Introduction

This report was written at the request of the management of Kestrel Gold Inc. It describes a soil geochemistry survey carried out at their Gold Run Property, 50 km southeast of Dawson City in Yukon, Canada. The soil geochemistry survey was carried out with the objectives of: expanding previously discovered soil anomalies, expanding anomalous soil zones around previously discovered gold values in rock from trenched samples, and exploring for new soil geochemical anomalies. The over-arching goal is to discover an economic gold deposit on the property. Costs associated with the work described here are being applied for assessment work credits on the claims.

Property Location, Access and Physiography

The Gold Run Property comprises 44 quartz claims with a total area of about 9.2 km² (919 ha, 2271 acres), located about 50 km southeast of Dawson City, Yukon. The Gold Run Property is within the Dawson Mining District, covered by NTS map sheets 115O/15 and 115O/10, and is centred at approximately 63° 44' north and longitude 138° 45' west (Figures 1, 2). The property lies mainly along the divide separating the Gold Run Creek and Sulphur Creek drainages.

Road access from Dawson City to the property, a distance of about 80 km, is via the government-maintained Hunker Creek and Sulphur Creek roads. From the junction of Sulphur Creek Road with the Dominion Creek Road; it is about 5 km northeast along the government-maintained Dominion Road to the unmaintained "Gold Run Road" which serves a number of placer operations on that creek. About 8 km northwest up the Gold Run road, an ATV trail crosses the creek and heads up the ridge, giving access to the main showings on the property. A few more overgrown trails access other parts of the claims.

The property was unaffected by the most recent continental glaciations. It lies on the Klondike Plateau, which is characterized by low rolling hills dissected by deeply incised stream valleys. The highest point on the property is along the ridge between Gold Run and Sulphur Creeks at over 1040m above sea level (asl). Elevations range to a low of about 620 m asl on Gold Run Creek at the southeast corner of the property (Figure 3). The majority of the property is forested. Higher elevations are covered by mixed spruce and brush, with some sub alpine meadows on Dominion Mountain and adjacent ridges. The amount of tree cover increases at lower elevations and on south facing slopes.

The un-glaciated Klondike Plateau region experienced strong surface weathering during the early and mid-Tertiary, with the effects of surface weathering extending to depths of as much as 80 metres or more (Kreft, 2009). Regolithic material in the vicinity of the Doron Zone averages 2 metres in thickness (Kreft, 2007). Bedrock is essentially restricted to old trenches, road cuts, and sporadically along the ridge along the western edge of the property. Permafrost is widespread on north facing slopes, and sporadically occurs in other areas.

Claim Status

The 44 quartz claims comprising the Gold Run Property are owned by Bernie Kreft and are subject of a 2010 option agreement with Kestrel Gold Inc. The specifics of this option

agreement are beyond the scope of this report. A listing of claims and their status is attached in Appendix I.

Figure 1. Location map of Kestrel Gold Inc. properties including Gold Run. Also shown are creeks with historic placer workings (in yellow) and mineral showings from Yukon MINFILE (grey boxes).

Figure 2. Claim map of Gold Run Property, comprised of the GR 1 to GR 44 claims (outlined). Yukon MINFILE occurrence 1150 132 (Doron) is indicated by the black dot.

Figure 3. Gold Run Property showing property outline, topography, geographic features, and soil sampling lines. Grid coordinates are UTM (NAD 83).

Exploration History

Three main showings are on the claims: Devine (Doron), Kentucky West, and Doron NW. The Doron has had the most exploration in recent times, with a number of trenches. Kentucky West has a quartz vein exposed in a shaft with no reported assays (Davidson and Wallis, 1987). Doron NW is a recent discovery, marked by soil geochemical anomalies and a single trench.

The work to date has essentially comprised historic surface workings, soil sampling, and some excavator trenching.

The Yukon MINFILE report for the Devine showing (now known as Doron, 115O 132; Figure 2) notes the first quartz claim staking in the area in 1901. Shallow shafts and trenches were dug from that time until 1903. The area was re-staked in 1922 and further small scale surface exploration continued until 1928, when it was re-staked again and had further shallow surface exploration recorded until 1938.

