INTRODUCTION

The Klaza property lies within the Dawson Range Gold Belt in southwestern Yukon. It hosts gold-silver mineralization associated with a series of subparallel vein and breccia zones. The property is owned by Rockhaven Resources Ltd.

From June to September 2011, Rockhaven conducted an exploration program involving: i) 13,630 m of diamond drilling; ii) 2,940 m of reverse circulation percussion drilling; iii) 4050 m of excavator trenching; iv) soil geochemical sampling; v) 326 line km airborne magnetic and radiometric surveys; and, vi) 76 line km airphoto survey. Archer, Cathro & Associates (1981) Limited managed the exploration program. Most of the work was done from a tent camp on the property. The authors participated in and supervised the program. Appendix I contains the authors' Statements of Qualifications.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The property is located in southwestern Yukon at latitude 62°07′ north and longitude 137°17′ west on NTS 115I/3 (Figure 1). It consists of 333 contiguous mineral claims registered with the Whitehorse Mining Recorder in the name of Archer Cathro, which holds them in trust for Rockhaven. Claim registration data are listed below while the locations of individual claims are shown on Figure 2.

on the two-wheel drive Nansen Road to the Mount Nansen mine site. The Nansen Road is a narrow gravel road maintained by the Yukon Territorial Government. From the mine site, the road deteriorates in quality but continues approximately 11 km north to the Klaza River valley, passing within 0.5 km of the property. The camp and the main area of exploration interest can be reached by a 1.7 km long four-wheel drive road that connects to the Nansen Road. By road this point is 250 km from Whitehorse and 430 km from the year-round tidewater port at Skagway, Alaska.

HISTORY

The Klaza property covers the Esansee Showing and Rico work target, which are recorded as Yukon Minfile occurrences 115I-067 and 115I-080, respectively (Deklerk, 2004). In 1937, K. Paulson was rumoured to have discovered high grade silver-lead float at what is now the Esansee Showing. The first claims were staked in October 1947 by G. Dickson. He immediately optioned them to Conwest Exploration Limited, which performed minor bulldozer trenching later that year. Dickson restaked the target as West claims in 1960, but these claims were allowed to lapse without reported work.

In 1967, J. Smith and associates of Whitehorse restaked part of the area as the May claims and collected reconnaissance soil samples that yielded anomalous lead and silver values. This group also dug one bulldozer trench but no mineralization was intersected. In 1968, Esansee Explorations Ltd. optioned the adjoining Sue claims that had been staked in September 1967 by J. Wheeler. Esansee performed geochemical surveys in 1967 and 1968, an EM survey in 1968 and bulldozer trenching from 1967 to 1970. In 1968 and 1969 it also built a 14 km tote road from the Mount Nansen mine site to the edge of the property. The option on the Sue group was dropped in 1970.

The western portion of the Klaza property was explored by AEX Minerals Corporation in 1973 and 1974. AEX performed geological mapping, soil and silt sampling and a ground magnetic survey.

The showing was restaked as the Tawa claims in 1979 by BRX Mining & Petroleum Ltd., which explored in 1980 with soil geochemical surveys, three short bulldozer trenches (two of which deepened 1968 trenches) and seven diamond drill holes totalling 447.30 m. In 1981 BRX conducted magnetometer and VLF-EM surveys.

In 1982, the property was restaked again as the Tawa claims by T. Hanlon, who transferred them back to BRX. Chevron Canada Resources Ltd. optioned the property in 1986 and explored with soil sampling, mapping, EM-16 surveys and excavator trenching that year, and road building and bulldozer and excavator trenching in 1987.

BYG Natural Resources Inc. sub-optioned the property from Chevron and explored it with excavator trenching and six diamond drill holes (373.98) in 1988 and three excavator trenches in 1989. In 1996, BYG carried out a large geophysical program that included ground EM and magnetic surveys over most of the Klaza claims. The company followed with several lines of

soil sampling over the southeast corner of the claim block and three drill holes (307.64 m) in 1998. BYG subsequently went bankrupt and the claims went into receivership.

ATAC Resources Ltd. staked the Klaza 1-24 claims in January 2005 and optioned them to Bannockburn Resources Limited in October 2005. In 2006, Bannockburn completed a gradient array induced polarization survey across an 1800 by 1450 m area in the eastern part of the property (Wengzynowski, 2006). This survey identified two prominent chargeability anomalies.

Rockhaven purchased 100% of the Klaza 1-24 claims from ATAC in November 2009 and staked additional claims in 2010. The 2010 exploration program identified bulk tonnage and high grade gold-silver mineralization from both diamond drilling and excavator trenching. Soil geochemical sampling and helicopter-borne magnetic and gamma-ray geophysical surveys were also completed in 2010.

Rockhaven enlarged its property in November 2011 by purchasing the Dic and Eagle claims, which adjoin the southeast boundary of the Klaza claims. These claims had received some historical work, including prospecting, soil and silt sampling and ground VLF-EM and magnetic surveys in 1986 (Heberlein,1986) and 1987 (Sutherland, 1988), and a total of 7.8 km of excavator trenching, none of which reached bedrock.

GEOMORPHOLOGY

The eastern part of the property covers a broad rounded ridge that lies between Mount Nansen and the Klaza River. The rest of the property is mostly underlain by low hills and valley bottom, flanking the Klaza River. Creeks draining the property flow directly into the Klaza River or southeast to Nansen Creek, both of which are part of the Yukon River watershed. Local elevations range from 1200 to 1500 m above sea level. The area escaped Pleistocene continental glaciation but experienced some local Pleistocene to Holocene valley and alpine glaciation. Outcrop is nonexistent across most of the property and overburden typically consists of a few centimetres of organics, 0 to 5 cm of volcanic ash and up to 200 cm of loess and immature soil mixed with locally derived rock fragments over deeply weathered bedrock. At lower elevations, thick glaciofluvial outwash and till blanket the valley floors. Permafrost is extensive, particularly on the north- and west-facing slopes.

The area has a continental climate with low levels of precipitation and a wide temperature range. Summers are normally pleasant with extended daylight hours whereas winters are long and cold. Tree line is at 1200 m on north facing slopes and about 1400 m on south facing slopes. Typical vegetation consists of willow, alder and black spruce at lower elevations giving way to dwarf birch, alder and stunted spruce, and finally to grass and lichen on ridge tops.

GEOLOGICAL SETTING

Regional Geology

The area containing the Klaza property was visited by J.B. Tyrrell and D.D. Cairnes for the Geological Survey of Canada in 1898 and 1914, respectively and mapped by H.S. Bostock

(1936), D.J. Tempelman-Kluit (1974 and 1984) and G.G. Carlson (1987). The geology was revised in a compilation by Gordey and Makepeace (2000). The following discussion is based on maps prepared by Gordey and Makepeace.

The Klaza property lies within the Yukon-Tanana Terrane (YTT) approximately 100 km southwest of the Tintina Fault (Figure 3). YTT comprises a variety of Late Devonian to Early Mississippian metavolcanic and metasedimentary rocks, and represents both arc and back-arc environments (Colpron et al., 2006; Piercey et al., 2006). The Tintina Fault is a transcurrent structure that experienced about 450 km of dextral strike-slip movement during the Eocene. This movement offset an outlier of YTT in the Finlayson Lake District of southeastern Yukon from the main body of YTT, which lies southwest of the fault.

Regional stratigraphy in the area of the Klaza property is summarized in Table I. The basement rocks near the property are mainly schists and gneisses, which include autochthonous gneisses (Pelly Gneiss), allochthonous metasedimentary rocks (Nisling) and enigmatic units (amphibolite). Basement rocks are cut by foliated plutonic rocks (Long Lake Suite) which with the schists and gneisses were metamorphosed and uplifted in the Jurassic. The youngest rocks in the area are unfoliated and are represented by four plutonic/volcanic events that occurred between the Lower Cretaceous and Tertiary (Whitehorse Suite, Mount Nansen, Prospector Mountain Suite and Carmacks). Local geology in the area of the Klaza property is shown on Figure 4.

