COMMENTS

This hole mainly comprises medium-dark grey cherts with bleached zones. Mineralization occurs in veinlets and lesser disseminated in the rock matrix, and consist of pyrrhotite, arsenopyrite, pyrite, sphalerite, galena, chalcopyrite. Fracturing is common, mainly occurring at 35-40 tca.

COMMENTS

This hole mainly comprises medium-dark grey cherts with bleached zones. Mineralization occurs in veinlets or disseminated in the rock matrix , and consist of pyrrhotite arsenopyrite, pyrite, sphalerite, galena, chalcopyrite. Fracturing is common, mainly occurring at 35-40 tca.

COMMENTS

This hole mainly comprises a light-medium grey chert with bleached zones. Fracturing is common, mainly occurring at 30-45 tca. Bedding is present thru ought the interval at 60 tca. Mineralization occurs in veinlets and fine disseminated in the rock matrix. Pyrrhotite is dominant followed by galena, arsenopyrite, sphalerite, pyrite and chalcopyrite.

In darker bands we notice the foliation bedding at a variable tca along the interval (58-70).Bands of bleached zones (15-35 cm), host mineralized veinlets enveloped in white-pink matrix. Mineralization is : weak pyrrhotite and trace galena, sphalerite, chalcopyrite, arsenopyrite, pyrite. Sulphides are fracture controlled and disseminated in the matrix thru ought the interval. Trace chlorite appears as green patches on the fractures.

Intense black hairline veinining system is present at 30 -45 tca and variable tfa. Mineralization is just trace pyrrhotite and Pyrite. However is to be notice that Pyrite occurs smeared on the fractures plans suggesting sheared movements in the unit. Alteration is present as Chlorite ,green patches throughout the interval.

COMMENTS

This hole mainly comprises of intercalated light to medium grey limestone and siltstone. Black argillaceous lenses are only present in the top 36.82 m of the hole. Contacts between limestone and siltstone layers are very diffuse. >>Calc-silicate altered zones are mottled light grey to pale green and buff, and host the majority of the mineralization. Weak to moderate oxidation is present on many fractures, locally pervasive. >>Mineralization occurs as fracture-fills, disseminations and occasionally as mineral replacement (in sub-massive zones). Galena > sphalerite > pyrrhotite > chalcopyrite > pyrite > arsenopyrite. >>Laminations are common and mainly occur at 44-70° TCA. Fracturing occurs at 25-30° TCA.

						LST	LT GY		LA	44-70°						w	chl	w									Limestone weakly to strongly effervesces. Calcareous fracture-filling is common throughout the unit and resembles weak to moderate stockwork with veinlets between 1-8 mm. Clay alteration is locally pervasive, but mainly occurs along fractures. Alternating light to medium grey laminations dip 44-70° TCA
						ARG	BK & RUSTY		LA	44-70°						m-ms	cly	m				Py	w				Black and gritty argillite with fine grained, blebby, fracture filled (1-2 mm) pyrite. Soft, locally altered zones contain a soft, angular rusty-white clast displaying a brecciated/jig-saw texture. This texture is most noticeable near contacts with the LST unit. Oxidized 1 mm seams are common throughout.

36.82	52.94	16.12				LST/ SLT	LT GY								w	m-s	ble	w-m		w		Py	w				Light grey, weakly to strongly oxidized, fine to very fine grained, intercalated silty limestone and siliceous siltstone with washed out/bleached calc-silicate altered zones. Calc-silicate altered zones are noticeably different and usually pale green to white and host most of the fine grained black sphalerite. Cross-cutting fractures are 1-10 mm and filled with pyrite or calcite. Pyrite also occurs as fine grained blebs (4-20 mm). Most fractured surfaces are moderately to strongly oxidized and coated with chlorite.

			171.40	183.40	12.00	LST/SLT							m		w	w	alt	w									Light to dark grey intercalated limestone and siltstone with buff to medium grey-green calc-silicate altered zones. Light grey zones effervesce while dark grey intervals are more siliceous and do not fizz. Locally, buff altered zones contain a light pink, soft, mineral that occurs in 1-2 mm lenses and strongly fizzes, pink calcite.

			216.70	245.00	28.30	LST/ SLT	LT GY								m	w	chl	m	m	w-s	w-s	Cp	f	Py	w		Light grey to pale green, bleached, intercalated siltstone and limestone with fine to coarse grained galena, sphalerite, pyrrhotite, chalcopyrite and mino pyrite. Galena is locally sub-massive but mostly coarse grained with euhedral crystals. Chalcopyrite occurs as blotches but also interstitially between sphalerite and galena. Mineralization throughout is mainly blotchy and disseminated. Pale to medium green calc-silicate alteration is locally pervasive and intermittently seen throughout the zone. Chlorite alteration is prominent on fractured surfaces. Calcareous stringers and veins (1-2 cm) are scattered throughout, and cut across mineralized zones (post-mineralization).

