INTRODUCTION

The Rackla Gold property comprises a 1600 km^2 area of highly prospective platform to basin facies sedimentary host rocks located along the northern edge of the Tintina Gold Belt at the transition from the Selwyn Basin to the Mackenzie Platform, in east central Yukon Territory. Various commodities have been explored for and discovered within the 8,117 contiguous claims that make up the property. Historically, this exploration focused on base metal mineralization, while recently the emphasis has been directed towards the gold potential. The property is owned 100% by ATAC Resources Ltd.

This report describes the methods and results of an extensive regional exploration program conducted throughout the property from May 24th to October 10th 2011. All geochemical sampling and geologic mapping was conducted by Archer, Cathro & Associated (1981) Limited on behalf of ATAC. The authors participated in and supervised the geochemical sampling and mapping programs as well as collecting ground control points used in georeferencing remote imagery. The geochemical sampling program resulted in the collection of 13,144 soil samples, 1,772 silt samples and 180 rock samples. Remote sensing data that was collected over the course of the season includes property wide, orthorectified satellite imagery, high resolution contours and aerial photos in areas of interest. The authors' statement of qualifications appears in Appendix I.

PROPERTY LOCATION, CLAIM DATA, ACCESS AND INFRASTRUTURE

The Rackla Gold property consists of 8,117 contiguous mineral claims located at a latitude of 64°11´N and longitude stretching from 135°27´W to 131°54´W on NTS map sheets 105M/14, 15, 106C/01, 02, 03, 04, 05, 06, 106D/01, 02, 03, 06, 07, 08 & 106B/04 (Figure 1). The claims are all registered with the Mayo Mining Recorder in the name of Archer Cathro, which holds them in trust for ATAC. Specifics concerning claim registration are tabulated below in Table I while the locations of individual claims are shown on Figures 1-3.

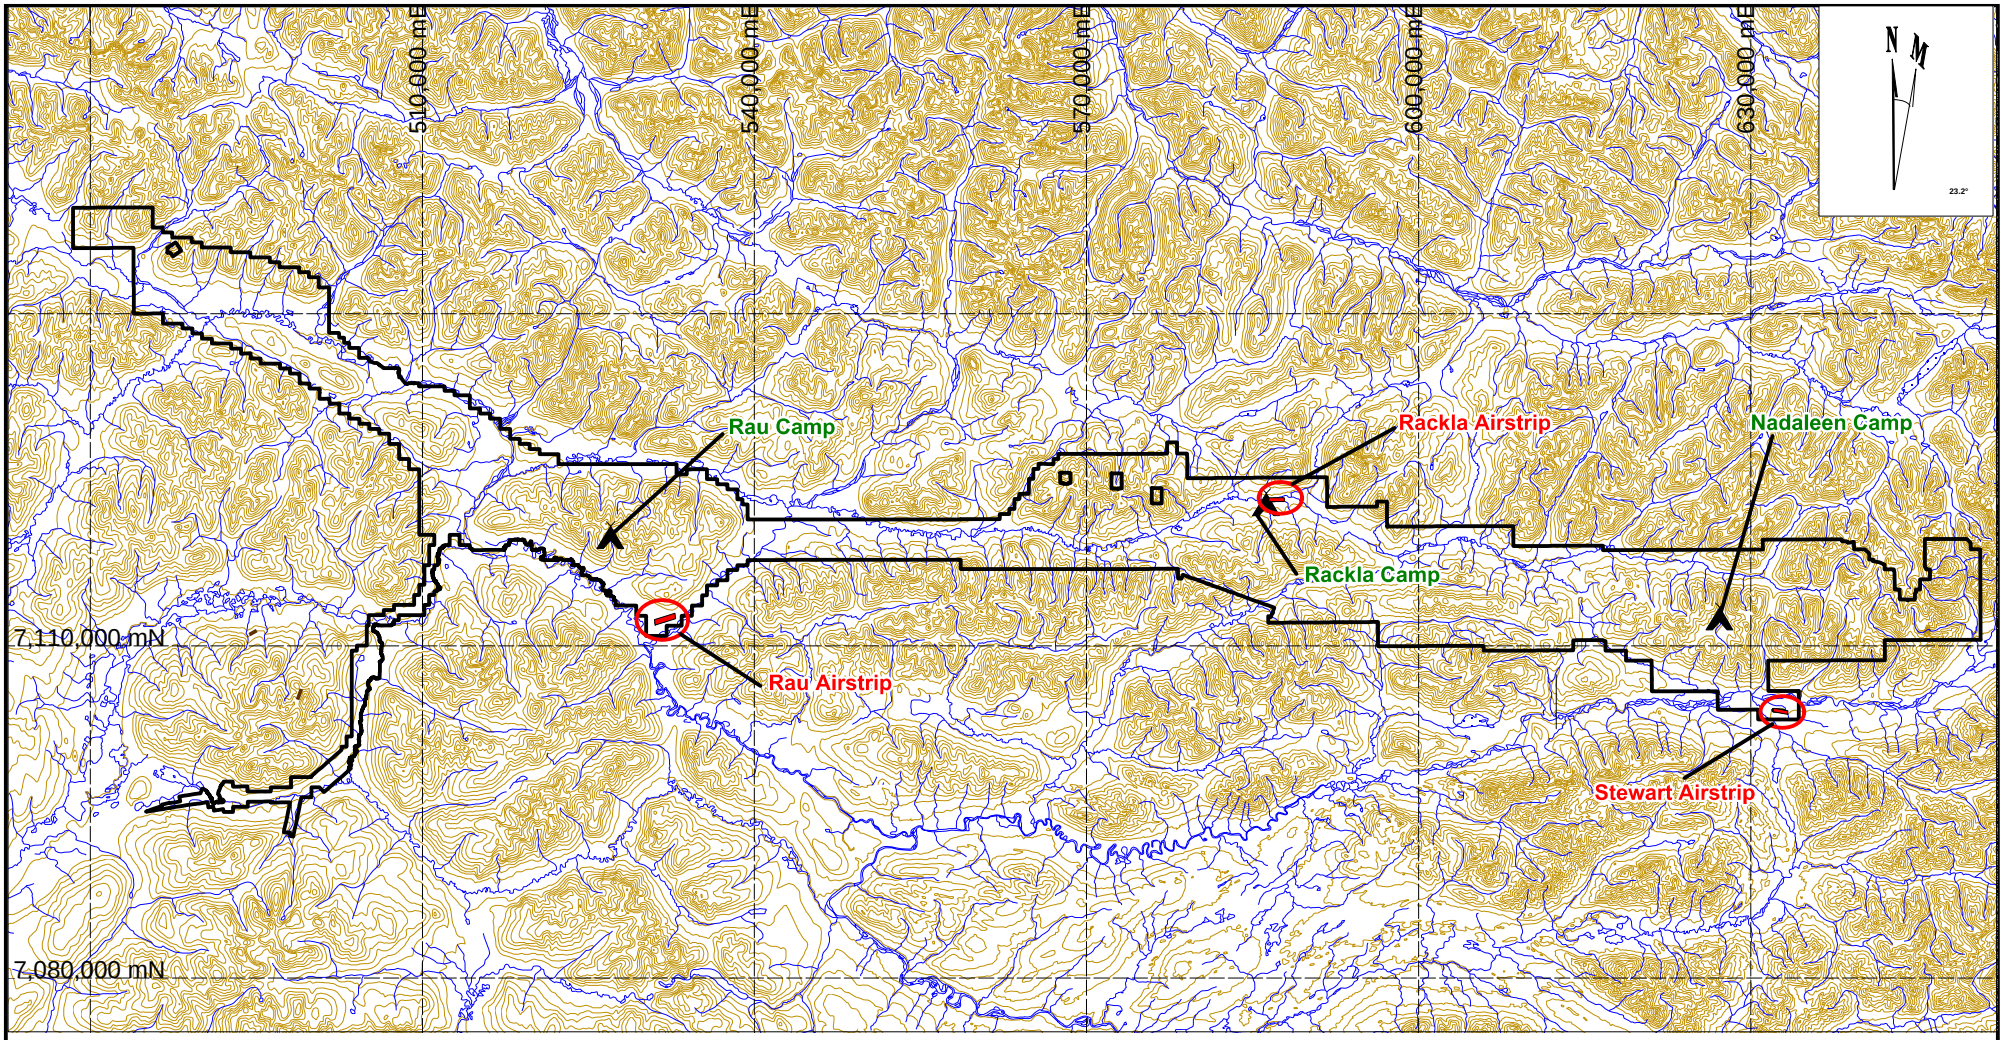
* Expiry dates include 2011 work which has been filed for assessment credit but not yet accepted.

