ancillary equipment consisted of a high sensitivity cesium magnetometer, radar and laser altimeters, video camera, digital data recorder, and an electronic navigation system. The instrumentation was installed in an AS-350-B2 turbine helicopter (Registration C-GJIX) that was provided by Questral Helicopters Ltd. The helicopter flew with a nominal EM sensor height of approximately 35 metres.

Table VI lists the corner coordinates of the survey area in NAD83, UTM Zone 9N, central meridian 129°W.

Figures 23 and 24 are coloured contour plots of the airborne magnetics. Overlain on the Total Magnetic Intensity ("TMI") and Tilt Derivative ("TD") magnetic plots are the soil geochemistry contours for gold, silver, arsenic, antimony and thallium values and geologic structures for reference.

The TMI plot (Figure 23) shows a prominent magnetic high feature on the west side of the claim block. This may be related to a buried intrusive, but no outcrop evidence supports this theory. Neither is there elevated soil geochemistry in this area. A second prominent, albeit smaller, magnetic high is located in the vicinity of the Neve (J.O.-Saddle Zones). This magnetic feature is probably related to the abundant Cretaceous dykes located in this area, which are likely feeders to buried intrusive body. A few smaller, less significant magnetic high features trend across the southeastern portion of the Oro Property.

The Tilt Derivative plot (Figure 24) details more structural information. The general NW-SE lithological trend is readily apparent, especially in the southern half of the property. The most prominent feature on this map is a strong NW-SE high paralleling the Golden Ridge Zone, related either to the conglomerate unit or the underlying thrust fault. Several cross structures show up on this plot, and additional geophysical interpretations are recommended in order to fully evaluate the importance of the various features projected.

Figure 25 and 26 are coloured contour plots of apparent resistivities using 7200 Hz and 56,000 Hz frequencies, respectively. By no coincidence, the Neve area (J.O.-Saddle-Canol Zones) lies along a strong structural break as shown by the steep resistivity gradients. Cross structures, which are important in Carlin gold systems, are also visible trending through this area. As with the Tilt Derivative, the Golden Ridge Zone also shows up prominently as a resistivity high feature. Other zones, such as the Repeater Zone and Area 51 lie generally within a belt of low resistivities with subtle associated highs. As with the magnetic data, it is recommended that more detailed geophysical interpretations also be undertaken with the resistivity data in order to identify important features for follow up exploration work.

Table VII summarizes the discrete EM anomaly responses interpreted from the survey data with respect to conductance grade and interpretation for the survey areas. Fugro's interpretation map, which includes magnetic and EM anomalies, is shown on Figure 27.

TABLE VII
EM ANOMALY STATISTICS

CONDUCTOR GRADE	CONDUCTANCE RANGE SIEMENS (MHOS)	NUMBER OF RESPONSES
7	>100	124
6	50 – 100	164
5	20 – 50	441
4	10 – 20	683
3	5 – 10	1057
2	1 – 5	6529
1	<1	2246
*	INDETERMINATE	257
	TOTAL	11501

CONDUCTOR MODEL	MOST LIKELY SOURCE	NUMBER OF RESPONSES
D	DISCRETE BEDROCK CONDUCTOR (THIN DYKE MODEL)	1392
B	BEDROCK CONDUCTOR	6460
S	CONDUCTIVE COVER	3524
E	EDGE OF WIDE CONDUCTOR	10
H	ROCK UNIT OR THICK COVER	115
	TOTAL	11501

The interpretation map (Figure 27) shows prominent magnetic and conductive zones outlined in red or blue, respectively. Linear features that have been interpreted from either the magnetic or resistivity data, and which may reflect possible structural breaks within the survey area, are shown with a dashed green line.

The Oro Property survey area is dominated by a highly conductive zone, R1. It seems to reflect a broad conductive unit, which is made up of multiple, closely spaced, thin conductive trends. The conductivity associated with R1 seems to reflect sources at depth, as the low frequency resistivities are generally lower than those calculated from the high frequency. The changes in the calculated resistivities one frequency to another, gives an approximation of the subsurface.

Conductivity depth sections, such as differential resistivity sections, may be useful in defining the characteristics of complex conductive units such as R1. Differences in depth to conductor, and change in conductivity with depth are readily apparent.

R1 displays some correlation with the magnetic data, as many of the possible breaks identified on the magnetic parameters are also on the resistivity parameters. Several moderately magnetic units, M1, M2 and M3, are situated near the edges of conductive zone R1. All are situated in areas of complexity in the magnetic data, as many prominent breaks are evident in the vicinity of all three magnetic zones. M1 is situated at the northern limit of R1. It is interesting as it seems to be part of an oval shaped magnetic feature defined on the calculated first vertical magnetic derivative map. This also lines up with the J.O.-Saddle-Canol Zones.

M5 differs from M1, M2 and M3 as it is situated within R1 rather than near the edge of the zone. It is coincident with a resistive zone within R1 which is associated with a topographic high. This area is underlain by Devonian volcanic units.

Less extensive conductive zones, R2 and R3, reflect conductive sources at depth. Neither displays any direct correlation with the magnetic data, as they are situated within the relatively non-magnetic northwest area of the survey block. R4, which is situated to the north of R1, also reflects possible bedrock conductivity. Its southern limit is coincident with a prominent northwest/southeast trending break in the magnetic data.

M4 is a complex magnetic zone, with magnetic features generally associated with topographic highs. Many possible structural features, inferred from the magnetic data, intersect this zone. The strongest magnetic feature within M4 is situated at the northern edge of the zone, immediately to

the west of a prominent north-northwest/south-southeast trending magnetic break. Conductive zone R5 is situated along this break, and may reflect weakly conductive features at depth.

Extensive conductive zones such as R1 often reflect formational conductors that may be of minor interest as direct exploration targets. However, attention may be focused on areas where these zones appear to be faulted or folded or where anomaly characteristics differ along strike. Such structural breaks are considered to be of particular interest as they may have influenced mineral deposition within the survey area.

Fugro's conclusions and recommendations state:

The survey has been successful in mapping the magnetic and conductive properties of the survey areas. The survey was also successful in locating anomalous zones that may warrant additional work. The various maps included with this report display the magnetic and conductive properties of the survey areas. It is recommended that a complete assessment and detailed evaluation of the survey results be carried out, in conjunction with all available geophysical, geological and geochemical information.

The interpreted bedrock conductors and anomalous targets defined by the survey should be subjected to further investigation, using appropriate surface exploration techniques. Anomalies that are currently considered to be of moderately low priority may require upgrading if follow-up results are favourable.

It is also recommended that image processing of existing geophysical data be considered, in order to extract the maximum amount of information from the survey results. Current software and imaging techniques often provide valuable information on structure and lithology, which may not be clearly evident on the contour and colour maps. These techniques can yield images that define subtle, but significant, structural details.

The entire Fugro report can be seen in Appendix XI.

ASTER Imagery

In 2011, Colorado contracted Ward Kilby, P.Geo. of Cal Data Ltd. to conduct an ASTER Satellite Imagery review on the Oro Property. The following summary, conclusions and recommendations are excerpted from the report, which can be found in its entirety in Appendix XII.

Summary

Cal Data Ltd. was contracted by Colorado Resources Ltd. to acquire and analyze ASTER Multispectral imagery covering the ORO claim group in eastern Yukon. A search for available ASTER and other imagery was performed. The claim area had very poor ASTER coverage with all imagery having issues with cloud cover or sensor problems.

Good LandSat 7 (ETM+) imagery was available for the claim group. Initially the best available ASTER image was purchased. The preview image showed some problems with the image in the area of the claims but it was felt there could be some useful portions. Unfortunately when acquired virtually the whole region of the claims was useless. The LandSat image was processed

and evaluated. LandSat only has reasonable spectral coverage in the VNIR portion of the spectrum with very limited capabilities in the SWIR (one band). Examination of the LandSat image showed several areas of potential interest.

Two additional ASTER images were acquired to add some additional spectral and spatial resolution in the areas of interest from the LandSat evaluation.

The LandSat image files were obtained through the NASA Land Processes Distribution Active Archive Center (LPDAAC) at no cost. The required ASTER imagery was identified through the LPDAAC website and then purchased from ERSDAC (Earth Remote Sensing Data Analysis Centre) in Japan.

The claim area was fully exposed in the LandSat image but significantly cloud covered in the ASTER images. The two ASTER images that were used in the analysis had VNIR and TIR sensor data and one had SWIR data.

Image analysis included converting the imagery from digital number format (DN) to relative reflectance values through standard preprocessing techniques. The imagery was rectified to the UTM Zone 9 projection, WGS 84 datum.

A full range of products were constructed from the imagery. In the case of the LandSat image these included a pan-sharpened natural colour image, temperature map as well as the mineral maps generated during the analysis. In the case of the ASTER imagery the products included; near-natural colour imagery, DEMs, anaglyph images, temperature maps and mineral maps generated from the spectral analysis.

The spectral analysis was performed on the ORO claim area using hyperspectral and multispectral techniques on both the LandSat and ASTER imagery. Any mineral or rock identification made based on ASTER or LandSat spectra must be considered an estimate as the spectral and spatial resolution of the sensors is not adequate to positively identify individual materials in most cases.

<u>Conclusions and Recommendations</u>
Standard LandSat analysis techniques were applied to the imagery with good results. Crosta Targeted Principal Component Analysis mapped hydroxyl and iron-oxide bearing minerals nicely. Spectral Angle Mapping using spectra from the ORO deposit and a potential jarosite occurrence highlighted a number of sites for field investigation. The 5^{th} factor of a Tasseled Cap transformation also highlighted prospective areas. In most cases all the above analysis tended to identify the same areas. The fact that the known Neve area (J.O.-Saddle-Canol Zones) was positive in all these mappings suggests that other sites identified with these methods may be important. When selecting targets from the analysis reference should always be made to the corresponding natural colour imagery to assure that the prospective area is rock and not some combination of clouds, snow or vegetation that could have a spectral signature similar to the targeted rock. When examining all the mineral map images one should only assume that the very best image matches (red pixels) represent the subject spectra.

Silicification was mapped with the ASTER emissivity data. When using this technique it is especially important to assure that the highlighted pixels are representing good rock exposure as clouds and the thin edges of clouds can give a very similar thermal signature to quartz. Only through field verification should any reference to the existence of a mineral be taken as a given.

In addition to the mineral mappings a number of products were generated from the ASTER data. These included natural colour images, digital elevation models and temperature maps.

The Aster and Landsat imagery spectral plots identified a number of colour anomalies and potential indicator mineral occurrences. In order to provide the best usage, these plots need to be used in conjunction with geological, geochemical and geophysical data. The main Neve occurrence area shows up strongly in multiple parameters, but weaker anomalies have not yet been examined in the field.

11) CONCLUSIONS

On the Oro Property gold and associated indicator element geochemistry, combined with airborne geophysical survey results, have identified several significant mineralized zones.

The Oro Property lies within the Selwyn Basin, along the geological trend from Atac Resources Ltd.'s Carlin gold discoveries. The Neve occurrence (J.O.-Saddle-Canol Zones) was identified in the 1980s by AGIP Canada Ltd. as having the potential to host Carlin style gold mineralization. Geological, geochemical and geophysical work completed in 2011 by Colorado corroborates AGIP's conclusions.

Throughout the Selwyn trend, Cretaceous aged Tombstone plutonic rocks are responsible for gold occurrences such as at Brewery Creek and Dublin Gulch, where strong Au-As associations occur. These associations are also apparent in the J.O.-Saddle Zones where Cretaceous dykes produce elevations in gold-arsenic and other indicator elements. As well, these same dykes and nearby fault structures have been interpreted by Metcalfe (2011) to potentially intersect limey Carlin host units at depth below the J.O.-Saddle-Canol Zones. The gold-arsenic mineralization therefore, could also be interpreted to be an indicator of a buried Carlin deposit.

Detailed geological/structural mapping carried out in the J.O.-Saddle-Canol Zones identified three potential limestone host units, calculated their geometries and postulated their locations of interception with structures (faults and dykes) that may be responsible for deposition of Carlin style gold mineralization. These structural intersections are key diamond drilling targets for 2012.

A good geological compilation map has been produced for most of the Oro Property by Abbott (2012) showing the lithological trends and significant structures. This geology provides a good base for correlations and interpretations of the airborne geophysical survey . More detailed geophysical interpretations are required in order to fully understand the significance of the various anomalous trends and structural breaks identified.

The geochemical surveys produced several strong, often multi-element anomalous zones. Again the geochemistry highlights the J.O.-Saddle-Canol zones, expanding the anomalies to a four kilometre strike length. Several additional areas such as Golden Hinge, Golden Ridge, North Steel, Area 51, Limey Ridge and Repeater Zone also have strong multi-element soil geochemical signatures. Detailed follow up is required in 2012 in order to determine the significance of these anomalous areas.

12) RECOMMENDATIONS

Due to the success of the exploration program on the Oro Property in 2011, an expanded program is recommended for 2012. The 2012 exploration program should consist of continued infill soil geochemical sampling and geological mapping in key target areas. Up to 10,000 soil samples should be collected. Excavator trenching is recommended to follow up soil geochemical anomalies, along with 5000 metres of diamond drilling.

While the soil sampling, trenching and mapping is planned to be conducted over several anomalous areas, diamond drilling should at least initially target the Neve occurrence area (J.O.-Saddle-Canol Zones) where structural mapping, geophysics and geochemical indicators all suggest a strong possibility of locating a buried Carlin gold target.

Estimated cost for the 2012 exploration program is $4.5 million. Work should commence in mid to late May as soon as conditions allow.

Respectfully submitted,

Linda Dandy, P.Geo.
February 22, 2012

14) COST STATEMENTS

Two separate work filings were done in 2011 for the Oro Property. The initial filing covered the airborne geophysical survey costs. The second, later filing included the field work component of the 2011 exploration program. For this second filing, the claims were put into 3 groups. The cost statement is broken down to reflect the two work filings and the 3 individual groupings. This report covers all the work complete on the property in 2011.

INITIAL FILING – AIRBORNE GEOPHYSICAL SURVEY

AIRBORNE GEOPHYSICAL SURVEY: 2114 line km @ $188	$397,432.00
FOOD AND ACCOMMODATION (Mac Pass): 52 mandays @ $400	20,800.00
TRANSPORT AND MOBILIZATION:	16,500.00
TOTAL AIRBORNE GEOPHYSICAL SURVEY COSTS:	$434,732.00

2ND FILING – GROUP 1

GEOLOGISTS:	108 days @ $750	$ 81,000.00
PROSPECTORS:	81 days @ $500	40,500.00
SAMPLERS:	198 days @ $450	89,100.00
ANALYSES:	1090 ROCK SAMPLES @ $30.05	32,755.00
	9921 SOIL/SILT SAMPLES @ $21.08	209,135.00
HELICOPTER:	413 HOURS @ $1250	516,250.00
	FUEL	76,322.00
MINI-EXCAVATORS:	720 HOURS @$50	36,000.00
	OPERATORS: 105 days @ $450	47,250.00
FOOD AND ACCOMMODATION (Watson Lake) 620 mandays @ $400:		248,000.00
SUPPLIES, FREIGHT, TRAVEL AND MISCELLANEOUS:		25,500.00
REPORT PREPARATION:		19,000.00
TOTAL COSTS:		$1,420,812.00

2ND FILING – GROUP 2

GEOLOGIST:	5 days @ $750	$ 3,750.00
PROSPECTORS:	23 days @ $500	11,500.00

SUPPLIES, FREIGHT, TRAVEL AND MISCELLANEOUS:		7,500.00
REPORT PREPARATION:		7,000.00
TOTAL COSTS:		$244,187.00

15) QUALIFICATIONS

I, Linda Dandy, hereby certify that:

1. I am a Consulting Geologist having an office at 4900 Warm Bay Road, Atlin, British Columbia, V0W 1A0.

2. I am a graduate of the University of British Columbia with the degree of Bachelor of Science in Geology (1981).

3. I am a member of the Association of Professional Engineers and Geoscientists of British Columbia (Registration No. 19236) and a Fellow of the Geological Association of Canada (Membership No. F5201).

4. I have practiced my profession in North America since 1981, having worked as an employee and consultant for Major Mining Corporations, Junior Resource Companies and government.

5. This report is based upon personal examination of all available company and government reports pertinent to the subject property, and upon fieldwork undertaken on the property from June to September 2011. I have directly supervised all field work on the property.

February 22, 2012
Atlin, BC

Linda Dandy, P.Geo.
Consulting Geologist

SUMMARY

The area mapped during 2011 fieldwork is underlain by a homoclinal sequence of Palæozoic clastic sedimentary rocks with minor limestone and exhalative units. This homoclinal sequence is north-facing, presented in the axis and overturned limb of a north-vergent syncline. The syncline is overthrust from the south by a panel containing Lower Palæozoic Road River Group and is open to the north to the limit of outcrop. Its axial plane dips moderately to the south and its axial plunge appears near-horizontal, but was not determined accurately during 2011 fieldwork.

Rocks exposed in the syncline compose a near-complete paraconformable sequence ranging in age from Ordovician to Mississippian. At the base of this sequence is the Road River Group comprising siltstone of the Steel Formation overlain by argillaceous limestone of the Sapper Formation. The overlying Devonian Earn Group (Portrait Lake Formation) comprises siliceous shale, argillaceous chert and minor bedded barite of the Niddery Lake member at is base, overlain by siliciclastic rocks of the MacMillan Pass member, in turn overlain by siliceous and carbonaceous shale of the Fuller Lake member. The MacMillan Pass member exhibits a facies variation, fining from chert cobble conglomerate in the east to siltstone in the west. With the exception of a sandy limestone unit near the top of the Fuller Lake member, the Portrait Lake Formation lithologies are non-calcareous. This limestone unit returned conodonts of Late Frasnian age.

Grey shale, siltstone and sandstone overlying the Portrait Lake Formation were identified as the Itsi Formation. This unit is exposed on the south side of the mountain's peak and has a true thickness of roughly 150 m. The Itsi Formation is overlain by argillaceous chert and siliceous shale grading up into carbonaceous shale and siltstone. A limestone unit near its base returned conodonts of Tournaisian age; lithologies north of the peak are therefore assigned to the basal part of the Tischu Group.

An inferred subvertical fault (the "Secondary Fault") with a strike of 130 repeats the basal Tischu Group section on its north side. The fault is interpreted as downthrown to the north, setting the upright beds to the south against the overturned limb of the fold to the north. The Tischu Group succession north of this fault passes upsection through a siliciclastic strata with

calcareous cement and a non-calcareous shale unit to the thick Caribou Pass limestone and overlying shale and quartzite units at the limit of exposure.

The sedimentary section has been intruded by numerous irregular suvertical dykes with strikes between 290 and 310. The dykes are peraluminous, with minor garnet as a phenocryst phase and are identified as microgranodiorite porphyry (garnet-bearing, quartz+biotite+plagioclase phyric) in an independent study. The dykes have undergone moderate patchy to intense pervasive phyllic alteration with replacement of all phenocrysts with fine grained dioctahedral mica. The dykes are weakly mineralized with pyrite and arsenopyrite, with late-stage, fracture hosted realgar, orpiment and, less commonly, stibnite. The dykes carry a shear fabric with apparent dextral and minor north side down movement, but their relationship to the Secondary Fault is not known. A second subvertical fault with a strike of 070 passes to the south of the drill area and offsets the dyke swarm and the Secondary Fault with sinistral sense; displacement is estimated to be 85 m.