Calcareous fracture filling and veinlets are scattered throughout and show no preferred orientation. Entire zone moderately to strongly effervesces. Fine grained pyrite occurs as disseminations or as 1-2 cm elongate blebs with a white calcareous border. 1-2 mm light to dark grey laminations are dipping 70-85° TCA,

COMMENTS

The hole encountered a faulted zone consisting of meta-sediments, graphitic argillite, and siltstone. Contacts between these units are diffuse. >>Mineralization is very weak and localized, and consists of sphalerite, galena, chalcopyrite, pyrite and arsenopyrite. >>Oxidation and chlorite alteration vary from weak to intense and are mainly observed on fractured surfaces. Oxidation is locall pervasive. >>Laminations in the siltstone unit range from 20-30° TCA.

COMMENTS

The hole intersected a weakly mineralized, intercalated limestone and argillite to 38.85 m, and a moderately to strongly mineralized, intercalated limestone and siltstone until the end of hole. Contacts between the limestone and siltstone are very diffuse. >>Mottled, light grey-green and bleached calc-silicate alteration is prominent in mineralized zones. Mineralization is primarily fracture-controlled, but occasionally occurs as sub-massive bands dipping 45-60° TCA. Chalcopyrite mineralization increases downhole. Galena > sphalerite > pyrrhotite > chalcopyrite > arsenopyrite > pyrite. >>Laminations are common and dip 45-70° TCA. Sub-parallel to mineralized banding. >>Hole was shutdown somewhat earlier due to dry hole.

Fine to coarse grained galena, sphalerite, pyrrhotite, arsenopyrite, chalcopyrite, and pyrite occur as fracture-fills, disseminations, or as 'blotches' (where Gn, Sp, Po & Cp occur adjacent to each other). Mineralization concentrates in bleached zones. Euhedral arsenopyrite crystals occur as clumps, often independent of other sulphides. Oxidation is fair and mainly occurs along fractures. Medium to dark green chlorite alteration is present along fractures. Laminations are occasionally visible and dip 55° TCA.

Mineralization consists of sphalerite, galena, pyrrhotite, chalcopyrite and pyrite. The interval varies from weakly to locally strongly mineralized. Crude banding consisted of sphalerite, galena and pyrrhotite, and dipped 45-55° TCA (roughly sub-parallel to laminations). Arsenopyrite locally occurs in 'clumps' of euhedral fine to coarse grained crystals. Pale creamy pink, dull, non-calcareous, soft mineral occurs in weakly to strongly calc-silicate altered zones (?).

Light and dark grey layers are interfingering throughout. Fine grained chalcopyrite, galena and pyrrhotite occur along few fractures. Laminations dip 45-60° TCA. Chlorite and carbonate alteration occur along fractured surfaces which strongly effervesce. Chlorite alteration is locally pervasive.

Semi-massive bands are between 3-10 cm wide. Chlorite and calcite alteration is prevalent along fractured surfaces. Chalcopyrite is mainly blebby and interstitial. Banding dips between 45-50° TCA. Mineralized fracture-filling is also prevalent.

COMMENTS

The hole mainly comprises light-medium grey, fine grained, finely laminated (1-2mm) siliceous siltstones and metasediment. Minor units of silty limestone are found within and argillite occurs at the end of hole. Contacts are diffuse across all units. >> Fair clay and moderate chlorite alteration occur throughout the hole. >> Weak fair mineralization in this hole occurs predominantly in calcite filled fractures oriented between 30-60°, Pyrite > Pyrrhotite > Sphalerite > Galena > Arsenopyrite. Trace-weak disseminated and blebby pyrrhotite occur throughout the hole.

Laminations average 40 degrees to core axis but can locally vary from 20 to 70 degrees. Weak oxidation is present and generally is found along fractures ; weak chlorite alteration is widespread with areas of increased alteration. Clay alteration occurs in localized zones (at 14.90m, 25.65m, 32.70m, and 33.80m) and the zones are approximately 5cm in thickness.

Weak pyrrhotite is associated with some micro fractures and is also disseminated throughout the interval.
38.39	100.32	61.93				M-SED	MD GY	fg				w	chl	ms-s	LA	50-60			t-w								"Metasediments" (M-SED) - medium grey, fine grained metasediments with laminations mainly between 50 and 60 degrees to core axis which appear to be compositional bedding with interlayered light and dark grey laminations. Moderately strong to strong chlorite alteration throughout with small areas (about 5cm wide) undergoing clay alteration. Fine grained pyrrhotite is found disseminated throughout (entire unit is weakly magnetic) but locally occurs in small veinlets up to 2 mm in width parallel to laminations (primary?). Much of the rock has been highly deformed and brecciated with clasts up to 3cm within the folded laminations. Undeformed rock is more siliceous and appears in segments up to 30cm.

Fracture contains moderately strong fine grained pyrrhotite, moderate galena and chalcopyrite, and trace to weak sphalerite and arsenopyrite. The area has undergone moderately strong chlorite alteration and has been strongly infilled by fine grained calcite (effervesces readily).