The property lies 100 km northeast of Mayo, the nearest supply centre. The closest road access is to the community of Keno City, situated about 49 km by road northeast of Mayo and 55 km by air southwest of the property. Mayo and Keno City can be reached in all seasons by two wheel drive vehicles using the Yukon highway system. The Wind River trail is also accessible via the Yukon highway system from McQuesten Lake near Keno City and crosses the western portion of the property. This winter trail has been used intermittently by various exploration companies since it was built in the late 1960s.



In 2011 the construction of two new airstrips, one in the eastern and the other on the western portion of the property, facilitated transportation to and from the camps where the regional work was based out of. The locations of these airstrips relative to the claim block can be viewed in Figure 4. Prior to the 2011 construction of the Rau Airstrip (900 m long) and Stewart Airstrip (600 m long), shuttling of supplies and personnel into the Rackla Gold Property was done using fixed wing aircraft, to the pre-existing Rackla Airstrip.

Daily transportation of employees to and from work sites was facilitated by a combination of four helicopters stationed at various camps around the property. Throughout the exploration season Fireweed Helicopters Ltd. supplied a combination of Eurocopter AS350 SD2, Hughes 500D and MD 520 N helicopters as well as a Bell 206L4. In addition Horizon Helicopters provided a Eurocopter AS350 SD2. The Eurocopter AS350 SD2 as well as Hughes 500D and MD 520 N models provided support to samplers and geologists working on the regional program out of Nadaleen camp as well as Rackla camp throughout the season. The Bell 206L4 provided transport to and from work areas for geologists and samplers working on the regional program from the Rau camp at the west end of the property.

HISTORY AND PREVIOUS WORK

WEST END

The earliest reported exploration within the area of the Rackla Gold property occurred in 1922 following the discovery of silver mineralization at Keno Hill; prospectors first identified and staked mineralized float occurrences at Carpenter Ridge in the far northwest corner of the current property. In 1924, reconnaissance work conducted by the Geological Survey of Canada

discovered galena-calcite-siderite in float on the southwest end of Carpenter Ridge. A sample of this float returned 8.75 oz silver and 56.0% lead (Cockfield, 1925); however, the source of this mineralization was not found. Hand pits were dug in 1927 and 1928 but little record remains of the work completed during this period. All claims were ultimately dropped.

Nearby at Grey Copper Hill, 9 km to the southeast, silver-rich tetrahedrite float was discovered in 1923 by an independent prospector. This showing and other nearby prospects were staked later that year. Several investigatory adits were dug into the hillside during follow up exploration but eventually all claim holdings lapsed.

Between 1930 and 1974 Grey Copper Hill was staked several times by independent prospectors and exploration companies, including Cypress Resources Limited and United Keno Hill Mines Limited. Little work was reported (Hilker, 1969) and all claims ultimately expired.

Hesca Resources Corporation Ltd restaked Grey Copper Hill in 1974 and conducted prospecting, soil sampling, hand trenching and adit maintenance. In addition, two shallow, small diameter diamond drill holes totalling 56.3 m were drilled; however, the results from this drilling are not documented. No further work was done by Hesca and the claims were dropped (Deklerk and Traynor, 2004).

In spring 1978 Prism Resources Limited restaked the area and conducted prospecting and geochemical sampling later that year. Soil sampling identified several lead and silver anomalies; however, follow up prospecting failed to explain them (Sivertz, 1979). A sample collected from an outcrop of dolomite yielded 0.60% lead and 51.43 g/t silver, while a tetrahedrite sample collected near an old adit assayed 7000 g/t silver (Sivertz, 1980). Prism allowed the claims to lapse.

Grey Copper Hill was again restaked in 1983 by a prospector who conducted grid soil sampling later that year. This program delineated silver anomalies coincident with surface lineations. No further work was completed and the claims expired.

In 1988 Bonventures Limited staked the area and conducted limited blast trenching, prospecting, mapping plus soil and rock sampling. A gossan zone with pyrite and strong fracture filling malachite and azurite was identified between two collapsed adits (Carlyle, 1989). These claims eventually lapsed.

The area remained open until August of 2005 when an independent prospector staked four claims over the Grey Copper Hill showing. No work on these claims has been reported and they are now surrounded by the Rackla Gold property.

Approximately 45 km to the southeast, Cominco Limited staked the Beaver claims in 1968 based on results of regional geochemical sampling done the year before. Later that year, L. Elliott staked the nearby Now claims and optioned them to Cominco, which completed mapping and soil sampling in 1968 and 1969 (Johnson and Richardson, 1969a and b).