The Oro gold occurrence is hosted by the above stratigraphy, in proximity to the quartz-phyric dykes. It is probable that more consistent grade occurs at the conjunction of the sheared dykes and the reactive argillaceous and silty limestone of the Sapper Formation. It is necessary that any future drill program test the mineralized zone beginning at the shallower, known mineralization, but it is recommended that testing continue to depths where the contact between the Sapper Formationand the overlying Niddery Lake member is predicted by the geometry of the fold. Shallower drilling preceding this deeper testing should take careful note of the limestone units at the base of the Tischu Group and at the top of the Fuller Lake member as aids to refining the fold geometry.

Plate 1. Geological map of trench area ..... In pocket

INTRODUCTION

This geological report describes briefly the lithologies encountered on the mountain hosting the main trench area and discusses the structures which possibly control or modify the mineralization observed to date. Units of measure in this report are metric. Maps are presented in Universal Transverse Mercator (UTM) projection, using the 1983 North American Datum (NAD'83); the tenure lies in Zone 9V.

FIELD PROCEDURES

Topographic and geological base

2011 fieldwork used a field topographic base comprising National Topographic Database (NTDB) vector topographic information and digital elevation models (DEMs) at 1:50,000 scale. Orthogonal (vertical) views and maps were generated using MapInfo® v.8.0, incorporating these data. Oblique views of the terrain were generated using Global Mapper® v.11.01 to produce computer graphics images (CGIs), incorporating DEM and elements of the topographic data.

Mapping

Mapping was carried out by the author, on solo traverses and also assisted by Mr. Nicholas L. Barber. Field stations were located using a Garmin GPSMap 62 global positioning unit. Sample stations were numbered alphanumerically and the quoted error of the global positioning unit, number of satellites sampled and signal strength were all recorded at each field station, together with lithological and structural data.

Map compilation

Waypoint locations were downloaded and plotted, together with circular error envelopes with radii twice that of the recorded satellite error. Field stations were checked for consistency and the extents of outcrops examined during fieldwork were plotted accurately. Structural information was keyed to waypoint-specified outcrops, with offset of symbols to avoid obscuring data points and small outcrops. The symbol set used is based upon that of the British Columbia Geological Survey Branch (1997).

RESULTS OF GEOLOGICAL MAPPING

A geological map of the area examined is shown in Plate 1. The area mapped lies in the keel and/or upper limb of a north-vergent overturned syncline dissected by west-northwest- and east-northeast-striking transcurrent faults.

Stratigraphic units

Layered rocks

The considerable amount of work carried out in the area by Abbott and Turner(1991), Cecile and Abbott (1992), Cecile (2000) and most recently by Abbott (in prep.) is beyond the scope of this report and (moreover) obviates the necessity for detailed descriptions of each stratigraphic unit. The reader is referred to these for detailed descriptions and regional implications; this report will confine itself to a brief description of each unit and to their disposition within the study area.

Ordovician to Devonian Road River Group

The Road River Group comprises three formations[1]. The uppermost two, (Steel and Sapper formations) are exposed in the immediate study area in the keel of the syncline and in a north-vergent overthrust panel in the extreme south of the area mapped (Plate1). The sequence is not well exposed and estimates of unit thickness are reliant on Abbott's work.

Steel Formation

The Steel Formation comprises thickly laminated bioturbated, non-calcareous siltstone with a "wispy aspect" The unit weathers to a tan colour and bioturbation is most noticeable on weathered surfaces. Abbott (pers. comm.) also noted a distinctive, musical crunching of Steel talus underfoot.

Considerable exposures are visible elsewhere on the property but the Steel Formation is rarely exposed locally, possibly because of comminution and dismemberment near the thrust fault

v

[1] The reader should note that capitalisation of the word "formation" denotes a formally defined stratigraphic unit; lack of capitalisation denotes informal use. The same convention is applied to members within a formation. Formal terms in the plural are not capitalised.

Sapper Formation

The Sapper Formation comprises dark grey argillaceous and silty limestones and calcareous shale and siltstone. The unit weathers a distinctive colour, familiarised as "black and tan" on dry scree slopes; the "tan" component is closer to sienna or medium brown. The unit weathers recessively; exposures other than proximal float are rare in the mapped area.

The Sapper Formation is of interest to exploration for Carlin-type gold deposits, as a reservoir of carbonate. Lithologies in this formation are strongly calcareous, the carbonate being mainly calcite. Subordinate dolomite may also be present.

The thickness of the Sapper Formation in the general area is estimated to be from negligible to as much as 200 m. In the immediate area it is estimated to be well in excess of 100 m (Abbott pers. comm. 2011)

Devonian Earn Group

The Earn Group comprises mainly fine grained sedimentary rocks with two intervals of coarser grained siliciclastic rocks, the older representing coarse clastic sediment movement from the west, the younger consisting of material transported from the north. Excepting the coarsest rocks, the closely similar lithologies hinder identification of members and formations within the group; identification of specific stratigraphic units on the basis of lithology is often contextual (Abbott pers. comm. 2011).

Portrait Lake Formation

Niddery Lake member

The basal member of the Portrait Lake Formation comprises thinly to thickly laminated black siliceous shale and argillaceous chert with lesser, interlaminated carbonaceous shale. A single occurrence of bedded barite occurs in subcrop in Trench H. The unit is roughly 90 m thick and weathers a distinctive pale bluish grey, an attribute shared with the Fuller Lake lithologies, upsection.

MacMillan Pass member

The basal part of the MacMillan Pass member comprises brown weathering thinly bedded to thickly laminated siltstone and shale with a thickness of roughly 60 m. The lithology is

relatively prominent and is overlain by a discontinuous chert pebble conglomerate facies. The latter is the best exposed lithology on the mountain, owing to its generally coarser and more durable nature. Clasts include chert and are as large as cobbles or small boulders in the conglomerate's main exposure to the southeast of the main trench area. Here, the facies attains its greatest local thickness of as much as 100 m, thinning west along strike to as little as two metres in the valley to the east of the Canol Zone. Clasts in this western exposure rarely exceed small pebble size. The conglomerate is absent further west. In its main exposure, it is overlain, by a coarse grit to coarse sandstone unit with a carbonaceous matrix and abundant rip-up clasts of black shale, apparently a transition to the lithology of the overlying unit.

Fuller Lake member

The Fuller Lake member is not well exposed even in trenches, generally forming large pale blue-grey weathering talus exposures. The unit is lithologically very similar to the Niddery Lake member, albeit with a slightly greater content of carbonaceous material, and records a return to quiet siliceous shale sedimentation, following deposition of the MacMillan Pass siliciclastic rocks. The Fuller Lake member exposed in Trench H on the southern slope of the mountain has a thickness of roughly 40 m. Possible variations in this thickness are discussed below.

Itsi Formation

The Itsi Formation, initially defined as a member of the Portrait Lake Formation, overlies the latter unconformably in the area mapped (Abbott pers. comm. 2011). The basal (southern) contact is poorly exposed and there is no evidence to suggest removal of part of the Fuller Lake section.

The Itsi Formation is characterised by brown weathering shale, siltstone and fine sandstone. These lithologies are very similar to those of the finer (shale and sandstone facies) of the MacMillan Pass member. A significant difference (Abbott pers. comm. 2011) is the presence of detrital muscovite in the Itsi Formation; none occurs in the MacMillan Pass member. This difference is less useful than it seems, as discussed in the section on metamorphism and alteration, below.

Devonian to Mississippian Tischu Group

The Tischu Group is exposed on the north side of the mountain, north of the east-southeast-striking Secondary Fault. Its basal contact was not observed, but the basal argillaceous chert and siliceous shale unit is exposed immediately to the north of the fault and its age confirmed by palæontological sampling (Abbott pers. comm. 2011). This basal member has a thickness of greater than 70 m. Overlying the basal siliceous member is a sequence of tan brown weathering, thinly laminated to thinly bedded shales and siltstones with rare beds of fine grained quartz arenite as thick as 1 m. This siltstone/shale member is roughly 150 m thick.

Upsection from the siltstone/shale member, coarser-grained and thicker beds are more common and the matrices of the clastic rocks are calcareous. The base of this member is a thickly laminated to thinly bedded calcareous siltstone and silty limestone, a few metres thick. Lithologies in this unit exhibit a complete gradation, from silica cement to calcite cement within a single quartz arenite bed, over quite short distances along strike. Notwithstanding its patchy distribution, the calcite in these beds is a second, important reservoir of carbonate for a Carlin-style setting. Upsection, the carbonate peters out, but the clastic lithology remains roughly the same.

The Caribou Pass formation (Abbott in prep.) is the only distinctive lithology within the Tischu Group. It is a massive to thickly bedded, beige to light grey weathering dark grey bioclastic calcarenite, resistant to weathering. The unit is roughly 150 m thick and incorporates a brown weathering dark grey thinly bedded shale and siltstone interval 15 m in thickness in the basal third of the formation. This may not be laterally persistent but this shale interval is also exposed on the ridge to the east of the trench area. The Caribou Pass represents the third reservoir of carbonate and a possible host/trap for a Carlin-type environment. The formation is overlain by 50 m of very poorly exposed dark grey shale and siltstone and another 50 m of quartz-cemented quartz arenite or orthoquartzite; these two units record the apparent resumption of a coarsening upward sequence after the Caribou Pass transgression. The orthoquartzite is the youngest sedimentary unit exposed on the mountain and is of inferred Mississippian age.

Intrusive rocks

Cretaceous quartz phyric dykes

The only igneous rocks exposed on the mountain are felsic dykes, locally as thick as 50 m, with a penetrative brittle shear fabric. The dykes compose a small swarm at or near the peak of the mountain and are associated with an airborne magnetic anomaly.

Nine samples of the dykes, in various stages of alteration, underwent detailed petrographic analysis described in a separate report. The dyke lithologies are all garnet-bearing and quartz - plagioclase phyric and include microgranodiorite, microtonalite and andesite compositions. Some of the samples contain biotite phenocrysts; the more strongly altered samples contain muscovite phenocrysts, possibly after biotite. Quartz is the most noticeable phenocryst phase in hand specimen, commonly less than 4 mm and anhedral in most cases but in some dykes the quartz phenocrysts are subhedral, with either trigonal or tetragonal outlines. The latter forms are pseudomorphs after cristobalite and evidence of high-temperature emplacement. Most significantly, the mode of less altered samples includes minor anhedral garnet, indicating that the dykes are peraluminous granitoids, possibly part of the Cretaceous gold metallogene present in the Yukon.

Analytical results from whole-rock analysis confirm that the fresh samples of the dykes are peraluminous potassic granitoids with normative compositions in the monzogranite field. They contain as much as 10% sulphide locally, the bulk of which appears to be pyrite but with a significant component of very fine-grained arsenopyrite; arsenic concentrations are as high as 450 ppm in the fresh rock. Au concentrations in the dykes are generally low but there are fair correlations ($R>0.93$) with As and Hg. When the single high As (and Au) value is eliminated, fair correlations between Au, Sb Tl and Se are also observed. These element correlations are also observed in soil and these elements should be treated as pathfinders for the gold mineralization, whatsoever its genesis.

Timing of intrusion

Thicker dykes have sheared margins and undeformed interiors, indicating a syn-to post-deformational crystallisation period. The shearing appears to be subparallel to the Secondary Fault, this in turn subparallel to the dextral Hess Fault, which has a Cretaceous history of

movement. However, movement on the Secondary Fault in the Saddle Zone appears to be mainly vertical (see below), in conflict with apparently dextral kinematic indicators in the shear fabric within the dykes. The number of measurements taken of the dykes' shear fabric is not statistically significant at the time of writing; future work may resolve the apparent conflict.

The shear fabric in the dykes is rotated about a vertical axis peripheral to the ENE trending fault across the saddle between the main trenches and the ridge to the ESE. The rotation gives explicit sinistral movement on this fault, which also appears to displace the Secondary Fault by as much as 100 m (best estimate 85 m). ENE to NE striking faults throughout the Canadian Cordillera typically moved in the Eocene (Murray Journeay pers. comm. *ca*. 2004), this suggests that the dykes' age is Cretaceous.

Structure

Folding

Three kilometres to the east of the main trench area, on a range dubbed "The Horseshoe" during 2011 fieldwork, Cecile and Abbott (1992) located an overturned syncline, plunging to the west. Subsequent work by Abbott (in prep.) confirmed that the syncline involved Devono-Mississippian Tischu Group rocks. The southern half of the same structure is observed in the northern half of the present study area; 2011 fieldwork confirmed the presence of Tischu Group from its basal member to the orthoquartzite, north of the area drilled by AGIP.

A significant loss of exposure occurs between the small knoll to the north of the trench area and the trench area itself. This is interpreted as the trace of the Secondary Fault (see below). To the south of the fault, bedding is homoclinal and vertical. The shale and siltstone at the peak of the mountain was initially interpreted as the Itsi member of the Portrait Lake Formation, with Fuller Lake shale upsection and downsection.

A limestone bed is exposed within the black shales just beyond the northern contact of the presumed Itsi Formation, at a location just below the north side of the mountain peak. A second exposure on this north side of the presumed Itsi Formation was discovered by Mr. Barber, in an identical stratigraphic location in trench I on the mountain's northwest side. A third "northern" limestone exposure was mapped by the author on the initial day of fieldwork but its significance was not realised at the time. The three limestone locations provide three points from the north

side of the putative Itsi Formation. A three-point solution gives a strike of 128 for the bed, dipping at 73 degrees to the south. If allowance is made for an inferred 16 m dextral displacement on a small fault near the peak, the limestone bed has a strike of 116 and is vertical. These calculations are consistent with all high-confidence measurements of bedding made in the area and are supportive of a northward-facing sequence in the upright or overturned limb of a north-vergent fold. They are inconsistent with the geological model (AGIP) hitherto proposed for the mountain. The sequence to the south of the fault was interpreted by this author as the upright/overturned limb of the same north vergent fold, albeit somewhat displaced.

There is a problem with this interpretation. Abbott (pers. comm. September 2011) noted that the unit presently defined as the Itsi Formation does not occur within the Portrait Lake Formation, but overlies the latter unconformably in this area. He further noted that the shale to the north of the putative Itsi Formation outcrop area did not resemble the typical basal Tischu Group to the north of the saddle. Colpron and Abbott therefore proposed that the synclinal axis in the southern block lies to the south of its previously mapped location, within the outcrop area of putative Itsi Formation south of the peak. Implicit in this hypothesis is the interpretation of the shale sequence to the north as the Fuller Lake member exposed in the northern limb of the syncline.

The latter hypothesis is preferable to that of a homoclinal sequence for two reasons. Firstly, the aforementioned limestone bed close to the "Saddle Shales' southern contact is mirrored by a thin limestone unit encountered in Trench H, just beneath the basal contact of the putative Itsi Formation. Secondly, the zone of disrupted ground of such a fold's axial plane is permissive both for the igneous intrusions encountered there and for mineralising fluids. A objection to the hypothesis lies in the disparity of thickness between the vertically dipping shale sequence in the Saddle Zone (roughly 200 m) and that of the black shale section on the south side of the mountain, near the Canol Zone (40 m). The increase in thickness could owe to replication of the shale section by isoclinal folding (Plate 1) or by fault replication along the Secondary Fault. The fold geometry is significant for a realistic depth estimate to the target Sapper Formation within the mineralized zone.

Testing of folding hypothesis by palæontological analysis

Sampling of the limestone units in the black shale sequences on either side of the peak was carried out by the author and by Mr. Barber in September 2011. Samples from locations PM11-853, PM11-969 and PM11-1022 were examined for microfossils by Dr. M. Orchard of the Geological Survey of Canada.

The ensuing report from the Geological Survey of Canada is pending at the time of writing. Conodonts were recovered from sample PM11-853, from Trench H south of the exposure of inferred Itsi Formation and from sample 1022, north of the exposure of inferred Itsi Formation.

The two sample populations are different; that from PM11-853 is Late Devonian (late Frasnian) in age based on common *Palmatolepis* and rare *Ancyrognathus* specimens. There are also radiolarians and sponge spicules in this collection and the Conodont Alteration Index (CAI) is a consistent 5 (M. Orchard pers. comm. to P. Metcalfe, January 2012).

PM11-1022 is confirmed as Early Carboniferous (Tournaisian) in age based especially on abundant specimens of *Siphonodella*. The CAI ranges from 5 (black) to 7 (white), implying some high heat flow thereabouts: variation like this has previously been related to hydrothermal alteration (M. Orchard pers. comm. to P. Metcalfe). This is consistent with the latter sample location's proximity to a quartz phyric dyke and its situation within the phyllic alteration halo.

On the basis of these analytical results both hypotheses can be rejected. The sequence to the south of the saddle zone is homoclinal rather than folded, but it does not consist entirely of Portrait Lake and Itsi formations; rather the sequence is complete between the basal part of the Portrait Lake Formation (Niddery Lake member) at the Canol Zone through MacMillan Pass and Fuller Lake members south of the peak, Itsi Formation at the peak and, overlying the Itsi Formation, the basal siliceous shales of the Devono-Mississippian Tischu Group, grading upsection into shale and siltstone in the Saddle Zone, adjacent to the Secondary Fault. This revision of the section has implications for the movement of the Secondary Fault, discussed below.

Faulting

All but one of the faults identified by AGIP (including the torsional fault on Cecile and Abbott's 1992 map) were deemed suspect because their displacements are not apparent and the drill data

(zones of core loss) from which they were derived do not stand up to a 3D treatment (Barber and Dunlop unpubl.). The Main Fault in particular retains no credible planar structure when viewed in 3D and has been discarded.

The exception is the Secondary Fault (Aupperle 1985) whose trace runs across the Saddle; the fault is inferred to be responsible for the poor exposure and intensely fractured rock at that location. Its 3D geometry constrains the fault to a strike of 131 and the dip to no less than 87 degrees to the southwest. The Secondary Fault is one of two linear structures that clearly juxtaposes one rock unit against another.

Neither the sense nor extent of movement on the Secondary Fault are known. Horizontal slickensides were located along the fault trace west of the Saddle Zone and the orientation of the fault parallel to the Hess Fault suggests at least some history of dextral movement. Moreover, shearing in the margins of the Cretaceous dykes is apparently dextral with a minor north-side-down component and indicates that timing of the dextral movement was syn and post intrusion. However, the number of in-situ outcrops available for structural measurements is small and by no means represents a statistical sample.

On the basis of the geophysics, Abbott suggested that the Secondary Fault may have a more profound vertical component of movement. Vertical slickensides found at a separate location are evidence for this hypothesis.

Abbott (pers.comm. to Metcalfe September 2011) noted that, if the sequence north of the peak were to be of Tischu Group, this removed the need for the Secondary Fault as a regional structure. Certainly the need for dextral movement on such a structure is removed, contradicting the limited structural data collected from the sheared dykes. However, the basal Tischu argillaceous chert immediately north of the peak passes northwards (upsection) to siliceous shale. Immediately north of the Saddle, the section is repeated, strongly suggesting fault replication. Moreover, the consistent, steep dips in bedding south of the Saddle are most easily rconciled with the overturned, north-facing and steeply south dipping strata north of the Saddle by vertical dislocation of an overturned fold as shown in Plate 1. This model is in agreement with the 2011 aeromagnetic data, which exhibit weakening of the magnetic anomaly to the north of the Secondary Fault, consistent with downthrow to the north.

A second fault became apparent in the last three days of fieldwork. This fault traces down the gully to the east of the trenches in a manner similar to the “Main Fault”, but does not loop northwestward over the peak of the mountain. Instead, its trace is along azimuth 250 up the gully and over the saddle between the trenched area and the exposures of chert pebble conglomerate to the southeast. Drag folding of foliation in a dyke displaced by the fault is about a vertical axis and clearly indicates at least one phase of sinistral movement. The throw is not known but the apparent displacement of the Secondary Fault across this Saddle Fault is estimated to be 85 m. This is consistent with the observed "bend" of rock units from east to west along the southern slope of the mountain. There is no evidence for any vertical component of throw, but the conglomerate facies of the MacMillan Pass Member has not been observed northwest of the Saddle Fault and the fault’s displacement might be more than presently inferred. The brittle nature of the displacement of the dykes and the Secondary Fault suggests post-Cretaceous movement.