242.15	257.96	15.81				M-SED	LT-MD GY	fg					chl	s													"Deformed Metasediments" (M-SED) - Light to medium grey metasediments with a light green alteration (likely chlorite, possibly some serricite) with pervasive microfracturing. Microfractures are calcite filled and often cause a jigsaw brecciated texture. High density fractures with fine grained pyrite between 0.1-0.5cm in thickness are consistently oriented at 47 degrees to core axis. Fractures range in density from 10-20/m with the highest concentration occurring between 249.00m and 251.60m. Microfractures (<1mm) of pyrrhotite are found within the interval at all orientations but are smaller and less pervasive than those found both before and after the interval. Moderate clay alteration is pervasive, with some areas experiencing strong alteration (see sub intervals). Laminations are undistinguishable due to high density microfracturing.

Moderate to moderately strong chlorite alteration with fair light pink, very soft clay alteration (appears propylitic?) is pervasive through the interval. Within clay altered zones deformed laminations become visible. The upper contact is interbedded with fine grained, laminated dark grey siliceous metasediments. Fractures filled with fair fine grained pyrrhotite and trace to weak pyrite occur at a high veining density up section and a moderate density further down section. Fine grained quartz carbonate fractures with moderate fine grained pyrite and trace to fair pyrrhotite increase in veining density down section. Some fractures contain fine grained sphalerite (see sub sections). Fractures generally occur at 20-35 degrees to core axis but can locally be found at steeper angles.

COMMENTS

Hole KEG-11-09 consists of intercalated limestone and siltstone with trace to moderate mineralization. The argillaceous limestone is noticeably darker and unmineralized. Contacts between units are sharp. Laminations across all units are faint and measure between 45-65°. >>Mineralization consists of fracture-filled and disseminated sphalerite, galena, chalcopyrite and pyrrhotite. Few mineralized bands dip between 45-57° TCA. >>Calc-silicate alteration is prominent in mineralized zones. Oxidation, bleaching and chlorite alteration are present throughout the hole.

Laminations are faint and dip ~60° TCA. Fine grained pyrrhotite is disseminated throughout. Fractured surfaces are moderately oxidized in the top 8.5 m. Few fine grained, euhedral arsenopyrite crystals are observed along fractures.

Mineralization consists of fracture-filling and disseminated fine to coarse grained galena, sphalerite, chalcopyrite and pyrrhotite. Mineralized zones locally display banding between 45-57° TCA. Frosty white coating occurs on numerous rusty fractured surfaces (hydro-zincite ?). Dark green chlorite alteration is mainly observed on fractures, but also occurs interstitially. Few areas resemble arsenopyrite weathering - scorodite (?). Calcareous stringers and coatings on fractures are common. Light creamy beige, soft mineral occurs locally and strongly effervesces, calcite (?).

COMMENTS

Mineralization in the intercalated silty limestone and siliceous siltstone concentrates in calc-silicate altered zones. >>The fault contact at 208.10 m is sharp, and the argillaceous limestone beneath is unmineralized and comparatively unaltered.

Contacts between units are diffuse and discernable with muriatic acid. Light grey limestone layers stronger effervesce, while darker siltstone layers do not. Calcareous veinlets are common throughout and host fine grained sphalerite, galena, pyrrhotite and chalcopyrite. Calc-silicate altered zones host the majority of mineralization within fractures and as disseminations. Fine to medium grained, euhedral arsenopyrite crystals are present as 'clumps'/aggregates. Crystalline calcite cavities are common between 45.5 to 72.0 m. A light pink, non-calcareous and mineral occurs intermittently. Dark green chlorite alteration is prevalent in calc-silicate altered zones. Oxidized fractures are common throughout. Locally cracked and fractured. Sharp lower contact.

White calcite fracture-fills and veinlets occur throughout and show no preferred orientation. Laminations are 1-3 mm wide and dip between 55-65° TCA. Trace pyrite occurs on few fractured surfaces. Moderate chlorite alteration is prevalent along most fractures.

COMMENTS

Hole mainly comprises light to medium grey siliceous siltstones with moderate to strongly clay altered 1m wide shear zones. Pervasive clay alteration occurs in a 15m interval from 117-133m. Intercalated argillaceous sediments with moderate graphite occur at the bottom of the hole. >> Moderately dense calcite fracture fill, oriented predominantly at 30° and 60°, with fair fine grained pyrite and pyrrhotite and occasionally trace sphalerite and galena, is common throughout hole. Weak fine to medium grained arsenopyrite appears predominantly in the clay altered sediments.

Interval is intercalated with weak fine grained limestone (5cm intervals). Contacts between siltstone and limestone are diffuse. Interval contains fair clay alteration (light pink, buff sections, very soft). Moderately strong fracture controlled calcite is found throughout the interval. Fine laminations (1-2mm) are oriented from 25-60 degrees to core axis but generally occur at 40 degrees to core axis.