PROPERTY GEOLOGY

On the Klaza property, the Paleozoic or older metamorphic country rocks are not exposed, and the igneous suites are limited to a biotite-hornblende granodiorite stock, which is believed to be of Mid-Cretaceous age and belong to the Whitehorse Suite, plus younger porphyry dykes and minor volcanic cap rocks. The granodiorite contains up to 30% hornblende and biotite, is coarse grained and is non-foliated. Northwest trending porphyry dykes (up to 30 m wide) cut the granodiorite in the main area of interest and elsewhere. These dykes contain up to 15%, 1 to 2 mm orthoclase phenocrysts plus rare biotite and quartz phenocrysts in a buff aphanitic groundmass. Commonly the dykes are strongly fractured and associated with both fault and vein zones. These dykes are considered to be satellites to a Late Cretaceous Prospector Mountain Suite porphyry stock situated immediately east of the property. This intrusive center is thought to be the main heat source for hydrothermal cells responsible for the mineralization at Klaza. Volcanic rocks are found on the periphery of the property and include medium green-grey andesite flows and pyroclastic rocks with occasional buff to tan rhyolitic tuff.

Most of the central and western portions of the property lie within the Klaza River valley, which contains little to no bedrock exposure. Frost boil mapping conducted by Aho (1975) identified porphyry intrusive rocks within this area. These findings have been integrated into the local geology map on Figure 4.

Two main fault trends (NW and NE) are present on the property. The first set strikes north-northwest and dips between 60 and 80° to the southwest. These faults lack strong topographic expression, but they host mineralized veins and breccia zones. They also appear to control the distribution of porphyry dykes. The second set of faults strikes northeast and dips subvertically. They form prominent topographic linears and cut the mineralized zones. These faults vary in their sense and magnitude of displacement.

MINERALIZATION

The Klaza property lies within the Mount Nansen Gold Camp (MNGC), a northwest trending structural corridor that hosts 30 known mineral occurrences. Mineralization within the MNGC exhibits zonation from a weakly mineralized porphyry zone outward to mesothermal and epithermal veins (Cyprus – minfile 115I066). The hydrothermal system is centered around potassic alteration cores related to the porphyry complex (Hart, 1997).

Mineralization discovered to date on the Klaza property consists of fault-controlled, gold and silver bearing epithermal and mesothermal vein and breccia showings hosted within several subparallel structural zones. The main mineralized structures discovered to date include the BRX, Klaza, BYG and HERC zones. All four zones range from 5 to 50 m wide and contain unmineralized quartz-feldspar porphyry dykes and variably mineralized, sheeted veins and veinlets with local breccias. The host granodiorite exhibits pervasive weak argillic alteration within the zones and up to 30 m around them. Sericitization and potassic alteration are found directly adjacent to hydrothermal channel ways. Depth of surface oxidation ranges from 0 to 100 m depending on fracture intensity, the type of mineralization and local geomorphology, with the deepest weathering occurring in strong, pyritic veins located along ridge tops or on south facing slopes.

The mineralization is spatially and probably genetically related to the porphyry dykes, which strike west-northwesterly and dip steeply to moderately towards the south. The dykes pinch and swell in three dimensions and, although coupled with mineralization, are themselves mostly barren.

The structural zones contain veins, veinlets and breccias hosting pyrite, arsenopyrite, galena, sphalerite, stibnite and jamesonite in quartz, carbonate and barite gangue. The sulphide minerals typically comprise 1 to 10% of the rock, often increasing to between 20 and 80% over 25 to 200 cm intervals. Petrographic analysis of a few mineralized core specimens was done by John Payne, Ph.D., P.Geol. of Vancouver Petrographics and his report is found in Appendix II. The petrographic work confirmed the presence of the main sulphide minerals and identified native gold/electrum in one specimen.

Textures and mineralogy observed at the Klaza property indicate that both epithermal and mesothermal vein environments are present. Examples of epithermal veining are seen in three of the four main structural zones with varying intensity. Breccia zones tend to be wider and more frequent where epithermal rather than mesothermal veining predominates, and include rare breccia pipes. The Klaza zone best exemplifies epithermal veining and often shows comb structures, colloform textures and symmetrical banding.

Mesothermal veining is present in all four of the main zones, but is best represented in the more southerly structures. Areas of mesothermal veining have exceptional continuity and generally feature lenses or bands of semi-massive pyrite, arsenopyrite, galena and sphalerite, which are up to 3.5 m across. Silver-lead ratios of approximately 4 oz. Ag: 1% Pb commonly occur within these veins – these high ratios are characteristic of mesothermal systems (Dong, 1995). The BRX zone, which is thought to be primarily mesothermal, is distinguished from the other mineral zones by an apparent lack of brecciation, colloform textures and stockworking.

Quartz is the dominant gangue mineral in both epithermal and mesothermal veins. It occurs in a variety of textures including chalcedonic, comb, banded, speckled and vuggy. Smoky quartz is the most common colour variation; however, milky and clear quartz are locally abundant.

Breccias form tabular zones and occasionally pipes. They commonly consist of heterolithic wallrock clasts, which include granodiorite as well as various volcanic lithologies, and matrices of fine-grained black sulphides with disseminated galena and sphalerite. Breccias are mostly observed within drill core from the Klaza zone where they range up to 2 m in width.

EXCAVATOR TRENCHING

In 2011, trenches totalling approximately 4050 m were completed using a Hitachi 550 excavator and a ripper equipped Caterpillar D7-G bulldozer, both owned and operated by 15317 Yukon Ltd. of Whitehorse. Trench locations were selected based on results from historical programs and pre-stripping done in 2010. The trenches were positioned 100 to 200 m apart and were generally aligned at 030° to intersect the northwest trending structural zones.

A total of 12 trenches were excavated in 2011. Figure 5 is a plan view map showing trench locations and significant assays, while individual trench maps appear in Appendix III. Trench samples taken in 2011 are described on their respective trench maps.

A total of 2384 chip samples were collected from bedrock exposed in trenches. Chip samples were taken along the west rib of each trench or where bedrock was the most stable. Sample preparation and analytical procedures are described in Appendix IV. Certificates of Analysis are in Appendix V.

Excavator trenching has traced the Klaza zone for a strike length of 1100 m. The zone is made up of approximately seven individual veins that range between 0.5 to 3.5 m wide. Some residual pyrite, arsenopyrite, galena, sphalerite, and/or stibnite are present in most vein exposures. Breccia textures are visible in some heavily oxidized exposures. Quartz-feldspar porphyry dykes are common adjacent to veins but are not significantly mineralized.

Results from trenches within the western part of the Klaza zone indicate that the zone bifurcates into a series of narrower mineralized structures. Four trenches in this area, which were spaced 100 m apart, all intersected high grade gold and silver veins along strike of the Klaza zone. Vein exposures in these trenches graded from 4.87 g/t gold and 634 g/t silver across 1.30 m to 1.25 g/t gold and 177 g/t silver across 9.00 m.

One trench that tested the eastern part of the Klaza zone (TR-11-26) returned 7.17 g/t gold and 16 g/t silver over 7.11 m. It was cut 20 m east of the most easterly drill hole. Trench TR-11-22, located 650 m further to the east, exposed a strongly altered zone that averaged 1.31 g/t gold and 26 g/t silver over 13.89 m. Infill work will have to be done to confirm that this is the extension of the Klaza zone.

In general, the gold signature within the Klaza zone is strongest in the central and eastern portions of the zone. Silver-lead grades appear to increase in the western part of the zone. This pattern suggests a more distal setting to the west and a more proximal setting to the east, relative to heat sources.