The displaced southeastern section of the Secondary Fault is not exposed on the mountain, but deranged and subdued topography (with two or three landing sites on an otherwise unfavourable slope) suggest its approximate trace. It emerges on the western slopes of the Horseshoe, east of the mapped area, where it sets brown siltstone, inferred to be Tischu Group on its north side, against chert pebble conglomerate and blue-grey weathering black shale of the MacMillan Pass and Fuller Lake members to the south. At this point it may converge or be conjugate with the northerly trending structure mapped by Abbott along the western slope of the Horseshoe, but this is not immediately relevant to the structure and economic geology of the mountain itself. The Secondary Fault is possibly traceable some 12 km to the east, where it merges with the trace of the Hess Fault.

The continuity of the MacMillan Pass conglomerate unit from the eastern slopes of the mountain onto the western slopes of the Horseshoe precludes the presence of a north-striking fault along the valley bottom of the creek between. The necessary movement is along a fault trace along the western hillside of the Horseshoe, as noted by Abbott (in prep.).

Metamorphism and/or alteration

Aupperle (1985) records alteration near and in the dykes thus:

> *The most prominent alterations are bleaching (removal of carbonaceous-graphitic material) and silicification of the shales. Clay alteration is more restricted in extent.*
>
> *Bleaching occurs either as narrow bands adjacent to fractures and bedding planes or pervasively over intervals up to 3 meters. Pervasive weak silicification occurs throughout. Local zones of intense silicification also occurs (sic). In fault-gouge zones, clay alteration commonly reduces the shale to soft, massive clay.*
>
> *Almost all the monzonite intrusives (*sic*) exhibit weak to moderate sericitization, clay alteration, limonitization, bleaching and rarely silicification. The largest and most intense zone of bleached and silicified shale . . . . is spatially related to a swarm of weakly to strongly clay altered monzonite intrusives. Within this zone, unaltered shales have been observed in contact with the monzonite. These shales become bleached and silicified away from the intrusives. An increase in fracturing and faulting, both in shales and monzonites, appears to be the major control on alteration within this zone.*
>
> *Intense clay development in gouge zones, local silicification and rare bleaching occur in . . . . fault zones. Clay zones from 0.1 to 8.4 m in true thickness were intersected in all drill holes.*

Notwithstanding this excellent description, the zone surrounding the main area of dyke intrusion was subsequently described by Hulstein and Keyser (1989) as a zone of "hornfelsing". No hornfelsing whatsoever was observed during the course of 2011 fieldwork, although it is possible that such once existed and were overprinted by the pervasive alteration noted by Aupperle. Two addenda to Aupperle's description are: firstly, that the fine-grained muscovite alteration he describes is more widespread than assumed, much of it masquerading as clay alteration; secondly: that the expression of this alteration in the siliceous shales is far more subdued than in the siliciclastic rocks, being confined to (possibly) recrystallization of the silica and (certainly)

development of graphite on bedding-parallel and oblique cleavage surfaces. The graphite would have acted as a buffer for oxygen fugacity during alteration and probably through the mineralising process.

A further consequence of muscovite/sericite alteration of the siliciclastic units is the appearance of non-detrital dioctahedral mica (muscovite), masking the detrital component and confusing still further attempts at discriminating between Itsi Formation and the finer-grained facies of the MacMillan Pass member.

Mineralization

Two types of mineralization are present in the area mapped, neither associated with significant quantities of hydrothermal quartz. The first-formed is a fine grained dissemination of pyrite and minor arsenopyrite hosted by the relatively unaltered parts of the dykes and interpreted as a late magmatic or early deuteric event. Subsequent shearing and related tensional fracturing host locally abundant realgar, orpiment and stibnite, interpreted as a low temperature remobilization of the magmatogenic sulphide. The later phase appears supergene in nature but, while this can be true of orpiment, realgar does not form from water cooler than 100°C and more commonly 144-170°C. This late phase is therefore closer to epithermal in character.

As noted above, weak values of Au in the dykes exhibit fair covariance with As, Sb, Hg Se and Tl; these should be treated as pathfinder elements. Other elements will become apparent when the sample population exceeds 6.

A note on 2011 soil sampling

The 2011 soil survey covered an immense amount of ground and a commensurate length in line kilometres. The resulting sample output is, apparently, still in process at Acme. Both rapid coverage and pre-screening of the samples by X-ray fluorescence spectrometry were necessary in order to complete the project. Nevertheless, the results will be constrained both by natural and by anthropogenic processes.

Implications of sample depth

The author sampled a soil profile exposed at the northern end of Trench J. The reasons for the choice of location were:

1. The location exposed a complete section to the surface of a relatively unaltered arsenopyrite-bearing dyke;
2. Analysis tested the association of Au with the dykes and:
3. It was a lot easier than the author digging his own hole.

The sample location was on a hillside with an average slope of roughly 25°. Colluvium almost entirely composed of dark grey shale composed the upper 80 cm of the profile, underlain by clay and sericite altered dyke material. Six samples were taken from the profile, the upper three from the thin organic later and two washes of colluvium.

During the course of fieldwork, the maximum depth of soil hole encountered by the author was 75 cm. It is axiomatic that transported anomalies will be the rule rather than exceptions.

Implications of the sample sieving procedure

During the course of submitting samples for the normal screening procedure, the author observed the condition of the sample sieve between samples. A sharp rap on a hard surface dislodged between 50 gm and 100 gm of material from the screen. The field assistant carrying out the sieving had access neither to compressed air nor to ultrasonic cleaning. It is, consequently, not a question of whether samples were cross contaminated but by how much and in what sequence. Happily, the samples were sieved in numerical order, so the cross-contamination will present as blurring of an anomaly through a first-order rate law, down the line from the anomalous sample site(s). There will be a wild attractor in gold, owing to nugget effects, but the contamination is amenable to statistical treatment of base element values and further screening (this time by statistical methods).

CONCLUSIONS

Mapping in 2011 and subsequent analysis indicates that the area is underlain by a homoclinal sequence of Palæozoic clastic sedimentary rocks with minor limestone and exhalative units. This homoclinal sequence is north-facing, presented in the axis and overturned limb of a north-vergent syncline. The syncline is overthrust from the south by a panel containing Lower Palæozoic Road River Group and is open to the north to the limit of outcrop. Its axial plane dips

moderately to the south and its axial plunge appears near-horizontal, but was not determined accurately during 2011 fieldwork.

Rocks exposed in the syncline present a near-complete paraconformable sequence ranging in age from Lower Palæozoic Road River Group to Devono-Mississippian Tischu Group. At the base of this sequence is the Road River Group comprising siltstone of the Steel Formation overlain by argillaceous to silty limestone of the Sapper Formation. The overlying Devonian Earn Group (Portrait Lake Formation) includes basal siliceous shale and argillaceous chert of the Niddery Lake member, siliciclastic rocks of the MacMillan Pass member and siliceous and carbonaceous shale of the Fuller Lake member. North of the peak and extending to the Saddle, are basal argillaceous cherts and siliceous shale and siltstone of the Devono-Mississippian Tischu Group. Replication of the basal Tischu section on the other side of the Saddle confirms the presence of the Secondary Fault, but requires vertical rather than strike-slip movement, downthrowing that part of the syncline on the north side of the fault.

The sedimentary sequence is intruded, in the vicinity of the peak by a number of irregular, subvertical dykes with sheared margins, possibly with dextral sense. This sense of movement is inconsistent with the movement of the Secondary Fault and may predate the latter. The shearing, combined with previous bedding-parallel movement and parasitic folding associated with development of the syncline, will have optimised permeability for hydrothermal fluids. It is suggested here that elongation of the elevated gold zone subparallel to bedding and its coincidence with the location of the dykes implies involvement of the dykes as a heat source for the mineralizing system. A phyllic alteration halo occurs around the dykes and the formation of graphite on bedding and cleavage surfaces in the carbonaceous, siliceous shales is interpreted as a composition-specific response to this phyllic alteration. This might fulfil one requirement of a Carlin-type system, if calcareous units are in proximity. The limestone unit at the base of the Tischu Group is thin but may be responsible for locally elevated gold grades at or near surface in the area drill-tested to date.

Not one but two large calcareous units are available, excluding the Caribou Pass Limestone on the basis of its distance from the dykes. The Squirrel Pass calcareous member within the Tischu Group is much shallower and moreover explicitly in contact with a dyke of the quartz phyric

suite on the north side of the Secondary Fault. There is little alteration or mineralization in the vicinity, but the potential of this unit should be noted.

A far more prospective unit is the 150 m thick argillaceous limestone of the Sapper Formation, overlain by the siliceous and carbonaceous shale of the Niddery Lake member. Indeed the coincidence of the mineralization at surface with this contact on the southern slope of the mountain (the "Canol Zone") was noted by Hulstein and Keyser (1989). Garagan (1983) noted that the sycline's geometry required that the contact between the Sapper argillaceous limestone and the overlying siliceous and carbonaceous shale of the Niddery Lake member be present at between 300 and 500 m beneath the Saddle Zone. This author suggests a somewhat greater depth of 600 m or more beneath the peak of the mountain.

This author submits, with respect, that the encouragement encountered in the 1980s drilling records only the tip of the system and that the zone of more regular gold values lies, as Mr. Barber has suggested, at greater depth. It is recommended that deeper drilling be contemplated and that a closer study made of existing information on gold:silver ratios in the system. Exploration should make use of oriented core with particular attention to core-bedding angles and the location of the two limestone units above and below the Itsi Formation. The target zone for the gold mineralization should be tested from surface to the intersection of the dykes with the Sapper/Niddery Lake contact.

ACKNOWLEDGEMENTS

Mapping benefited greatly from the assistance of Nicholas L. Barber in the field; Mr. Barber continued with mapping of the trenches in the area. Maurice Colpron and Grant Abbott provided crucial help with their hypotheses regarding structure and regional geology, without which the structure would not have been resolved by the conodont expertise of Mike Orchard of the Geological Survey of Canada. Adam Travis, Mike Cathro, Linda Dandy and Dugald Dunlop provided much-needed support and advice.

PETROGRAPHIC REPORT

9 HAND SAMPLES

ORO PROJECT:
MACMILLAN PASS AREA, YUKON

February 3, 2012

Prepared for:
Adam Travis,President, CEO & Director
& Linda Dandy, P.Geo., Exploration Manager
Colorado Resources Ltd.
110- 2300 Carrington Road,
West Kelowna, BC
Canada V4T 2N6

phone: 250-804-0729
kgeo@telus.net

Background

Nine hand samples were received from Paul Metcalfe & Dugald Dunlop on behalf of Colorado Resources Ltd. in October, 2011 for petrographic analysis. The samples were taken from the Oro property, Macmillan Pass area, Yukon. The goal of the work was basic transmitted and reflected light observations, including description of lithologies, alteration and mineralization. Nine polished thin sections were prepared from the samples at Vancouver Petrographics Ltd. Kathryn Dunne, P.Geo. carried out the petrographic analysis at her office in Salmon Arm, B.C. All percentages in the descriptions are approximate based on visual estimation.

Summary

Lithology

Sample #	Lithology	Page #
PM11-908	Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase phyric]	4
PM11-913	Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase phyric]	8
PM11-925	Leucocratic microtonalite	15
PM11-926	Leucocratic microtonalite	21
PM11-930	Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase phyric]	27
PM11-930A	Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase phyric]	33
PM11-935	Andesite porphyry [quartz-biotite-plagioclase phyric]	38
PM11-937A	Leucocratic microtonalite porphyry [muscovite-quartz-plagioclase phyric]	44
PM11-980	Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase phyric]	49

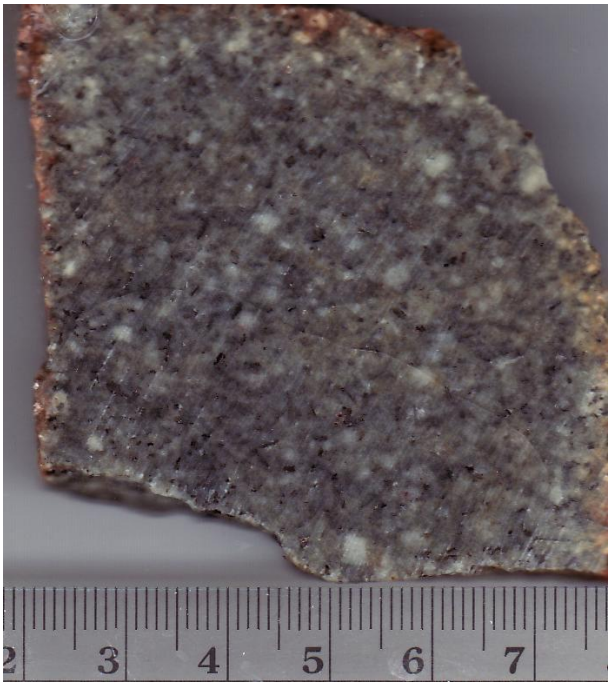
The samples in this suite of rocks comprise a variety of hypabyssal intrusive rocks including:

- Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase phyric]
  The microgranodiorite porphyry comprises weakly altered fine to medium-grained plagioclase phenocrysts ~40%, biotite phenocrysts ~7% and quartz phenocrysts from 3-10% in a fine-grained matrix comprising dominantly orthoclase and quartz with minor plagioclase and altered biotite. In one sample quartz phenocrysts are surrounded by granophyric texture. Traces of fine-grained garnet occur disseminated.
- Leucocratic microtonalite and microtonalite porphyry
  -The microtonalite comprises moderately altered fine to medium-grained plagioclase (formerly ~50%), quartz (~30%) and platy muscovite (~15%) with minor sulphides and trace to minor K-feldspar (origin uncertain).
  -The microtonalite porphyry comprises moderately altered fine to medium-grained altered plagioclase phenocrysts (formerly ~30%), quartz phenocrysts (~15%) and platy muscovite phenocrysts (~7%) in a fine-grained matrix dominated by plagioclase and quartz
- Andesite porphyry
  The andesite porphyry comprises strongly altered fine to medium-grained plagioclase phenocrysts and glomerocrysts ~30%, biotite phenocrysts ~10% and resorbed quartz phenocrysts ~7% in a very fine-grained strongly carbonate-sericite altered feldspathic matrix

Alteration

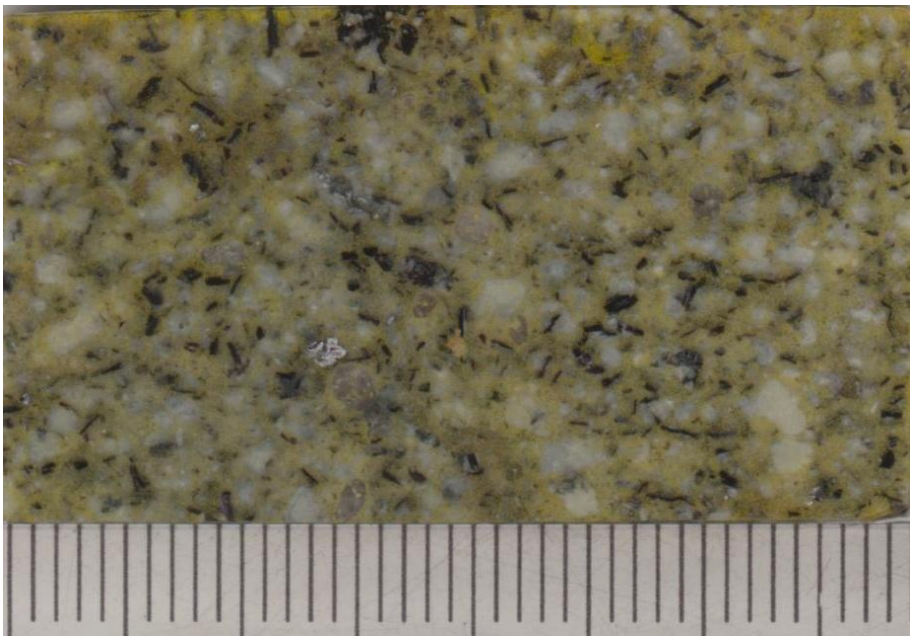
- **Sericite** occurs in minor to major (2-8%) amounts as selective replacement of plagioclase in microgranodiorite porphyry samples and in major (25%) amounts as selective replacement of plagioclase in andesite porphyry. **Muscovite/sericite** occurs in major amounts (~30-35%) extensively replacing plagioclase in leucocratic microtonalite and microtonalite porphyry. *Note: sericite is defined in this report as a general term for a fine-grained member of the mica group, usually muscovite, but may include paragonite or illite.

Alteration cont.



- **Carbonate** typically occurs in trace to minor amounts selectively replacing plagioclase in microgranodiorite porphyry and in major amounts (~25%) as replacement of plagioclase and biotite phenocrysts and matrix in andesite porphyry. Carbonate occurs in major amounts (~5-8%) in leucocratic microtonalite.
- **Chlorite** occurs in minor to major amounts (1-5%) partly replacing biotite in microgranodiorite porphyry samples
- Trace amounts of **Ti-ox** aggregate occur partly replacing biotite or muscovite in all samples.
- Major amounts of red-brown **Fe-ox** occur extensively replacing carbonate and partly replacing pyrite and marcasite aggregates in sample PM11-925. Trace amounts of Fe-ox occur rimming and replacing sulphides in sample PM11-930. Minor amounts of Fe-ox occur in sample PM11-980 as fracture and cavity infill, partly replacing pyrite and staining rock adjacent to fractures.
- Major to minor **pyrite** occurs dissseminated and associated with platy muscovite in microtonalite and microtonalite porphyry samples. Minor pyrite occurs disseminated, as patchy aggregates associated with carbonate alteration, partly replacing biotite phenocrysts and as vug infill in sample PM11-935.
- Traces of **K-feldspar** occur as very fine aggregates (origin uncertain) and may be be an early ?replacement of plagioclase in leucocratic microtonalite samples.

Mineralization



- **Pyrite** occurs in major amounts (up to 7%) to rarely in all the samples as disseminated grains, partly replacing platy biotite or muscovite and as patchy aggregates. In some samples pyrite is intergrown with marcasite.
- **Pyrrhotite** occurs in minor amounts (up to 3%) as disseminated grains and associated with biotite in sample PM11-913. Pyrrhotite occurs rarely disseminated and partly replaced by pyrite in sample PM11-935. Pyrrhotite occurs rarely disseminated in sample PM11-980.
- **Marcasite** occurs in trace to minor amounts (~1%) intergrown with pyrite in samples PM11-925 and 926.
- **Arsenopyrite** occurs rarely disseminated in samples PM11-913, 925 and 930.
- **Sphalerite** occurs disseminated in trace amounts in sample PM11-926.
- **Chalcopyrite** occurs disseminated in trace amounts in sample PM11-980 and as inclusions in pyrrhotite in sample PM11-913.