Fair fine grained pyrite, weak pyrrhotite and sphalerite, and trace arsenopyrite are present. Fracture orientation ranges from 25-55 degrees to core axis but is preferentially oriented at 25 and 40 degrees. Fractures occur at a moderate density (7/m).

COMMENTS

The hole intersected an intercalated silty limestone, and siliceous siltstone to 369.13 m. Contacts between the intercalated units are diffuse. Mineralization ranges from trace to strong, but the bulk of it occurs from 77.12 m to 247.07 m, in fractures, veins, and replacements. Sections of green-coloured, intense calc-silicate alteration occur throughout, and is associated with replacement mineralization. Mineralization is generally medium grained, and consists of pyrrhotite, sphalerite, galena, chalcopyrite, and arsenopyrite. Bedding generally ranges from 50° to 70° TCA, but increases to 85° at the end of the intercalated siltstone and limestone. At 369.13m, a gradational contact to the argillaceous limestone occurs. The underlying unit continues until 387.00 m, which is the end of the hole.

Strong calc-silicate alteration locally and weak chlorite alteration in places. Fine grained medium brown-buff coloured alteration seen. Bleaching of the units occurs along fractures, and also as bubbly-spots ~1cm in diameter. Buff-coloured alteration occurs in 10-45cm sections throughout. Chlorite alteration seen mainly along fractures/veins, and is especially prevalent from ~25-28m in depth. Unit is generally softer and more effervescent farther up-hole. Strong mineralization is separated out into sub-intervals. Smaller amount of mineralization in the interval (but not included in the sub-interval) is largely oxidized and/or fine-grained in calcite veins/veinlets and fractures. Pyrrhotite, sphalerite, galena, and chalcopyrite seen in small amounts. Mineralization seen to increase with depth.

Mineralization style are as: 1) Large (15-35cm) mineral replacement sections. 2) Small amounts, but locally widespread mineral disseminations. 3) Within and alongside calcite veins/veinlets.
													ep?	t														Pyrrhotite mostly in veins or replacements, but small amounts are seen in disseminations.
																												Chalcopyrite mostly in veins or replacements. Minor presence in disseminations.
																												Galena mostly as veins or replacement, none seen in mineral disseminations.
																												Sphalerite only seen by veins or in mineral replacements.
																												Larger mineralized sections separated out as sub-sub intervals:
			40.00	40.16	0.16	VN	MX				w				VN	25				s	ms	Cp	f					Calcite vein hosting sphalerite, galena, and some chalcopyrite. Sphalerite (dark brown) and galena are semi-massive. Chalcopyrite forms interstitially within the semi-massive sphalerite and galena. Calcite vein is milky, and fine grained.
			40.39	40.58	0.19	VN	MX				ms				VN	27			m	ms	s	Cp	m					Calcite vein inside of a quartz vein. Galena and sphalerite (dark brown-black) occur semi massively, while pyrrhotite & chalcopyrite form interstitially within the semi-massive sphalerite & galena. Calcite vein is coarse grained, while the quartz vein is fine grained. Sulphides likely brought in with the SiO2 rich fluids, while the calcite vein came later.
			41.80	42.00	0.20	MX					m				BN				w	m	t							Mineral replacement section. Large semi-massive sphalerite crystals (dark brown- black, 0.5-0.7cm in diameter) forming interstitially with tabular semi-radial calcite crystals. Hard, small pinkish crystals present (Garnet?)
			44.01	44.52	0.51	MX		MG			s		chl	w					s	ms	ms	Cp	w					Mineral replacement section. Pyrrhotite occurs in blebs, and in several 0.1-0.2cm thick irregular veinlets. Galena occurs closely with the pyrrhotite. Galena is semi-massive. Sphalerite occurs throughout and is dark brown to black, and is semi-massive. Chalcopyrite is anhedral and interstitial, mostly to the sphalerite.

			69.00	70.00	1.00	MX					i								m	m	t						Sphalerite & pyrrhotite blebs with trace galena. Minerals are subhedral, and medium grained.
77.12	98.11	20.99				LST/ SLT	LT-MD GY	cBX	m		i								s	w	w	Cp	t	As	t		Light-medium grey, partially light green, mottled, weakly chloritized, strongly calc-silicate altered, intercalated, silty limestone and siliceous siltstone. Mineralization is mostly fracture controlled, with moderate & partial crackle brecciation in places. Mineralized veins are also present. Rock is unoxidized. Chalcopyrite is found in veinlets and in filled fractures, as clusters of crystals and 0.5cm-1.0cm subhedral blebs. Pyrrhotite is found in large amounts in filled fractures, as well as veinlets, semi-massive, and subhedral. Dark honey-brown to black sphalerite is found with pyrrhotite, and occurs mostly in filled fractures. Galena is found mostly in a mineral replacement zone, separated as a sub interval.

