INTRODUCTION

The Nadaleen Trend project covers an area of anomalous gold and arsenic stream sediment geochemistry situated within a geological belt favorable for sediment hosted gold mineralization, 100 km along trend of ATAC Resources Ltd.'s highly prospective Tiger Zone. They are both part of the Rackla Gold Property which is wholly owned by ATAC.

This report describes work conducted on the east end of the Rackla Gold property at the Nadaleen Trend project between March 16 and October 23, 2011 by Archer, Cathro & Associates (1981) Limited on behalf of ATAC. Drilling began on May 29 while mapping occurred between June 3 and September 15, 2011. The authors directed this program and their Statement of Qualifications are in Appendix I.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The Nadaleen Trend project consists of 1406 contiguous mineral claims, which are located in central Yukon at latitude 64°4′ north, and longitude 132°30′ west on NTS map sheets 106C/01 and 106C/02 (Figure 1). In June 2009 the initial 20 claims were staked; additional claims were then added that fall and the following summer. Collectively the project covers an area of approximately 28,300 hectares (283 sq km). The claims are all registered with the Mayo Mining Recorder in the name of Archer Cathro, which holds them in trust for ATAC. Specifics concerning claim registration are tabulated below while the locations of individual claims are shown on Figure 2.

The Nadaleen Trend project lies 180 km east-northeast of Mayo, the nearest supply centre. The closest road access is at the community of Keno City situated about 49 km by road northeast of Mayo and 150 km by air west-southwest of the property. Mayo and Keno City can be reached in all seasons by two wheel drive vehicles using the Yukon highway system.

Access to the project in 2011 was by fixed-wing aircraft to the Rackla airstrip, about 40 km to the west-northwest of the project and then by helicopter to the camp location; or to the newly constructed Stewart Airstrip 10 km south of the project and then by helicopter to the camp location. Daily access to work areas on the project was provided by a combination of three helicopters. Throughout the exploration season Fireweed Helicopters Ltd. supplied a combination of Eurocopter AS350 SD2, Hughes 500D and MD 520 N models. In addition, Horizon Helicopters provided a Eurocopter AS350 SD2. All machines were stationed out of the Nadaleen Trend camp.

HISTORY AND PREVIOUS WORK

The earliest recorded exploration within the Nadaleen Trend exploration area occurred when McIntyre Mines staked the Birkeland claims, then called Tom and Mom in 1974 on the northeastern corner of the Nadaleen Trend project, approximately 200 km east of Mayo. Mapping, geochemical soil sampling, trenching and 10 BQ and 22 Winkie holes were carried out

in 1975. The best results were 4.4% Zinc, 0.5% Lead and 2.7 g/t Silver over 1.8 m in DDH75-31 (Shearer, 1975). In 1978 McIntyre Mines entered a joint venture with Canadian Superior Exploration, Ltd. No further work was reported and the Birkeland claims expired.

In 1976 the Sian claims were staked approximately 37 km southwest of the Birkeland claims by McIntyre Mines following prospecting of geological targets. Mapping, geochemical soil sampling and EM, mag and SP geophysical surveys were carried out in 1977. Gold was tested for in 4 grab samples; however, results did not exceed the detection limit for gold (Birkeland, 1978). After entering a joint venture with Canadian Superior Exploration, detailed mapping, trenching and sampling was completed in 1979. Results of this work found low grade Lead and Zinc throughout a folded dolomite unit. One diamond drill hole was completed in 1980 but did not intersect any mineralization. No further work was recommended and in 1982 the Sian property passed to Serem Ltd, after which the claims were voided and no further exploration was reported.

The Star claims located approximately 12 km to the west of the Sian claims were staked by private prospectors and optioned to Prism Resources, Ltd in 1976. Mapping and soil geochemical testing completed by Prism Resources in 1977 had disappointing results and all claims were dropped. The Lee and Nod claims were staked to the south of the Leah claims in December of 1976 and were optioned to Tay River Mines. No work is on record for these claims and they were allowed to lapse (Deklerk and Traynor, 2005).

McIntyre Mines staked the Jam property in 1977, 4.2 km north of its Sian property. Soil and silt sampling in conjunction with mapping later that year found a favorable dolomite breccia host rock with associated zinc and lead sulphide mineralization. No further work was reported and the Jam claims lapsed (Deklerk and Traynor, 2005).

In 1976, the Black, Ida, Red and Eira claims, located approximately 8 km east of the Sian claims, were staked by the Ortell Syndicate (Precambrian Shield Resources Ltd, Giant Yellowknife Mines Ltd, Nemco Resources Ltd and Highwood Resources Ltd). In 1977, the Black and Ida claims were optioned by a joint venture between DeJour Mines Limited and Nova-Co Exploration Limited (Thompson, 1977). Mapping and geochemical sampling on the Ida claims later that year returned moderately anomalous zinc values, with erratic lead and silver support.

Also in 1977, prospecting and stream sediment sampling carried out on the Eira property by the Ortell Syndicate returned anomalous silver and zinc results, up to 2.4 ppm and 680 ppm respectively (Curry, 1977). This led to more detailed grid soil sampling and geological mapping. This work returned a number of moderate, non-coincident silver, zinc and lead anomalies.

In 2001, the Geological Survey of Canada completed a regional stream sediment sampling program (Heon, 2003), which included coverage of the current Nadaleen Trend project. Creeks draining the area of the Nadaleen Trend project returned strong gold and arsenic anomalies.

ATAC's initial interest in the area was to follow up a strong arsenic silt anomaly collected by the Geological Survey of Canada in 2001. Over a three day period in 2009, 89 stream sediment, one rock and nine soil samples were collected on the Sten claims, located 19 km west of the original

Birkeland claims. These samples returned a string of moderately to very strongly anomalous results ranging from 12 to 1775 ppb gold and 123 to 155,000 ppm arsenic (Eaton, 2010). As a result, additional claims were staked by ATAC.

Follow-up prospecting of the anomalous creek in the summer of 2010 led to the discovery of in situ gold mineralization occurring within a folded, deformed carbonate horizon now referred to as the Osiris Zone. A follow up soil grid consisting of 50 m line spacing and 50 m sample spacing was conducted over this carbonate horizon. Results from the soil grid yielded four distinct gold anomalies known as Osiris, Conrad, Isis and Isis East.