Sample: PM11-908 **Offcut #: AT-1**

Rock sample; scale in cm

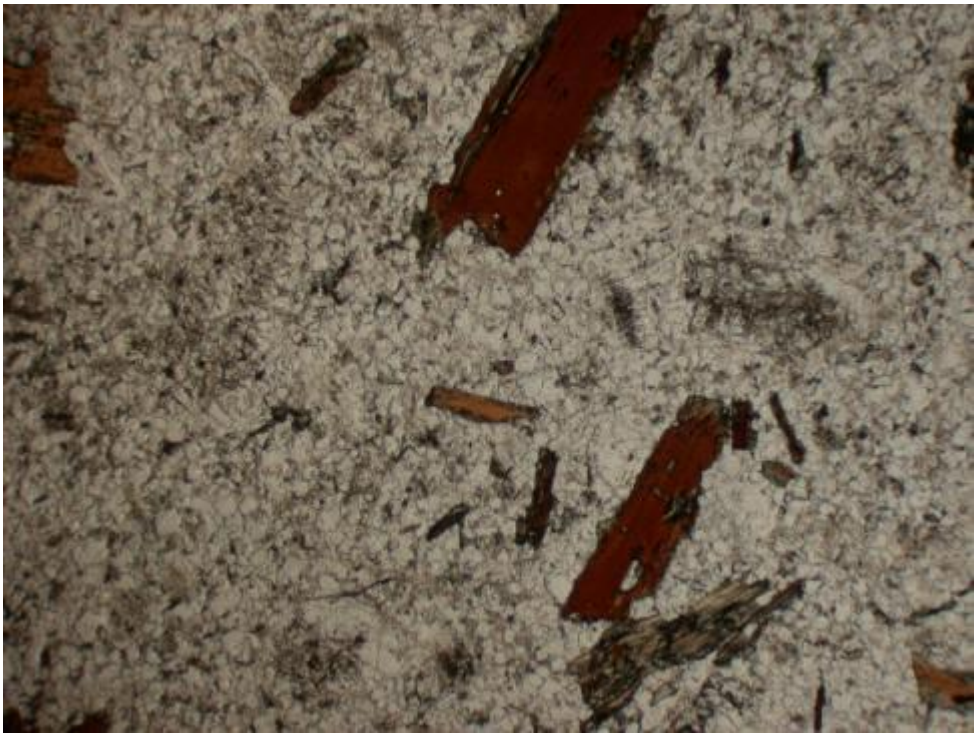
Etched and stained section offcut; scale in mm

Hand Sample and Stained Offcut Description:
Porphyry with approximately 40% plagioclase phenocrysts (< 3 mm), 3% quartz phenocrysts (< 3 mm) and 7% black biotite phenocrysts (typically < 2 mm) in a very fine K-feldspar-quartz dominant matrix (based on stain). No reaction to magnet. No reaction to cold, dilute HCl. Positive test for K-feldspar using etching by HF and sodium cobaltinitrate (~25%, yellow) stain.

Sample: PM11-908 **Offcut #: AT-1**

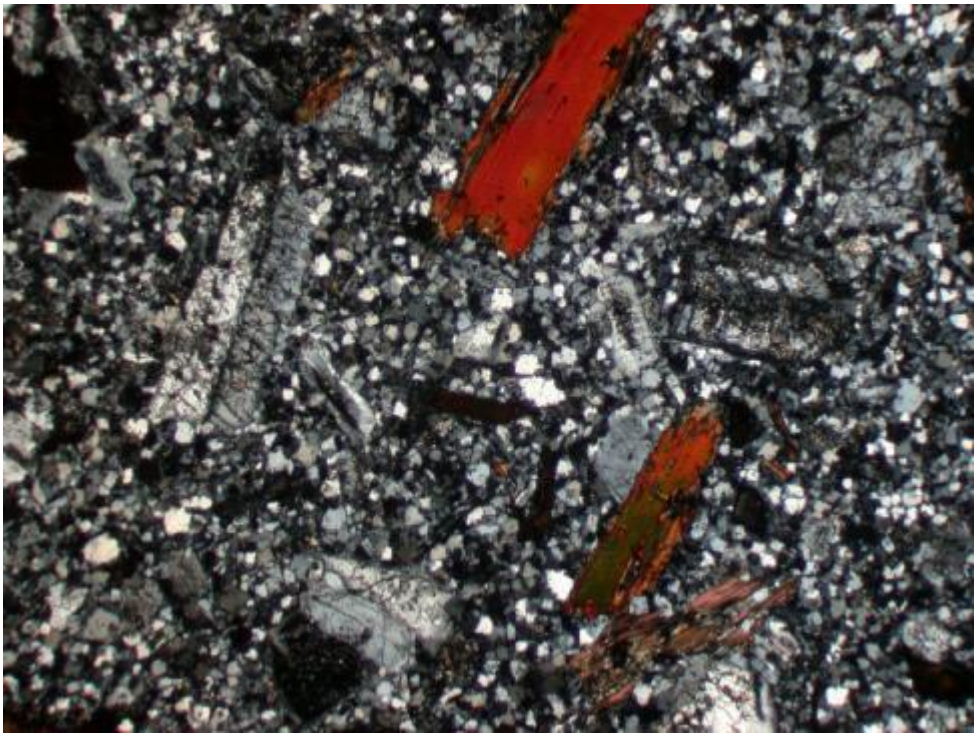
LITHOLOGY: Microgranodiorite porphyry
[garnet-bearing, quartz-biotite-plagioclase-phyric]
ALTERATION MINERALS (> 1%): Sericite, chlorite, carbonate
ALTERATION MINERALS (< 1%): Ti-ox
INTENSITY OF ALTERATION: Weak
MINERALIZATION: (Pyrite)

Polished Thin Section Description:
This section is a weakly sericite-chlorite-carbonate-(Ti-ox)-altered, quartz-biotite-plagioclase-phyric microgranodiorite porphyry. The microgranodiorite porphyry comprises weakly altered fine to medium-grained plagioclase phenocrysts ~40%, biotite phenocrysts ~7% and minor quartz phenocrysts ~3% in a fine-grained matrix comprising dominantly orthoclase and quartz with minor plagioclase and altered biotite. Traces of fine-grained garnet occur disseminated. Rare apatite, zircon and ?monazite occur as accessory phases. Plagioclase is commonly zoned and partly replaced by sericite and patchy colourless carbonate. Biotite is partly replaced by chlorite and Ti-ox aggregate. Traces of ilmenite occur locally associated with biotite along cleavage traces. Rare very fine-grained subhedral pyrite occurs disseminated.



MAJOR MINERALS

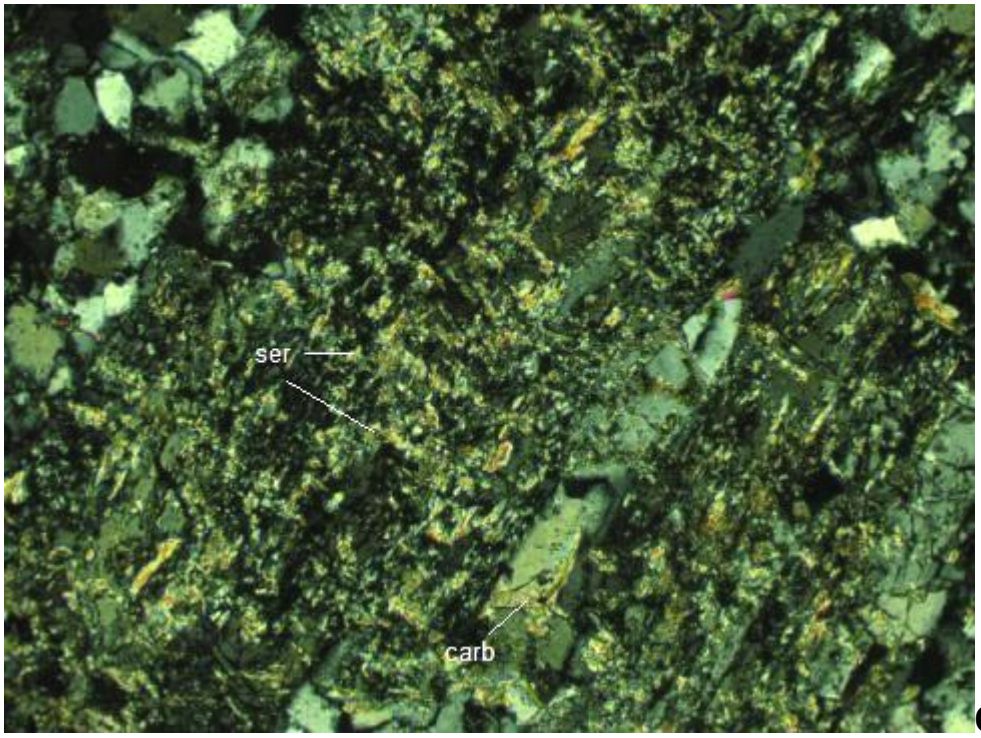
Mineral	%	Distribution & Characteristics*	Optical
Plagioclase, (oligoclase-andesine)	38	-fine to medium-grained (0.2-3 mm), phenocrysts, strongly zoned, composition of An_{27-40} (based on 4 estimates), variably partly replaced by sericite and carbonate -fine-grained (0.05-0.1 mm), occurs in matrix, partly replaced by sericite and carbonate	*polysynthetic twinning A/C*
Quartz	25	-medium-grained (0.5-2.5 mm), resorbed phenocrysts (~3%) -fine-grained (0.05-0.1 mm), anhedral, occurs intergrown with orthoclase as matrix	
Orthoclase	25	fine-grained (0.05-0.1 mm), cloudy aggregates, incipient clay alteration, intergrown with quartz and altered mafic phases as matrix	
Biotite	7	-fine to medium-grained (0.2-2 mm), phenocrysts, locally zoned, variably partly replaced by chlorite and Ti-ox aggregate -fine-grained (< 0.2 mm), occurs as matrix, partly replaced by chlorite and Ti-ox	*red-brown*



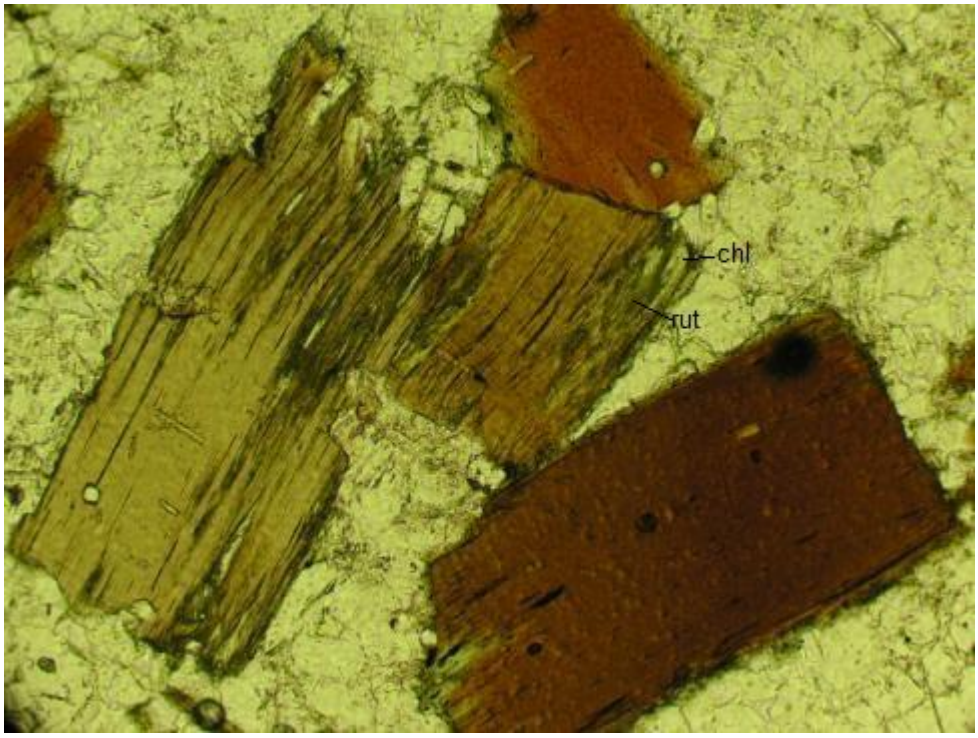
MINOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Sericite	2	very fine-grained, flaky aggregates, partly replaces plagioclase	
Carbonate	1	very fine-grained, occurs replacing plagioclase	
Chlorite	1	very fine-grained, occurs replacing biotite	
Ti-ox	tr	very fine-grained aggregate, partly replaces biotite	
Ilmenite	tr	fine to very fine-grained (< 0.1 mm), associated with biotite	
Garnet	tr	fine-grained (0.2 - 0.3 mm), occurs disseminated	*colourless*
Pyrite	r.	very fine-grained 25 µm), subhedral, disseminated	
Apatite	r.	very fine-grained (< 0.25 µm), disseminated	*high relief*
Zircon	r.	fine-grained (< 0.15 mm), rare anhedral grains	*high relief*
?Monazite	r.	fine-grained (~0.8 mm), anhedral grains, pale yellow	*high relief*

*size ranges: coarse-grained > 5mm; medium-grained 1-5mm; fine-grained 0.05-1mm; very fine-grained <0.05mm



A

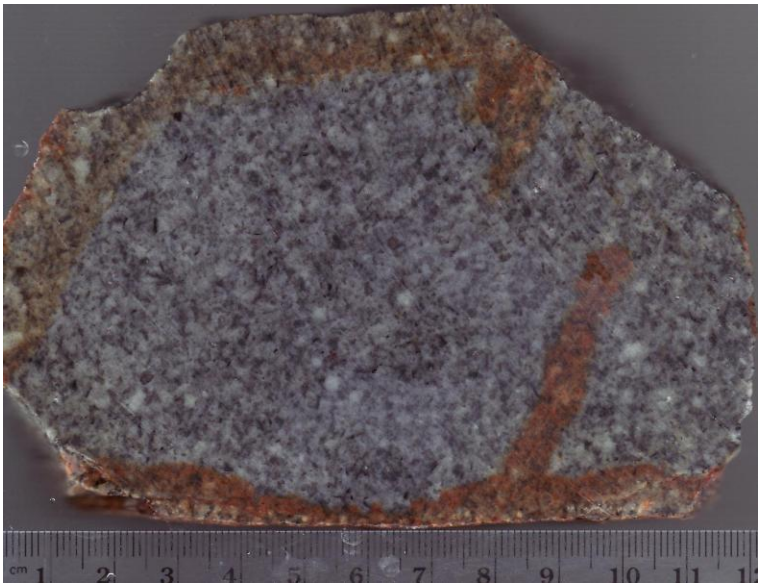


B

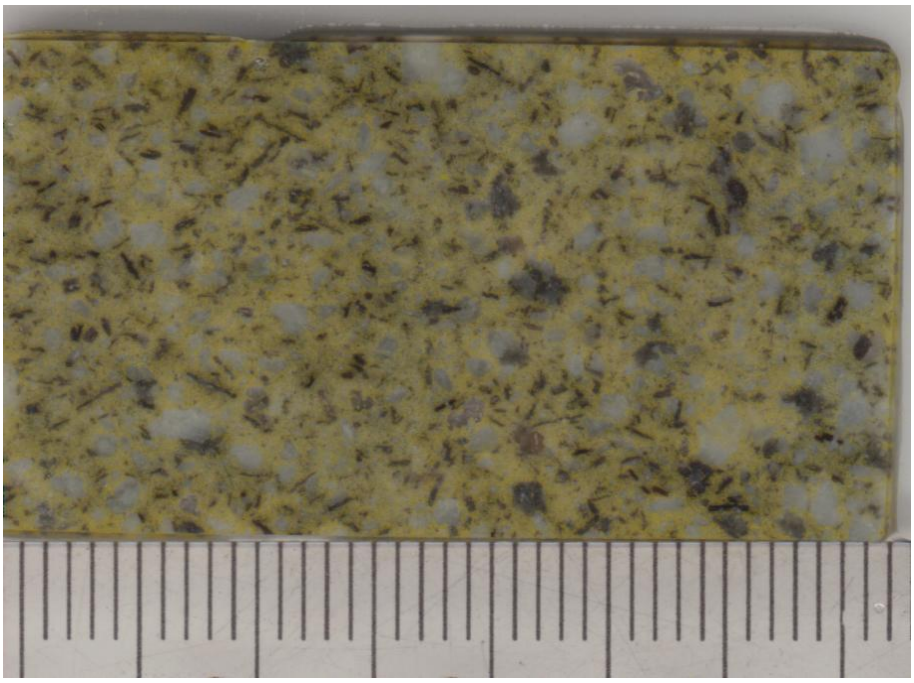
Sample: PM11-908

A & B) Representative view microgranodiorite porphyry with prominent plagioclase and biotite phenocrysts. Note quartz phenocrysts absent in this FOV. A) PPL, B) XPL, FOV = ~ 4.5 mm.

C



D



Sample: PM11-08

C) Plagioclase phenocryst partly replaced by sericite and patchy carbonate. XPL, FOV = ~ 1.3 mm. D) Biotite phenocrysts partly replaced by chlorite and Ti-ox aggregate. PPL, FOV = ~ 1.3 mm.

Sample: PM11-913 **Offcut #: AT-2**

Rock sample; scale in cm

Etched and stained section offcut; scale in mm

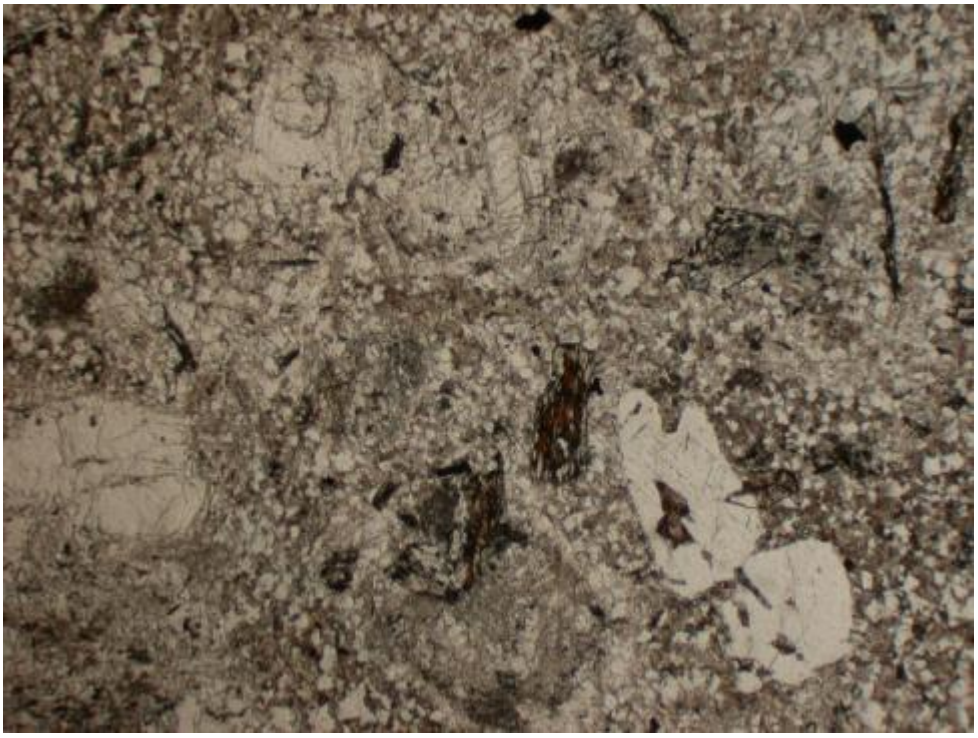
Hand Sample and Stained Offcut Description:
Porphyry with approximately 40% plagioclase phenocrysts (< 3 mm), 3% quartz phenocrysts (< 3 mm) and 7% black biotite phenocrysts (typically < 2 mm) in a very fine K-feldspar-quartz dominant matrix (based on stain). No reaction to magnet. Trace local reaction to cold, dilute HCl. Positive test for K-feldspar using etching by HF and sodium cobaltinitrate (~25%, yellow) stain.