			318.25	320.30	2.05	LST/ SLT	MD-LT GY	FG				ms															Same original rock unit as interval, but is broken up (5-10cm), angular and oxidized. Some sections of full core between broken up sections.
			323.85	324.14	0.29	MX													w	w		Cp	f				Section of calcite veinlets & fracture infill with fine to medium grained, subhedral pyrrhotite, sphalerite and chalcopyrite mineralization.
															VT	50											Pyrrhotite, sphalerite, chalcopyrite calcite veinlet at 323.92m
			355.10	357.00	1.90	BD	LT-MD GY	FG																			Section of convolute bedding (soft sediment deformation?). Wavy and irregular bedding lines seen.
			358.60	360.30	1.70	MX													w	w		Cp	w				Section of fracture infill, fine to medium grained subhedral blebs of pyrrhotite, chalcopyrite, and sphalerite. Blebs are 0.2 to 0.5cm in diameter.
369.13	387.00	17.87				ARG/ LST													t								Dark grey, fine grained, heavily calcite veins, unbleached, unchloritized, uncalc-silicate altered argillaceous limestone. Trace pyrrhotite mineralization seen as medium grained and subhedral fracture infill. Calcite brecciation seen from 381.00m to 385.00m.
															VN	35											Calcite vein, no mineralization, 3.0 to 4.0cm thick at 370.70m
															VT	68											Calcite veinlet set (0.5 to 2.0 cm thick) from 375.00m to 379.30m.
EOH																											End of hole. 387.00 m

7.70	145.75	138.05	LST/SLT	Weakly to intensely calc-silicate altered, intercalated silty limestone and siliceous siltstone. Mineralization is sparse and consists of fine grained pyrrhotite, sphalerite, galena and chalcopyrite.
145.75	199.70	53.95	LST/SLT	Interfingering limestone and siltstone. Minor pyrrhotite, sphalerite, galena and chalcopyrite occur within calcite veinlets.
199.70	224.44	24.74	LST/SLT	Interlayered limestone and siltstone. Moderately to strongly mineralized in calc-silicate altered zones. Mineralization was fracture-filling, disseminated, blebby and locally sub-massive and consisted of sphalerite, pyrrhotite, galena, chalcopyrite, and arsenopyrite.

COMMENTS

The hole mainly intersected a weakly mineralized, intercalated silty limestone and siliceous siltstone, and a moderately to strongly mineralized, calc-silicate altered limestone. Contacts between units are diffuse. >>Mineralization is fracture-filling, disseminated, locally sub massive, and replacement-like and consisted of fine to coarse grained sphalerite, galena, chalcopyrite, pyrrhotite, and arsenopyrite. Few shallow dipping (10-30° TCA) calcite filled and mineralized fractures occur. >>Laminations are common and dip 50-72° TCA. >>Hole was shutdown early due to unstable and washed out drill pad.

7.70	273.41	265.71				LST/ SLT	LT GY-WH & LT BF-GN		w		w-i	t-i	chl	w-m	Fx	25-30°			t-f	t-f	t-f	Cp	t				Light grey-white to dark grey and light buff-green, fine to very fine grained, weakly to intensely calc-silicate altered, intercalated silty limestone and siliceous siltstone. Contacts between units are diffuse and mainly discernable with muriatic acid. Overall mineralization is sparse. Light grey-white limestone layers strongly effervesce, while dark grey siltstone layers do not. Oxidation is locally pervasive in clay altered zones, and mainly observed along fractures. Calc-silicate altered zones are bleached and light buff-green. Fracture-filling fine grained pyrrhotite, sphalerite, galena and chalcopyrite. Mineralized fractures dip 25-30° TCA. Calcite veinlets occur throughout but concentrate in calc-silicate altered zones as 5-30 cm crystalline fracture-fills. Crystalline calcite cavities are common between 21.0 to 65.3 m. Laminations are dipping 65 72° TCA. Chlorite is mainly present along fractures and alongside mineralized fractures.

Light grey limestone layers strongly effervesce while dark grey siltstone layers do not. Sparse mineralization within calcite fracture-fills consists of fine to medium grained galena, sphalerite, pyrrhotite and chalcopyrite. Mineralized fractures can be difficult to identify (ie. moderately mineralized fractured surface along a 1 mm wide fracture). Laminations dip between 65-75° TCA. Oxidized fractures occur throughout. *Calc-silicate alteration significantly decreases in this interval.

Interval is fairly to strongly mineralized in calc-silicate altered zones. Mineralization style is fracture-filling, disseminated, replacement, blebby and occasionally sub-massive and consists of fine to medium grained pyrrhotite, sphalerite, galena, chalcopyrite and arsenopyrite. Laminations and crude mineralized bands dip between 55-65° TCA. Chalcopyrite commonly occurs alongside pyrrhotite and sphalerite. Chlorite is prominent along fractures surfaces. Sparse white calcite cavities (4-10 cm wide).