After a period of no recorded work, the area comprising the current Gold Run claims were re-staked in 1984 by Gatenby, who undertook some soil sampling. Ninety-two samples were collected with a maximum value of 124 ppb Au obtained (Gatenby, 1984), and these were followed up with trenching in 1985.

In 1986 Doron Explorations acquired ground in the area, and in 1987 and 1988 undertook soil and rock sampling. They discovered four anomalous areas, with up to 858 ppb Au from a soil sample in the area of the Doron Zone trenches (Lueck and Davidson, 1988).

The property lapsed and the ground was partly covered by the G Hawk claims. Wealth Resources optioned the claims and carried out a soil sampling program. Results up to 845 ppb Au were obtained and were interpreted to outline weak northwest trending anomalies in the Doron Zone area (Southam, 1994).

In 2000, KSL Exploration (Yukon) Ltd. acquired the ground by staking, and collected several hundred collected soil samples from 2000-2003. Many of the samples were analyzed by MMI (mobile metal ion) leaching and conventional methods (Adamson and Thomas, 2001). Their soil sampling outlined anomalies in the Doron and Kentucky West areas, as well as to the north of Kentucky West (Adamson and Thomas, 2002, 2003, 2004). All the anomalous areas identified lay on the northeast side of the ridge between Gold Run and Sulphur Creeks.

Bernie Kreft acquired the current GR claims in 2007, and undertook a program of soil sampling (94 samples) and excavated five trenches (61 rock samples). Narrow (<10 cm) quartz and quartz-carbonate veins uncovered in the trenches yielded high grade gold values, and weighted averages of up to 2.242 g/t Au over 18.2 m, including 9.06 g/t Au over 1.8 m, were reported (Trench T7-04; Kreft, 2008). In 2008, Kreft followed up with further soil sampling and re-sampling of some trenches. Pyrite + Fe carbonate alteration zones were identified. Further soil sampling and trenching in 2009 extended the Doron Zone to the northwest, and also suggested that mineralization is primarily vein hosted rather than also included in wall rock (Kreft, 2010). Trench results included 0.33 g/t Au over 14.6 m in Trench GRT09-03 and 14.7 g/t Au over 1.9 m in GRT09-02 (Kreft, 2010).

Geology

Regional Geology

Descriptions of regional and property geology are taken largely from Mortensen (1996) and his collaborators (e.g., Mackenzie et al., 2007). Debicki (1985) also produced regional geology maps of the area.

The Gold Run Property lies within the Yukon-Tanana Terrane (YTT). Yukon-Tanana Terrane is composed of Proterozoic to upper Paleozoic polyphase deformed metasedimentary, metavolcanic and metaplutonic rocks. Plutonic rocks intruded episodically in the Permian, Jurassic, Cretaceous, and Tertiary periods. Intrusive events were accompanied by volcanism, especially in the Upper Jurassic to Lower Cretaceous. Tectonic deformation included subduction and accretion of the terrane. Imbricated fault slices of allochthonous Slide Mountain Terrane are interpreted to be interleaved with the YTT.

In the area south and southeast of Dawson City, the YTT is dominantly composed of two supracrustal (dominantly metasedimentary) assemblages and three metaplutonic suites. The younger supracrustal assemblage is named Klondike Schist and is of Late Permian age. Klondike Schist can be further subdivided into felsic and mafic schists and meta-clastic units.

Klondike schist lithologies are interlayered on the 1-100 m scale and are pervasively foliated and recrystallized, with few primary features recognizable. The Klondike Schist forms the upper thrust slices of a stacked pile of supracrustal rocks and local intercalated slices of ultramafic rocks of probable Slide Mountain Terrane origin (Mortensen, 1996).

Figure 4. Regional geology of the Klondike area, from Mackenzie et al., 2007. DM= Dominion Mountain, KSD= King Solomon Dome. The Gold Run property is located at the star.

Property Geology

Mapping by Mortensen (in Mackenzie et al., 2007) shows the Gold Run Property to be underlain by the mafic schist member of Klondike Schist. This mafic schist lies in the hanging wall of a regional thrust fault, which is shallowly southwest dipping and trends northwestward along the northeast part of the property.