Sample: PM11-913 **Offcut #: AT-2**

LITHOLOGY:	Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase-phyric]
ALTERATION MINERALS (> 1%):	Sericite, chlorite, (carbonate)
ALTERATION MINERALS (< 1%):	Ti-ox
INTENSITY OF ALTERATION:	Weak
MINERALIZATION:	Pyrrhotite, (pyrite, arsenopyrite)

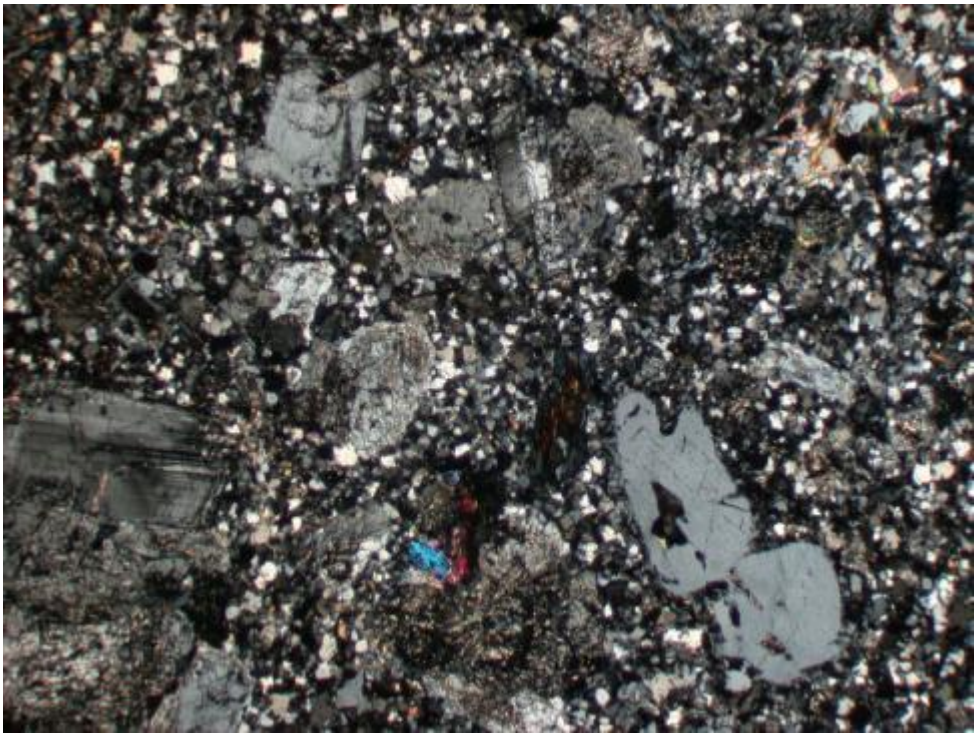
Polished Thin Section Description:
This section is a weakly sericite-chlorite-(carbonate-Ti-ox)-altered, garnet-bearing, quartz-biotite-plagioclase-phyric microgranodiorite porphyry. The microgranodiorite porphyry comprises weakly altered fine to medium-grained plagioclase phenocrysts ~40%, biotite phenocrysts ~7% and minor quartz phenocrysts ~3% in a fine-grained matrix comprising dominantly orthoclase and quartz with minor plagioclase and altered biotite. A few quartz phenocrysts are surrounded by granophyric texture. Minor muscovite occurs as radiating aggregates with quartz and locally carbonate as infill of cavities (?miarolitic). Traces of fine-grained garnet occur disseminated. Rare apatite and ?monazite occur as accessory phases. Plagioclase is commonly zoned and partly replaced by sericite and patchy colourless carbonate. Biotite is partly replaced by chlorite, Ti-ox aggregate and locally sericite. Traces of ilmenite occur locally associated with biotite along cleavage traces. Minor pyrrhotite occurs disseminated and associated with biotite phenocrysts. Rare very fine-grained subhedral pyrite occurs disseminated. Rare euhedral ?arsenopyrite occurs disseminated and locally enclosed by pyrrhotite.

Sample: PM11-913 **Offcut #: AT-2**



MAJOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Plagioclase, (oligoclase-andesine)	36	-fine to medium-grained (0.2-2.4 mm), phenocrysts, strongly zoned, composition of An $_{25-42}$ (based on 3 estimates), variably partly replaced by sericite and carbonate -fine-grained (0.05-0.1 mm), occurs in matrix, partly replaced by sericite and carbonate	*polysynthetic twinning A/C*
Quartz	25	-medium-grained (0.5-2 mm), resorbed phenocrysts (~3%), locally granophyric texture developed as phenocryst rims -fine-grained (0.05-0.1 mm), anhedral, occurs intergrown with orthoclase as matrix -fine-grained (< 0.2 mm), occurs with muscovite and locally carbonate and pyrrhotite as cavity infill (?miarolitic)	
Orthoclase	25	fine-grained (0.05-0.1 mm), cloudy aggregates, incipient clay alteration, intergrown with quartz and altered mafic phases as matrix	



MINOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Biotite	4	-fine to medium-grained (0.2-3 mm), phenocrysts, locally zoned, partly replaced by chlorite, Ti-ox aggregate and locally sericite -fine-grained (< 0.2 mm), occurs as matrix, partly replaced by chlorite and Ti-ox aggregate	*red-brown*
Chlorite	3	very fine-grained, occurs partly replacing biotite	
Pyrrhotite	3	fine to very fine-grained (< 0.65 mm), anhedral grains and aggregate, rare inclusions of chalcopyrite, disseminated and associated with biotite	
Sericite	2	very fine-grained, flaky aggregates, partly replaces plagioclase, partly replaces biotite	
Muscovite	1	fine-grained (< 0.4 mm), locally radiating aggregates, occurs with quartz as infill of cavities (?miarolitic)	
Carbonate	tr	-very fine-grained, occurs replacing plagioclase -fine-grained (< 0.6 mm), occurs as cavity infill (?miarolitic)	
Garnet	tr	fine-grained (<0.6 - 1.1 mm), occurs disseminated	*colourless*
Ti-ox	tr	very fine-grained aggregate, partly replaces biotite	
Ilmenite	r.	very fine-grained, associated with biotite	
Pyrite	r.	very fine-grained (30 µm), subhedral, disseminated	
?Arsenopyrite	r.	very fine-grained (~25 µm), subhedral, disseminated	
Apatite	r.	fine to very fine-grained (< 0.35 mm), disseminated	*high relief*
?Monazite	r.	fine-grained (< 0.5 mm), anhedral grains, pale yellow	*high relief*

*size ranges: coarse-grained > 5mm; medium-grained 1-5mm; fine-grained 0.05-1mm; very fine-grained <0.05mm

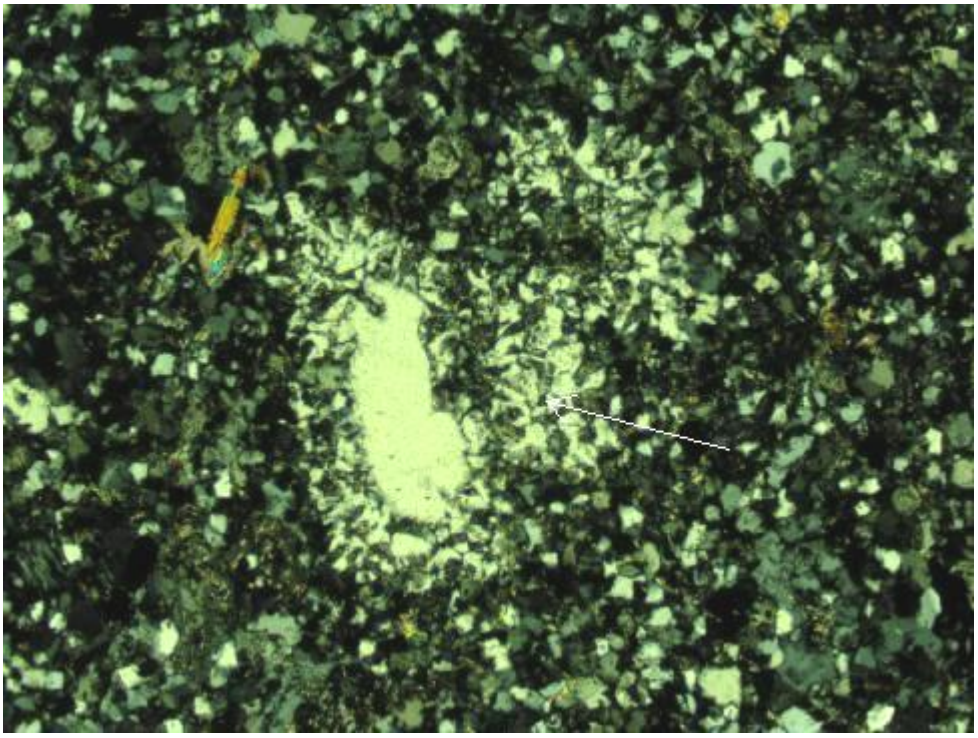
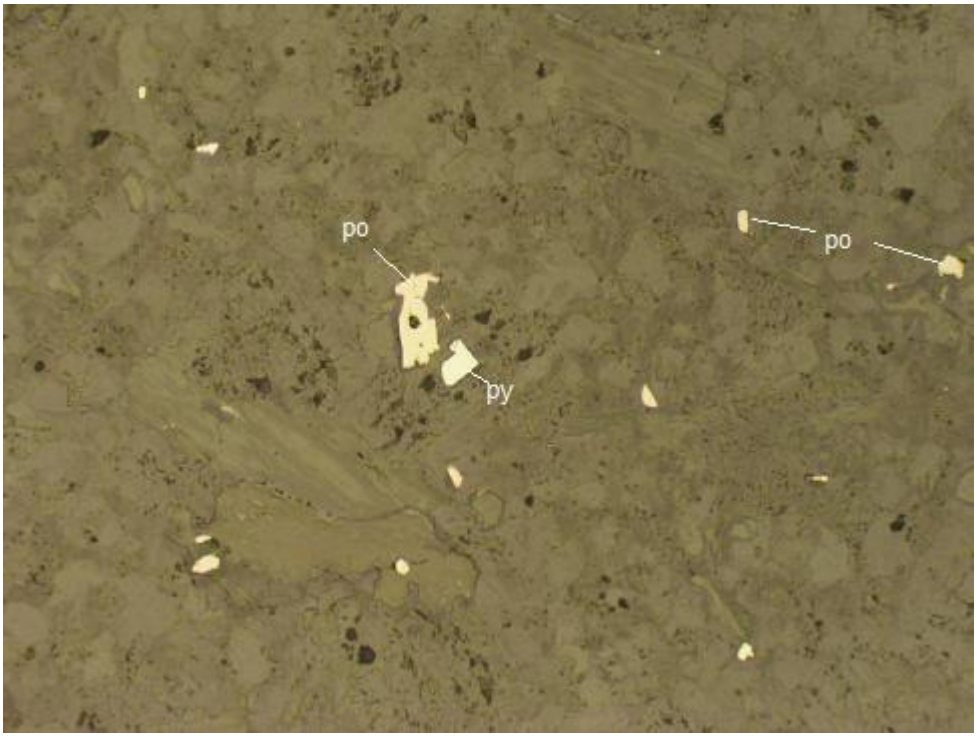
Sample: PM11-913

A & B) Representative view microgranodiorite porphyry with altered plagioclase and biotite phenocrysts and resorbed quartz phenocrysts (lower right). A) PPL, B) XPL, FOV = ~ 4.5 mm.

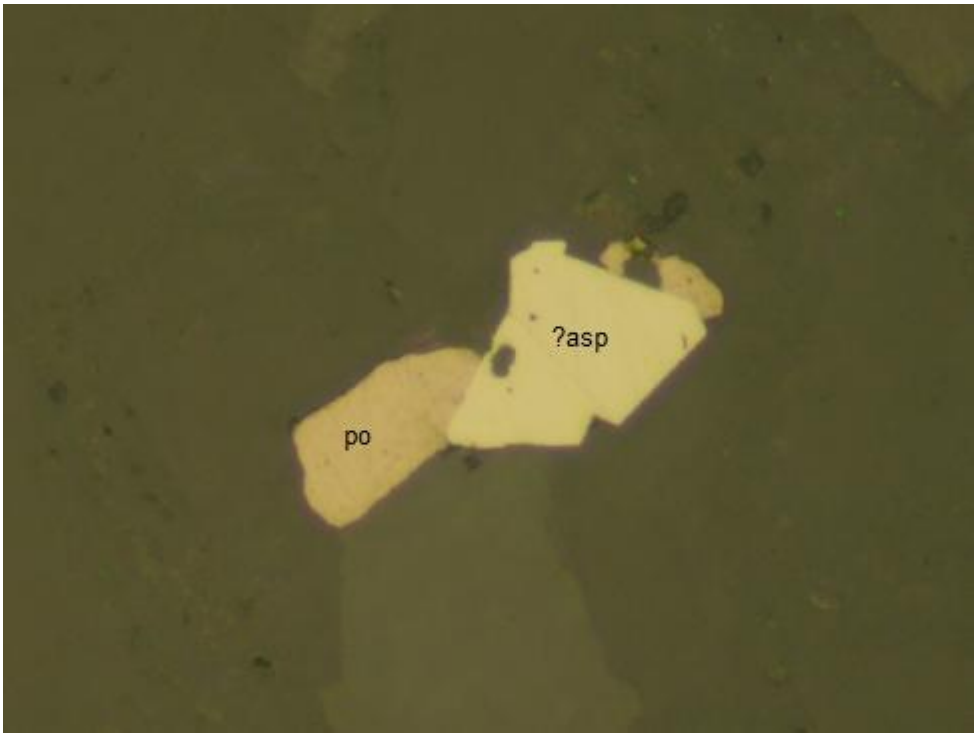


C



D

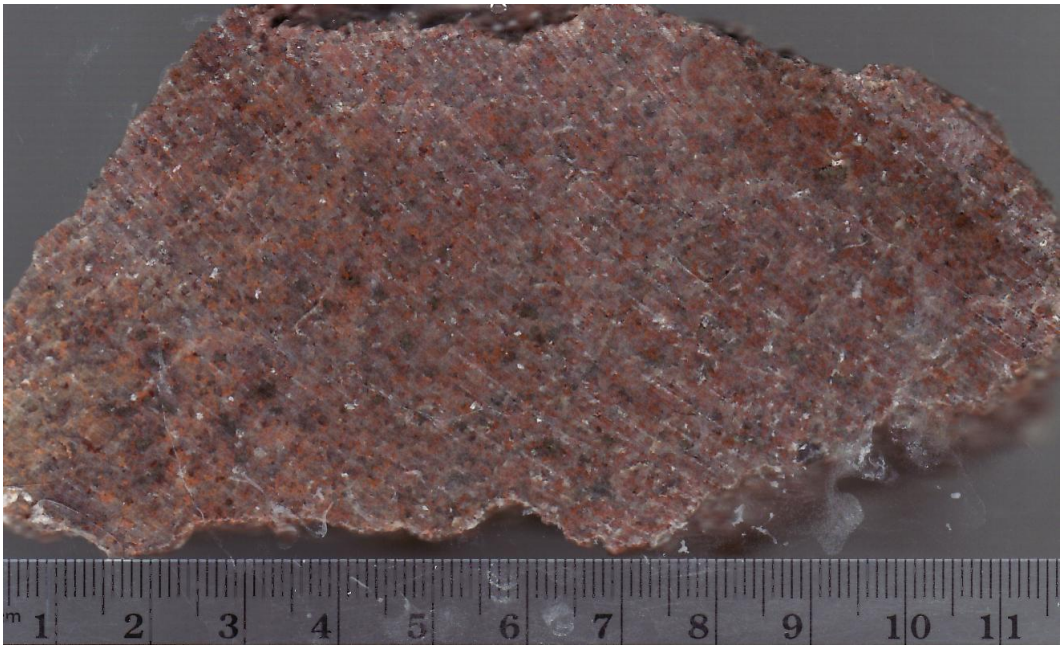
Sample: PM11-913
C) Plagioclase partly replaced by sericite and patchy carbonate. XPL, FOV = ~ 0.7 mm. D) Disseminated ragged garnet. PPL, FOV = ~ 2.6 mm.



E

F

Sample: PM11-913



E) Granophyric texture surrounding resorbed quartz phenocryst. XPL, FOV = ~ 2.6 mm. F) Disseminated pyrrhotite and pyrite. RL, FOV = ~ 1.3 mm.

G

Sample: PM11-913
G) Disseminated pyrrhotite and ?arsenopyrite. RL, FOV = ~ 0.2 mm.

Sample: PM11-925 **Offcut #: AT-3**

Rock sample; scale in cm

Etched and stained section offcut; scale in mm

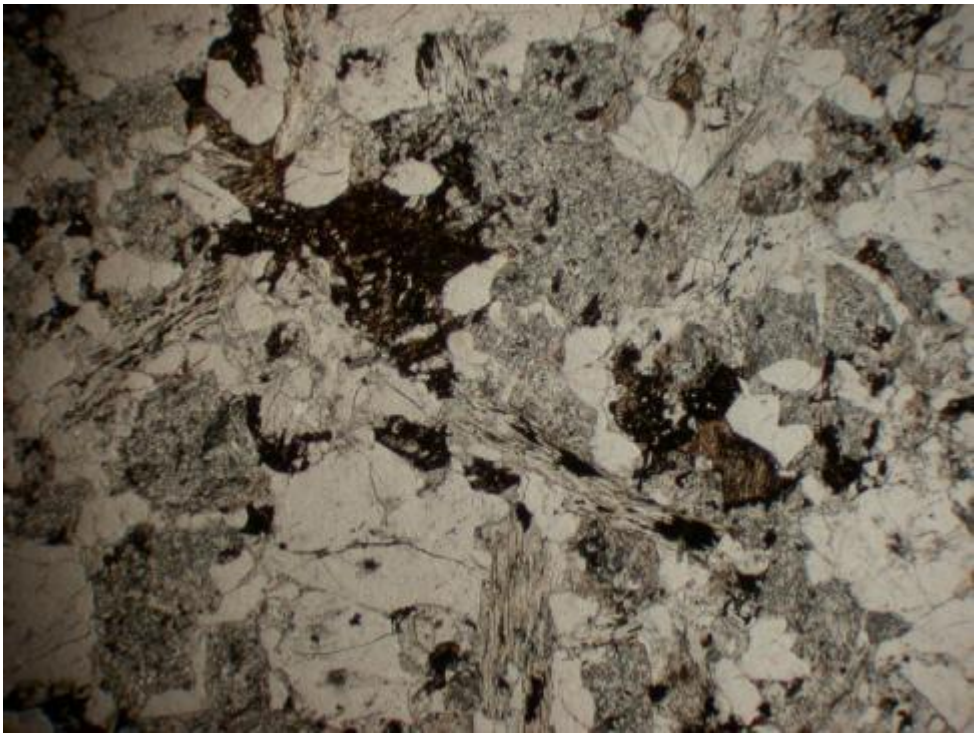
Hand Sample and Stained Offcut Description:
Brownish-grey medium-grained leucocratic equigranular rock with approximately 50% plagioclase (< 3 mm), 30% quartz (< 3 mm) and 15% platy muscovite (typically < 2 mm). No reaction to magnet. Trace local reaction to cold, dilute HCl. Mostly negative test for K-feldspar using etching by HF and sodium cobaltinitrate (trace yellow stain).