COMMENTS

Hole is mainly comprised of light to medium grey, fine grained siltstone, with some minor lithic wacke up section and argillite mid-section following a major interval of faulting. First 100m contains abundant faults, noted by highly deformed, clay altered and rubbly intervals. Siltstones are moderately chlorite and clay altered. Minor intercallated limestone is found throughout hole. >> Mineralization is composed of fracture controlled pyrite and arsenopyrite until ~175m when weak, fine grained, fracture controlled sphalerite and galena occur at a moderate density with a dominant orientation of 54° to core axis. Base metal mineralization drops out at 375m until the end of the hole. No replacement style mineralization is seen within the hole.

5.00	5.18	0.18				OVB						s															"Overburden" (OVB) - Rounded pebbles of sediments, strongly oxidised, light orange in colour.
5.18	12.49	7.31				SLT	LT-MD GY	fg				ms	cly	ms	LA	43											"Oxidized Siltstone" (SLT) - Moderately strongly oxidised and clay altered siliceous siltstone. Minor argillite appears interbedded (5-10% of interval). In areas less altered fine laminations (<1mm) are oriented at 43° to core axis. Most of the interval is rubbly and has pervasive limonite staining.Large Fault zone?
12.49	28.55	16.06				ARG	BK	fg				w			LCTC	54											"Argillite" (ARG) - Black, fine grained argillite. Interval is weak, and crumbles by hand. Interval contains moderate graphite. More competent sections seem to incorporate less clay and could be considered argillaceous siltstone. Much of unit is faulted. Calcite microfractures occur at a low density in the more competent sections. Weak limonite staining occurs along fractures. Upper contact is gradational and appears to be parallel with the laminations of the overlying siltstone, lower contact is conformable and is oriented at 54° to core axis. No visible mineralization within the interval.

Metasediments can be broken by hand in sections o strong clay alteration. Un-clay altered sections show strong competency. Moderate quartz carbonate fracture fill occurs at all angles to core axis. Fine grained weak pyrite and trace arsenopyrite are often associated with the fractures. Trace pyrrhotite is rare. Laminations are visible in less clay altered sections and are oriented at 50° to core axis. Upper contact is gradational with the lithic wacke and is parallel with the laminations. Lower contact is also gradational and is intercalated with the argillite. (entire interval a fault/shear zone??)

169.42	260.90	91.48				SLT	LT-MD GY	fg					cly	w	LA	70											"Chlorite altered Siltstone" - Light to medium grey, fine grained siltstone. Interval is moderately chlorite altered and weakly clay altered. Interval is distinguishable by the light green discoloration due to chlorite alteration. Clay alteration tends to be light pink/ buff coloured. In sections where the original rock fabric is visible fine laminations (~1mm) oriented at 70° to core axis are seen. Moderate to strong calcite fracture fill is visible at all orientations to core axis. Much of the section appears brecciated due to calcite fractures. The upper contact is gradational with the argillaceous sediments.

															Fx	30			w	t		Py	w	Cp	t		Mineralization is associated with calcite fracture fill at all orientations to core axis. Fractures are generally 1-2mm in width. Up section mineralization is predominantly weak, fine grained pyrite with trace arsenopyrite. Further down section the primary mineralization becomes weak pyrrhotite with trace chalcopyrite. Fractures occur at all orientations to core axis but predominantly occur at 30° to core axis.

COMMENTS

The hole intersected a weakly calc-silicate altered intercalated limestone and siltstone. This unit was weakly to strongly mineralized to 46.95 m, and weakly mineralized to a depth of 109.81 m. A black argillaceous limestone was intersected to a final depth of 394.91 m. Contacts between the intercalated limestone and siltstone units are diffuse. A fault breccia was intersected at 163.15 m, followed by the argillaceous limestone unit. Mineralization consists of fracture-filled, replacement-style, and disseminated pyrrhotite, chalcopyrite, galena and chalcopyrite.

Mineralization styles include fracture-filling, replacement, disseminated and blebby, and consist of fine to coarse grained sphalerite, arsenopyrite, pyrrhotite, and chalcopyrite. Black sphalerite is locally sub-massive. Fine to coarse grained arsenopyrite crystals are euhedral, and disseminate throughout (but also occurs in 'clumps'/bands 1-5 cm wide). Mineralized fracture-fill and replacement zones are 1-14 mm wide. Few shallowly dipping mineralized calcite veins/fracture-fills dip 22° TCA (ie. at 28 m). Unmineralized, white calcite veinlets and fracture-fills are abundant. Locally intensely oxidized zones are broken up and display a thick limonite coating along fractures. Chlorite alteration is weak and mainly observed on fractured surfaces. Malachite is present on few oxidized surfaces. Dendritic manganese staining is observed on few fractures. Lower contact is diffuse and marked by a sharp decrease in mineralization and oxidation.