Drilling in the fall of 2010 defined three gold bearing zones (Lane 2011). The Osiris Zone returned the most significant gold grades yielding 65.20 m of 4.65 g/t Au in OS-10-01. Five more holes were drilled within the Osiris Zone with all but one (OS-10-05) intersecting significant gold mineralization. The Conrad Zone, one kilometer to the east was drilled to target a gold bearing trench. Assay results from this area included 8.03 g/t Au over 21.13 m in OS-10-08. A second hole drilled in the Conrad Zone intersected arsenic sulphide mineralization in a siliciclastic package (OS-10-09) with an averaged gold grade of 1.61 g/t over 39.76 m. Drilling in the Isis Zone one kilometer west of the Osiris Zone (OS-10-07) returned comparatively lower, albeit anomalous, gold grades averaging 0.92 g/t over 17.00 m.

GEOMORPHOLOGY AND CLIMATE

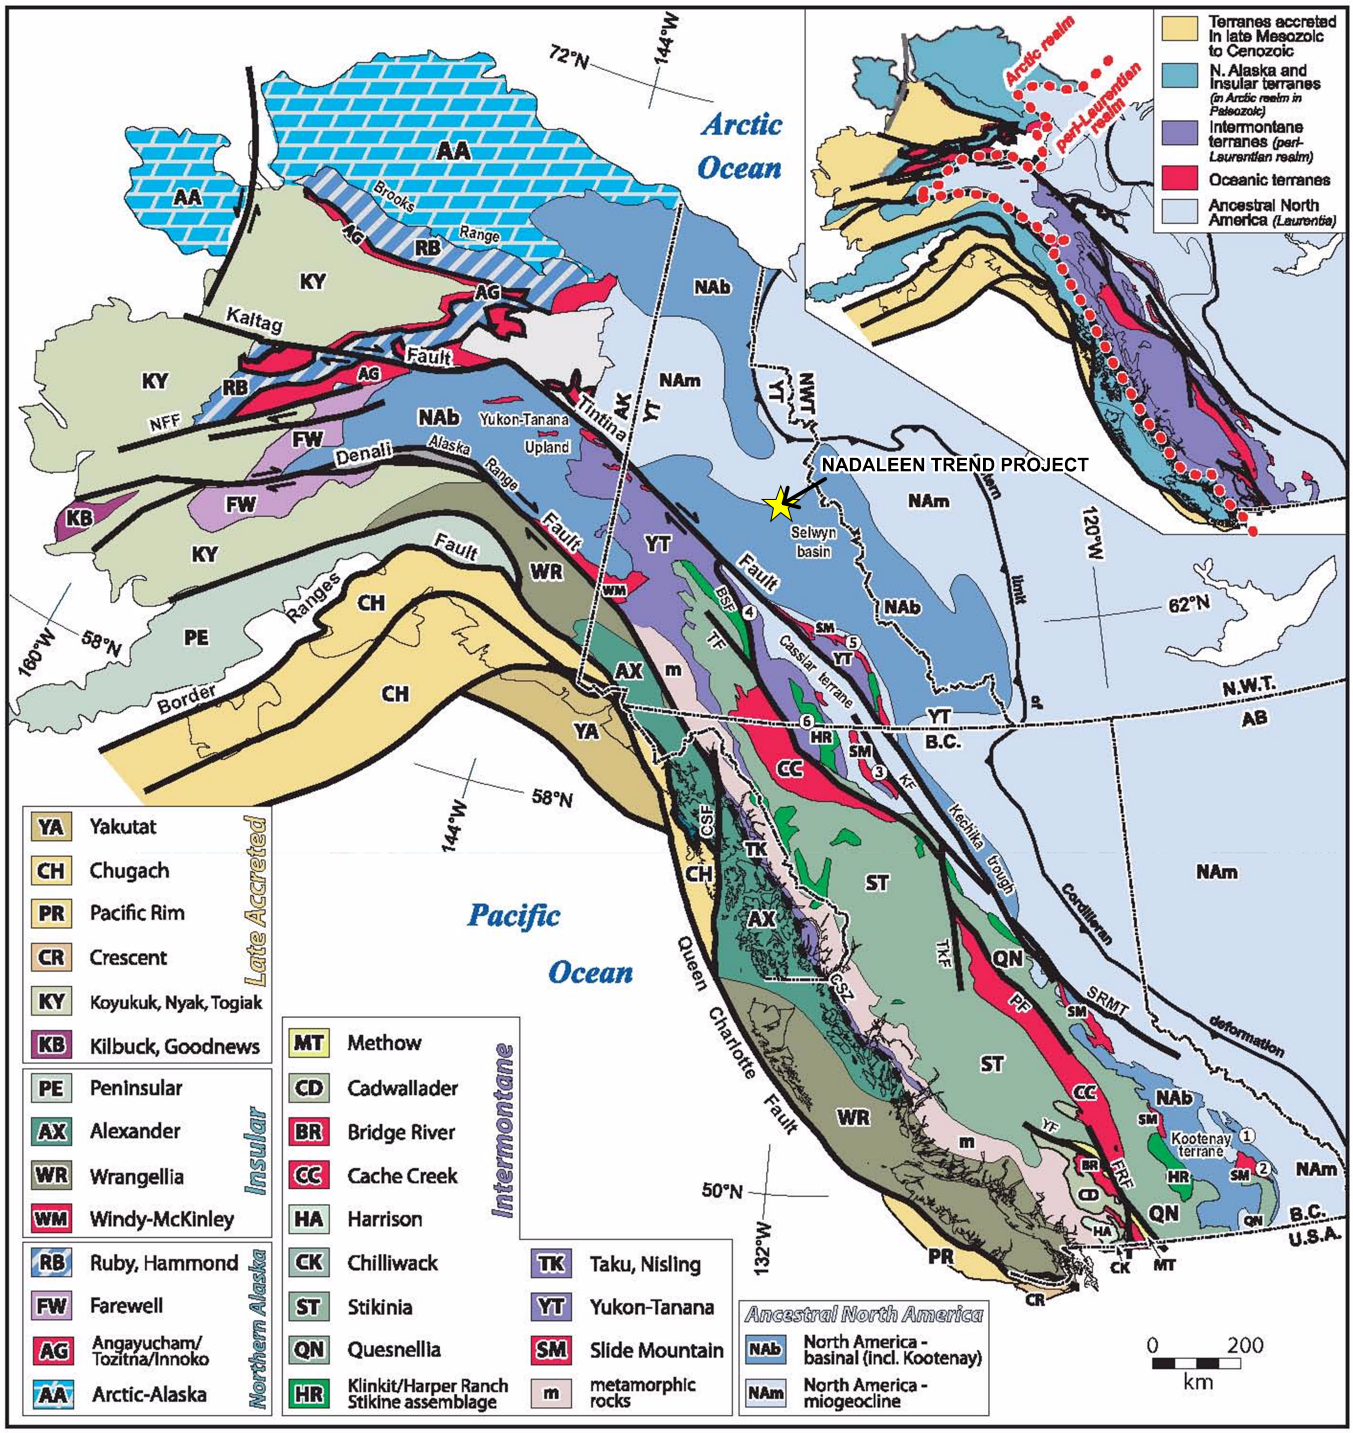
The Nadaleen Trend project is situated in the Selwyn Mountains and is drained by tributaries of the Nadaleen and Stewart rivers, which are both part of the Yukon River watershed. Local topography is alpine to subalpine and feature north- and south-trending rocky spurs and valleys that flank a main east-west trending ridge. Elevations range from approximately 1000 to 2000 m above sea level (asl).