Sample: PM11-925 **Offcut #: AT-3**

LITHOLOGY:	Leucocratic microtonalite
ALTERATION MINERALS (> 1%):	Muscovite/sericite, pyrite, carbonate, Fe-ox
ALTERATION MINERALS (< 1%):	?K-feldspar, Ti-ox
INTENSITY OF ALTERATION:	Moderate
MINERALIZATION:	Pyrite, marcasite, (arsenopyrite)

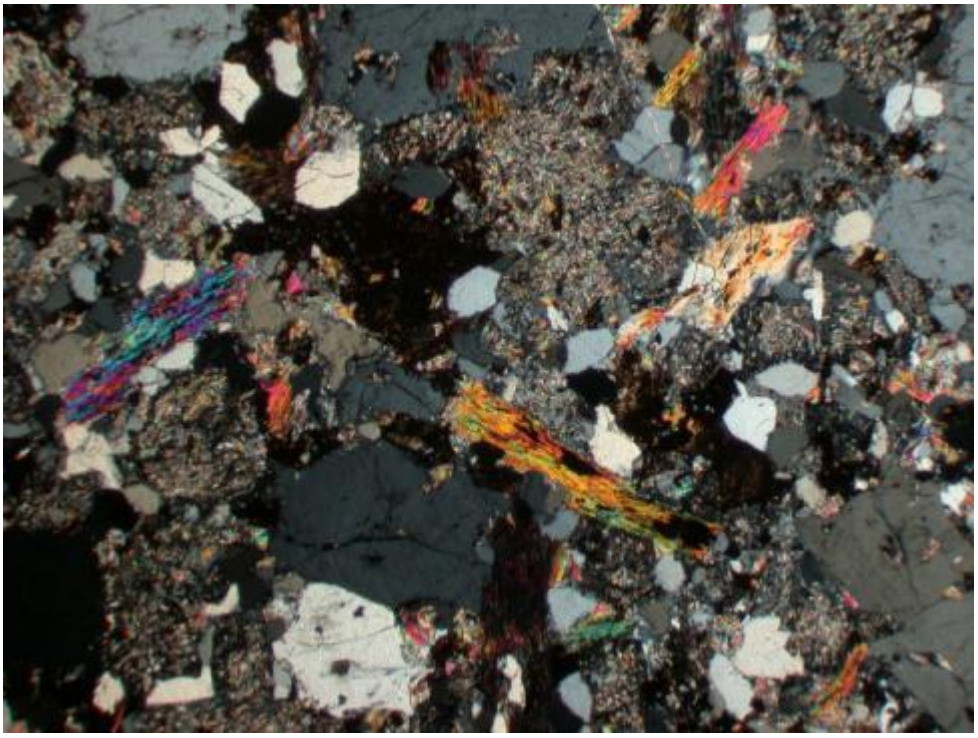
Polished Thin Section Description:
This section is a moderately muscovite/sericite-carbonate-pyrite altered fine to medium-grained, seriate inequigranular leucocratic microtonalite that has undergone weathering resulting in major red-brown Fe-ox staining of the rock. The microtonalite comprises fine to medium-grained plagioclase (formerly ~50%), quartz (~30%) and platy muscovite (~15%). Rare apatite and zircon occur as accessory phases. Plagioclase is extensively replaced by muscovite/sericite and rhombic to anhedral Fe-bearing carbonate. The carbonate is partly replaced by red-brown Fe-ox aggregate. Traces of K-feldspar occur as very fine aggregates (origin uncertain) and may be be an early ?replacement of plagioclase (based on stained offcut). Platy muscovite is locally partly replaced along cleavage traces by Ti-ox aggregate and pyrite ± marcasite aggregate. Minor pyrite and marcasite occur intergrown and are locally partly rimmed and replaced by Fe-ox aggregate. Rare arsenopyrite occurs disseminated as diamond-shaped grains.

Sample: PM11-925 **Offcut #: AT-3**



MAJOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Muscovite (sericite)	30	very fine-grained, platy radiating and flaky aggregates, selectively replaces plagioclase	
Quartz	30	fine to medium-grained (0.2-1.6 mm), intergrown with plagioclase and muscovite	
Muscovite	15	fine to medium-grained (0.2 to 1.6 mm), platy, intergrown with quartz and plagioclase, partly replaced along cleavages by Ti-ox, pyrite-marcasite and Fe-ox aggregates	
Plagioclase	10	fine to medium-grained (0.4-2 mm), intergrown with muscovite and quartz, extensively replaced by muscovite (sericite) and carbonate	*polysynthetic twinning A/C*
Carbonate, (Fe-bearing)	5	fine to very fine-grained (< 0.6 mm), rhombic to anhedral aggregates, occurs replacing plagioclase, extensively replaced by Fe-ox aggregate	
Fe-ox	5	very fine-grained, extensively replaces carbonate, partly replaces pyrite and marcasite aggregates	*red-brown*



MINOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Pyrite	3	fine to very fine-grained (< ~0.5 mm), anhedral aggregates, intergrown with marcasite, fracture and replaced by Fe-ox	
Marcasite	1	very fine-grained, intergrown with pyrite, partly replaced by Fe-ox	
K-feldspar	tr	very fine-grained, cloudy aggregates, origin uncertain, possibly secondary ?replacement of plagioclase, overprinted by muscovite (sericite)	
Ti-ox	tr	very fine-grained aggregate, locally partly replaces muscovite	
Arsenopyrite	r.	fine to very fine-grained (< 0.1 mm), euhedral, disseminated	
Apatite	r.	very fine-grained, disseminated	*high relief*
Zircon	r.	fine-grained (~ 0.1 mm), disseminated	*high relief*

*size ranges: coarse-grained > 5mm; medium-grained 1-5mm; fine-grained 0.05-1mm; very fine-grained <0.05mm

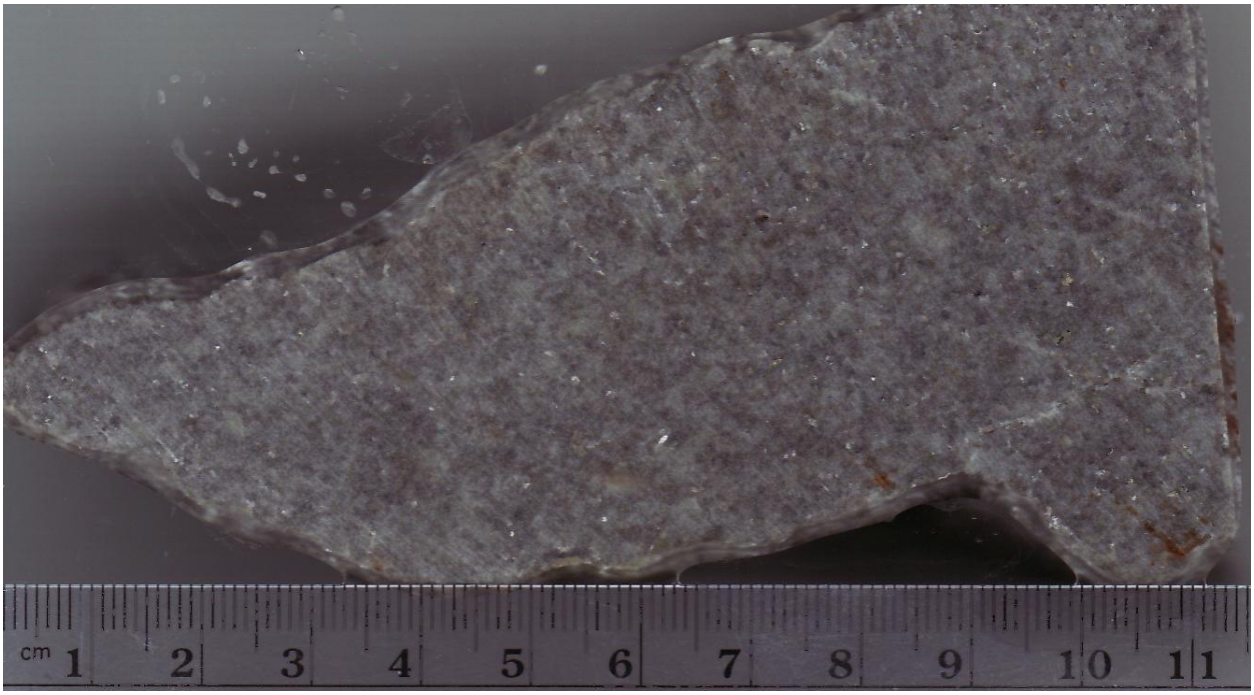
D

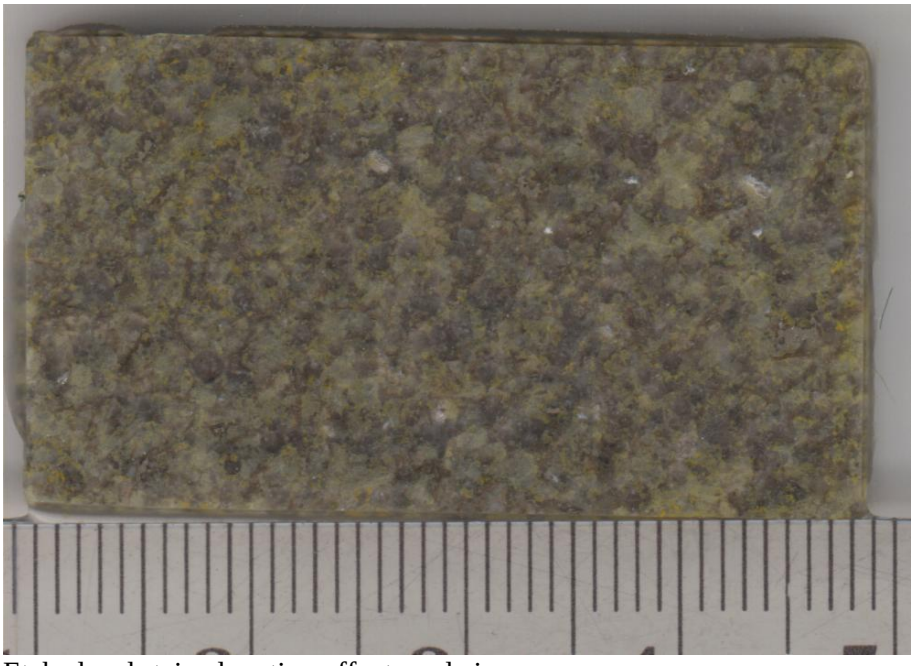
Sample: PM11-925

C) Detailed view of plagioclase replaced by muscovite/sericite and patchy carbonate replaced by Fe-ox. XPL, FOV = ~ 1.3 mm. D) Patchy K-feldspar ?replacement of plagioclase (yellow in this view of stained offcut). RL, FOV = ~ 1.3 mm.

E



F



Sample: PM11-925

E) Patchy pyrite-marcasite aggregate. RL, FOV = ~ 2.6 mm. F) Disseminated arsenopyrite. RL, FOV = ~ 0.7 mm.

Sample: PM11-926 **Offcut #: AT-4**

Rock sample; scale in cm

Etched and stained section offcut; scale in mm

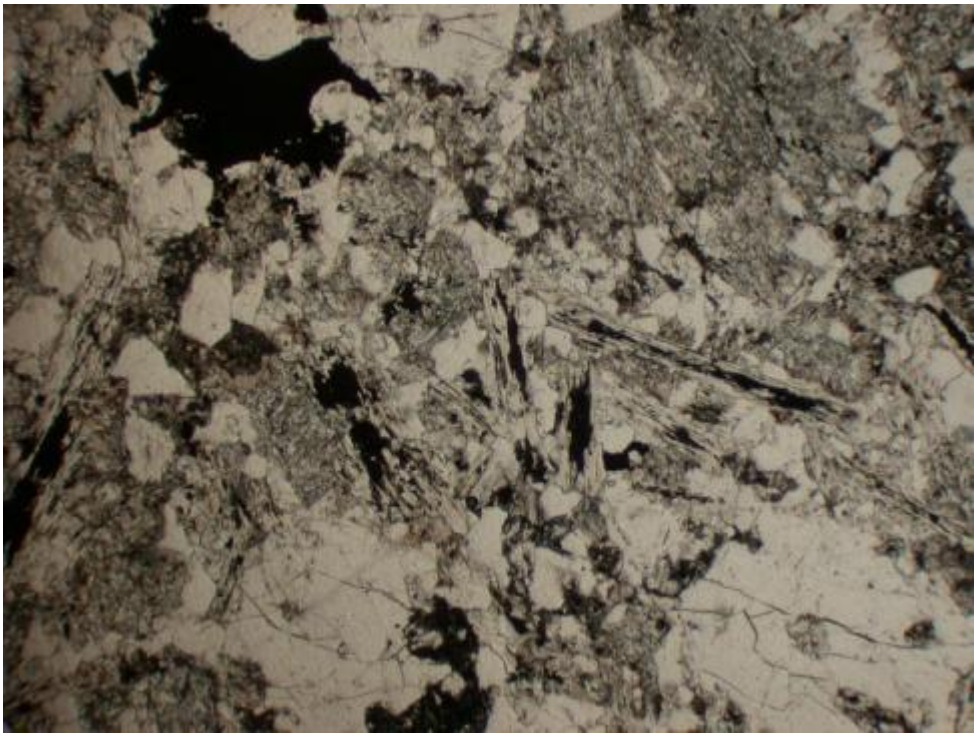
Hand Sample and Stained Offcut Description:
Medium-grey medium-grained leucocratic equigranular rock with approximately 50% plagioclase (< 4 mm), 40% quartz (< 3 mm) and 7% platy muscovite (typically < 2 mm). No reaction to magnet. No reaction to cold, dilute HCl. Positive test for K-feldspar using etching by HF and sodium cobaltinitrate (minor yellow stain - rims plagioclase).

Sample: PM11-926 **Offcut #: AT-4**

LITHOLOGY:	Leucocratic microtonalite
ALTERATION MINERALS (> 1%):	Muscovite/sericite, carbonate, pyrite ?K-feldspar
ALTERATION MINERALS (< 1%):	Ti-ox
INTENSITY OF ALTERATION:	Moderate
MINERALIZATION:	Pyrite, (marcasite, sphalerite)

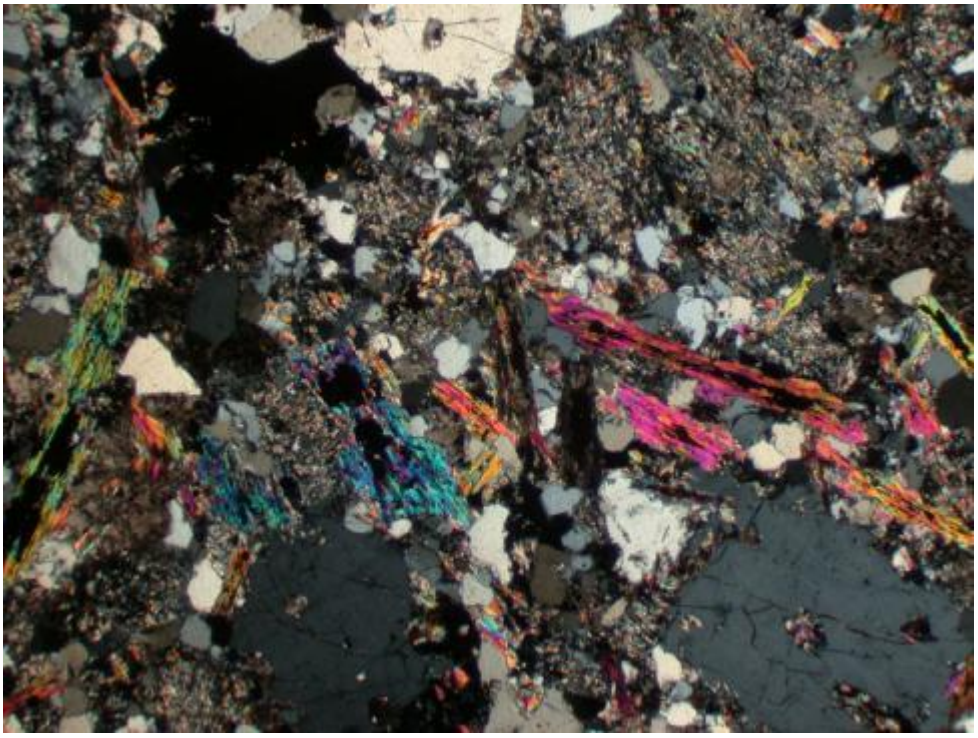
Polished Thin Section Description:
This section is a moderately muscovite/sericite-carbonate-pyrite altered fine to medium-grained, seriate inequigranular leucocratic microtonalite. The microtonalite comprises fine to medium-grained plagioclase (formerly ~50%), quartz (~30%) and platy muscovite (~15%). Rare apatite and zircon occur as accessory phases. Traces of an unknown mineral and acicular rutile occur as infill of fine cavities. Plagioclase is extensively replaced by muscovite/sericite and anhedral carbonate. Minor of K-feldspar occur as very fine aggregates (origin uncertain) possibly an early ?replacement of plagioclase (based on stained offcut) and/or primary orthoclase replaced by carbonate. Platy muscovite is locally partly replaced along cleavage traces by Ti-ox aggregate and pyrite aggregate. Minor pyrite occur disseminated; locally with traces of marcasite. Rare dark sphalerite occurs disseminated.

Sample: PM11-926 **Offcut #: AT-4**



MAJOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Muscovite (sericite)	30	very fine-grained, platy radiating and flaky aggregates, selectively replaces plagioclase	
Quartz	30	fine to medium-grained (0.1-1.5 mm), intergrown with plagioclase and muscovite	
Muscovite	15	fine to medium-grained (0.2 to 2.6 mm), platy, intergrown with quartz and plagioclase, partly replaced along cleavages by Ti-ox & pyrite aggregates	
Plagioclase	10	fine to medium-grained (0.4-2 mm), intergrown with muscovite and quartz, extensively replaced by muscovite (sericite) and carbonate	*polysynthetic twinning A/C*
Carbonate	8	very fine to medium-grained (< 2 mm), anhedral aggregates, occurs replacing plagioclase and intergrown with quartz	*cloudy*



MINOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Pyrite	4	fine to very fine-grained (< ~0.3 mm), anhedral aggregates, locally intergrown with marcasite, pitted	
K-feldspar	2	very fine-grained, cloudy aggregates, origin uncertain, possibly secondary ?replacement of plagioclase, overprinted by muscovite (sericite), fine-grained, possibly primary ?intergrown with fine quartz and replaced by carbonate	
Marcasite	tr	very fine-grained, intergrown with pyrite	
Ti-ox	tr	very fine-grained aggregate, locally partly replaces muscovite	
Unknown	tr	very fine-grained, low relief, vug infill	*1st order δ*
Rutile	tr	fine-grained (< 0.2 mm), acicular, occurs with unknown as vug infill	
Sphalerite	tr	fine-grained (~0.2 mm), anhedral, chalcopyrite disease, disseminated	*dark*

Rock sample; scale in cm

Etched and stained section offcut; scale in mm

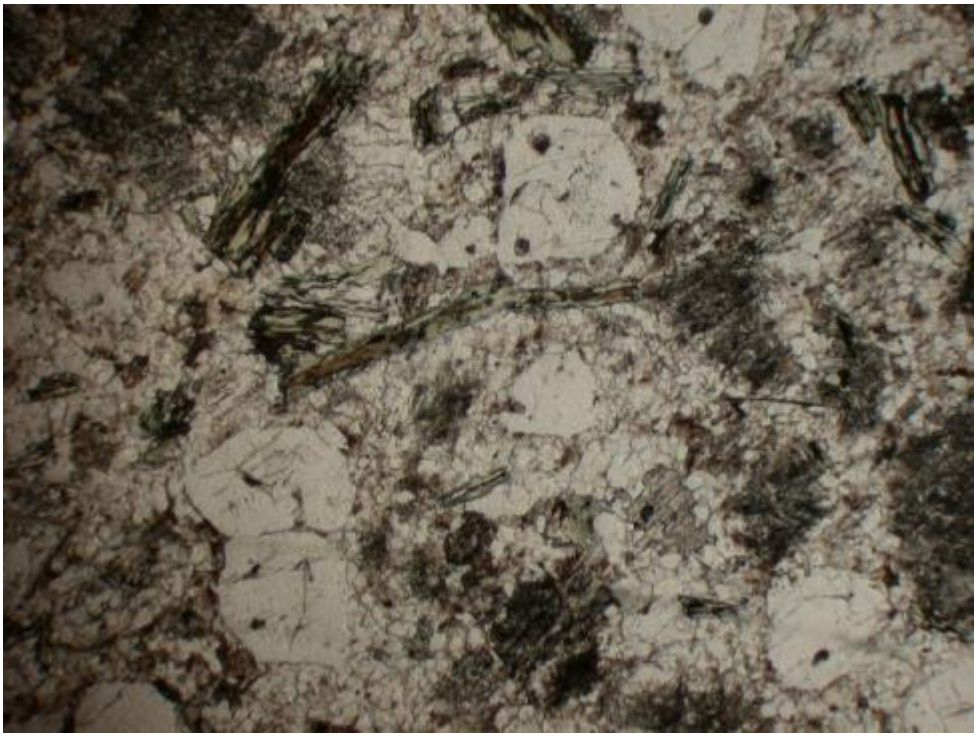
Hand Sample and Stained Offcut Description:
Porphyry with approximately 45% plagioclase phenocrysts (< 2 mm), 7% quartz phenocrysts (< 1 mm) and 7% black biotite phenocrysts (typically < 3 mm) in a very fine K-feldspar-quartz dominant matrix (based on stain). Note two autoliths (< 1 cm size) of more mafic composition than host rock. No reaction to magnet. No reaction to cold, dilute HCl. Positive test for K-feldspar using etching by HF and sodium cobaltinitrate (~20%, yellow) stain.