Light grey-white limestone layers strongly effervesce, while dark grey siltstone layers do not. Contacts between layers are diffuse and discernable with muriatic acid. Mineralization consists of fracture-filled and disseminated galena, sphalerite, pyrrhotite and chalcopyrite. Mineralized fracture-fills are calcite-rich. Laminations are convoluted, but mainly dip 25-35° TCA. Chlorite is present on most fractures. Clay alteration is prevalent in oxidized zones.

COMMENTS

The hole intersected a trace to strongly mineralized, weak to fairly calc-silicate altered, intercalated silty limestone and siliceous siltstone until 432.00 m (EOH). Mineralization varies, but the bulk of it occurs from 35.05 m to 246.30 m. Mineralization occurs in fractures, veins and replacements. Green sections of calc-silicate alteration are associated with replacement style mineralization (usually along bedding). Mineralization includes pyrrhotite, sphalerite, galena, chalcopyrite, arsenopyrite, and pyrite. Bedding ranges from 50° to 60° TCA, until approximately 110.00 m, where it steepens to 70° to 80° TCA until approximately 190.00 m. After that, bedding flattens to 50° to 60° TCA, until approximately 360.00 m, where it ranges from 50° to 80° TCA until EOH.

Limestone is dominant (~70%) in this interval. Spotty/ speckled chlorite alteration present. Mineralization in this interval is controlled by veins and infilling of fractures. Mineralization is fine grained, partially semi-massive and subhedral. Larger pyrrhotite-sphalerite fracture infill from 13.30m to 13.47m.

Spotty chlorite alteration visible in places. Large (>5cm) tabular calcite crystals seen at several locations. Mineralization styles are through veins, fracture infill, and replacements. Weakly dissemination sections also present. Mineralization is generally moderate, pyrrhotite and sphalerite mos common, but chalcopyrite is prominent locally. Some pyrite visible sporadically throughout. Bleaching alongside venation/fractures. Malachite staining visible at 80.85m.

Slightly-moderately weathered. Bleaching occurs along fractures/veins. Chloritization is moderately strong. Mineralization occurs in veins, replacements (including disseminations) and less commonly as fracture controlled infill. Chalcopyrite is usually blebby (0.5-1cm) and found in veins or replacements, and is medium grained and subhedral. Pyrite is found as disseminated blebs, veins and as fracture infill, especially in a following subinterval, and is fine to medium grained and subhedral. Pyrrhotite is found throughout, in veins, replacements, fracture infill and is fine to medium grained and subhedral. Pyrrhotite is often found with chalcopyrite and sphalerite. Sphalerite occurs often with pyrrhotite and chalcopyrite, and is brown-black. Sphalerite is present in replacements and veins. Galena seen in trace amounts, and is medium grained and found in veinlets. Some heavier mineralized sections separated out as subintervals for descriptions.

			420.35	421.20	0.85	MX							chl	s					w	t		Cp	w				Section of strongly chloritized altered skarn, with mineralization. Mineralization occurs in blebs, and in fracture controlled mineralization. Large (>5cm) tabular calcite crystals found near the bottom of section with the pinkish-reddish mineral. Chalcopyrite seen in weak amounts in fine-medium grained blebs, while pyrrhotite occurs more commonly with fracture infill.
			425.65	426.06	0.41	BLE																					Section of bleaching in bubbly texture, rounded bleached zones spherical, 0.75cm across.
			427.22	427.41	0.19	MX													w	w	w						Section of weak, medium grained, euhedral sphalerite, pyrrhotite, and galena in replacements.
			429.90	429.90	0.00	VN									VN	32											Calcite vein, no mineralization, unoxidized, reddish pinkish hard mineral seen at the edges. Vein is 2-3 cm thick.

COMMENTS

Hole is mainly composed of light to medium grey siltstone with occasional silty limestone interlayering present at the top of the hole. The bottom of the hole is characterized by a dark grey argillaceous limestone intercalated with a medium grey silty limestone and pyrite mineralization. Laminations are commonly 50-60° tca for the majority of the siltstone unit. Mineralization in primarily fracture controlled with pyrrhotite>sphalerite>galena >chalcopyrite for the majority of the mineralized zone.

Weak calc-silicate alteration is present across unit. Contacts between Siltstone and LST are diffuse and SLT tends to be darker in colour than LST and LST is discernable through HCl. Mineralized fracture in fills are 1-7mm across unit and is dominated by calcite; crystals range up to 4mm. Mineralized fractures occur at 60° tca. mineralization is also present in bleached zones that compose 25% of the unit and crystals do Po and Sp (t-w) range from < 1-2 mm as disseminated grains. Occasional growths of white-beige spherulite-like concentric and subrounded mineral clusters are cross cut by mineralized fracture infills. Veining of calcite occurs across unit with orientations of 60° and about 30° tca. Alteration of Limonite and chlorite are common across fractured surfaces. Calc-silicate alteration is weakly present within zones of unit and chlorite alteration is often associated with these zones.