Fourteen trenches excavated at the BRX zone in 2010 and 2011 traced the structure for a length of 2000 m. All of the vein exposures in the BRX zone host abundant sulphides and quartz veinlets. KL-10-04, in the eastern part of the zone, exposed a broad system of sub-parallel arsenopyrite and galena veins that averaged 1.01 g/t gold and 15.5 g/t silver over 80 m. Higher grade intervals were found in KL-10-18 and KL-10-21, which returned 4.18 g/t gold with 360.0 g/t silver over 3.50 m and 4.00 g/t gold with 434.8 g/t silver over 8.68 m, respectively. The remaining eleven trenches in the BRX zone each returned a significant interval of mineralization, indicating good continuity of structure and grade over the known length of the zone.

The BYG zone has been traced by excavator trenches for 530 m and hosts veins developed along the selvage of two dyke systems. Trench TR-11-26 returned the best result from the BYG zone in 2011 – 6.10 g/t gold and 19 g/t silver over 4.27 m.

The HERC zone was discovered by excavator trenching in 2010, which followed up historical soil geochemical results. The best exposure was in TR-10-12, which returned 3.06 g/t gold and 48.5 g/t silver over 7.60 m. Mineralization at the HERC zone has been traced for a 460 m strike length on surface. Other trenching along the projected strike to the west failed to identify significant mineralization, although strong alteration was exposed along the inferred trend.

Table II lists the significant mineralized intervals from the 2010 and 2011 excavator trenches.

DIAMOND DRILLING

A 52 hole diamond drill program was completed on the Klaza property in 2011. The holes were designed to expand on favourable results returned from previous diamond drilling and test targets identified by trenching, geophysical surveys and soil geochemical sampling completed in 2010.

The first hole was collared on June 3, and the last hole was completed on August 28. Drilling was contracted to three companies: Swiftsure Diamond Drilling Ltd. of Nanaimo, British Columbia; Strike Diamond Drilling of Kelowna, British Columbia; and, Elite Diamond Drilling of Vernon, British Columbia. The work was done using two skid mounted, diesel powered A-5 drills and one skid-mounted, diesel powered JKS-300 drill. The A-5 drills used HQ equipment while the JKS-300 used BTW equipment. A total of 13,630 m of diamond drilling was completed.

The plan view locations for all diamond drill holes are plotted on Figure 6, while cross-sections showing geology for all 2011 drill holes and histogram assay plots for the Klaza zone drill holes

The 2011 diamond drill program successfully expanded zones of gold and silver mineralization identified by previous operators, and discovered new zones elsewhere on the property. The most significant expansion of the known zones occurred at the Klaza and BRX zones.

The Klaza zone is the most northerly of the four main gold-silver bearing structural zones identified on the Klaza property. In 2011, it was tested by 10,335 m of diamond drilling in 37 holes. The drill holes are located approximately 50 m apart, and most are on section lines that each comprise three to four holes.

The 2011 diamond drilling at the Klaza zone intersected significant mineralization along an 850 m strike length and to a maximum depth of 250 m downdip of near surface trench exposures. The zone remains open for expansion along strike in both directions and at depth. Mineralization exhibits exceptional continuity with 36 of 40 diamond drill holes that tested the Klaza zone in 2010 and 2011 intersecting at least 1.0 gram gold equivalent/tonne over widths ranging between 3.04 and 36.50 m (average 1.81 g/t gold and 31 g/t silver over 13.04 m). The continuity is further illustrated by gram-metre multiples (g/t gold equivalent multiplied by intersected core length), with 78.5% of the holes that tested the Klaza zone returning greater than 15 gram-metre multiples.

Mineralization within the central and western portions of the Klaza zone (west of section KL 10+200 m) is hosted within a laterally extensive complex of steeply dipping veins, breccias and sheeted veinlets that are associated with a swarm of quartz-feldspar porphyry dykes. The best developed veins are typically found along dyke selvages. These veins consist of smoky and chalcedonic quartz, range from 1 to 200 cm in width and host disseminated to semi-massive pyrite, arsenopyrite, stibnite, galena and sphalerite. Heterolithic breccia zones are developed locally along the veins and host disseminated to blebby pyrite, arsenopyrite, sphalerite and galena in a black sulphide matrix. The best result returned from this part of the Klaza zone in 2011 was from hole DDH-KL-11-16, which graded 6.09 g/t gold and 101 g/t silver over 6.78 m.

The eastern portion of the Klaza zone (extending east from section KL 10+200) breaks into two sub-parallel bands, the Upper and Lower Klaza zones. The best mineralization in these bands is generally hosted in the Upper Klaza zone which is on the hanging wall side of the dyke swarm. Hole KL-11-56, produced the best results from 2011 drilling on the Upper Klaza zone, an interval that averaged 5.03 g/t gold and 14 g/t silver over 12.51 m.

Mineralization within the Lower Klaza zone is similar that in the western and central portions of the zone where veins are emplaced along or near the margins of dykes. The mineral assemblages are also similar, although with significantly less galena. The deepest intercepts (200-250 m downdip from surface) intersected the best mineralization in the Lower Klaza zone, with hole KL-11-44 returning 2.67 g/t gold and 50 g/t silver across 10.15 m.

Figure 29 is a vertical longitudinal section that demonstrates assay results returned from diamond drilling and excavator trenching at the Klaza zone.

The heterolithic breccias and multi-phase veining seen within the Klaza zone are characteristic features associated with many significant epithermal precious metal deposits. Individual veins typically exhibit symmetric zoning from the centre to the borders, suggesting deposition from evolving fluids in an active, extensional environment. In many cases, the centre of the veins exhibited brecciated textures, indicative of a final explosive event.

Magnetic susceptibility measurements taken from the 2010 and 2011 core indicate that the hydrothermally altered structural zones are considerably less magnetic than the unaltered granodiorite which surrounds them. Table IV illustrates the results from the drill holes completed in 2010 and 2011.

TABLE IV: MAGNETIC SUSCEPTIBILITY DATA

Drill Hole ID	Average Magnetic Susceptibility of core from hanging wall of zone (SI)	Average Magnetic Susceptibility of core within zone (SI)	Average Magnetic Susceptibility of core from footwall of zone (SI)
Klaza zone	10.10	1.26	8.73
BRX zone	5.85	0.37	6.96

The BRX zone is the most southerly mineralized zone identified to date on the Klaza property. Nine diamond drill holes tested the BRX zone in 2011 at 150 to 225 m intervals along a strike length of 1.3 km. Eight of the nine drill holes intersected significant gold-silver mineralization approximately 25 to 150 m downdip from surface. Combined with historical work, the BRX zone has been traced over a total strike length of 2 km by diamond drilling and excavator trenching. It is still open to extension along strike in both directions and downdip.

Mineralization within the BRX zone is associated with a single, laterally extensive quartz-feldspar porphyry dyke. Mesothermal-type vein mineralization occurs on the selvage of that dyke. Where the dyke appears to split into two or more ‘fingers’ the vein intensity typically increases, which results in wider mineralized intervals. The best result from 2011 drilling at the

BRX zone was from an interval in KL-11-37, which assayed 5.43 g/t gold and 50 g/t silver over 14.80 m. Three individual high grade veins ranging between 1.22 to 1.70 m in width contributed most of the grade from this interval.

The BYG zone is a third largest zone discovered to date. It parallels the Klaza zone, 125 m to the south. This zone demonstrates good grades with continuity along strike and downdip, where tested. The BYG zone is associated with a series of siliceous, brown quartz-feldspar porphyry dykes. Ten diamond drill holes were completed through the zone in 2010 and 2011, and all intersected significant mineralization. The best intercepts graded 4.57 g/t gold with 51.6 g/t silver across 3.97 m and 6.29 g/t gold with 342 g/t silver across 1.43 m. The BYG zone has been drilled along strike for 330 m and remains open for expansion in all directions.