Sample: PM11-930 **Offcut #: AT-5**

LITHOLOGY:	Microgranodiorite porphyry [garnet-bearing, quartz-biotite-plagioclase-phyric]
ALTERATION MINERALS (> 1%):	Sericite, chlorite
ALTERATION MINERALS (< 1%):	Carbonate, Ti-ox, Fe-ox
INTENSITY OF ALTERATION:	Weak
MINERALIZATION:	(pyrite, arsenopyrite)

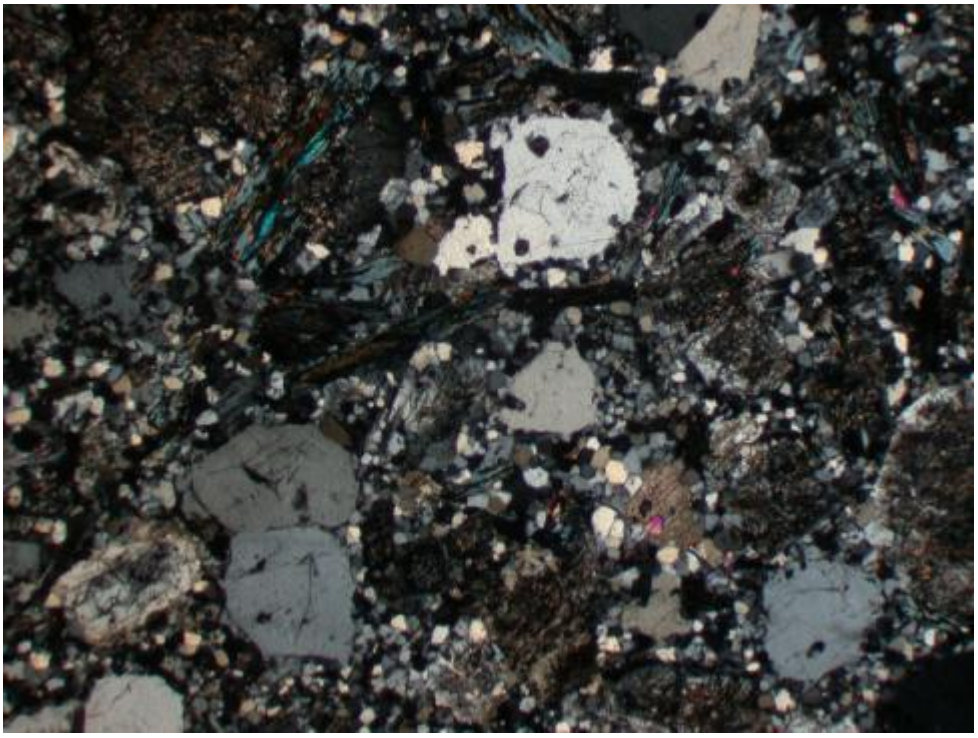
Polished Thin Section Description:
This section is a weakly sericite-chlorite-(carbonate-Ti-ox-Fe-ox)-altered, garnet-bearing, quartz-biotite-plagioclase-phyric microgranodiorite porphyry with former biotite-rich autolith (~1 cm size). The microgranodiorite porphyry comprises weakly altered fine to medium-grained plagioclase phenocrysts ~40%, biotite phenocrysts ~7% and quartz phenocrysts ~10% in a fine-grained matrix comprising dominantly orthoclase and quartz with minor plagioclase and altered biotite. Traces of muscovite occur as radiating aggregates with quartz and chlorite as infill of cavities (?miarolitic). Traces of fine-grained garnet occur disseminated. Rare apatite and zircon occur as accessory phases. Plagioclase is commonly zoned and selectively replaced by sericite and carbonate aggregate. Biotite is selectively replaced by chlorite, Ti-ox aggregate and locally sericite. Traces of pyrite and rare arsenopyrite occur disseminated. The autolith comprises a fine-grained equigranular aggregate of biotite, plagioclase, quartz and traces of K-feldspar and pyrite. The feldspars are partly replaced by rhombic carbonate and sericite aggregate. Biotite is replaced by chlorite, rutile and sericite aggregate.

Sample: PM11-930 **Offcut #: AT-5**



MAJOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Plagioclase	40	-fine to medium-grained (0.4-2 mm), phenocrysts, strongly zoned, selectively replaced by sericite and carbonate -fine-grained (0.05-0.4 mm), occurs in matrix, partly replaced by sericite	*polysynthetic twinning*
Quartz	26	-fine-grained (0.3-1 mm), resorbed phenocrysts (~10%) -fine-grained (0.05-0.1 mm), anhedral, occurs intergrown with orthoclase as matrix -fine-grained (< 0.2 mm), occurs as cavity infill (?mairolitic)	
Orthoclase	20	fine-grained (0.05-0.1 mm), cloudy aggregates, incipient clay alteration, intergrown with quartz and altered mafic phases as matrix	
Sericite	5	very fine to fine-grained (< 0.1 mm), flaky aggregates, partly replaces plagioclase, partly replaces biotite	
Chlorite	5	-very fine-grained, occurs selectively replacing biotite -fine-grained (< 0.2 mm), anhedral to radiating aggregates, occurs with muscovite and quartz as cavity infill	



MINOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Biotite	1	fine to medium-grained (0.2 to 2 mm), phenocrysts, extensively replaced by chlorite, Ti-ox and sericite	
Pyrite	tr	fine to very fine-grained (< 0.4 mm), subhedral, disseminated, occurs also within autolith, locally partly replaced by Fe-ox	
Garnet	tr	fine to medium-grained (0.6- 1.4 mm), occurs disseminated	*colourless*
Carbonate	tr	-fine-grained (< 0.4 mm), rhombic to anhedral aggregates, partly replaces plagioclase -fine-grained (< 0.8 mm) occurs as cavity infill	
Muscovite	tr	fine-grained (< 0.2 mm), radiating, cavity infill with quartz	
Ti-ox	tr	very fine-grained aggregate, partly replaces biotite	
Zircon	r.	fine-grained (< 0.15 mm), disseminated	*high relief*
Ilmenite	r.	fine to very fine-grained (< 0.1 mm), associated with biotite	
Fe-ox	r.	very fine-grained, rims and replaces sulphides	*red-brown*
Arsenopyrite	r.	very fine-grained, subhedral, partly replaced by Fe-ox	
Apatite	r.	very fine-grained, hexagonal forms, disseminated	*high relief*

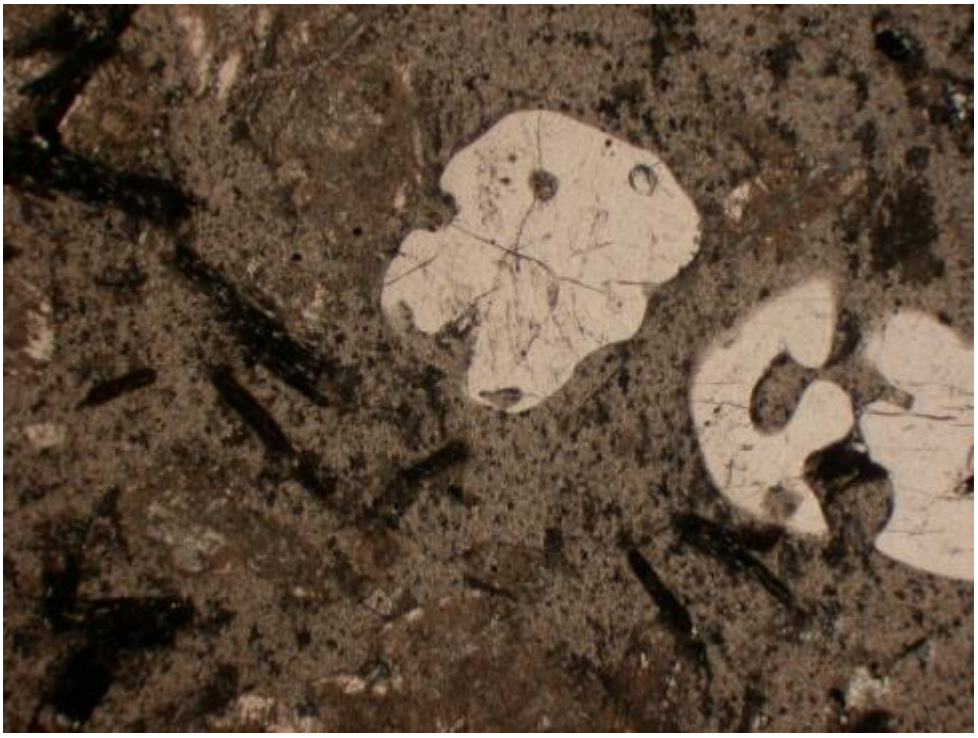
LITHOLOGY:	Andesite porphyry [quartz-biotite-plagioclase-phyric]
ALTERATION MINERALS (> 1%):	Sericite, carbonate, pyrite, muscovite
ALTERATION MINERALS (< 1%):	Ti-ox
INTENSITY OF ALTERATION:	Moderate
MINERALIZATION:	Pyrite, (pyrrhotite)

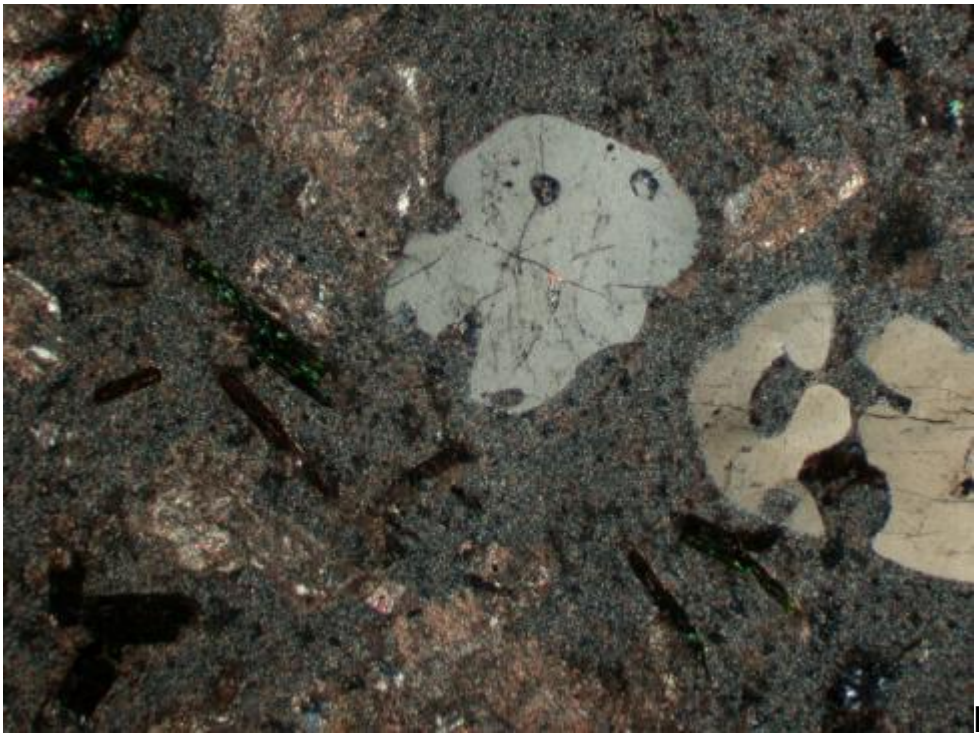
Polished Thin Section Description:
This section is a moderately sericite-carbonate-pyrite-muscovite-(Ti-ox)-altered, quartz-biotite-plagioclase-phyric andesite porphyry. The andesite porphyry comprises strongle altered fine to medium-grained plagioclase phenocrysts and glomerocrysts ~30%, biotite phenocrysts ~10% and resorbed quartz phenocrysts ~7% in a very fine-grained strongly carbonate-sericite altered feldspathic matrix. Traces of quartz, carbonate, muscovite and pyrite occur as infill of cavities. Traces of apatite and rare zircon occur as accessory phases. Plagioclase phenocrysts are selectively replaced by very fine sericite and carbonate aggregate. Biotite is selectively replaced by carbonate, Ti-ox aggregate and muscovite. Minor pyrite occurs disseminated and locally pyrite replaces biotite along cleavages. One grain of fine pyrrhotite occurs in matrix and is rimmed and partly replaced by very fine pyrite aggregate.

Sample: PM11-935 **Offcut #: AT-7**



MAJOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Plagioclase	25	-fine to medium-grained (0.2-2.2 mm), phenocrysts and glomerocrysts (composition An_{27-55}, based on 3 estimates), selectively replaced by sericite and carbonate -very fine-grained, occurs as matrix, partly replaced by sericite and carbonate	*polysynthetic twinning*
Sericite	25	very fine-grained, flaky aggregates, partly replaces plagioclase phenocrysts and matrix, partly replaces biotite phenocrysts	
Carbonate	25	-very fine-grained, anhedral aggregates, partly replaces plagioclase and biotite phenocrysts, occurs as patchy aggregates in the matrix -fine-grained (< 0.1 mm), occurs as vug infill	
K-feldspar	10	very fine-grained occurs with plagioclase as matrix	
Quartz	7	-fine to medium-grained (0.1-2 mm), resorbed phenocrysts -very fine-grained, occurs as vug infill with carbonate, muscovite	



MINOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Pyrite	4	fine to very fine-grained (< 0.1 mm), eu-anhedral, occurs disseminated, as patchy aggregates associated with carbonate alteration, partly replacing biotite phenocrysts and as vug infill	
Biotite	2	fine to medium-grained (0.2 to 2.2 mm), phenocrysts, partly replaced by carbonate, Ti-ox and muscovite aggregate, locally pyrite replaces biotite along cleavages	
Muscovite	1	fine to very fine-grained (< 0.1 mm), occurs replacing biotite, occurs as radiating aggregates infilling cavities	
Apatite	tr	very fine-grained, hexagonal forms, disseminated	*high relief*
Ti-ox	tr	fine to very fine-grained aggregate, partly replaces biotite, locally associated with disseminated pyrite	
Pyrrhotite	r.	fine-grained (~0.3 mm), rimmed and partly replaced by very fine pyrite aggregate	
Zircon	r.	fine-grained (< 0.25 mm), disseminated	*high relief*

Hand Sample and Stained Offcut Description:
Porphyry with approximately 40% plagioclase phenocrysts (< 2 mm), 5-7% quartz phenocrysts (< 3 mm) and 7% black biotite phenocrysts (typically < 2 mm) in a very fine K-feldspar-quartz dominant matrix (based on stain). No reaction to magnet. No reaction to cold, dilute HCl. Positive test for K-feldspar using etching by HF and sodium cobaltinitrate (~25%, yellow) stain. Fractures infilled by red-brown Fe-ox and adjacent rock is stained red-brown.

Sample: PM11-980 **Offcut #: AT-9**

LITHOLOGY:	Microgranodiorite porphyry [garnet-bearing, quartz-?biotite-plagioclase-phyric]
ALTERATION MINERALS (> 1%):	Sericite, chlorite, Fe-ox
ALTERATION MINERALS (< 1%):	Ti-ox
INTENSITY OF ALTERATION:	Weak
MINERALIZATION:	Pyrite, (chalcopyrite, pyrrhotite)

Polished Thin Section Description:
This section is a weakly sericite-chlorite-(Ti-ox)-altered, garnet-bearing, quartz-?biotite-plagioclase-phyric microgranodiorite porphyry that has undergone surface weathering resulting in minor red-brown Fe-ox infill of fractures and staining. The microgranodiorite porphyry comprises weakly altered fine to medium-grained plagioclase phenocrysts ~40%, former platy likely ?biotite phenocrysts ~7% and quartz phenocrysts ~7% in a fine-grained matrix comprising dominantly orthoclase and quartz with minor plagioclase and altered platy phases. Traces of muscovite occur as radiating aggregates with quartz and locally chlorite as infill of cavities (?miarolitic). Traces of fine-grained garnet occur disseminated. Rare apatite and ?monazite occur as accessory phases. Plagioclase is commonly zoned and selectively replaced by sericite aggregate. Former platy phases (likely ?biotite) are replaced by chlorite, Ti-ox aggregate and locally sericite. Minor pyrite and traces of chalcopyrite and pyrrhotite occur disseminated and associated with former platy phenocrysts.