Examination of a few scattered outcrops and trenches by the author in 2011 confirms quartz-chlorite schist as a dominant lithology. In the Doron Zone, carbonate and iron oxide alteration was confirmed. Quartz and quartz carbonate veins were generally very thin. The Doron NW trench was also examined, but the Kentucky West showing was not located.

2011 Exploration Program

Exploration Objective

An economic gold deposit is the exploration target for Kestrel Gold Inc. on the Gold Run Property. Lode gold mineralization in the Klondike area is generally considered to be of the orogenic type (Mackenzie et al., 2007), with gold occurring in quartz (+/- carbonate) veins, and locally in the altered wall rock adjacent to veins. From examination of the trenches at Doron Zone, alteration is expected to typically exhibit increased carbonate, pyrite, chlorite, and locally epidote and hornblende, depending on original lithologies.

Detailed geochemical surveys have proven to be effective in the area, as evidenced by recent discoveries to the south at White Gold and the Coffee Property. The region is generally blanketed by deeply weathered, oxidized soils in an unglaciated, periglacial environment (Fekete, 2011). Therefore the best representation of underlying bedrock will be from relatively deeper soils. Solifluction and similar freeze-thaw mechanisms may be important agents, in this permafrost area, in the transport of certain elements from bedrock sources (B. Kreft, pers. comm., 2011).

A soil geochemistry program was devised to follow up on known geochemical anomalies on the property, and expand these zones and search for new ones. Geophysical surveys were also completed in 2011, which will be reported on separately.

Procedures

This section on sampling procedures, and the following section on sample preparation, analysis and security, are taken largely from a memorandum written by Carl Schulze, P.Geo., principal of All Terrane Mineral Exploration Services of Whitehorse, YT (All-Terrane). All-Terrane conducted the soil sampling program under the direction of management of Kestrel Gold Inc. Mr. Schulze designed and oversaw the quality assurance-quality control (QA-QC) procedures outlined here, in consultation with Kestrel management.

Soil sampling lines were spaced at 100 metre intervals, with samples collected every 50 m. In the southeast corner of the property around the Doron Zone, sample spacing was reduced to 25 m. In the northwestern part of the property, line spacing was increased to 200 m. Lines were oriented approximately northeast, to cross the regional northwest trend of stratigraphy (Figure 3). Sampling lines covered essentially the entire property, leaving out areas where recent previous sampling had been done to avoid duplication. The soil sampling grid layout is shown in Figure 3.

A total of 1569 soils were collected (Figure 5). Soil sampling was completed during the period June 20 to July 26, 2011 by employees of All Terrane, under the direction of Mr. Carl Schulze, P.Geo. Sampling crew members navigated by means of handheld GPS units and compass. Sampling lines were flagged every 25 m utilizing orange flagging tape; actual sample stations

were marked with orange and blue flagging displaying the respective sample number. GPS coordinates were recorded every 200 m for sample line control, and every 100 m in areas having 25 m station spacing. Soil samples were collected by means of hand operated soil augers (“dutch augers”) from the “C” soil horizon where possible. Sample depths ranged from 20 to 95 cm, averaging 44 cm. Permafrost was noted at about 20% of sample sites, primarily along north and east-facing slopes. Three duplicate samples were taken during the course of the program.

Information recorded at each sample site included: location (UTM – NAD 83), traverse line number, soil horizon, depth, slope angle, colour, presence of permafrost, vegetation type, surficial geology where determined, percent organics, date, sampler and comments, where applicable (Appendix II). Samples with significant coarse rock chips were also noted, to facilitate later examination of the coarse reject fraction if desired.

Where “C” horizon material was unavailable, the “B” horizon was sampled. The minimum sample weight was 0.25 kg, before drying and preparation for analysis. Samples were placed in standard “kraft” paper envelopes. Unique sample number tags supplied by Eco Tech Laboratory Ltd. (a subsidiary of Stewart Group, now an ALS Group Company) placed in the sample bag, and the sample number written on both sides of the bag with felt pen. The sample number was also written with felt pen on blue flagging tape and attached at the sample site area. Samples were transported to All-Terrane’s camp at Scribner Creek, where they were then dried as much as possible before shipping.