The HERC zone was tested in 2011 by two diamond drill holes spaced 150 m apart. Both holes failed to replicate favourable results returned from trenching in 2010, but the zone should be further tested to fully evaluate its potential. The best result from 2011 drill was an interval that graded 1.63 g/t gold and 1.3 g/t silver over 1.00 m.

Four scout diamond drill holes were also completed in 2011 around the Caanan placer mine, located to the west of the main zones. These holes tested magnetic lows similar to those associated with the known zones. One of the holes also tested a coincident quartz-clay vein discovered by the placer miner. New discoveries were made in three of the four holes. No names have been given to the new zones as further work is needed to better determine how these discoveries relate to each other and to the known zones. All the mineralized intervals resemble the epithermal to mesothermal type veins identified elsewhere on the property. The best intercepts grade 2.94 g/t gold with 94 g/t silver over 1.30 m and 0.01 g/t gold with 422 g/t silver over 1.80 m.

While individual mineralized intercepts within the Klaza zone are generally comparable to those at other zones on the property, parts of the Klaza zone have bulk tonnage potential because a series of sub-parallel veins are relatively closely spaced within a structural zone that is 10 to 75 m wide. This style of mineralization is well illustrated by the histogram plots showing gold equivalent grades along the length of the Klaza zone drill holes.

Significant results from the 2010 and 2011 diamond drill program are shown on Table V below.

DENSITY MEASUREMENTS

Density measurements were taken on core, throughout the 2011 drill program with a total of 107 density measurements from 37 of the 52 holes. Measurements included vein, dyke, fresh granodiorite and mineralized granodiorite material. Sample densities were determined by cutting a 10 cm long section of core and then determining its weight dry and its weight in water. That data is applied to the following formula to establish the density of each sample:

Density = (dry weight ÷ weight in water) x [Pi x (diameter of core ÷ 2)^2 x length of core]

Results from the density program are shown in Tables VI and VII.

TABLE VI: DENSITY VALUES COMPARING ROCK TYPES

Results returned from the density measurements were generally as visually expected. Mineralized veins usually contain significant concentrations of pyrite and galena, both of which have much higher specific gravities than normal rock forming minerals. More thorough density measurements are proposed for future work on the property, especially to characterize different styles of mineralization.

REVERSE CIRCULATION PERCUSSION DRILLING

A 21 hole reverse circulation percussion drill program was completed at the Klaza property in fall 2011. The holes were designed to test targets identified by geophysical and soil geochemical surveys conducted in 2010. The majority of the holes were drilled west of the known mineralized zones and in the southeast portion of the Klaza river valley.

The first hole was collared on August 31, 2011 and the last hole was completed on September 30, 2011. The work was contracted to Midnight Sun Drilling Ltd. of Whitehorse, Yukon. The drilling was done using a track-mounted, diesel-powered reverse circulation percussion drill. The drill used equipment capable of drilling up to 500 m down hole depending on ground conditions. A total of 2940 m of reverse circulation percussion drilling was completed.

The plan view locations for the 2011 reverse circulation percussion drill holes are plotted on Figure 30. Sampling and Analytical Procedures for the chips are explained in Appendix IV, Certificates of Analyses are provided in Appendix V, and Geological Logs are given in Appendix VII. Key data concerning the 2011 reverse circulation percussion drill holes are shown on Table VIII.

The 2011 reverse circulation percussion drill program successfully identified areas containing pathfinder minerals and favourable alteration types, but unfortunately it did not discover any well mineralized vein zones. Galena, arsenopyrite and sphalerite were recognized in percussion holes 18 and 19, where they appeared to be disseminated throughout zones of phyllic altered granodiorite up to 20 m in width. Surprisingly, no significant gold or silver values were returned from samples taken over these intervals.

All 21 of the percussion drill holes cut altered granodiorite that was interpreted to represent alteration halos around structural zones.

PDH-15 intersected a volcanic feeder dyke at depth, which was not cut by the other percussion or diamond drill holes. The dyke was intersected between 84 and 94 m.

GEOPHYSICAL SURVEYS

A high sensitivity helicopter-borne magnetic and gamma-ray spectrometric survey was conducted by New-Sense Geophysics (NSG) of Toronto, Ontario between July 15 and 16, 2011. A total of 326 line km were flown on a grid that covered the northwestern parts of the property (Klaza 99 to 308 claims). The survey was flown with a Bell 206B3 helicopter operated by Northern Air Support from a temporary base at Carmacks, with intraday refuelling from a fuel cache at the Klaza camp. Survey equipment and techniques are described in a report contained in Appendix VIII. The 2011 survey expanded upon a similar survey flown over the southeastern part of the property in 2010.

Quality control was completed by Condor Consulting, Inc. of Lakewood, Colorado. Condor produced a 3D model of the total field magnetics and identified numerous structural lineaments across the survey area. The Condor report is attached in Appendix IX.

Magnetic data is shown on Figures 31 and 32 for both the 2010 and 2011 survey areas. The known structural zones and their inferred trends are overlain on both the total magnetic field and 1st vertical derivative maps. The known structural zones correlate well with magnetic lows. This observation is supported by the low magnetic susceptibility results returned from core samples within these structural zones compared to those from surrounding wallrocks.

The 2011 magnetic survey identified a number of prominent linear lows in the western half of the property, but the strongest feature is a north-south striking magnetic trough that cuts across the property. This feature's significance is unknown as there are no outcrops in this area and no trenching or drilling has been done there. Aho (1975) identified numerous frost boils containing porphyry fragments in the vicinity of the magnetic trough.

A number of linear magnetic lows were tested by the 2011 reverse circulation percussion drilling. All of the holes returned intervals of strongly altered granodiorite that resemble altered intervals surrounding known veins.

Potassium radiometric data is shown on Figure 33. Elevated potassic radioactivity is coincident in the general area of known mineralization in the eastern part of the property. The numerous porphyry dykes identified within this area are the probable source of this radioactivity.

The Klaza River valley returned generally subdued radiometric response. This is likely due to thick vegetation and water saturation in the flats adjacent to the river. Elevated radioactivity that directly correlates with the Klaza River is probably caused by exposed river gravels, which include abundant granitic material.

SOIL GEOCHEMICAL SAMPLING

The soil geochemical survey conducted in 2011 was designed to explore along strike of known vein zones. Most of the sampling was conducted between two and six kilometres northwest of the known zones along strike of previously outlined linear soil anomalies that are attributed to the vein mineralization.

A total of 2798 soil samples were collected at 50 m intervals along lines spaced 100 m apart within the main grid. Sampling and Analytical Procedures for the soil samples are explained in Appendix IV and the Certificates of Analyses are provided in Appendix V. The 2011 soil sample locations are shown on Figure 34.

Results of the 2011 soil geochemical survey are summarized as thematic maps for gold, silver, lead and arsenic on Figures 35, 36, 37 and 38, respectively. The results from the 2011 geochemical survey correlate well with those from previous geochemical and geophysical programs. The following table lists the threshold values used to evaluate soil from the property.

TABLE IX: THRESHOLDS FOR SOIL VALUES

	Anomalous Thresholds			
Element	**Weak**	**Moderate**	**Strong**	**2011 Peak Value**
Gold	≥ 5 < 10 ppb	≥ 10 < 20 ppb	≥ 20 ppb	320 ppb
Silver	≥ 0.5 < 1 ppm	≥ 1 < 2 ppm	≥ 2 ppm	61.3 ppm
Lead	≥ 10 < 20 ppm	≥ 20 < 50 ppm	≥ 50ppm	606 ppm
Arsenic	≥ 10 < 20 ppm	≥ 20 < 50 ppm	≥ 50 ppm	213 ppm

Compiled soil geochemical data outlines a number of anomalies across the property. Some are near known showings but others are unexplained. Targets that are considered to be particularly prospective for new discoveries are briefly described below.