In 1977, Prism Joint Venture (Asamera Oil Corp, Chieftain Development Company Limited, Prism Resources Ltd, Siebens Oil & Gas Limited and E & B Exploration Limited) restaked Cominco's claims as part of a larger block that extended for about 20 km along the north side of the Beaver River. In 1979, Dome Petroleum Ltd replaced Siebens in the joint venture.

Prism conducted most of its activities around the original Beaver claims. Soil sampling and mapping were performed in 1977 (Montgomery and Dewonck, 1978) and additional soil sampling and trenching were done in 1978 (Prism Joint Venture, 1979a). In 1979 Prism completed six diamond drill holes totalling 610 m (Dewonck, 1980). This work focused primarily on sedimentary exhalite and Mississippi Valley type lead-zinc mineralization, but resulted in the discovery of a narrow gold-rich vein material (the Now Showing).

NDU Resources Ltd. staked claims over the Now Showing in 1987 to cover the lead, zinc and silver soil geochemical anomalies identified by Cominco and Prism. The following year, NDU conducted a geochemical sampling program which focused on the gold vein mineralization at the Now Showing (Cathro, 1989).

In 1977, 6.25 km further to the northwest, Prism conducted mapping, soil sampling and electromagnetic surveys. Numerous samples from that program returned high zinc-in-soil values ranging from 2100 ppm to 12.2%. One sample collected from a large transported gossan (Ocelot Showing) yielded 3.8 g/t silver, 800 ppm lead and 12.2% zinc (Montgomery and Cavey, 1978), suggesting the metals were leached and remobilized in acidic groundwater before being reprecipitated when the fluids were neutralized. These promising results were not followed up. In 1977, Prism also performed minor soil sampling near a strong gossan developed along the eastern edge of the current Rau property (Kathy Showing) (Prism Joint Venture, 1979b).

In 1979 and 1980, Prism explored in two areas approximately 16 km southeast of the current Ocelot Showing and conducted prospecting, soil geochemical sampling and one diamond drill hole. This work led to the discovery of scheelite mineralization at the Blue Lite and Flat Top Showings. Well mineralized tremolite skarn specimens from the Flat Top Showing assayed up to 8.4% WO_3, but most material graded below 0.04% (Churchill, 1980). No further work was done at either showing.

ATAC's interest in the area was prompted by an isolated, high gold value (150 ppb) reported by a regional-scale stream sediment geochemical survey, conducted by the Geological Survey of Canada (Hornbrook, et al 1990). This value is in the 99^{th} percentile of gold results from the survey and is supported by a 99^{th} percentile tungsten value (25 ppm). The sample was collected near the Rackla Pluton, east of the Tiger Zone.

In summer 2006, ATAC staked 64 claims to cover the anomalous drainage. During the staking, a number of rock and soil samples were collected, many of which returned anomalous values for tungsten and a few were notably enriched in gold, lead, zinc, silver and copper. Cursory prospecting relocated scheelite-bearing tremolite skarn (Flat Top Showing) and discovered tungsten in diopside-actinolite skarn and highly fractionated intrusive rocks, about 1500 m to the south.

In 2007 ATAC completed geological mapping, prospecting, grid soil sampling and helicopter-borne variable time-domain electromagnetic (VTEM) surveys (Eaton and Panton, 2008). This work partially delineated a large hydrothermal system centered on the largely buried Rackla Pluton. Following that program, ATAC staked an additional 32 claims, mostly to improve coverage around a very strong gold-in-soil anomaly outlined on the western edge of the grid.

ATAC and Yankee Hat Minerals Limited signed an option agreement in spring 2008 concerning 40 claims that covered the Rackla Pluton and the tungsten-bearing skarns. During the summer of 2008 Yankee Hat conducted prospecting and a total of 437.38 m of diamond drilling in three holes (Dumala, 2008). Several narrow skarn bands with weak to moderate tungsten mineralization were identified within the carbonate host rocks. The option agreement was terminated in late 2008 following poor results and the claims were returned to ATAC.

Also in the summer of 2008, ATAC conducted geological mapping, prospecting, soil and stream sediment geochemical sampling, 3,423.21 m of diamond drilling in 18 holes and property-wide helicopter-borne magnetic variable time-domain electromagnetic (VTEM) surveys on the claims not covered by the Yankee Hat option agreement. Drilling identified three stacked, gold-bearing horizons in what is now known as the Tiger Zone (Dumala, 2009). The central horizon (Discovery Horizon) contains gold in iron carbonate replacement and hosts the most abundant mineralization. In 2008 grid soil sampling and stream sediment sampling was extended to the northwest. In response to positive results, ATAC added 1,340 claims to cover the favourable stratigraphy along the anomalous trend.

In 2009, ATAC continued to delineate the Tiger Zone with an additional 58 diamond drill holes totalling 9,578.30 m (Dumala and Lane, 2010). Drilling identified a significant oxide component to the northwest, within the Tiger Zone. Prospecting in 2009 also identified several new showings containing mineralization similar to that found at the Tiger Zone. These include the Cub, Lion, Jaguar, Panther, Cougar, Puma, Cheetah and Lynx Showings.

In 2010, ATAC continued definition drilling at the Tiger Zone resulting in the completion of a NI 43-101 compliant resource estimate of the sulphide and oxide horizons (Stroshein, et al 2011). Results of the resource estimate using a 0.3 g/t gold cut off yield an indicated resource estimate of 508,000 ounces of gold and an inferred resource estimate of 290,200 ounces of gold for the oxide and sulphide horizons combined.

Prospecting at the geochemically anomalous Ocelot Showing in 2010 resulted in the discovery of high grade Ag-Pb-Zn-In massive sulphide mineralization. Grab samples from this area included 2100 g/t Ag, 55.33% Pb and 62 g/t In (Dumala, 2011).

EAST END

The earliest recorded exploration on the eastern side of the Rackla Gold property occurred when McIntyre Mines staked the Birkeland claims, then called Tom and Mom in 1974 approximately 200 km east of Mayo. Mapping, geochemical soil sampling, trenching and 10 BQ and 22 Winkie holes were carried out in 1975. The best results were 4.4% Zinc, 0.5% Lead and 2.7 g/t Silver over 1.8 m in DDH75-31 (Shearer, 1975). In 1978 McIntyre Mines entered a joint venture

with Canadian Superior Exploration, Ltd. No further work was reported and the Birkeland claims expired.