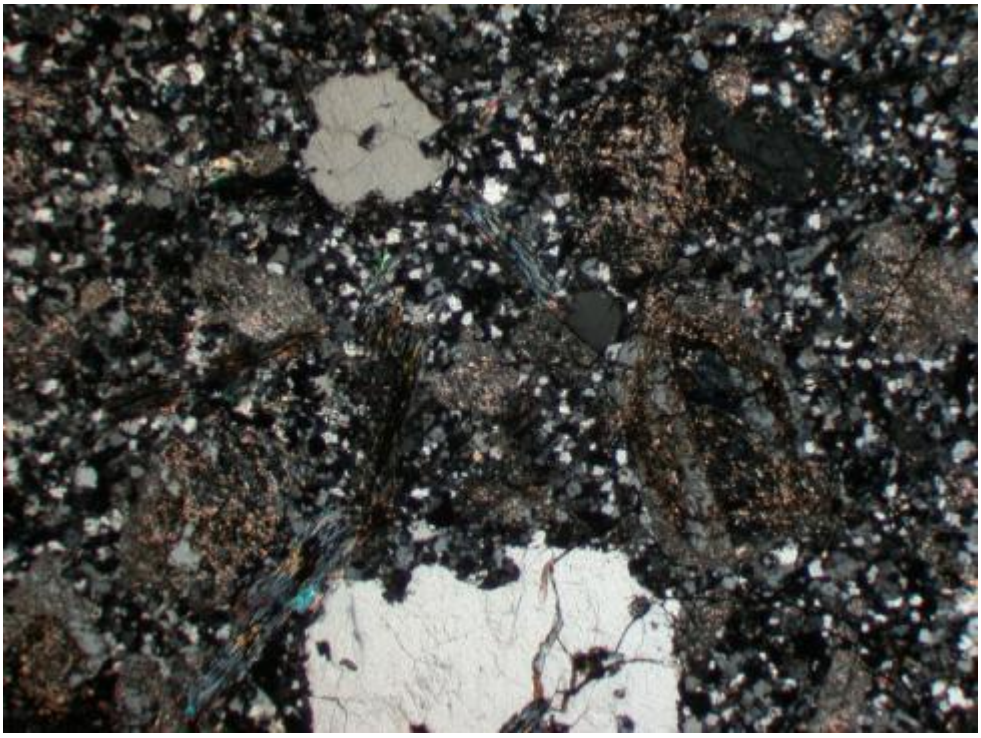
MAJOR MINERALS

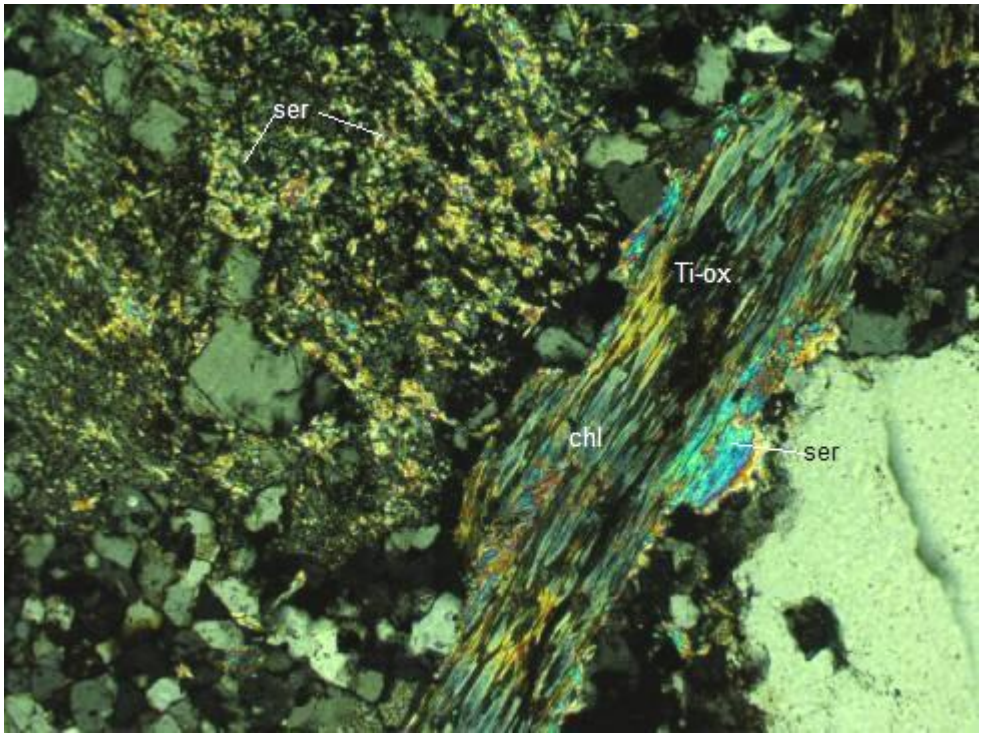
Mineral	%	Distribution & Characteristics*	Optical
Plagioclase	30	-fine to medium-grained (0.5-2 mm), phenocrysts, strongly zoned, selectively replaced by sericite -fine-grained (0.05-0.5 mm), occurs in matrix, partly replaced by sericite	*polysynthetic twinning*
Quartz	30	-medium-grained (0.4-3 mm), resorbed phenocrysts (~7%) -fine-grained (0.05-0.2 mm), anhedral, occurs intergrown with orthoclase as matrix -fine-grained (< 0.2 mm), occurs with muscovite and chlorite as cavity infill (?mairolitic)	
Orthoclase	25	fine-grained (0.05-0.2 mm), cloudy aggregates, incipient clay alteration, intergrown with quartz and altered mafic phases as matrix	
Sericite	8	very fine to fine-grained (< 0.1 mm), flaky aggregates, partly replaces plagioclase, partly replaces biotite	



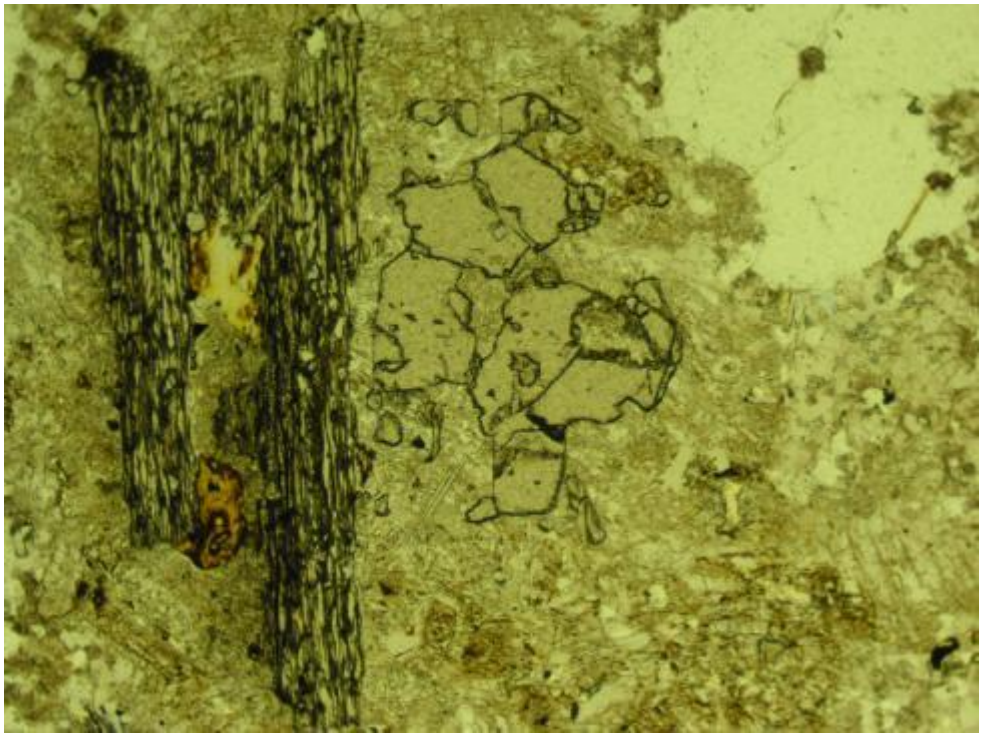
MINOR MINERALS

Mineral	%	Distribution & Characteristics*	Optical
Chlorite	4	-very fine-grained, occurs selectively replacing former platy phenocryst (likely ?biotite); -fine-grained (< 0.2 mm), anhedral to radiating aggregates, occurs with muscovite and quartz as cavity infill	
Fe-ox	1	very fine-grained, occurs as fracture and cavity infill, stains adjacent rock, rims and replaces pyrite	*red-brown*
Pyrite	1	fine to very fine-grained (< 0.3 m), subhedral, disseminated, locally partly replaced by Fe-ox aggregate	
Garnet	tr	fine-grained (< 0.8 mm), occurs disseminated	*colourless*
Muscovite	tr	fine-grained (< 0.1 mm), radiating, cavity infill with quartz	
Ti-ox	tr	very fine-grained aggregate, partly replaces former platy phenocryst (likely ?biotite)	
Chalcopyrite	tr	fine to very fine-grained (< 0.1 mm), subhedral, disseminated	
Pyrrhotite	r.	fine to very fine-grained (< 0.1 mm), disseminated, partly replaced by Fe-ox aggregate	
Apatite	r.	fine-grained (< 0.4 mm), acicular, disseminated	*high relief*
?Monazite	r.	fine-grained (< 0.7 mm), anhedral grains, pale yellow	*high relief*

*size ranges: coarse-grained > 5mm; medium-grained 1-5mm; fine-grained 0.05-1mm; very fine-grained <0.05mm



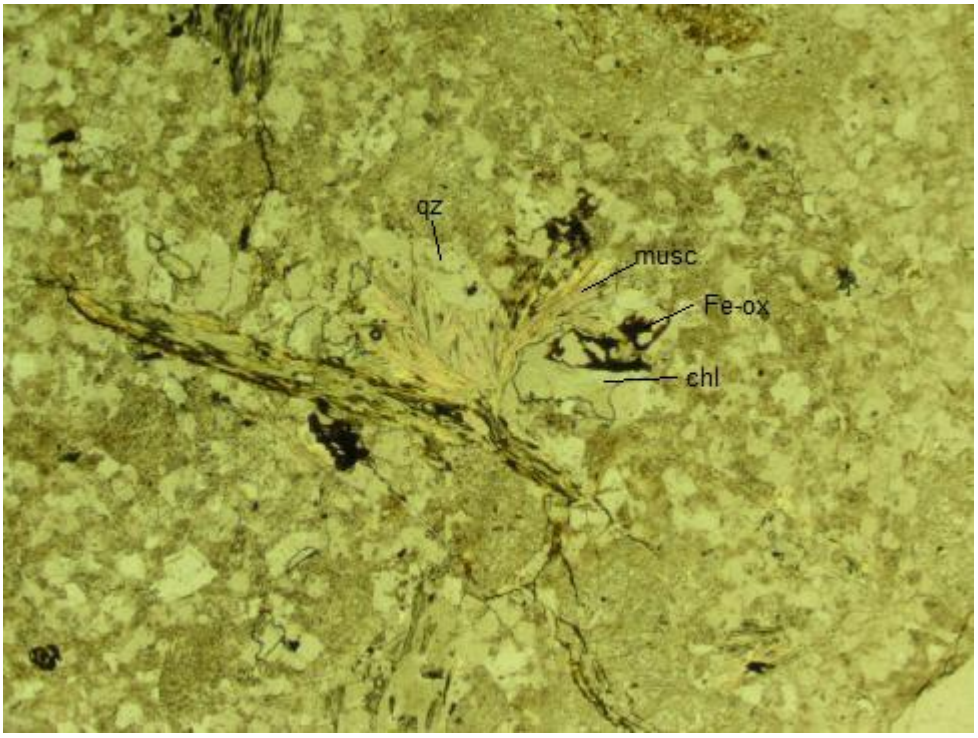
A



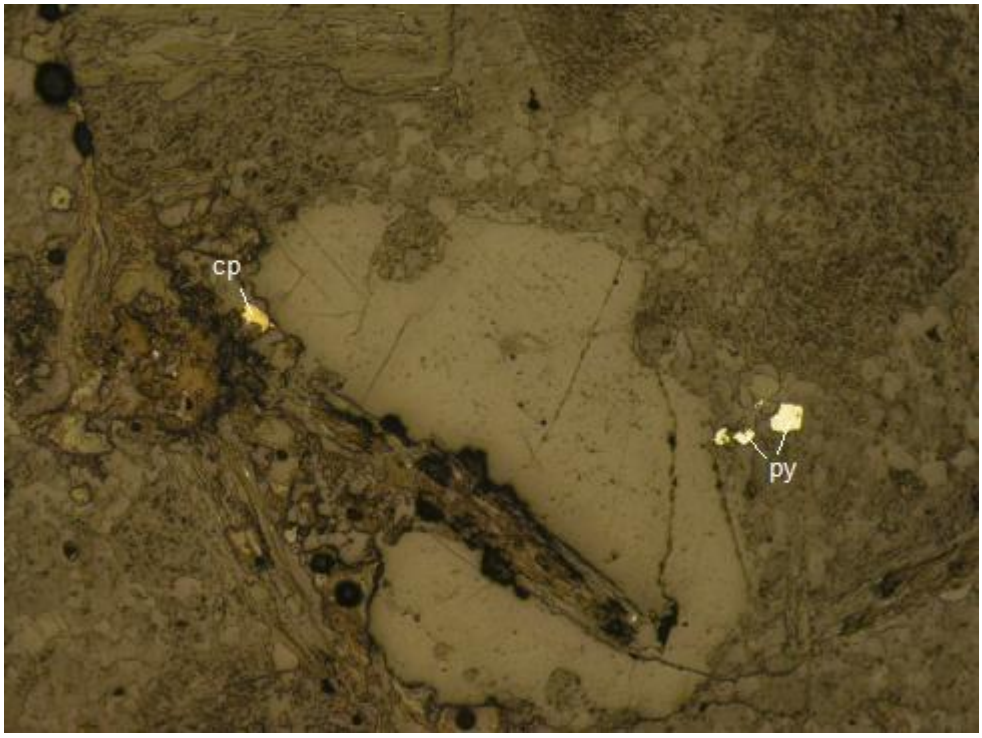
B

Sample: PM11-980

A & B) Representative view microgranodiorite porphyry with altered plagioclase and former platy phenocrysts and resorbed quartz phenocrysts. A) PPL, B) XPL, FOV = ~ 4.5 mm.



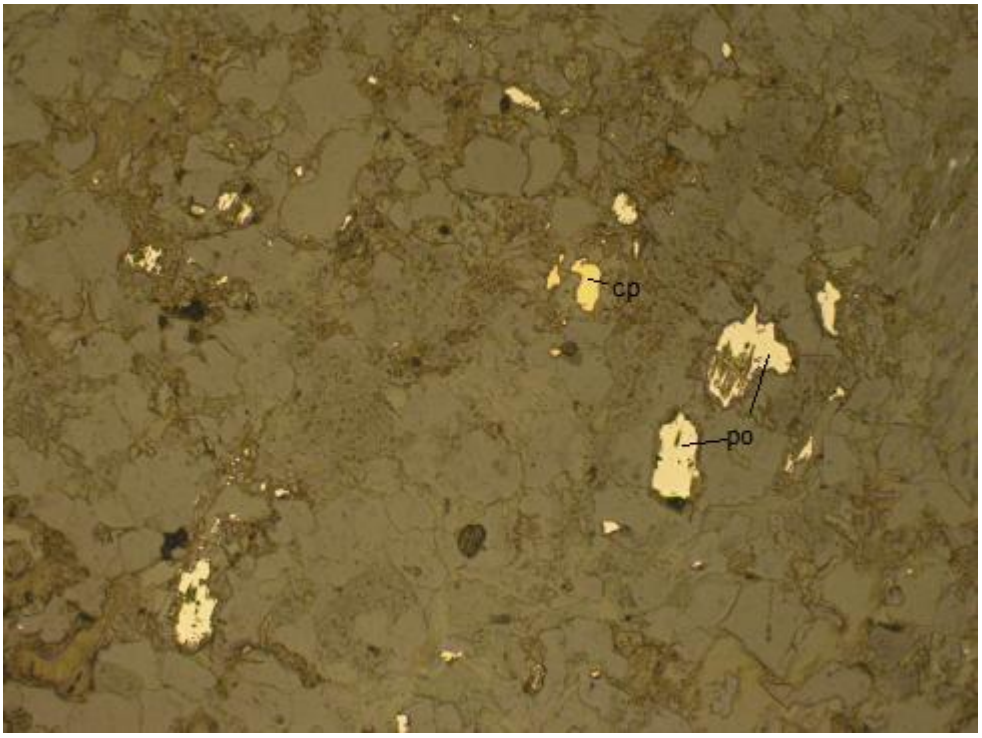
C



D

Sample: PM11-980

C) Plagioclase phenocryst (left) selectively replaced by sericite; platy phenocryst (right) replaced by chlorite, sericite and Ti-ox aggregate. XPL, FOV = ~ 1.3 mm. D) Former platy ?biotite phenocryst (left) and disseminated ragged garnet (centre). PPL, FOV = ~ 2.6 mm.



E

F

Sample: PM11-980

E) Former irregular cavity (centre) with infill by muscovite, quartz, chlorite and Fe-ox aggregate. PPL, FOV = ~ 2.6 mm. F) Disseminated chalcopyrite and pyrite. RL, FOV = ~ 2.6 mm.

G

Sample: PM11-980
G) Disseminated pyrrhotite (po) and chalcopyrite (cp). RL, FOV = ~1.3 mm.

Statement of qualifications: Kathryn P.E. Dunne

I, Kathryn P.E. Dunne, of the city of Salmon Arm, province of British Columbia, do hereby certify that:

1. I am an independent consulting geologist, with a business office at 4610 Lakeshore Road NE, Salmon Arm, B.C., Canada. My business mailing address is: Bag 9000, # 207, 190B Trans Can Hwy NE, Salmon Arm, BC, V1E 1S3.

2. I am a graduate in geology, with a BSc in geology from The University of British Columbia (1985).

3. I received my Masters degree in geology from The University of British Columbia, Vancouver, B.C. in 1988.

4. I am a registered member of the Association of Professional Engineers and Geoscientists of the Province of British Columbia (No. 18674).

5. I am a fellow of the Geological Association of Canada and a member of the Society of Economic Geologists and Mineralogical Association of Canada

6. I have practiced my profession as a geologist for approximately 22 years: 4 years as geologist with the British Columbia Geological Survey Branch, 3 years as research coordinator at the Mineral Deposit Research Unit housed within the Department of Earth and Ocean Sciences at the University of British Columbia, and 15 years as an independent consultant.

7. The petrographic data of this report was collected by me in January and February 2012.

……..……

Kathryn P.E. Dunne, M.Sc., P.Geo.
Consulting Geologist
February 3, 2012

CERTIFICATE OF ANALYSIS WHI11000515.1

CLIENT JOB INFORMATION

Project: Oro Property
Shipment ID: #2
P.O. Number
Number of Samples: 70

SAMPLE DISPOSAL

DISP-PLP Dispose of Pulp After 90 days
DISP-RJT Dispose of Reject After 90 days

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
R200-250	70	Crush, split and pulverize 250 g rock to 200 mesh			WHI
3B	70	Fire assay fusion Au by ICP-ES	30	Completed	VAN
1DX	70	1:1:1 Aqua Regia digestion ICP-MS analysis	0.5	Completed	VAN

ADDITIONAL COMMENTS

Invoice To: Colorado Resources Ltd.

CERTIFICATE OF ANALYSIS WHI11001055.2

CLIENT JOB INFORMATION

Project: Oro Property
Shipment ID: #11
P.O. Number
Number of Samples: 126

SAMPLE DISPOSAL

STOR-PLP Store After 90 days Invoice for Storage
STOR-RJT Store After 90 days Invoice for Storage

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
R200-500	126	Crush, split and pulverize 500 g rock to 200 mesh			VAN
3B	126	Fire assay fusion Au by ICP-ES	30	Completed	VAN
1DX	126	1:1:1 Aqua Regia digestion ICP-MS analysis	0.5	Completed	VAN

ADDITIONAL COMMENTS

Version 2: Revised Sample ID's - Samples 1227151 to 1227165 revised to 1277151 to 1277165

Invoice To: Colorado Resources Ltd.

CERTIFICATE OF ANALYSIS WHI11000491.2

CLIENT JOB INFORMATION

Project: Oro Property
Shipment ID: #1
P.O. Number
Number of Samples: 320

SAMPLE DISPOSAL

RTRN-PLP Return
DISP-RJT-SOIL Immediate Disposal of Soil Reject

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
Dry at 60C	313	Dry at 60C			WHI
SS80	313	Dry at 60C sieve 100g to -80 mesh			WHI
1DX3	311	1:1:1 Aqua Regia digestion ICP-MS analysis	30	Completed	VAN
1DX1	2	1:1:1 Aqua Regia digestion ICP-MS analysis	0.5	Completed	VAN

ADDITIONAL COMMENTS

Invoice To: Colorado Resources Ltd.