Anomaly A is located west of the Klaza zone and corresponds with the northern margin of a magnetic low and active placer mine. The anomaly is defined by auger soil samples that returned strong silver, lead and arsenic values and between 5 and 29 ppb gold, over a 550 by 400 m area. Two diamond drill holes (DDH-11-49 and DDH-11-54) tested 100 m south of this anomaly. Both holes intersected strongly phyllic altered granodiorite with long intervals of brecciation. The best intercept grade 0.55 g/t gold and 144 g/t silver over 0.95 m.

Anomaly B lies along the inferred western extension of the BRX zone and is parallel to Anomaly A. Samples taken in this area returned strong silver, gold and arsenic values as well as moderate lead values. Permafrost hampered the collection of good soil samples at several sites, so the target could be larger than indicated. The anomalous values correspond to a series of weak magnetic lows. Four percussion drill holes that tested the western edge of Anomaly B failed to return significant gold or silver values. However, the anomaly is at the base of a steep slope and could represent downhill dispersion from an untested linear magnetic low located uphill.

Anomaly C is in the northwesterly corner of the main soil grid. The anomaly comprises of between 10 and 202 ppb gold values that are scattered throughout a 400 by 300 m area. The elevated gold results are accompanied by strong arsenic values and weak silver and lead values. This anomaly is about 800 m east of a large, relatively intense historical soil anomaly. Anomaly C is situated in the valley bottom where deep overburden may have compromised the quality of some soil samples. This target has not been drilled or trenched.

Anomaly D lies between Anomalies A and C and consist of a 1.5 km long, linear cluster of strong gold, silver, lead and arsenic values. The anomaly is orientated parallel to the four main zones on the property and is directly along strike from the Klaza zone. It is situated in a difficult to sample area on the floor of the Klaza river valley. This target has not been tested by trenching or drilling.

Surface prospecting was done concurrently with soil sampling; however, it was ineffective because of vegetation and overburden cover

AIR PHOTO SURVEY

A high resolution, air photo survey was conducted by Underhill Geomatics Ltd. of Whitehorse, Yukon on August 31, 2011. A total of 76.19 line km were flown on a grid that covered the Klaza 1 to 316 claims. The survey was flown with an Aero Commander 690A fixed wing airplane operated by Geographic Air Survey Ltd. of Edmonton, Alberta from a temporary base at Whitehorse. The survey equipment used was a Wild RC 30 camera equipped with a 15/4 UAG A-S13238 lens and Agfa Colour X 100 film. A total of 88 pictures were taken across five lines spaced 800 m apart at an average scale of 1:10,000. Subsequently, Underhill used the airphotos to prepare a detailed topographic map for the eastern half of the property.

QUALITY ASSURANCE (QA) / QUALITY CONTROL (QC)

The authors implemented all QA/QC protocols for the 2011 Klaza Project, under supervision of H. Smith, P. Geo. Rules, which all employees that worked in or around the drills, core/sawing facility and trenches were required to follow, include: 1) maintaining a clean and uncontaminated work environment; 2) preparing blank samples in a dry, secure and separate location from the sample processing facility; 3) implementing a blank and standard insertion schedule in the sampling; 4) proper packaging and labelling of outgoing samples; and, 5) documented chain of custody from the worksite to the analytical laboratory.

Digital analytical results were cross referenced for silver, gold, lead and zinc with certified hardcopy results from ALS Minerals. Analyses for blanks were then assessed for internal QC using a five times standard deviation multiple for acceptable tolerance, which for the blanks used was the lowest detection limit for the analytical instruments used at ALS Minerals. Values exceeding tolerance levels were further scrutinized for possible influence by strongly mineralized samples that may have preceded the blank samples.

Internal standards analyses were assessed in a similar manner. Tolerances for failure were calculated for each of the four Certified Standards. Precision tolerances were calculated using three standard deviations on either side of the mean, while bias tolerances were calculated using two standard deviations for two consecutive samples on the same side of the mean. Additional assessment was conducted by examining the sample series immediately preceding a failed sample for carry-over effects. Acceptable tolerance carry-over contamination is 1% of the preceding sample. All batches that had failures of standards and/or blanks were determined to pass once this tolerance was applied to data.

Four different Certified Standards were used during the drilling and trenching program. The PL-2 standard was randomly inserted into batches that were expected to return higher grade values for gold and silver. Batches that appeared to contain mainly average to lower grade samples had the CDN-ME-16 standard randomly inserted. After all the results from the program were received, the samples that were within the significantly mineralized intervals were reanalysed for lead and zinc using certified standards CDN-FCM-6 and CDN-ME-19.

The PL-2 standard material was prepared, homogenized and packaged by WCM Minerals of Burnaby, BC while the CDN standards were prepared, homogenized and packaged by CDN Resource Laboratories Ltd. of Delta, B.C. All standards were certified by Smee & Associates Consulting Ltd. of North Vancouver, BC. The certified mean and three standard deviations for the various standards are shown on following tables.

QC procedures for core samples involved the insertion of two blanks, two standards and one duplicate sample in every batch. Procedures for trench and percussion samples consisted of one blank and one standard in every batch. Results for the standard and blank samples from drilling and trenching are shown in Appendix X.

The final results for both the 2011 drilling and trenching presented are from batches that passed the QC testing.

DISCUSSION AND CONCLUSIONS

The Klaza property is situated in an active placer gold mining camp and historical hard rock gold and silver mining district, which lie within the southern, road accessible portion of the Dawson Range Gold Belt. Other important areas within this belt include the prolific Klondike Goldfields, the Casino porphyry copper-gold-molybdenum deposit and the recently discovered Coffee and Whitegold gold prospects.

Systematic excavator trenching and diamond drilling have only been done in approximately 5% of the 66 km^2 Klaza property. Four laterally contiguous zones have been defined within a 1500 m wide, northwesterly trending structural corridor. The individual zones have been traced by excavator trenching and drill holes over strike lengths of 500 to 2000 m. All zones are open to extension at depth and along strike.

The Klaza zone has responded very favourably to trenching and drilling. It has been traced on surface by excavator trenching for 1100 m and has been successfully tested by diamond drilling over 850 m along strike and up to 250 m downdip. Mineralization at the Klaza zone is open to extension along strike in both directions and downdip. Highlights from drilling at the Klaza zone include 7.20 g/t gold and 260 g/t silver over 15.30 m, 5.03 g/t gold and 14 g/t silver over 12.51 m and 6.09 g/t gold and 101 g/t silver over 6.78 m. Wide zones of mineralization observed at the Klaza zone may be in part due to enhanced structural framework caused by a relatively high concentration of riddle shears, which are observed in trench exposures. More trenching and drilling are needed to fully define the role structure played in localizing mineralization.

The BRX zone has been traced by excavator trenching and diamond drilling for an aggregate strike length of 2000 m. Historical drilling focussed on the eastern part of the zone, where widely spaced holes were drilled below the best trench showings with reasonable success. Some of the historical drilling was hampered by poor core recovery within the ore zones. In 2011, nine drill holes successfully tested the western projection of the BRX zone as outlined by magnetic lows, with eight of the nine holes intersecting significant mineralization. The best result was returned from an interval in KL-11-37, which averaged 5.43 g/t gold and 50 g/t silver over 14.80 m. Hole Kl-11-39, which stepped out a further 200 m to the west, returned 23.50 g/t gold and 239 g/t silver across 1.65 m. The BRX zone is also open for extension along strike in both directions and downdip.

The BYG zone has been traced by three excavator trenches for 500 m and was tested in 2011 by twelve diamond drill holes. The best intercepts were 4.57 g/t gold and 51.6 g/t silver across 3.97 m and 6.29 g/t gold and 342 g/t silver across 1.43 m. The BYG zone has only been drilled along strike for 330 m and remains open for expansion.