In 1976 the Sian claims were staked approximately 37 km southwest of the Birkland claims by McIntyre Mines following prospecting of geological targets. Mapping, geochemical soil sampling and EM, mag and SP geophysical surveys were carried out in 1977. Gold was tested for in 4 grab samples; however, results did not exceed the detection limit for gold (Birkeland, 1978). After entering a joint venture with Canadian Superior Exploration, detailed mapping, trenching and sampling was completed in 1979. Results of this work found low grade Lead and Zinc throughout a folded dolomite unit. One diamond drill hole was completed in 1980 but did not intersect any mineralization. No further work was recommended and in 1982 the Sian property passed to Serem Ltd, after which the claims were voided and no further exploration was reported.

The Star claims, located approximately 12 km to the west of the Sian claims, were staked by private prospectors and optioned to Prism Resources, Ltd in 1976. Mapping and soil geochemical testing completed by Prism in 1977 had disappointing results and all claims were dropped. The Lee and Nod claims were staked to the south of the Leah claims in December of 1976 and were optioned to Tay River Mines. No work is on record for these claims and they were allowed to lapse.

McIntyre Mines staked the Jam property in 1977, 4.2 km north of its Sian property. Soil and silt sampling in conjunction with mapping later that year found a favorable dolomite breccia host rock with associated zinc and lead sulphide mineralization. No further work was reported and the Jam claims lapsed.

In 1976, the Black, Ida, Red and Eira claims, located approximately 8 km east of the Sian claims, were staked by the Ortell Syndicate (Precambrian Shield Resources Ltd, Giant Yellowknife Mines Ltd, Nemco Resources Ltd and Highwood Resources Ltd). In 1977, the Black and Ida claims were optioned by a joint venture between DeJour Mines Limited and Nova-Co Exploration Limited (Thompson, 1977). Mapping and geochemical sampling on the Ida claims later that year returned moderately anomalous zinc values, with erratic lead and silver support.

Also in 1977, prospecting and stream sediment sampling carried out on the Eira property by the Ortell Syndicate returned anomalous silver and zinc results, up to 2.4 ppm and 680 ppm respectively (Curry, 1977). This led to more detailed grid soil sampling and geological mapping. This work returned a number of moderate, non-coincident silver, zinc and lead anomalies.

In 2001, the Geological Survey of Canada completed a regional stream sediment sampling program (Heon, 2003), which included coverage of the current Sten claims, located 19 km west of the Birkland claims, in an area now referred to as the Nadaleen Trend. Creeks draining this area returned strong gold and arsenic anomalies.

ATAC's initial interest in the area was to follow up a strong arsenic silt anomaly collected by the Geological Survey of Canada in 2001. Over a three day period in 2009, 89 stream sediment, 1 rock and 9 soil samples were collected on the Sten claims. These samples returned a string of

moderately to very strongly anomalous results ranging from 12 to 1775 ppb gold and 123 to 155,000 ppm arsenic (Eaton, 2010). As a result, additional claims were staked by ATAC.

Follow-up prospecting of the anomalous creek in the summer of 2010 led to the discovery of in situ gold mineralization occurring within a folded, deformed carbonate horizon now referred to as the Osiris Zone. A follow up soil grid consisting of 50 m line spacing and 50 m sample spacing was conducted over this carbonate horizon. Results from the soil grid yielded four distinct gold anomalies known as Osiris, Conrad, Isis and Isis East.

Drilling in the fall of 2010 defined three gold bearing zones (Lane 2011). The Osiris Zone returned the most significant gold grades yielding 65.20 m of 4.65 g/t Au in OS-10-01. Five more holes were drilled within the Osiris Zone with all but one (OS-10-05) intersecting significant gold mineralization. The Conrad Zone, one kilometer to the east was drilled to target a gold bearing trench. Assay results from this hole included 8.03 g/t Au over 21.13 m in OS-10-08. A second hole drilled in the Conrad Zone intersected arsenic sulphide mineralization in a siliciclastic package (OS-10-09) with an average gold grade of 1.61 g/t over 39.76 m. Drilling in the Isis Zone one kilometer west of the Osiris Zone (OS-10-07) returned comparatively lower, albeit anomalous, gold grades averaging 0.92 g/t over 17.00 m.

GEOMORHOLOGY AND CLIMATE

The Rackla Gold Property stretches 185 km from east to west in the Selwyn and Werneke Mountains and is drained by creeks that flow into the Nadaleen, Rackla, Stewart and Beaver Rivers, all part of the Yukon River watershed. Local topography varies from low forested valleys to alpine areas and features east-west to northwest trending major valleys and ridges, north-south trending rocky spurs and valleys that flank a main east-west trending ridge. Elevations range from about 600 to 2000 m above sea level. Outcrop is most abundant near ridge crests and in actively eroding creek beds. Most hillsides are talus covered at slope breaks and are blanketed by glacial till at lower elevations. The region was glaciated in the Late Pleistocene, 22,000 years ago (Duk-Rodkin, A. 1999) with ice flow from east to west.