Figure 5. Soil sample locations (crosses) on Gold Run property grid. Grid coordinates are UTM values (NAD 83).

Sample Preparation, Analysis and Security

All individual soil samples in kraft bags were sealed with a locking plastic tie (“Zap Strap”); samples were then placed in labelled rice bags which were also sealed with a “Zap Strap”. The sample stream included systematic insertion of a pair of “standard” and “blank” samples at a frequency of roughly one pair per 100 field samples. Standard and blank samples are discussed below. The sealed rice bags were then transported by All-Terrane personnel and delivered directly to a Whitehorse-based preparatory lab owned by Eco Tech Laboratory Ltd., a member of the Stewart Group with ISO 17025: 2005 accreditation. The Stewart Group was recently acquired by ALS Laboratories Inc. The majority of samples were shipped from Whitehorse directly to the main Eco Tech facility in Kamloops, BC, although a few shipments underwent drying and screening in the Whitehorse prep lab prior to shipping.

At either Whitehorse or Kamloops preparatory facility, soil samples were screened to 180 μ size (minus-80 mesh). At Eco Tech’s Kamloops lab, the fine fraction then underwent gold analysis by 30-gram fire assay with inductively coupled plasma – atomic emission spectroscopy (ICP – AES) finish, providing a detection limit of 0.005 g/t Au. All samples also underwent multi-element analysis by (ICP-AES), after digestion of a sample aliquot in aqua regia. A suite of 35 elements were analyzed, consisting of: Ag, Al, As, Ba, Be, Bi, Ca, Cd, Co, Cr, Fe, Hg, K, La, Li, Mg, Mn, Mo, Na, Ni, P, Pb, S, Sb, Se, Sn, Sr, Ti, U, V, W, Y, Zn.

All-Terrane Services provided a comprehensive quality assurance – quality control (QA-QC) regimen, consisting of the use of duplicate sampling, and insertion of pairs of standard and blank samples. Standards are utilized to determine the accuracy of analysis; blanks test for any contamination from neighbouring samples during analysis. Two sets of standard samples provided by CDN Resource Laboratories of Langley, British Columbia, Canada, were utilized: standard CDN-GS-P2 had an average gold content from 30 gram fire assay of 0.214 +/- 0.020 g/t; CDN-GS-P4A, had an average gold analysis of 0.438 +/- 0.032 g/t. Two of each of these standards were inserted throughout the program.

Information from CDN Resource Laboratories website (www.cdnlabs.com) indicates that the CDN-GS-P2 standard was prepared utilizing ore from Barrick Gold Inc.’s “Carlin-style” Bald Mountain Mine in Nevada, U.S.A. The reject material was dried, crushed, pulverized and passed through a 270 mesh screen; the sample utilized the minus 270 fraction only. This was mixed for five days in a double-cone blender, with splits sent to 14 commercial laboratories for round-robin assaying. Standard deviations per individual lab varied from 0.0042 to 0.0114.

The CDN-GS-P4A standard was prepared utilizing ore from Barrick’s “Carlin-style” Cortez Hill Mine in Nevada. To prepare the standard, 42 kg of ore was combined with 730 kg of a blank, granitic rock. The reject material was prepared in the same manner as the CDN-GS-P2 blank, with splits sent to 15 commercial laboratories for round-robin assaying. Standard deviations per individual lab ranged from 0.0053 to 0.0208.

The blank samples provided by All-Terrane Services consisted of dolomitic sand commonly utilized in gardens, purchased at Canadian Tire Corporation. No analytical data is available.

The four CDN-GS-P2 samples analyzed by Eco Tech Labs returned gold values from 205-220 ppb y, within the range of 214 +/- 20 ppb provided by CDN Resource Laboratories. The 11 CDN-GS-P4A samples returned values ranging from 395-445 ppb gold. All but one of these (the 395 ppb analysis) was within the range of 438 +/- 32 ppb provided by CDN Labs. This indicates a high level of analytical accuracy of the Kamloops laboratory. All 15 blank samples returned sub-detection (<5 ppb) gold values, and un-elevated values of all other elements, except for calcium and magnesium, the main elements comprising dolomite, which both exceeded 10% per volume. These indicate that the analytical procedure is clean, with individual samples free of contamination from adjacent samples in a batch. Supported by repeatability of results from the standards, the analytical results from this program may be relied upon.