The HERC zone was discovered by excavator trenching in 2010. The best result from 2011 work was from an exposure in TR-10-12 which returned 3.06 g/t gold and 48.5 g/t silver over 7.60 m. Trenching further west in the HERC zone failed to identify significant mineralization but strong alteration was exposed along the inferred trend. Only two drill holes tested the HERC zone, the better of which (KL-11-48) cut 1.63 g/t gold and 13 g/t silver over 1.00 m. More work is needed to fully evaluate this target.

In large hydrothermal systems related to porphyry centres, silver and lead are usually concentrated in the distal structural environments, while gold is generally more abundant closer to the core of the system. At the Klaza property, the silver-lead grades appear to increase in the western-most trenches and holes and decrease to the east, thus indicating the main heat source for the mineralizing fluids is probably located farther to the east. The Cyprus porphyry, centered two kilometers to the east of the property, is likely the main thermal driver for the hydrothermal system that deposited mineralization in the veins on the Klaza property.

The age and structural relationship between the veins, veinlets, and breccias is unknown, although they are spatially and probably genetically related to the porphyry dykes, which parallel and locally cross-cut the mineralized zones. Although the dykes are barren or only weakly mineralized, the heat, fluid circulation and structural preparation provided by them were probably essential for vein formation.

Multi element soil geochemical anomalies mark the known mineralized zones and similar, mostly untested anomalies have been identified along strike and parallel to the zones. Hydrothermal fluids that flowed within and around the mineralized structures appear to have locally destroyed magnetite in the host rocks. Magnetic susceptibility measurements taken from the 2011 core confirmed that the mineralized zones are considerably less magnetic than the surrounding, unaltered granodiorite and this demagnification is further indicated by helicopter-borne surveys that outlined magnetic lows along the known zones. Numerous linear magnetic lows, which parallel the orientation of the known structural zones in other parts of the property, are considered priority exploration targets.

The next phase of exploration should consist of 20,000 m of diamond drilling in about 80 holes with continued excavator trenching on magnetic lows, especially where there are coincident soil geochemical anomalies. Emphasis should be placed on continued definition of downdip and along strike extensions of the Klaza and BRX zones.

Samples: KL-10-03-A Klaza, KL-10-03-B Klaza, KL-11-52 Klaza, KL-11-29 BRX

Summary:

Sample KL-10-03-A Klaza is of a vein that is dominated by coarse grained galena, with lesser patches of sphalerite (in part with exsolution blebs of chalcopyrite), arsenopyrite, pyrite (commonly intergrown intimately with galena), chalcopyrite (commonly with inclusions of pyrite), and marcasite (probably secondary after pyrrhotite; associated with pyrite galena, and ankerite. Gangue minerals include quartz (mainly at one end of the section), lesser ankerite (interstitial to sulphides), and minor sericite.

Sample KL-10-03 B Klaza is of a zoned vein with zones as shown in the scanned section. Zone A is a breccia dominated by fragments of sphalerite in a groundmass of extremely fine grained quartz and calcite. Zone B is of arsenopyrite-pyrite with minor sphalerite and trace native gold-electrum; it is cut by a veinlet of quartz-(ankerite). Zone C is dominated by quartz with abundant disseminated subhedral to euhedral grains of arsenopyrite and minor sphalerite. Zone D is dominated by anhedral pyrite grains enclosed in a much finer grained groundmass of pyrite with minor quartz and sphalerite. Zone E is gradational into Zone D and contains fragments of pyrite enclosed in a groundmass of quartz. A veinlet is dominated by barite with much less abundant ankerite and quartz.

Sample KL-11-29 BRX is of a massive sulphide vein? dominated by pyrite with much less abundant quartz and arsenopyrite, minor ankerite and galena, and trace sericite and chalcopyrite. It was fractured coarsely and fractures were filled by veinlets dominated by quartz with much less abundant ankerite. A few veinlets are dominated by ankerite; bordering some of these pyrite and arsenopyrite were fractured strongly. Some other ankerite-rich veinlets contain abundant angular inclusions of pyrite and lesser arsenopyrite.

Sample KL-11-52 Klaza is of breccia. It contains numerous fragments of veins dominated by one or more of quartz, ankerite, and barite, with minor to abundant sulphides. It also contains a few fragments of granodiorite/quartz diorite (altered to quartz-sericite). The breccia matrix is dominated by extremely fine grained plagioclase (altered slightly to sericite and possibly minor kaolinite) and generally lesser quartz, some of which may actually be strongly granulated fragments. A few large fragments are dominated by ankerite, and some also contain abundant amounts of one or more of barite, quartz, and sphalerite. Minor fragment types include plagioclase/sericite (altered latite), sericite aggregates, barite, pyrite, and sphalerite. A few fragments contain abundant sulphides, mainly pyrite and sphalerite with locally abundant galena.

Precious-metal minerals (native gold/electrum) were identified only in Sample KL-10-03 B Klaza, which is the highest-grade sample. The high silver content of Samples KL-10-03 A could be caused by silver in the structure of galena. No tetrahedrite/tennantite was identified; however, some of the smaller grains identified as galena might be of a Pb-sulphosalt.

Photographic Notes:

The scanned sections show the gross textural features of the sections; these features are seen much better on the digital image than on the printed image. For the photographs, sample numbers are shown in the upper left corner, photo numbers are shown in the lower left corner, and the letter in the lower right corner indicates the lighting conditions: P = plane light, X = plane light in crossed nicols; R = reflected light, RP = reflected light and plane incident light; ~RX = reflected light in moderately crossed nicols and incident light in crossed nicols. Locations of photographs are shown on the scanned sections. Descriptions of the photographs are at the end of the report.

Sample KL-10-03-A Klaza Vein: Galena-Sphalerite-Arsenopyrite-Pyrite-Chalcopyrite-Quartz-Ankerite

The vein is dominated by coarse grained galena, with lesser patches of sphalerite (in part with exsolution blebs of chalcopyrite), arsenopyrite, pyrite (commonly intergrown intimately with galena), chalcopyrite (commonly with inclusions of pyrite), and marcasite (probably secondary after pyrrhotite; associated with pyrite galena, and ankerite. Gangue minerals include quartz (mainly at one end of the section), lesser ankerite (interstitial to sulphides), and minor sericite.

mineral	**percentage**	**main grain size range**
galena	70-75%	1-3 (a few up to 10 mm)
sphalerite	8-10	0.3-1.5 (a few up to 3 mm)
arsenopyrite	3- 4	0.2-1
pyrite	3- 4	0.05-0.3
chalcopyrite	2- 3	patches up to 1.5 mm
quartz	4- 5	0.2-0.8
ankerite	3- 4	0.03-0.07
sericite	0.1	0.002-0.005

Galena occurs mainly as coarse grained patches, along whose margins it commonly is intergrown much more finely with other sulphides and locally with ankerite.

Sphalerite forms patches up to a few mm across, some of which contain minor to moderately abundant exsolution blebs and bands of chalcopyrite. It ranges in colour from deep orange to medium reddish brown.

Arsenopyrite and pyrite commonly are concentrated near one end, in part as fine to medium grained aggregates and in part, especially pyrite, in intimate intergrowths with marcasite and galena.

Chalcopyrite is concentrated strongly in patches up to a few mm across in which it is intergrown finely with minor to abundant pyrite, sphalerite, and ankerite.

Marcasite occurs in a few patches as extremely fine grained aggregates intergrown with ankerite, pyrite, and galena.

Quartz occurs mainly near one end as anhedral grains.

Ankerite forms disseminated patches within sulphide aggregates.

Sericite forms minor patches up to 0.2 mm in size.