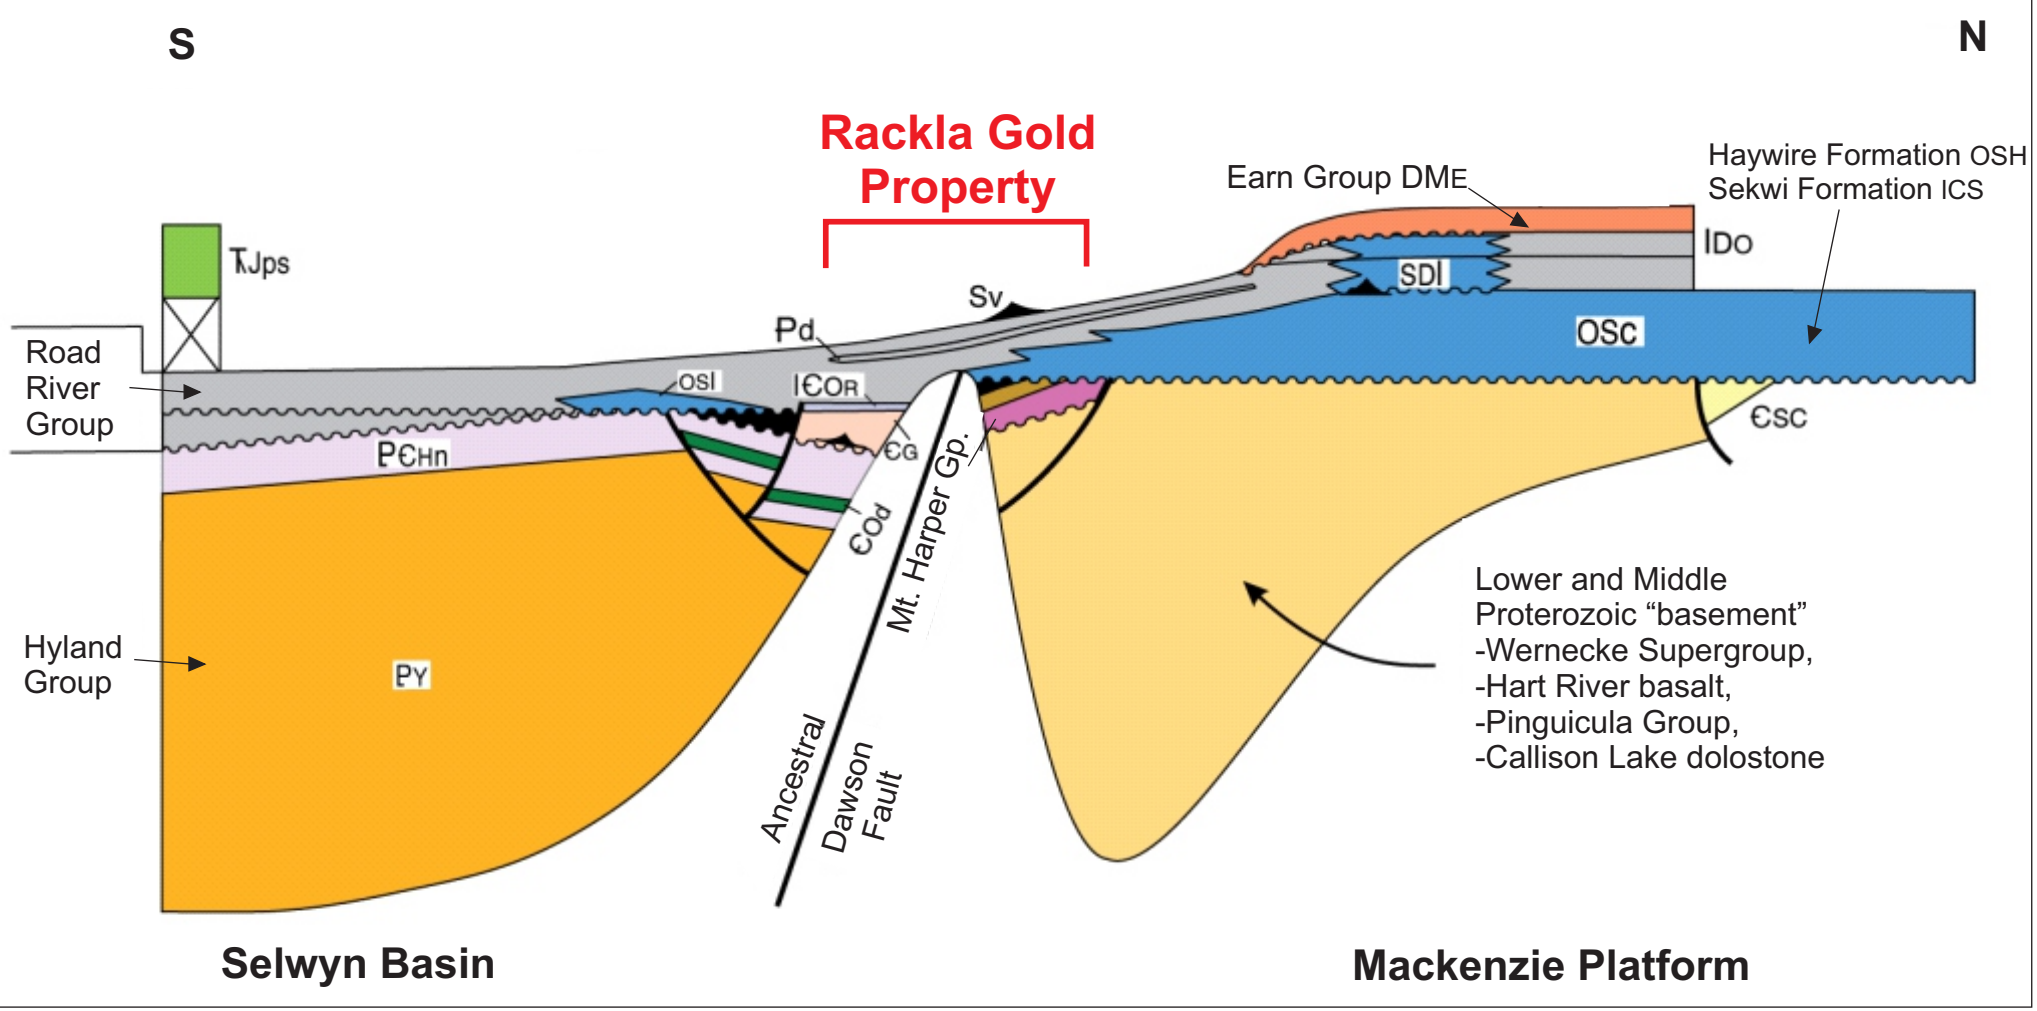
Treeline in the vicinity of the project is at about 1500 m. Slopes above that elevation, especially steep north facing slopes are unvegetated. Moderately steep, south facing slopes are well drained and are often lightly forested with poplar. The density and size of vegetation gradually increases on lower slopes, and the valley floors are well treed with mature black spruce. Understory vegetation typically consists of low shrubs and moss.

The climate in the Rackla Gold Project area is typical of northern continental regions with long, cold winters, truncated fall and spring seasons and short, mild summers. Although summers are relatively mild, arctic cold fronts often cover the area and snowfall can occur in any month. The property is mostly snow free from early June to late September.

PROPERTY GEOLOGY

The Geological Survey of Canada performed geological mapping in the vicinity of the Rackla Gold Property at 1:250,000 scale in the early 1970s (Blusson, 1974). In 1999, Gordey and

Makepeace completed a compilation of Yukon-wide geology and updated the lithological units named in the Rackla area. The Yukon Geological Survey completed mapping of 106C/03 and 106C/04 1:50,000 map sheets during 2010 and 2011 (Colpron, M., 2012, and Chakungal, J., Bennett, V., 2010.).