Treeline in the vicinity of the project is at about 1500 m asl. Slopes above that elevation are unvegetated. The density and size of vegetation gradually increases on lower slopes, and the valley floors are well treed with mature black spruce. Understory vegetation typically consists of low shrubs and moss. Moderately steep, south facing slopes are well drained and are often lightly forested with poplar. Steep, north facing slopes are usually unvegetated. Outcrop is most abundant near ridge crests and in actively eroding creek beds. Hillsides are talus covered at higher elevations and are blanketed by glacial till at lower elevations. Soil development is moderate to poor in most areas.

The climate in the Nadaleen Trend project area is typical of northern continental regions with long, cold winters, truncated fall and spring seasons and short, mild summers. Although summers are relatively mild, arctic cold fronts often cover the area and snowfall can occur in any month. The property is mostly snow free from early June to late September.

REGIONAL GEOLOGY

The Geological Survey of Canada performed geological mapping in the vicinity of the Rackla Gold Property at 1:250,000 scale in the early 1970s (Blusson, 1974). In 1999, Gordey and



Makepeace completed a compilation of Yukon-wide geology and updated the lithological unit names in the Rackla area. The Yukon Geological Survey completed mapping of 106C/03 and 106C/04 1:50,000 map sheets during 2010 and 2011 (Colpron, M., 2012, and Chakungal, J., Bennett, V., 2010).

The Rackla Gold Property straddles the boundary between the deep water dominantly clastic rocks of the Selwyn Basin to the south and the shallower water shelf strata of the Mackenzie platform to the north. The Dawson Fault, which juxtaposes rocks of Selwyn Basin against rocks of the Mackenzie Platform, is a crustal break that may date back to late Neo Proterozoic rifting and was reactivated as a north directed thrust in the Cretaceous (Macdonald, F.A. et al, 2010). The tectonic setting of the Rackla Gold Property is shown on Figure 3, while regional relationships and the importance of the Dawson Fault system are presented on Figure 4.

Regional scale property mapping was conducted during the 2011 field season. The distribution of lithologies and regional scale structures determined during this mapping program are shown Figure 5 and the stratigraphic units, are described in Table I.

Table I – Lithological Units (*after Gordey and Makepeace, 1999* and Turner, 2011)

Unit Name	Map Name	Terrane	Age	Description
Earn Group	DME		Devonian to Mississippian	Silvery-blue weathering black shale, argillite, cherty argillite and bedded chert; minor volcaniclastics and rare limestone.
Road River Group and Bouvette Formation	ODR		Ordovician to Devonian	Calcareous to non-calcareous sedimentary gravity flows; graded, sorted chert pebble conglomerates, lithoclastic floatstones, lithic arenites. Well bedded, fossiliferous limestone, thin bedded silty limestone, black chert, light banded chert, siliceous siltstone and argillite. Thick sequences of massive to bedded, reefal, variably fossiliferous limestone and minor siltstone, siliceous argillite and chert.
	Fault contacts			
Haywire Formation	OSH	Mackenzie Platform	Ordovician to Silurian	Medium to thick bedded, light grey to white dolostone, locally highly fossiliferous
Sekwi Formation	lCS	Mackenzie Platform	Lower Cambrian	Grey to bright orange weathering finely crystalline, massive to laminated dolostone; limestone, locally with stromatolite beds, white to purple bedded

PROJECT GEOLOGY

Detailed mapping in 2011 was carried out in the vicinity of the Osiris Zone. Lithologies have been broken into four clastic and carbonate stratigraphic successions, with faulted contacts obscuring most of the relationships between these successions. Table II describes the map units and Figure 6 shows their relative relationships.