Duplicate samples test for the distribution of gold at a particular site, focusing on the presence of coarse, nugget-style gold. During this program, the eight duplicate samples were taken at locations of background to low gold values. Gold values of both the “original” and duplicate samples ranged from <5 ppb and 5 ppb, to 10 ppb and 20 ppb, which do not demonstrate a significant difference between the pairs. Values of other elements showed a limited variability between the two sample types.

Eco-Tech Labs, as part of their in-house QA-QC regimen, reanalysed submitted samples at a rate of approximately 12%. In addition, the lab inserted their own standards at a rate of approximately 3%. Assay certificates for all soil samples collected during the program are in Appendix III.

2011 Soil Sampling Results

Assay results are listed in Appendix III. Maps of the grid with symbolically plotted Au, Ag, As, Pb, Zn, and Cu values are shown in Figures 6-12. Soil geochemistry values of these elements are discussed below.

Gold

Gold values reached a high of 200 parts per billion (ppb). The average was 6.2 ppb, calculated after reported values of <5 ppb were assigned a value of 2 ppb. The median value was 5 ppb. Standard deviation was 10.1 ppb. A threshold of 26 ppb (average plus two standard deviations) for anomalous values can be thus estimated. The 95th percentile value is 20 ppb.

The soil sampling confirmed anomalous gold in soil in the Doron Zone area on the GR 10 and GR 12 claims. The anomalous area was expanded both to the northeast and southwest of the Doron Zone trenches. The continuity of soil anomalies over approximately 600 m suggests a northward trending zone, across GR 12 and onto GR 11. A further zone of anomalous gold in soil occurs at the northeast corner of GR 11 and possibly extends across an unnamed creek onto GR 13 claim.

Sampling in the Doron NW area did not significantly expand the anomalous zone, however a group of three high Au values (over 50 ppb) over two lines about 250 m east of Doron NW, on the southeast quadrant of GR 18 claim at the head of an unnamed creek, is a promising target for follow-up.

No new gold values of significance were found where previous high values were reported southeast of the Kentucky West shaft. A small anomalous area (2 samples of 30 ppb Au or greater) was located about 600 m north of the Kentucky West shaft, on the GR 3 claim.

The most significant result are a broad belt of scattered 30 ppb + soil anomalies trending northeast through the central part of Gold Run Property. These anomalies are defined in soil sampling lines across 600 m. Overall, the belt of anomalies is about 200-400 m wide and 2,000 m long, lying mainly on the GR 36, 38, 40, 42 and 44 claims. The anomalous zone occurs across a slope drained by the southern two forks of 71 Pup. Near the centre of this belt is a single historical soil sample that assayed 1.135g/t Au (Adamson and Thomas, 2004).

No significant gold in soil anomalies were obtained in the northwestern third of the property, north and west of 71 Pup.

Figure 6 displays the gold in soil results of the current survey, and Figure 7 includes gold in soil results for historic work with the current results.

Figure 6. Gold in soil sample results from the current (2011) survey. Grid coordinates are UTM, NAD 83.

Figure 7. Gold in soil sample results from the current (2011) survey and historic results. Grid coordinates are UTM, NAD 83.

Silver

Silver in soil values were generally very low across the grid, with over 75% of analyses reporting less than detection limit. Maximum value was 3.0 parts per million (ppm). The average was 0.17 ppm, calculated after reported values of <0.2 ppm were assigned a value of 0.1 ppm. The median value was 0.1 ppm, below detection limit. Standard deviation was 0.19 ppm. A threshold of 0.55 ppm (average plus two standard deviations) for anomalous values can be thus estimated. The 95th percentile value is 0.6 ppm.

Anomalous silver in soil anomalies are almost wholly restricted to the southwest side of the property. There is no appreciable silver associated with Doron, Doron NW, or Kentucky W showings, although to the north and northwest of Kentucky West, there are widespread (if weak) silver in soil anomalies. Higher silver values are partly coincident with the new gold anomalies discovered north and northwest of Kentucky West.