The Rackla Gold Property straddles the boundary between the deep water dominantly clastic rocks of the Selwyn Basin to the south and the shallower water shelf strata of the Mackenzie platform to the north. The Dawson Fault, which juxtaposes rocks of Selwyn Basin against rocks of the Mackenzie Platform, is a crustal break that may date back to late Neo Proterozoic rifting and was reactivated as a north directed thrust in the Cretaceous (Macdonald, Francis A. et al, 2010.). The tectonic setting of the Rackla Gold Property is shown as an inset in Figure 1, while regional relationships and the importance of the Dawson Fault system are presented in Figure 5.

Regional scale geologic mapping was conducted during the 2011 field season. The distribution of lithologies and regional scale structures determined during this mapping program (Chadwick, P., 2011) are shown on Figure 6 and the stratigraphic units, are described in Table II.

Table II – Lithological Units (after Gordey and Makepeace, 1999 and Turner, 2011)

Unit Name	Map Name	Terrane	Age	Description
Earn Group	DME		Devonian to Mississippian	Silvery-blue weathering black shale, argillite, cherty argillite and bedded chert; minor volcaniclastics and rare limestone.
Bouvette Formation-time correlative with Road River Group	ODR		Ordovician to Devonian	Thick sequences of massive to bedded, reefal, variably fossiliferous limestone and minor siltstone, siliceous argillite and chert. Calcareous to non-calcareous sedimentary gravity flows; graded, sorted chert pebble conglomerates, lithoclastic floatstones, lithic arenites. Well bedded, fossiliferous limestone, thin bedded silty limestone, black chert, light banded chert, siliceous siltstone and argillite.
Fault contacts				
Haywire Formation	OSH	Mackenzie Platform	Ordovician-Silurian	Medium to thick bedded, light grey to white dolostone, locally highly fossiliferous
Sekwi Formation	lCS	Mackenzie Platform	Lower Cambrian	Grey to bright orange weathering finely crystalline, massive to laminated dolostone; limestone, locally with stromatolite beds, white to purple bedded quartz sandstone, red mudstone, dark grey argillite, calcareous polymict conglomerate.
Fault contacts				
Hyland Group	PCH	Selwyn Basin	Upper Proterozoic to Lower Cambrian	Dominantly terrigenous clastics Distinctive, recessive, interbedded maroon and apple-green shale; locally interbeds of quartz siltstone, sandstone and quartz-pebble conglomerate. (Narchilla Fm) Grey weathering, dark grey to grey-white, thin to thick bedded, very fine crystalline limestone, locally sandy; calc-silicate and marble; carbonate debrites. (Limestone member of Yusezyu Fm=Algae Formation?) Thin to thick bedded, brown to pale green shale, fine to coarse grained quartz-rich sandstone, grit and quartz-pebble conglomerate “grits”; minor argillaceous limestone; phyllite, quartzofeldspathic and micaceous psammite, gritty psammite and minor marble.(Yusezyu Fm)

The following descriptions of lithologic units exposed on the Rackla Gold Property and tectonic interpretations are taken from the Rackla Regional Program: 2011 Geological and Geochemical Report by P.Chadwick (Chadwick, P., 2011). The oldest rocks exposed on the Rackla Gold Property are a sequence of distinctive rusty weathering green, maroon, grey, brown and tan siltstones, mudstone and minor coarser clastic rocks tentatively correlated with the early Mesoproterozoic **Wernecke Supergroup**. Local exposures of this sequence of rocks are fault-bounded and are exposed exclusively on the north side of the Nadaleen fault.

A laterally consistent, non-fossiliferous sequence of rocks observed across the eastern quarter of the property has been tentatively correlated with the Meso-Proterozoic (<1.3 Ga; >1.0 Ga) **Pinguicula Group**. In its type section, Pinguicula overlies early Mesoproterozoic Wernecke Supergroup stratigraphy, while locally, relationships with these older rocks are not exposed. Pinguicula Unit A is a maroon and green to grey terrigenous siltstone with minor sandstone. It is overlain through a gradational contact by Pinguicula Unit B, a centimetrically to decimetrically layered lime mudstone and dolomudstone with minor quartz silt to very fine sand component. Silty quartz layers are associated with more dolomitic composition and commonly express current ripples and planar mechanical lamination. Unit B strata are pale to medium grey-weathering in general, with a conspicuously yellowish-orange weathering interval near its base as well as intermittently throughout the unit where quartz-silty intervals are present. Intraclastic rudstone lenses (10 cm to >1 m thick, tens to hundreds of metres wide) are a conspicuous component of unit B, and consist of randomly oriented to imbricated, tabular to equant clasts in a carbonate mudstone matrix. Clast composition is almost exclusively the same as enclosing carbonate mudstones, with the only variation being differences in the grey to buff colour of the clasts. Intraclastic floatstones are also present. This horizon is of particular interest since it is the host rock for the Osiris and Isis East mineralization

Overlying the sequence provisionally identified as Pinguicula Group is a thick section of clastic and carbonate rocks correlated with the Late Precambrian to Lower Cambrian **Hyland Group**. Although bedding appears conformable between the two groups, abrupt changes in depositional setting above and below the contact and inconsistencies in the lithologies exposed at the basal contact of the Hyland group where it overlies Pinguicula define it as an unconformable contact. Assumed age relationships between time of deposition of the Pinguicula and the Hyland Groups would require a significant time-section of stratigraphy to be missing from the stratigraphic column as exposed.

Regionally the Hyland Group consists of several kilometers of terrigenous-clastic dominated, deep-water basinal to shelf strata with unusual carbonate intervals. Pronounced lateral lithofacies variation, prevalence of debrite and turbidite facies within the carbonate intervals, and highly variable stratigraphic thicknesses of units within the Hyland Group are strong evidence

for synsedimentary tectonism during deposition of the Hyland Group, particularly in the eastern portion of the Rackla Property.

The Hyland Group has historically been broken into three subunits, but on the property these divisions are not easily discernible; rocks typical of each of the subunits are found consistently interbedded into thick, repetitive stratigraphic sequences.

The oldest of the defined Hyland sequences is the **Yusezyu Formation**. Equivalent to the historically labeled "Hadrynian Grit" unit, the Yusezyu Formation consists of fine to coarse, silt to sand grade terrigenous clastics and lesser quartz-pebble conglomerates. Grey, brown, buff, maroon and green siltstones, mudstones, lithic arenite, lithic quartz arenite, calcareous lithic arenite, flaggy brown limestone and distinctive, grey to brown, blocky weathering quartz arenite to quartz-pebble conglomerates define this unit.