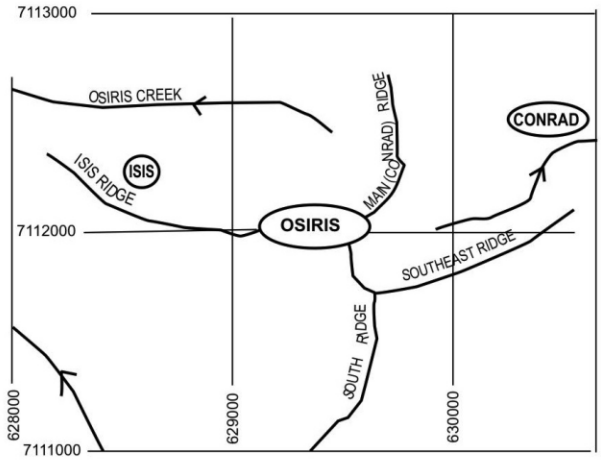
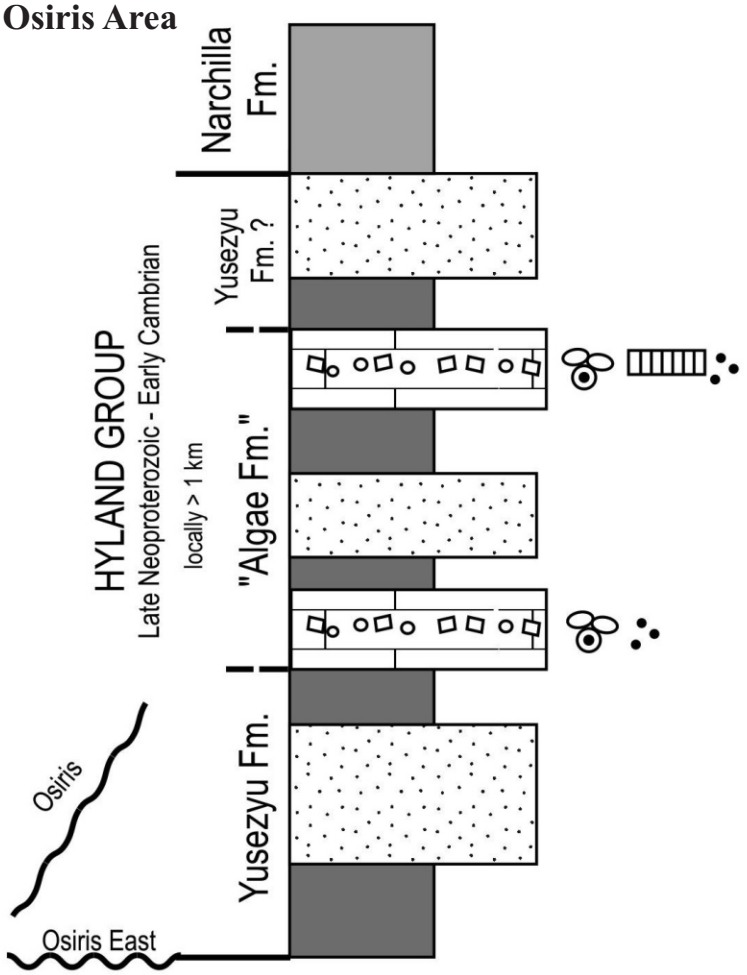
Nadaleen Fault			

MST1	Wernecke Supergroup	Mudstone	Light green-grey-teal mudstone with minor sandstone to pebble conglomerate occasionally carbonate cemented.

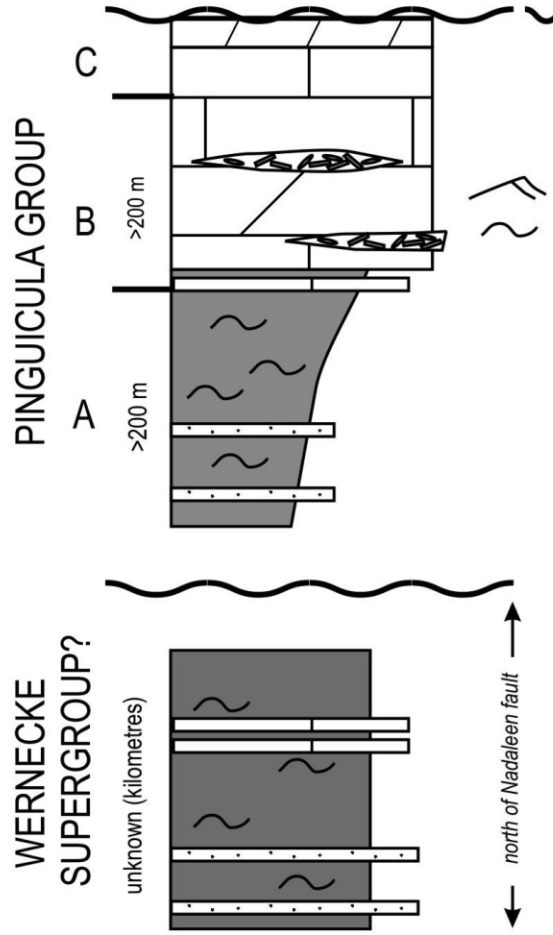
North of the moderate to steeply dipping Nadaleen Fault Zone, defined on Figure 6, is a distinctive rusty brown weathering thick sequence of light green to teal, maroon and brown mudstones with minor interbedded quartz pebble conglomerate. Regionally this may correlate with the Mesoproterozoic **Wernecke Supergroup**; but locally, all contacts with other units are faulted and its stratigraphic relationship cannot be determined.



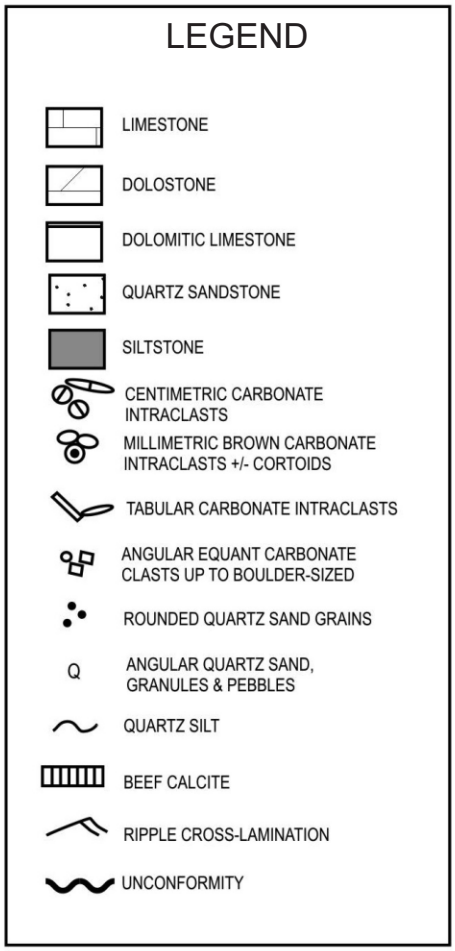
South of the Nadaleen Fault, on the east side of the project area, is a sequence of fine grained siliciclastic strata including siltstones and mudstones with lesser sandstone and minor conglomerate from terrigenous sources (Conrad Package). Interlayered with the clastics are lensoidal carbonate rich diamictites to carbonate boulder conglomerate up to several metres thick, interpreted as debrites. Within the siliciclastic sequence a thicker limestone unit referred to as the "Conrad Limestone" is a monotonous grey weathering lime mudstone with cone in cone calcite, and wispy fine quartz sand layers.