COMMENTS

The start of the hole intersects intercalated silty limestone and siliceous siltstone up to 41.59 m, where a siltstone with sections of moderate calc-silicate alteration begins. The intercalated limestone and siltstone continues to a depth of 313.56 m. The remainder of the hole consists of argillaceous limestone. Contacts between units are gradational. The bulk of the mineralization occurs from 41.59 m to 260.47 m. Mineralization occurs mostly in infille fractures, or as replacements (sometimes along bedding). Replacement mineralization is associated with calc-silicate alteration. Significant amounts of pyrrhotite, sphalerite, chalcopyrite is present, with lesser amounts of galena and arsenopyrite. Bedding is usually from 50° to 70° TCA, but varies locally from approximately 35° to 85° TCA. Fractures and veinlets are usually between 10° and 30° TCA, but measurements occur up to 50°.

			102.00	104.31	2.31	MX									MX	30											Section of mineral fracture infills with similar orientations. Infill fractures are ~0.2-0.5cm thick. Mineralization is medium grained galena, pyrrhotite, pyrite, and sphalerite.
			105.67	106.35	0.68	OX														f	w							Dark yellow/red/brown oxidized section. Pyrite and galena present. Pyrite is found in blebs (0.2cm across) as well as in fracture infill.
			106.35	109.51	3.16	MX													ms		ms	Py	ms	Cp	m		Section of strong fracture controlled mineralization, significant amounts of medium grained pyrite (in blebs 0.5 to 1.0cm across), fine grained pyrrhotite (replacement) and galena (separated out as a sub-sub interval).
			108.09	108.20	0.11	MX													w		40	py	ms	Cp	w		Section of mineral replacement. Significant, coarse to fine grained galena.
			109.51	110.82	1.31	QZ/ MX													t-w	i	t-w	As	ms	Cp	f		Large quartz vein (fractured white) with mineralization. Section inside (15 to 20cm) is country rock. Contacts not distinguishable. Contains significant amounts of sphalerite, intense, coarse grained arsenopyrite, fair amounts of chalcopyrite, and trace to weak fine grained to medium grained pyrrhotite, and galena. Two massive sections of sphalerite separated into subintervals.
			110.09	110.15	0.06	MX														35		Cp	s				Section of partly massive, coarse grained sphalerite, occurring with blebby (0.5cm to 1.0cm across) medium grained chalcopyrite.
			110.25	110.50	0.25	MX														70		As	s				Section of massive, coarse grained sphalerite, with smaller amounts of coarse grained arsenopyrite, next to each other.
			110.82	120.72	9.90	MX													ms	ms	w	Cp	f	As	w		Section of moderately strong replacement and fracture controlled mineralization. Eight sections of 15 to 40cm, of semi-massive mineral replacement. Mineralization consists of fair amounts of medium grained chalcopyrite, moderately strong amounts of fine to coarse grained pyrrhotite, and weak amounts of medium grained sphalerite, galena, pyrite and arsenopyrite. Chalcopyrite, sphalerite, and pyrrhotite often occur together.

COMMENTS

Hole is primarily composed of a fine to coarse grained lithic wacke intercallated with fine grained argillaceous sediments. Argilliceous sediments become increasingly dominant down section. The grains in the wacke appear to be cherty and are very hard. Mineralization is primarily trace pyrrhotite and pyrite associated with quartz carbonate fracture fill, with dominant orientations at 45 an 60 degrees to core axis.

Sands are composed of chert dominated lithics. The rock is hard (>5.5). Minor intercallated argilliceous siltstone (<5%) is found throughout the unit. Laminations oriented between 50-85° TCA (with a dominant orientation of 75°) are found within the siltstone. Trace to weak light green chlorite alteration is found in the siltstone and in highly fractured regions a light pink, soft clay alteration is apparent. Quartz carbonate fractures oriented between 50 and 80° TCA (dominant orientation at 60°) occur at a moderately high density. Fractures range from <1mm to 3mm in width.

Main difference between this unit and above is siltstones become more prevalent (65% wacke, 35% siltstone) and wacke becomes finer grained (fine-medium sand). Laminations are oriented at 70° to core axis and contacts parallel laminations.
													chl	t-w	Fx	45		3 to 12	t			As	t				Mineralization becomes slightly more prevalent down section. Trace pyrrhotite, pyrite and arsenopyrite are found (Po>Py>As). Pyrrhotite is generally associated with quartz carbonate fractures oriented at 45° to core axis. Pyrite is associated with quartz fractures oriented at 59° to core axis.

Siltstone shows laminations between 50 and 60° to core axis. Contacts between two rock types are parallel with laminations. Two sets of cross cutting calcite fractures oriented at 48 and 28° to core axis occur at a moderate density and often contain trace pyrrhotite. Trace, medium grained arsenopyrite is occasionally associated with clay altered segments (associated with faults?). Moderate chlorite alteration and trace to weak graphite are associated with the siltstone. Unit appears to be more faulted down section. Trace smeared pyrite is occasionally found in the argillite.