The Yusezyu Formation includes carbonate intervals that are laterally heterogeneous and highly variable in thickness, character and stratigraphic succession. Consistent throughout carbonate intervals within Yusezyu are the presence of fine intraclastic floatstones and wackestone. Also indicative of the carbonates within Yusezyu are millimetre scale, angular quartz sand grains and, less commonly, millimeter scale rounded intraclasts and ooids/cortoids. The occurrence of rare "beef" calcite within bedded silty limestones is also a distinguishing characteristic. In some areas carbonate intervals are dominated by sequences of debrites and turbidites within the Yusezyu clastics. These characteristics of the limestone member are consistently found in limestones of the Hyland Group across the property, and may correlate with limestones at the **Algae Formation** type-section.

Despite the laterally variable character of this unit, the consistent presence of quartz-rich clastic "grit" interbedded within or directly underlying it strongly suggests its association with the Yusezyu formation and its inclusion within the Hyland Group. This unit is the host rock for Conrad Zone mineralization.

Regionally the upper unit of the Hyland Group is the **Narchilla Formation**. It is distinguished by recessive weathering, maroon and apple-green siltstones and shales of the upper Arrowhead Member and drab, grey to brown and tan siltstone, shale and minor sandstone of the lower Senoah Member. The contact with the underlying Yusezyu Formation is gradational to abrupt. On the property, the Narchilla formation is most commonly seen as thin, truncated slices along thrust faults, rarely exceeding a couple of hundred of meters in thickness.

Possibly overlying the Hyland Group, but in fault contact on the property are strata of the Lower Cambrian **Sekwi Formation**. It includes thin bedded, grey to distinctive, bright orange weathering dolostone and limestone, thick sections of bedded, white to purple quartz arenite, minor, dark grey, rusty weathering siltstone with rusty, bright orange weathering stromatolitic limestone beds, orange to buff weathering slump deposits of calcareous, polymictic conglomerates and medium to thick bedded dolostone and limestone with white to purple quartz arenites, lithic arenites and maroon mudstone.

The late Cambrian to early Silurian **Haywire Formation**, a thick, somewhat monotonous stratigraphic section of cliff forming, medium to thick bedded, light grey to white weathering, finely crystalline dolostone is exposed north of the Kathleen Lakes Fault. Although commonly nondescript with few sedimentary structures, the dolostone can locally be highly fossiliferous including crinoids, favosites, halysites, and bryzoans. The base of formation is defined by distinctive, yellow to cream weathering, thin planar bedded to cross-laminated sandy dolostone with decimeter scale interbeds of maroon shales. The basal rocks may resemble Pinguicula "B" group rocks in outcrop and weathering patterns.

South of the Kathleen Lakes Fault sections of thick, light grey weathering fossiliferous Cambrian to Devonian carbonates, the **Bouvette Formation**, are tentatively correlated as time equivalents with the **Road River Group**. The limestones are often interbedded with or grade abruptly into dark, recessive weathering siliceous to calcareous argillites, shales, cherts and calcareous chert-pebble conglomerates.

Devonian to Mississippian **Earn Group** silvery blue weathering black shale, argille cherty argillite and chert are the youngest strata observed on the property.

The Rackla Gold property area underwent extensive deformation as part of a Mesozoic to early Cretaceous fold and thrust event, followed by transition into a probable strike slip regime. Two major regional structures transect the property: the Dawson Thrust and the Kathleen Lakes Fault. The Dawson Thrust, historically described as defining the northern edge of the Selwyn basin, places Pre-Cambrian Hyland Group rocks over Paleozoic shelf carbonates as part of Jurassic to Cretaceous compressional tectonics. It is likely a much older structure, possibly dating back to Precambrian rifting that was reactivated during compression. The Kathleen Lakes Fault marks the contact between Paleozoic platform rocks to the north and Paleozoic shelf to basin rocks to the south in the western part of the property and runs through a complex map pattern of Precambrian Hyland Group and Meso-Proterozoic Pinguicula Group rocks on both the north and south side of the fault to the east. Movement along this structure may be dominantly strike slip. The Nadaleen Fault near the eastern end of the property appears to be a splay off the Kathleen Lakes Fault.

SOIL, SILT AND ROCK GEOCHEMISTRY

The 2011 regional program conducted across the Rackla Gold property resulted in the collection and analysis of 1,172 silt samples and 13,144 contour, ridge and spur as well as grid soil samples and 180 rock samples. The goal of the 2011 regional program was to locate low temperature gold occurrences, similar to that found at the Nadaleen Trend project in 2010. Sample collection was focused on the east-central part of the property where sparse sampling in 2010 defined geochemical anomalies. The majority of soil samples were collected in grids over areas containing silts anomalous for arsenic and other indicators in their drainage. The Pyramid and Dale targets represent the areas that received the highest density of soil sampling in 2011. In addition, contour and follow-up grid sampling was done at the Ocelot Zone, the Blue Lite showing, and the Cheshire target, while first pass silt sampling targeted as many drainages as possible.

The locations of soil, silt and rock samples, along with the sample identifier are located in Figures 7-76. Sampling and analytical procedures are explained in Appendix II, rock sample descriptions are provided in Appendix III and certificates of analysis are given in Appendix IV.

Background and anomalous values for gold and arsenic were calculated for all soil and silt samples collected across the Rackla. Background, average, weak, moderate, moderately strong and strongly anomalous thresholds approximately correspond to the 50^{th}, 90^{th}, 95^{th}, 98^{th} and 99^{th} percentiles from these samples. The geochemical characteristics of the soil and silt samples are summarized in the following tables.

Table III – Thresholds for Soil Sample Values

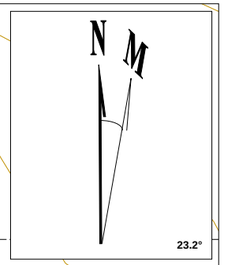
REMOTE SENSING SURVEYS



Regional scale and focused remote sensing surveys were conducted across the majority of the Rackla Gold property. Panchromatic and multispectral satellite imagery was collected with the hopes of identifying regional scale structures and unique spectral signatures associated with disturbed vegetation and ferruginous material. Unimap Integrated Solutions INC. was contracted to facilitate acquisition and processing of satellite imagery. All received data, including imagery and contours, were orthorectified.

In addition to satellite imagery, target specific remote sensing data was collected over two areas of interest within the Rackla Gold Property. Eagle Mapping Limited was contracted to facilitate the collection and processing of data for orthorectified LiDAR, high resolution aerial photography, and contour data to an accuracy of 1 m. Results from the surveys provided detailed information specific to the target areas and allowed for geologists to map the surface distribution of rock units and structural features with a greater degree of accuracy.