In the western portion of the Osiris Zone exploration area the oldest observed rocks are a distinctive maroon and green to grey and brown platey, non-calcareous terrigenous siltstone with minor sandstone (Figure 7). This is overlain through a gradational contact by a centimetrically to decimetrically layered, approximately 100 m thick sequence of interbedded lime-mudstone and dolo-mudstone with minor quartz silt to very fine sand component. The carbonate strata are pale to medium grey-weathering in general, with a conspicuously yellowish-orange weathering interval near its base as well as intermittently throughout the unit where silty intervals are present. Intraclastic rudstone lenses (10 cm to >1 m thick and tens to hundreds of metres wide) are a conspicuous component and consist of randomly oriented to imbricated, tabular to equant clasts in a carbonate mudstone matrix. Clast composition is almost exclusively the same as enclosing carbonate mudstones. At the Osiris Zone the top of the sequence is a grey to tan weathering massive to brecciated dolostone. This sequence is structurally repeated with the northern exposure referred to as the Osiris Horizon and the southern section referred to as the Isis Horizon.



The maroon and green siltstone and carbonate package described above strongly resembles strata of the Meso-Proterozoic (<1.3 Ga; >1.0 Ga) **Pinguicula Group**, exposed in its type section 70 km to the northwest. In the Osiris area they have tentatively been referred to as Pinguicula A (siltstone) and Pinguicula B (carbonates).



Overlying this stratigraphy is a basal polymict cobble conglomerate which grades upwards to grey brown weathering calcareous sandstone to carbonate cemented coarse quartz grit often graded and cross laminated with interbedded siltstones. This in turn is overlain by siltstones with minor sandstone component, a tan weathering crystalline dolostone and more fine grained clastic rocks. These non-fossiliferous rocks are tentatively correlated with late Proterozoic to Cambrian **Hyland Group**.

This interlayered package of Pinguicula and Hyland Group stratigraphy has been folded and intruded by a mafic dyke set which is exposed on the ridge between the Conrad and Osiris Zones and in drill holes on the west side of Conrad and the north end of Osiris.

DIAMOND DRILLING

Drilling was conducted at the Amon, Conrad, Dale, Isis, Isis East, Osiris, Ptah and Pyramid, Zones (Figure 8) between May 29 and October 16, 2011 by Superior Diamond Drilling Ltd. of Peachland, BC. The work was completed using HQ, NQ and BTW equipment on five heli-portable Discovery II drills and one heli-portable Prospector drill. A total of 26,675.84 m of diamond drilling was completed in 89 holes. Each drill was set up on a platform of 8" x 8" timbers covered with 2" x 8" planks, which was constructed on a site prepared by hand.

Drill collar locations are plotted on Figures 9 to 14 and key data for the holes is listed in Table III. Appendix II contains Figures 15 to 65, which illustrate cross-sections showing the 2011 drill holes. Significantly mineralized intervals are listed in Table IV. Geological and sample logs are given in Appendix III, sampling and analytical procedures are provided in Appendix IV, QA/QC results are summarized in Appendix V and certificates of analysis are shown in Appendix VI.

RESULTS

In general, gold mineralization is hosted in relatively thick, variably folded packages defined as the Osiris and Isis Horizons and the interlayered limestone and siliciclastic Conrad Package. All of these units occur adjacent to fault zones. Mineralization in the Osiris and Isis Horizon is distinguished by highly variable quantities of the arsenic sulphide minerals orpiment and realgar, with lesser amounts of sooty fine-grained pyrite. Alteration consists of distal calcite flooding of the limestone with proximal decalcification.

The Osiris Horizon is between 100 and 200 m thick and is composed of interlayers of silty and muddy-limestone with individual debrite packages up to 45 m thick. Debrite textures within the horizon range widely with boulder to gravel sized, sub angular to sub rounded clasts that are matrix to clast supported. Decalcification is variable and is directly related to mineralization, with the more strongly decalcified limestone hosting better mineralization. Of the 37 holes that tested the Osiris Horizon, 23 intersected significant gold mineralization with OS-11-088 having

the highest grade (11.15 g/t gold over 6.27 m) and OS-11-084 having the thickest interval of mineralization (4.41 g/t gold over 44.20 m).

The Isis Horizon is thought to be a structural repeat of the Osiris Horizon and was the subject of six drill holes in 2011. The holes were drilled following up on a 450 m long gold in soil geochemical anomaly defined as the Isis East zone. The holes intersected a stratigraphically equivalent sequence of mudstones and silty-limestones containing variable debrite textures. Mineralization is hosted in decalcified limestone, similar to the Osiris Horizon, with associated realgar mineralization. Of the six holes drilled, OS-11-073 contained both the longest (3.13 g/t Au over 51.82 m) and highest grading (12.51 g/t Au over 10.76 m) intervals.

The Conrad Zone occurs at the contact of an undifferentiated but extensive mudstone package that is juxtaposed against a limestone and siliciclastic package. The Nadaleen Fault defines this contact and is a zone up to 50 m wide. It is characterized by protolith dependent brittle and brittle-ductile strain textures. In areas of very high brittle strain, rocks have been reduced to complete rubble. Mineralization is structurally controlled within dissolution seams occurring in strain zones thought to be related to the Nadaleen Fault. While the limestone package is the most significant host for the mineralization, gold also occurs in the siliciclastic package where strain textures are present. Intermediate intrusive dykes and sills, ranging from 15 cm to over 7 m thick, parallel the strike of the Nadaleen Fault. These intrusive intervals are variably mineralized and show evidence of significant sericite alteration. Of the 29 holes drilled at the Conrad Zone in 2011, OS-11-010 had the longest (3.15 g/t Au over 114.9 m) while OS-11-014 had the highest grade (20.55 g/t Au over 6.09 m) intervals.

The Amon Zone also occurs along the Nadaleen Fault, three kilometres to the west of the Conrad Zone. Amon is situated to the northeast of a 100 m by 30 m kill zone where a silt sample collected in 2009 returned 15.5% Arsenic (Eaton, 2010). Eight holes were drilled in the Amon Zone. They intersected a thick dolostone package that showed complex multiphase calcite and dolomite veining. Realgar and orpiment are abundant, occurring in veins and veinlets overprinting earlier phases of veining. Significant arsenic sulphide mineralization was also related to the Nadaleen Fault. The highest gold grade encountered was 0.83 g/t Au over 1.52 m in OS-11-034.

One geologic hole was drilled to test the thickness of the mudstone unit north of the Nadaleen Fault along the northwest trend of the Conrad Zone arsenic anomaly in what is referred to as the Ptah Zone. The hole never transitioned out of mudstone.