Overall Ag anomalies coincide with base metal anomalies, and the segregation of relatively higher Ag in the southwest half of Gold Run Property area suggests a lithological influence rather than strictly mineralized vein or structure associations.

Arsenic

The maximum value was 110 ppm. The average was 8.5 ppm, calculated after reported values of <5 ppm were assigned a value of 2 ppm. The median value was 5 ppm, which is the analytical detection limit. Standard deviation was 8.4 ppm. A threshold of 250 ppm (average plus two standard deviations) for anomalous values can be thus estimated. The 95th percentile value is 20 ppm.

There are some scattered As anomalies, concentrated in the southwest quadrant of the grid. Many of the anomalous As soil anomalies seem to be aligned in northwest orientations, reflecting the base metals distributions. To some extent, As corresponds with high Ag, but correlations with gold are weak at best. The Doron, Doron NW and Kentucky W showings do not obviously correspond with arsenic in soil anomalies.

Lead

The maximum value was 237 ppm. The average was 11.84 ppm, calculated after reported values of <3 ppm were assigned a value of 1 ppm. The median value was 12 ppm and standard deviation was 11.4 ppm. A threshold of 35 ppm (average plus two standard deviations) for anomalous values can be thus estimated. The 95th percentile value is 21 ppm.

Lead anomalies occur in two general areas on the property: on the southwest side of the grid, mainly north and west of the Kentucky W shaft, some cohesive and large Pb in soil anomalies trend north and northwest. The second area, mainly with only weakly elevated gold, lies at the east end of the grid, 800 m north of the Doron Zone and beyond. There are no strong lead in soil anomalies associated with any of the three known showings. The lead anomaly that trends northward of Kentucky W is partly associated with gold, and correlates reasonably with the higher silver values. Copper and zinc also show a good correlation with lead in this area, as noted below.

Figure 8. Silver in soil sample results from the current (2011) survey. Grid coordinates are UTM, NAD 83.

Figure 9. Arsenic in soil sample results from the current (2011) survey. Grid coordinates are UTM, NAD 83.

Figure 10. Lead in soil sample results from the current (2011) survey. Grid coordinates are UTM, NAD 83.

Zinc

The maximum value was 1184 ppm. The average value was 68 ppm, the median 56 ppm, and the standard deviation was 70.2 ppm. A threshold of 209 ppm (average plus two standard deviations) for anomalous values can be thus estimated. The 95th percentile value is 126 ppm.

Anomalous zinc in soils on the Gold Run grid are mainly restricted to the southwest side of the grid, where two large areas of ≥ 150 ppm Zn lie on northerly and northwest trends. The anomalies agree very well with lead in soils.

There are some spot anomalies of zinc in the Doron Zone area, confirming historic results. Doron NW and Kentucky West do not have associated zinc in soil anomalies.

Copper

Maximum value was 240 ppm. The average value was 29 ppm, the median 22 ppm, and the standard deviation was 26.3 ppm. A threshold of 82 ppm (average plus two standard deviations) for anomalous values can be thus estimated. The 95th percentile value is 82 ppm.

Anomalous copper in soil is largely restricted to a belt of northwest trending zones on the southwestern side of the property, strongly coincident with Pb, Zn, and Ag. A few spot anomalies on the northeast side of the grid are partly coincident with lead anomalies.

The broad multi-element anomaly, trending about the same as the regional strike, suggests lithological control of the base metal anomalies on the southwest side of the grid.

Figure 11. Zinc in soil sample results from the current (2011) survey. Grid coordinates are UTM, NAD 83.

Figure 12. Copper in soil sample results from the current (2011) survey. Grid coordinates are UTM, NAD 83.

Summary, Interpretations and Conclusions

1569 soil samples were collected on Gold Run Property during the period June 20 to July 26, 2011. Samples were collected on a flagged grid consisting of about 71.5 line km of largely 100 m-spaced lines (Figures 3, 5). Samples were from the “C” soil horizon in most cases. All soil samples were analysed for gold and most for an additional 35 elements.