HERITAGE RESOURCES OVERVIEW ASSESSMENT STUDY

During the spring and summer, Matrix Resources Ltd. prepared and conducted a preliminary study of the Rackla Gold project to determine heritage potential of the area, assess the degrees of impact on any identified heritage resources and provide management recommendations. The entire claim block was classified into zones of heritage resources potential with moderate and high potential zones inspected on foot for above-ground heritage resources and, if deemed necessary, shovel testing to identify below-ground heritage resources. A copy of this report appears in Appendix V.

DISCUSSION AND CONCLUSIONS

Results from the 2011 regional program conducted on the Rackla Gold property have characterized multiple areas of interest that may prove favourable hosts to gold mineralization. Comprehensive sampling coupled with detailed geologic mapping has illustrated areas that share features associated with gold mineralization on both the west and west ends of the property.

Detailed analysis of geochemical results and inversion studies utilizing known gold occurrences has provided an in depth understanding of the geochemical signatures and halos found in the surficial environment that are associated with gold mineralization at depth. Knowledge of trace element fractionation in an oxidizing, alkaline environment dominated by low sulphidation mineralization and carbonate bedrock is essential when interpreting and prioritizing results from silt and soil samples. Utilizing the knowledge obtained from known gold occurrences is also key when searching for undiscovered mineralization. The structural, and stratigraphic settings associated with the gold mineralization on the Rackla Gold property are likely examples of features on a regional scale that are associated with other, currently undiscovered gold occurrences. High density soil and silt sampling, coupled with detailed geochemical analysis and inversion techniques, when viewed in a regional scale structural and stratigraphic context will result in the highest likelihood of further gold discovery.

The majority of the Rackla Gold property has experienced some degree of representative sampling. High priority areas for follow up in 2012 have been characterized in terms of favourable geochemistry and geology. It is likely that other, undiscovered gold occurrences within the Racka Gold Property will occur at depth and have a relatively subdued surface signature. The Osiris Zone within the Nadaleen Trend and the Tiger Zone within the Rau Trend are near surface gold occurrences with strong geochemical signatures. Remote sensing data collected in 2011 has resulted in the delineation of the surfaces traces of structures that may be associated with gold mineralization. Further exploration techniques should focus on the coincident presence of favourable indicator elements >90th percentile occurring in association with structural features and stratigraphic settings that appear favourable to facilitating auriferous fluid transport as well as gold deposition.

Respectfully submitted,

STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

I, Jordan McDivitt, geologist, with a business address in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in Vancouver, British Columbia, hereby certify that:

1. I graduated from the University of British Columbia in 2011 with a B.Sc. Honours in Earth and Environmental Science.

2. From 2010 to present, I have been actively engaged in mineral exploration in the Yukon Territory.

3. I am a Geoscientist in Training (GIT) with the Association of Professional Engineers and Geoscientists of British Columbia (Member Number 159033).

4. I have personally participated in the field work reported herein and have interpreted data resulting from this work.

APPENDIX II

SAMPLING AND ANALYTICAL PROCEDURES

2011 Rock Geochemical Samples

Rock geochemical sample sites on the property were marked with orange flagging tape labelled with the sample number. The location of each sample was determined using a handheld GPS unit. The rock samples were submitted to ALS in Whitehorse, Yukon where they were dried and fine crushed to 70% passing 2 mm. A 250 g split of the crushed material was then pulverized to better than 85% passing 75 microns. Separate splits of the pulverized fraction were analyzed for gold by fire assay and atomic absorption spectroscopy (Au-AA26) and for 49 other elements using a four acid near total digestion technique (ME-MS61m) at ALS in North Vancouver, British Columbia. Mercury was analyzed for using HG-CV41 methods by aqua regia digestion and atomic adsorption spectroscopy. Rock sample descriptions are presented in Appendix III.

2011 Soil Geochemical Samples

Soil sample types ranged from grid samples taken at lines along a constant bearing, to contour and ridge and spur samples targeting constant elevations and high elevations respectively. Soil samples were taken using an auger, targeting `C` horizon soils below organic cover; sample depths ranging from 10-90cm dependent on local soil development, vegetation and frozen ground conditions. Samples were placed in kraft soil sample bags, and sample sites were flagged and marked with stakes etched with assay tag number, line or point number and grid name. The soil samples were sent to ALS Chemex, where they were dried and screened to 180 microns. Soils samples were sent for 51 element, aqua regia digestion using ICP-MS and ICP-AES assay analysis (ME-MS41). Gold values in soils were determined using 25 gram, trace level aqua regia extraction, ICP-MS assay analysis (Au-TL43)

2011 Silt Geochemical Samples

Silt samples were taken from in-stream silt-rich sediment or from silty accumulation within the roots of overhanging moss at the creek edge where stream conditions did not allow for sufficient silt build-up. Flagging marked with the assay sample number was used to mark silt sample locations. The stream sediment samples were sent to ALS, where they were dried, screened to 180 microns, dissolved in aqua regia solution and then analyzed for 51 elements using an aqua regia digestion and a combination of ICP-MS and ICP-AES for analysis (ME-MS41). Gold in silt samples was analysed for using a 25 gram, trace level aqua regia extraction, ICP-MS assay technique (Au-ST43).

Comments: Taken below ridge 50 m downslope. Aprroximately 4 x 0.5m south facing LST outcrop with coarse rounded clastic fragments; probable debris flow. Clasts are up to 5 x 8 cm or smaller. This unit weathers grey-orange and is dark grey-black on a fresh break. The clastic unit is interbedded or capped by a more platy, thinly bedded LST (1-3cm beds). Attitude of bedding and karsted Clastic outcrop is ~302/60 NW. Localized folding was observed in thinly bedded LST further downslope. Good study outcrop.

Comments: This sample is to test the finely chopped DLST talus chips located above a subtle looking kill zone. The kill zone is mostly gravel with a spring flowing from the top with clear coloured water. Talus above this zone is east facing and approximately 5 m in length and 2.5 m high. Fine talus chips consist of lt-grey-white re-cemented "shattered" looking rock. Possibe shear zone or converging faults? S1 trends 306 degrees (?) ; S2 trends 276 (?) degrees- measured from a small recessive notch where spring water originates. Soil picket #2214736 at talus site.

Comments: Taken from a moss covered "whale back" style outcrop. Brittle, fractured, grey- dark grey weathering and dark grey-black on the fresh surface. Fine grained, tightly compacted rock, and weakly effervesces on acid test. Weak calcite flooding at the northern tip of exposure. Trend of outcrop is NE 072 degrees. Roughly 8x4 m in size.