A soil geochemical pathfinder anomaly at the Dale Zone, which occurs 10 km west of Osiris, was tested by two holes. DL-11-001 encountered a pale greenish grey, variably oxidized siltstone unit underlain by variably solution collapse brecciated dolostone. DL-11-002 intersected a pale green mudstone on top of a thinly bedded limestone unit showing intraclast rudstones, characteristic of the Osiris carbonate package. Both holes intersected trace visible realgar, but neither were significantly mineralized.

The Pyramid Zone another soil geochemical pathfinder anomaly, is located 10 km to the northwest of the Dale Zone. Five holes were drilled after massive orpiment boulders and realgar

cobbles were found in soil. The drilling was hindered by rubbly and gougy conditions that the drill could not penetrate. Many of the holes were abandoned short of the projected target. PY-11-004 was the only hole to intersect significant realgar and orpiment mineralization; unfortunately this hole failed to reach its target depth.

GEOPHYSICAL SURVEY

In July 2011 a combined airborne magnetic and radiometric geophysical survey was flown over the Pyramid target with the intention of gaining further understanding on the distribution of structures and lithologies occurring below glacial cover. Geochemical anomalies at the Pyramid target are widely dispersed by secondary mechanical processes. Geophysical surveys were used in hope of vectoring towards the source structures associated with the mineralized soil anomaly. Collection, processing and interpretation of the magnetic and radiometric data was carried out by Precision GeoSurveys Inc. A copy of Precision GeoSurveys report can be found in Appendix VII.

Results from the magnetic survey illustrate broad, curvilinear lineaments trending east-southeast. The distribution and trend of subsurface features defined by unique magnetic signatures coincide with the general trend of lithologies and structures in the area depicted by surface mapping. Total magnetic intensity and calculated vertical gradient both illustrate east-southeast trending features; total magnetic intensity appears to be more useful in defining the distribution of lithologic units while the calculated vertical gradient appears to characterize lineaments likely representative of structures.

DISCUSSION AND CONCLUSIONS

The Nadaleen Trend project lies at the boundary between Mackenzie Platform and Selwyn Basin, within geomorphological and geological settings that resemble those at the Carlin gold deposits in Nevada.

In 2010, soil sampling and prospecting at the Nadaleen Trend project identified the possible sources of the very high gold and arsenic values collected from silt samples in 2009. In addition, four mineralized showings were identified, and through drilling in 2010 and 2011 all were proven to contain moderate to significant gold mineralization.

Drill results from the Nadaleen Trend project warrant additional work to better assess the character and extent of the currently identified geochemical anomalies and mineralized showings, as well as to search for additional areas of economic interest. Soil sampling has proven to be a very effective technique at the Nadaleen Trend project and therefore an extensive soil sampling survey is recommended over a broader area. The survey should consist of closely

spaced contour and grid soil sampling, prospecting and detailed geological mapping to extend coverage beyond the 2011 work area. To accomplish this, widely spaced contour and grid soil sampling and prospecting should be completed, combined with stream sediment sampling and prospecting on creeks that have not been sampled to date.

Detailed mapping should be conducted around all geochemical anomalies. If mineralized showings are found, they should be extensively drill tested to define the source and extent of mineralization at depth. Fonseca (1998) stresses the importance of recognizing folds, faults and favourable carbonate strata, since they are the principal controls over the location of mineralization in gold-rich, carbonate-hosted replacement deposits. As such, particular emphasis should be placed on identifying these features.

An east-west trending arsenic sulphide bearing structure intersected during drilling (PY-11-01 and PY-11-04) is visible in the calculated vertical gradient grid data as a transitional lineament occurring between areas of high and low vertical magnetic gradient. Disruption of this structure towards the eastern end of the grid may be caused by a north trending cross structure inferred from surface mapping. This structural intersection should be considered a high priority target for future drilling. Results from the radiometric data appear to be spurious and fail to indicate any meaningful data regarding the distribution of subsurface material.

APPENDIX I

STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

I, Julia Lane, geologist, with business addresses in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in Vancouver, British Columbia, hereby certify that:

1. I graduated from the University of British Columbia in 2008 with a B.Sc. in Earth and Ocean Science.

2. From 2006 to present, I have been actively engaged in mineral exploration in Yukon Territory, British Columbia and Ontario.

3. I am a Geoscientist in Training (GIT) with the Association of Professional Engineers and Geoscientists of British Columbia (Member Number 157127).

4. I have personally participated in the fieldwork reported herein and have interpreted all data resulting from this work.

Julia Lane, B.Sc., GIT

STATEMENT OF QUALIFICATIONS

I, Joan Carne, geologist, with business addresses in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in Burnaby, British Columbia, hereby certify that:

1. I graduated from Middlebury College, Vermont, USA in 1974 with a B.A. in Geology and Mathematics.

2. I graduated from the University of British Columbia in 1979 with a M.Sc. in Geology.

3. From 1977-1984, I was actively engaged in mineral exploration in Washington and Alaska, USA, Yukon Territory and British Columbia.

4. From 2011 to present, I have been actively engaged in mineral exploration in Yukon Territory.

5. I have personally participated in the fieldwork reported herein and have interpreted all data resulting from this work.

0.00	72.80	72.80	MST	VF	Pale green, bedded, terrigenous mudstone. Bedding is defined by dominant pale green layers interbedded with minor, dark grey siliciclastic layers composed of fine grained quartzose sand. Structural influence is evident toward the end of the interval and coincides with the appearance of trace realgar on fracture faces.

72.80	117.45	44.65	LST	--	Variably decarbonitized transition zone between upper pale green mudstones and lower buff grey limestone. Various breccias; some tectonically derived and some that appear debritic in origin are present. Bedded mud material is also displayed variably throughout and consists of interbedded carbonate and terrigenous mud. Decarbonitization and associated realgar mineralization is abundant and present within tectonically influenced breccias, as well as bedded mud. Breccia matricies appear susceptible to decarbonitization. Stratabound alteration and mineralization is displayed where presumably a carbonate mud layer was present in between two terrigenous mud layers. Some of the altered, bedded material is heavily folded, highly porous and sandy in competency.