Sample KL-10-03 B Klaza Banded Vein: Quartz-Sphalerite-Arsenopyrite-Pyrite-Ankerite-Galena-Sericite-(Chalcopyrite-Electrum)

The sample is zoned as shown in the scanned section. Zone A is a breccia dominated by fragments of sphalerite in a groundmass of extremely fine grained quartz and calcite. Zone B is of arsenopyrite-pyrite with minor sphalerite and trace native gold-electrum; it is cut by a veinlet of quartz-(ankerite). Zone C is dominated by quartz with abundant disseminated subhedral to euhedral grains of arsenopyrite and minor sphalerite. Zone D is dominated by anhedral pyrite grains enclosed in a much finer grained groundmass of pyrite with minor quartz and sphalerite. Zone E is gradational into Zone D and contains fragments of pyrite enclosed in a groundmass of quartz. A veinlet in Zone B is dominated by barite with much less abundant ankerite and quartz.

mineral	**percentage**	**main grain size range**
quartz	30-35%	0.01-0.02; 0.1-0.5
sphalerite	17-20	0.05-1
arsenopyrite	12-15	0.05-0.3
pyrite	12-15	0.03-0.5
ankerite	4- 5	0.02-0.05
galena	2- 3	0.05-0.15
sericite	0.5	0.005-0.015
chalcopyrite	0.2	0.02-0.1
electrum	trace	0.02-0.1
veinlet		
1) barite-(ankerite-quartz)	1- 2	3-5 (ba), 0.03-0.1 (ak, qz)

Zone A contains abundant fragments dominated by sphalerite, some of which contain patches of less abundant arsenopyrite and/or pyrite, and a few of which were cut by early veinlets of ankerite. Fragments are contained in a groundmass of mainly extremely fine grained quartz, sericite, and ankerite, with scattered coarser grains of quartz (0.1-0.15 mm).

Zone B is dominated by a dense intergrowth of euhedral to subhedral arsenopyrite and anhedral to subhedral pyrite, with lesser patches of galena and of sphalerite (with minor exsolution blebs of chalcopyrite) and interstitial patches and veinlets of quartz and ankerite. A large veinlet up to 1.5 mm wide consists of a single grain of barite with much less abundant ankerite and quartz, mainly along the margins of the vein. A patch of native gold is 0.1 mm long by 0.03 mm wide. In a few patches, pyrite is dominant and arsenopyrite is minor. Locally sphalerite and quartz are very abundant and contain disseminated euhedral elongate grains of arsenopyrite. Chalcopyrite forms scattered patches up to 0.1 mm in size.

On the border of Zone B against Zone C is a discontinuous band averaging 0.5 mm wide dominated by sphalerite that contains abundant tiny inclusions of galena and of chalcopyrite.

Zone C is dominated by quartz with abundant disseminated grains and clusters of grains of euhedral to subhedral arsenopyrite. Some clusters also contain pyrite. Locally moderately abundant are sphalerite and galena intergrown coarsely with arsenopyrite and quartz. Adjacent to Zone D arsenopyrite is abundant, and the contact with Zone D is relatively sharp between arsenopyrite and pyrite.

Zone D is dominated by anhedral pyrite grains (0.2-0.7 mm) enclosed in much finer grained pyrite, with much less abundant patches of quartz and of sphalerite.

Zone E contains fragments of pyrite and minor sphalerite and galena enclosed in quartz with much less abundant patches of ankerite, mainly along the side of the section. It is gradational into Zone D in that the pyrite-rich fragment nearest Zone D has a texture similar to that of Zone D.

Sample KL-11-29 BRX **Massive Sulphide: Pyrite-Quartz-Arsenopyrite**
Veinlets: Quartz, Ankerite

The sample is a massive sulphide vein? dominated by pyrite with much less abundant quartz and arsenopyrite, minor ankerite and galena, and trace sericite and chalcopyrite. It was fractured coarsely and fractures were filled by veinlets dominated by quartz with much less abundant ankerite. A few veinlets are dominated by ankerite; bordering some of these pyrite and arsenopyrite were fractured strongly. Some other ankerite-rich veinlets contain abundant angular inclusions of pyrite and lesser arsenopyrite.

mineral	**percentage**	**main grain size range**
pyrite	60-65%	0.05-1.5
quartz	5- 7	0.03-0.1
arsenopyrite	4- 5	0.3-0.8
ankerite	4- 5	0.05-0.1
galena	0.3	0.03-0.05 (locally up to 0.15 mm)
sericite	trace	0.01-0.03
chalcopyrite	trace	0.02-0.05 (locally up to 0.1 mm)
veinlets		
1) quartz-(ankerite-sericite)	15-17	0.05-0.3 (qz), 0.03-0.1 (ak), 0.01-0.03 (se)
2) ankerite-rich	3- 4	0.05-0.1

Pyrite forms massive patches that contain minor inclusions of galena and of chalcopyrite. A few grains contain several blebby inclusions of galena (0.02-0.03 mm).

Arsenopyrite forms scattered anhedral to subhedral grains intergrown coarsely with pyrite or as fragments in quartz.

The rock was brecciated coarsely and cut by several veinlets dominated by quartz with minor to moderately abundant ankerite. Most larger veins are dominated by quartz, and several smaller ones are dominated by ankerite with only minor quartz. Sericite forms scattered patches up to 0.2 mm in size of unoriented flakes enclosed in quartz. A few ankerite-rich veins are up to 1.5 mm wide.

One quartz-rich veinlet 0.4 mm wide contains a concentration of pyrite grains along its centreline and scattered grains of ankerite, mainly near its margins.

A few veinlets up to 0.03 mm wide are of extremely fine grained quartz with scattered coarser grains of ankerite.

A few more strongly brecciated zones/veinlets, mainly from 0.3-0.5 mm wide, have a matrix dominated by ankerite.

Sample KL-11-52 Klaza **Breccia: Fragments: Quartz-Sericite; Ankerite-Sphalerite**
Matrix: Plagioclase-Sericite-Quartz

The sample contains a few fragments of granodiorite/quartz diorite (altered to quartz-sericite) and numerous fragments of veins dominated by one or more of quartz, ankerite, and barite, with minor to abundant sulphides. The breccia matrix is dominated by extremely fine grained plagioclase (altered slightly to sericite and possibly minor kaolinite) and lesser quartz, some of which maybe strongly granulated fragments. Moderately abundant fragments are of ankerite, some of these also contain one or more of sphalerite, barite, and quartz. Minor fragment types include plagioclase/sericite, sericite-rich, barite, pyrite, and sphalerite.

mineral	**percentage**	**main grain size range**
fragments		
quartz-(sericite-pyrite)	30-35%	0.5-1.5 (qz), 0.02-0.04 (se), 0.1-0.5 (py)
ankerite	12-15	0.05-0.15 (a few 0.01-0.02 mm)
sericite-rich	1- 2	0.02-0.05
barite	3- 4	0.5-1.0 (locally up to 2 mm)
pyrite	3- 4	0.05-0.5
sphalerite	2- 3	0.1-0.3
plagioclase/sericite	0.3	0.005-0.02
galena	0.2	0.05-0.4
matrix		
plagioclase	30-35	0.01-0.03 (a few up to 0.05 mm)
quartz	7- 8	0.02-0.05
sericite	3- 4	0.01-0.02

In a few fragments, patches of quartz are intergrown coarsely with patches of quartz-sericite; textures suggest that the latter intergrowths are secondary after subhedral plagioclase grains, and the parent rock probably was granodiorite or quartz diorite. One such fragment is cut by a veinlet of ankerite 0.1-0.2 mm wide.

Numerous fragments ranging from 0.5-5 mm in size are of quartz with minor to moderately abundant ankerite and pyrite, and some contain minor sericite. One quartz-rich fragment had been deformed and recrystallized moderately to much finer grained aggregate along an irregular fracture zone before brecciation.

Ankerite is dominant in several fragments up to 1.5 mm in size and one fragment 1 cm across. Many of these contain angular grains of pyrite and some also contains moderately abundant sphalerite. One ankerite-rich fragment is cut by a veinlet 0.02 mm wide of cherty quartz.

Barite occurs in several fragments, either alone or with ankerite and/or quartz. One large fragment contains a zone of ankerite-sphalerite and a zone of coarse barite grains enclosed in a matrix of extremely fine grained quartz and lesser ankerite.