From analysis of the geochemical data, the following interpretations and conclusions are reached:

- Existing anomalous areas in previous rock and soil samples were expanded in the current geochemical survey at the Doron Zone, but not significantly at Doron NW or Kentucky W.
- New gold in soil anomalies in a broad discontinuous northeasterly trending belt across the property, as well as along an unnamed creek draining east from the Doron NW zone. Gold in soil values reached a maximum of 200 ppb.
- Significant areas of anomalous silver in soil were not found. Elevated silver is mainly confined to the southwest side of the grid, where it correlates with higher base metal values, and to a lesser extent, to the newly discovered central gold anomalies
- Arsenic values are mainly in the southwestern quadrant of the claim, and display some apparent linear trends.
- Significant north and northwest trending lead and zinc anomalies were found along the southwestern half of the grid. The north trending lead-zinc anomaly partly coincided with the central belt of gold anomalies mentioned above. Minor lead anomalies were also found north of an unnamed creek on the eastern end of the grid.
- Copper anomalies generally corresponded to the lead plus zinc anomalies on the southwestern side of the grid.
- The tendency of base metal (plus silver) anomalies to be concentrated along the southwestern side of the grid, and display some trends parallel to regional strike, suggests that underlying lithologies may be important. However, some elements (particularly As, Pb, Au, and Zn) display some trends at a high angle to regional strike, and these may indicate crosscutting structures.
- The broad belt of gold anomalies across the central part of the property represent newly discovered targets for further exploration.
- Expanded area of gold anomalies at Doron Zone, and new gold anomalies along the unnamed creek draining east from the Doron NW area, are strong candidates for further exploration.

Figure 13 shows contoured areas of new and historic gold in soil anomalies, along with other anomalous areas of elements discussed here. Priority areas for follow up are: area A, the broad band of scattered gold anomalies at a high angle to regional geological trends; area B, the spot high gold anomalies east and north of the Doron NW zone; and area C, the Doron Zone and its northward extension. Area D, the north to northwest trending arcuate area of higher base metal values, is a lower priority for follow up, and may be reflecting different underlying lithologies. However these areas remain high priority where there are corresponding high Au values. Area E, corresponding to As in soil anomalies, is lower priority, but the apparent linearity of some of

these anomalies should be investigated further, as they may reflect associations with mineralized structures in bedrock.

Figure 13. Summary and compilation map of the main soil geochemistry anomalous areas arising from the 2011 geochemical survey. The areas shown in shades of yellow and orange are contoured gold-in-soil anomalies interpreted from current and historic data. A= a broad area encompassing spot high gold anomalies, the overall trend of which is apparently at a high angle to regional geology. B= spot gold anomalies which might be associated with Doron Zone if it is northwest-trending as proposed by some workers. C= anomalous gold area that may be a northern extension of Doron Zone. D= north and northwest-trending area of anomalous Zn, Pb, and Cu, possibly related to underlying lithological differences. Geological contacts and faults indicated by black dashed lines are from Debicki (1985). E= arsenic in soil anomalies that locally show strong linear aspect, possibly indicating the influence of mineralized bedrock structures. Grid coordinates are UTM, NAD 83.

Statement of Expenditures

Item and Service Providers	Cost
Soil geochemical survey: All Terrane Mineral Exploration Services, Eco Tech Labs Ltd., ALS Labs Ltd.	\$87,479
Drafting, Digitizing, GIS support: Luminai Drafting Ltd.	\$1,200
Report Writing: Len Gal, P.Geo.	\$3,840
TOTAL	\$92,519

Statement of Qualifications

I, Len Gal, of Courtenay, British Columbia hereby certify that:

- I am a Professional Geoscientist registered in good standing of the Association of Professional Engineers and Geoscientists of British Columbia (Registration No. 110007).
- I am a graduate of the University of British Columbia, with a B.Sc. in Geology (1986).
- I am a graduate of the University of Calgary, with a M.Sc. in Geology (1990).
- I have been engaged in geological work more or less continuously since 1986, in North and South America and Australasia, both in private industry and in public service.
- The information in this report is based upon review of analytical results, unpublished and published reports and maps, and materials supplied by the operator.
- I visited the Gold Run Property on two occasions, in May and July, 2011.

Signed this _____ day of February, 2012.