117.45	327.66	210.21	LST	--	Limestone interval containing bedded lime mud as well as floatstone and rudstone debrites. Lime mud consists of pale, buff grey, highly calcareous layers interbedded with minor, dark grey, carbonaceous layers. Bedding parallel diagenetic stylolites occur throughout. Debrites occur as intraclast rudstones and floatstones containing tabular to equant lime mud clasts that appear to have been derived from bedding planes. Contacts between debrites and mudstones generally appear conformable and often show evidence of soft sediment deformation. Material within this interval appears to representative of Pinguicula B stratigraphy and is texturally similar to Pinguicula B identified at Osiris.

1.22	73.85	72.63	MST	VF	Very fine grained mudstone containing decimeter scale intervals with more limey layers (mm - cm thick layers). Unit also contains several cm thick, more massive, sandy sections with a mm scale, aligned dark grey component (may be siltstone fragments). Limey layers are fine to medium grained and some contain cross bedding or convoluted bedding. The top 20 meters of the unit contain packages of polymictic, matrix supported conglomerate. Conglomerate packages are 10s of centimeters thick and contain angular clasts that range from a few mm to a few cm in diameter. These conglomerate units are interpreted to represent debrites.

73.85	132.00	58.15	FLR	CG	Heterogeneous clastic unit containing decimeter to several meter thick sections of pyrite bearing siltstone, conglomerate, limestone/limey mudstone, and terrigenous siliciclastic (sandstone). Some sections contain relict bedding fragments. They are generally hard and may fizz when scratched, indicating that they are dolomitic, silicic, or some combination of the two. Sub-parallel, mm scale dolomite veinlets typically form within these fragments, and are generally perpendicular to the interpreted bedding surface orientation (elongate axis of fragment). Strain fabrics are present in both the top and bottom of the interval. Realgar mineralization occur in the bottom 21 meters of the interval, particularly in areas with a moderately well developed strain fabric. Realgar can occur parallel to the strain fabric or in veinlets that crosscut the strain fabric. In some veinlets realgar occurs in association with calcite +/- quartz.

133.45	298.05	164.60	LST	MG	Medium to dark grey, fine to coarse grained limestone. In places that contain bedding, dark, softer, fine grained layers comprise up to 50% of the unit. These layers are dark grey to black, soft, and variably calcareous (organic-rich shale?). Carbonate layers range from fine grained to coarse grained and can contain mm scale, light grey clasts, cone-in-cone calcite, and beef calcite. All primary calcite in this unit appears recrystallized. Dark, clay-rich sections can form parallel to bedding or at an angle to bedding. These are variably interpreted to be shear bands or stylolites depending on their thickness and morphology. In places, soft black material (weakly calcareous) forms the matrix in a breccia containing tabular, grey calcareous clasts, soft black clasts, and angular coarse grained calcite (vein fragments). These textures indicate this unit has accommodated strain. Bedding in the unit is undulatory, and can change orientations within a single piece of core (folding). In places, seams of clay-rich material truncate bedding, and are interpreted to represent stylolites and/or shear fractures. Unit is variably brecciated & contains mosaic breccia & stockwork vein networks. Calcite veinlets and veins are most well defined in more competent limestone layers. In the upper part of the section, zones of decarbonitization are closely associated with intense brecciation and calcite veining (flooding).

This unit contains: 1) 10's of cm thick sections of fine grained mudstone to siltstone (45%) that is finely laminated, and in places folded, 2) cm to 30 cm thick sections of clastic matrix supported granule to pebble conglomerate (20%)containing < 10 % rounded to subrounded silicic clasts (chert to SST), and 3) up to 1.5 m sections of strained material (30%) containing angular/irregularly shaped silicic/dolomitic fragments(relict bedding?) up to several cm across. In lower part of section, clasts contain 1 - 3 mm thick dolomite veins. Lower section contains cherty/silicic beds (can fizz slightly when scratched, and may suggest a slight carbonate component). Pyrite is extensive (1-2%?). Upper part of unit is more strained than lower part of unit.

67.45	121.62	54.17	LST	FG	Medium grey, fine to medium grained limestone. Unit is well bedded locally, beds exist up to 6cm. Some coarser grained sandy beds appear to show gradation. Styolites are persistent throughout the unit, often found parallel to bedding. Beef calcite is also present locally, parallel to bedding. Minor shear zones are found frequently through the unit, often containing up to 5% realgar as well as clay alteration and DCA. Shears contain many lithic fragments which are often decalcified. Erratic calcite veinlets frequently cut the unit, up to 20% veins locally.

212.57	280.42	67.85	SLC	FG	Dark grey/black, fine to medium grained conglomerate with interbeds of fine grained siltstone. The conglomerate beds are generally matrix supported but can also be clast supported in few beds. Clast composition varies from quartz-rich fragments to cannibalized fragments of bedded siltstone. Numerous other unidentified fragments also exist. Clasts are subrounded to rounded with few being angular. Siltstone beds are generally fine grained with beds up to 2-3cm. Often there is graphite present along fracture surfaces. Small apparent shear/fracture zones exist within the unit, often with realgar, locally up to 20%. Few cross-cutting calcite veins exist within the unit.

1.20	35.05	33.85	MST	VF	Moderately competent, light to medium grey, variably oxidized mudstone with minor areas of limey bedding. Oxidization mainly found on fracture surfaces and as a halo around both dolomite and calcite veins/veinlets. Calcite and dolomite veins/veinlets are pervasive through unit, being found as either whole veins or vein fragments, both appear to be cross cut by calcite. Calcite lenses are found ranging between 1-2cm throughout mudstone. 10-30cm zones of more heavily oxidized mudstone, appearing as rubble and slightly more calcareous (calcite on fracture surfaces), as well as showing a dark brownish colour (limonite or goethite?). Many vuggy thicker (1cm) calcite veins. No mineralization. Oxidization appears to be offset by hairline fractures.

Limestone is angular, variable sized fragments occur in the fault zone around 40m.

Unit is mostly competent with pockets of highly fractured/clay/gouge sections. 10.67	34.90	24.23	MST	VF	Mudstone begins as highly oxidized and appears light grey-blue in appearance but turns medium grey and highly foliated and strained as unit deepens. Strain is evident due to undulating/ broken/ ductile calcite and dolomite veinlets and sections of mudstone folitation. Pyrite mineralization replaces random clasts/ fragements of dolomite (?) as well is weakly disseminated in the mudstone matrix and bedding.