A few fragments up to 1 mm in size are of extremely fine grained, cherty quartz.

A few fragments up to 0.5 mm across are of extremely fine grained mudstone(?); some contain up to 10% angular grains of pyrite and one contains 5% anhedral equant grains of sphalerite with minor exsolution blebs of chalcopyrite.

Pyrite forms angular fragments, mainly of single grains, ranging widely in size from 0.05-0.1 mm.

(continued on page 2)

Sphalerite forms a few angular fragments up to 0.5 mm in size and also is common in some ankerite-rich fragments. Sphalerite ranges in colour from pale to deep orange-brown or reddish-brown, and some grains are colour-zoned strongly. In places sphalerite is semi-opaque from exsolution blebs of chalcopyrite and extremely fine inclusions of pyrite. A few sphalerite-rich fragments contain one or two patches of galena up to 0.1 mm in size.

One fragment 1.2 mm across is of extremely fine grained plagioclase altered slightly to sericite

A few fragments are dominated by sulphide aggregates consisting mainly of pyrite and sphalerite with locally abundant galena.

The breccia matrix is dominated by equant plagioclase (altered slightly to locally moderately to sericite) and lesser, commonly coarser grained quartz, some of which may represent strongly granulated fragments. Ankerite forms scattered patches, for some of which the origin is uncertain whether it be fragments or party of the breccia matrix.

APPENDIX IV

SAMPLE HANDLING AND ANALYTICAL PROCEDURES

SAMPLING METHODS AND APPROACH

This section describes the sampling methods followed during the 1986 to 1989 and 2010 to 2011 exploration programs supervised by Archer, Cathro & Associates (1981) Limited and the 1998 program conducted by BYG Natural Resources Inc. There is not sufficient information to comment on the 1980 exploration program conducted by BRX or any of the earlier work programs.

Soil samples collected in 1986 and 1998 were taken from a 1400 by 2500 m northwest trending grid that covers most of the southeastern part of the property. Soil samples were collected at 50 m intervals on lines spaced 100 m apart using two northwest trending base lines for grid control. The base lines are approximately 800 m apart and marked at 50 m intervals with one metre high wooden lath, while the sample sites on cross lines were marked with 0.5 metre lath. All lath bear aluminum tags inscribed with the grid coordinates and sample numbers. The grids were established with hip-chain and compass, but later survey control was provided by hard-chain and transit. The soil samples were taken 20 to 50 centimeters below surface from B horizon material. They were placed in pre-numbered heavy gauge paper bags. A total of 1405 soil samples were collected in 1986 and 776 in 1998.

Soil samples collected in 2010 and 2011 extended sample coverage to the west and north of the earlier grids. The samples were taken using soil augers, between 30 cm and 130 cm below surface. Soil samples were collected at 50 m intervals along lines spaced between 100 to 200 m apart. The sample sites were marked by a 0.5 m lath with orange flagging tape labelled with the sample number. Soil samples were placed into individually pre-numbered kraft paper bags.

Channel samples were collected from bulldozer and excavator trenches in several parts of the property during programs conducted between 1986 and 1989 and in 2010 and 2011. Bedrock exposed in trenches was sampled on a continuous basis. A total of 231 channel samples were collected in 1986, 227 in 1987, 247 in 1988, 13 in 1989 and 2389 in 2010. In 1987, 43 soil samples were also collected from C horizon soil along the floor of various trenches that did not reach bedrock. The collection protocol for channel samples was:

1) Trenches were excavated.
2) The walls of trenches were cleaned, where necessary, with a shovel.
3) Trenches were mapped and sample intervals marked at geological breaks or at 1 to 10 m intervals depending on the intensity of alteration and mineralization.
4) Continuous channel samples were taken along one wall of the trench, as close to the floor of the trench as slumping would allow, using a geological hammer. The chips were collected either in a tub or on a sample sheet. Sample sizes averaged approximately two kilograms per linear meter sampled for intervals containing veins and about 7 kg per sample for intervals comprised primarily of altered wallrock.
5) Samples were placed in doubled 6 mm plastic bags along with a pre-numbered sample tag, then two or three samples were placed in a fiberglass bag sealed with a metal clasp and sample numbers were written on the outside of that bag with permanent felt pen.

A total of 107 **drill core samples** were collected in 1988, 176 were collected in 1998, and 965 were collected in 2010. During the programs drill core samples were collected using the following procedures:

1) Core was lightly washed and measured.
2) Core was geotechnically logged.
3) Core was geologically logged and sample intervals were designated. Sample intervals were set at geological boundaries, drill blocks or sharp changes in sulfide content.
4) Core recovery was calculated for each sample interval.
5) Core was split in half with either an impact core splitter or a rock saw. One-half was sent for analyses and one-half returned to the core box.
6) Samples were double bagged in 6 mm plastic bags, a sample tag was placed in each sample bag, then two or three samples were placed in a fiberglass bag sealed with a metal clasp and sample numbers were written on the outside of that bag with permanent felt pen.

SAMPLE PREPARATION, ANALYSIS AND SECURITY

This section describes the sample handling procedures followed during the 1986 to 1989 and 2010 to 2011 exploration programs managed by Archer Cathro and the 1998 program conducted by BYG. The procedures followed during earlier exploration programs are not known.

During the 1986 to 1989 programs all samples were transported from the property to Whitehorse by truck, escorted by a member of the geological crew, and then shipped via Canadian Airlines or a commercial trucking company to Chemex Labs (now ALS Minerals) in North Vancouver, B.C. Soil geochemical samples were dry sieved through a -35 mesh screen and ring pulverized to approximately -100 mesh before being analyzed for gold by neutron activation and inductively coupled plasma (ICP) analyses. Channel samples were fire assayed for gold and silver. The 1988 drill core samples were also fire assayed for gold and silver.

Drill core samples collected in 1998 were shipped directly from the site by company vehicle to the laboratory operated by Little Salmon Analytical in Carmacks. That laboratory was primarily established to process samples from the former Mount Nansen mine. The samples were assayed for gold and silver. The analyses were by the one ton fire assay method.

Samples collected in 2006 were submitted to ALS Chemex in North Vancouver, B.C. Analyses were done using industry-standard fire assay and ICP techniques. The ALS Chemex (now ALS Minerals) laboratory in North Vancouver carries ISO 9001:2000 registration and is accredited to ISO 17025 by Standards Council of Canada for a number of specific test procedures including fire assay Au by AA, ICP and gravimetric finish, and multi-element ICP and AA assays for Ag, Cu, Pb and Zn.

Samples collected from the 2010 and 2011 exploration programs were handled as follows. All drill core from 2010 was trucked to the Archer Cathro yard in Whitehorse for logging and splitting. Drill core from 2011 was logged and sawn or split at a processing facility of the property. All trench samples were collected and labelled at the trench. Rock chips were collected, split, and sampled at each respective drill site. Approximately 3 to 10 rock chips were

collected from each sampled interval and put into trays. The chips were later logged in the Archer Cathro office in Vancouver.

Analytical work was done by ALS Minerals with sample preparation in Whitehorse and assays and geochemical analyses in North Vancouver. All core, rock chips and trench samples were initially analyzed for gold by fire assay followed by atomic absorption (Au-AA24) and 35 other elements by inductively coupled plasma-atomic emission spectroscopy (ME-ICP41). Overlimit values for gold were determined by fire assay and gravimetric finish (Au-GRA22) and silver values were determined using Ag-OG46. Later sample pulps from mineralized intervals of drill core from 2011 were reanalyzed for lead and zinc as well as 46 other elements using four acid digestion followed by inductively coupled plasma-atomic emission spectrometry (ME-MS61). Overlimit values for silver, lead and zinc were determined by inductively coupled plasma -- atomic emission spectroscopy (Ag/Pb/Zn-OG62).