APPENDIX IV

SAMPLING AND ANALYTICAL PROCEDURES

2011 Core Geochemical Samples

Core was transported by helicopter from the drill sites to a logging area on the property where recovery was measured and geological and geotechnical logging was performed. Geologically and mineralogically favorable intervals from each hole were split in half using a diamond bladed core saw with one half sent for analysis and the other returned to the core box. All core is stored on the property.

Core samples were double bagged in plastic sample bags, grouped into batches of 36 and placed into rice bags for transport. Batches were flown out by helicopter to either the Rackla or Stewart airstrip then flown by fixed wing aircraft to Mayo. From Mayo the samples were transported by truck to Whitehorse escorted by a representative from Archer Cathro. The samples were submitted ALS in Whitehorse or further trucked to the Vancouver lab for preparation.

Core samples were dried and crushed to 70% minus 2 mm before a 250 g split was taken and pulverized to better than 85% minus 75 microns. To reduce contamination, equipment was twice washed with silica sand between samples. Splits of the pulverized fractions were routinely dissolved in four-acid "near-total" digestion and analyzed for 49 elements using the ME-MS61m method which includes combined inductively coupled plasma (ICP) with mass spectroscopy (MS) and atomic adsorption spectroscopy (AAS). Mercury was analyzed for using HG-CV41 methods by aqua regia digestion and atomic adsorption spectroscopy. Samples were analyzed for gold by fire assay finished with AAS (Au-AA26). Certificates of Analysis are found in Appendix VI.

APPENDIX V

QA/QC RESULTS

2011 QA/QC Results

During the field season, core samples were divided into batches, each containing 31 core samples, 2 blanks, 2 standards and 1 duplicate. A total of 614 blanks, 602 standards and 306 duplicates were inserted into the sample sequences. Blank samples each comprise 7 kg of landscaping marble obtained from a garden centre in Whitehorse. Samples of this material were randomly selected and analyzed prior to the field season define the baseline geochemical signature.

Four standards were chosen from CDN Resource Laboratories Ltd. prepared from matrix compatible material. Certificates for each of the standard samples occur in the following pages, while Table V summarizes the consensus and two standard deviation values for each of the standard samples used during the program.

Table V: Standard Sample Parameters

Sample	Consensus Value	2δ
NT-1	0.338 g/t Au	0.022
NT-2	2.59 g/t Au	0.18
NT-3	7.76 g/t Au	0.42
NT-4	15.98 g/t Au	0.71

Gold values from all blank samples were within acceptable range. Of the 283 batches analyzed in 2011, 21 contained standards that were out of acceptable range. All of these batches were reanalyzed by the laboratory to ensure results were accurate. Results from the reanalysis were typically showed little change in the values of non-standard values. A total of 306 duplicate samples, prepared from quarter core, were collected and analyzed throughout the program. In general there was little variation between the initial and duplicate samples.

CERTIFIED BY: Duncan Sanderson, B.Sc., Licensed Assayer of British Columbia
INDEPENDENT GEOCHEMIST: Dr. Barry Smee., Ph.D., P. Geo.
DATE OF CERTIFICATION: March 10, 2010

ORIGIN OF REFERENCE MATERIAL:

Standard CDN-GS-3G was prepared using ore supplied by Barrick Gold Inc. from their Goldstrike Mine in Nevada, USA. It is Carlin Style Mineralization in the prolific Northern Carlin Trend in Northern Nevada, USA. The source material is from Devonian carbonates of the Popovich Formation. Gold is strongly associated with pyrite and other sulfides including the arsenic minerals orpiment and realgar.

METHOD OF PREPARATION:

Reject ore material was dried, crushed, pulverized and then passed through a 270 mesh screen. The +270 material was discarded. The -270 material was mixed for 5 days in a double-cone blender. Splits were taken and sent to 15 commercial laboratories for round robin assaying. Round robin results are displayed below:

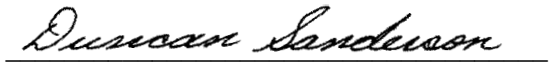
Statistical Procedures:



The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. Data from any one laboratory was removed from further calculations when the mean of all analyses from that laboratory failed a t test of the global means of the other laboratories. The mean and standard deviation were calculated using all remaining data. Any analysis that fell outside of the mean ±2 standard deviations was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data. This method is different from that used by Government agencies in that the actual "between-laboratory" standard deviation is used in the calculations. This produces upper and lower limits that reflect actual individual analyses rather than a grouped set of analyses. The limits can therefore be used to monitor accuracy from individual analyses, unlike the Confidence Limits published on other standards.

ORIGIN OF REFERENCE MATERIAL:

Standard CDN-GS-P3A was prepared using ore supplied by Barrick Gold Inc. from their Bald Mountain Mine in Nevada, USA. It is Carlin Style Mineralization in the prolific Battle Mountain-Eureka Trend in Northern Nevada, USA. The material is from breccias near the contact between the Mississippian Pilot Shale and the underlying Devonian Guilmette formation. Near the center of the system, micron-sized native Au occurs with base metal sulfides and sulfosalts. In peripheral deposits and in later stages of mineralization, Au is typically submicron in size and resides in pyrite or arsenopyrite.

METHOD OF PREPARATION:

Reject ore material was dried, crushed, pulverized and then passed through a 270 mesh screen. The +270 material was discarded. The -270 material was mixed for 5 days in a double-cone blender. Splits were taken and sent to 14 commercial laboratories for round robin assaying. Round robin results are displayed below:

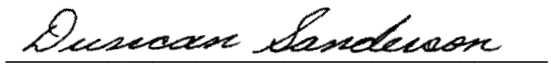
Statistical Procedures:



The final limits were calculated after first determining if all data was compatible within a spread normally expected for similar analytical methods done by reputable laboratories. Data from any one laboratory was removed from further calculations when the mean of all analyses from that laboratory failed a t test of the global means of the other laboratories. The mean and standard deviation were calculated using all remaining data. Any analysis that fell outside of the mean ±2 standard deviations was removed from the ensuing data base. The mean and standard deviations were again calculated using the remaining data. This method is different from that used by Government agencies in that the actual "between-laboratory" standard deviation is used in the calculations. This produces upper and lower limits that reflect actual individual analyses rather than a grouped set of analyses. The limits can therefore be used to monitor accuracy from individual analyses, unlike the Confidence Limits published on other standards.
