INTRODUCTION

The Hidden property hosts tungsten-rich skarn and stockwork targets with porphyry-size potential. It is located in the Big Salmon Range of southern Yukon and is wholly owned by Strategic Metals Ltd.

This report describes a soil geochemical sampling program conducted between July 7 and 12, 2013 by Archer, Cathro & Associates (1981) Limited on behalf of Strategic Metals. The author participated in the program and interpreted results, and his Statement of Qualifications is provided in Appendix I. A Statement of Expenditures is located in Appendix II.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The Hidden property is located approximately 75 km southwest of Ross River in southern Yukon. It lies on NTS map sheet 105F/06 at latitude 61°26'N and longitude 133°22'W, as shown on Figure 1.

The property consists of 22 contiguous mineral claims registered with the Whitehorse Mining Recorder in the name of Archer Cathro, which holds them in trust for Strategic Metals. The property covers a total area of approximately 450 ha (4.5 km²). Details concerning the claims are listed below, while their locations are shown on Figure 2.

<u>Claim Name</u>	<u>Grant Number</u>	<u>Expiry Date*</u>
Hid 1-12	YC19262-YC19273	March 7, 2024
13-22	YE15110-YE15119	March 7, 2018

* Expiry dates include 2013 work, which has been filed for assessment credit but not yet accepted.

Access to and from the property was provided by a Bell Jet Ranger II helicopter operated by Trans North Helicopters from the Faro airport, which is located 85 km north of the property. The 2013 crew mobilized to the property from a staging area on the seasonally maintained South Canol Road, 15 km east of the property.

The Hid claims lie within the traditional territory of the Teslin Kl'ingit First Nation. Neither the property nor probable ground access routes to it overlie first nations land.

HISTORY AND PREVIOUS WORK

In mid 1970s, Union Carbide Canada Limited conducted reconnaissance-scale stream sediment sampling in the vicinity of the Hidden property (Deklirk and Traynor, 2005). Numerous tungsten anomalies were identified, but most were not followed up.

In 1978, Cub Joint Venture (Cub JV), a syndicate of Union Carbide, Cassiar Asbestos Corporation Limited and Highland-Crow Resources Ltd., was formed to conduct tungsten exploration utilizing the earlier Union Carbide data. Cub JV staked claims in the area of the

current Hidden property after it found a tungsten bearing skarn (Discovery Showing). The 1978 work program included panning and soil geochemical sampling, limited mapping, hand trenching, and ground magnetic and electromagnetic surveys. This work outlined nearly coincident tungsten-in-soil and scheelite panning anomalies (Abbott and Cathro, 1978). Tungsten analytical techniques available in the late 1970s had relatively low upper detection limits so specific source areas could not be distinguished within the extensive zone of high values. Soil panning was used as an alternate exploration technique because of the high specific gravity and resistant nature of scheelite. In 1978, a 1900 m long by 500 to 1000 m wide area defined by greater than 200 grains of scheelite per pan was identified (Abbott, 1979), all of which is covered by the current Hidden property. The Discovery Showing is located in the northern part of this area and is marked by an isolated sample that yielded over 10,000 grains per pan. A large area of very anomalous response (>2000 grains of scheelite per pan) begins about 100 m south of the Discovery Showing within the broader anomaly described above. This strongly anomalous core is about 1000 m long and 300 m wide.

In 1979, Cub JV expanded its claim block and completed eight diamond drill holes totalling 915 m. The holes were drilled at the Discovery Showing and three nearby areas. Prospecting done in conjunction with drilling identified several skarn zones between the Discovery Showing and Nigel Peak, in the eastern part of the property (Figure 2). Later that year additional geological mapping, panning and soil geochemical sampling were performed south of the 1978 survey area (Abbott and Cathro, 1979). This work resulted in the southward expansion of the scheelite panning and tungsten-in-soil anomalies.

In 1981, Cub JV contracted W.A. Barclay Exploration Services of Toronto, Ontario to conduct a proton magnetometer survey over the core of the nearly coincident panning and geochemical anomalies. Cub JV also performed petrographic studies of samples taken from the 1978 trenches near the Discovery Showing (Main and Cathro, 1981). The magnetometer survey outlined several faults and porphyry dykes, while the petrographic study documented scheelite hosted in quartz veins cutting metamorphosed sediments.

The final work program by Cub JV was done in 1984. It included: three more hand trenches in areas with high tungsten panning values; localized ultraviolet night lamping surveys; and, collection of scheelite bearing soil samples from previously panned sites to compare assay values with panning results (Main, 1984). The comparative data is shown in the table below. The Cub JV claims lapsed in 1988.

Table I – Cub JV Comparison Data

1979 Panning Result (# scheelite grains)	1984 Soil Geochemistry (%WO₃)
16,600	0.067
1,500	0.056
22,000	0.090
20,000	0.073
17,000	0.180
9,000	0.298

5,000	0.032
25,000	0.078

In 2001, Strategic Metals staked the Hid 1-12 claims to cover the core of Cub JV's work area.

In 2003, Strategic Metals resampled the 1978 trenches, dug two new hand trenches, and performed a soil geochemical survey to assess the emerald potential of the property (Eaton, 2003). Although one small pale green opaque beryl was found and anomalous values for beryllium and vanadium were identified in soil, no follow up work was completed.

In 2007, Strategic Metals contracted Geotech Ltd. of Aurora, Ontario to conduct helicopter-borne magnetic and versatile time domain electromagnetic (VTEM) surveys across the property (Eaton, 2007). Two magnetic and two electromagnetic (EM) anomalies were identified in the vicinities of the Discovery Showing and the 1979 panning and soil geochemical anomalies. One of the EM anomalies was not completely delineated and appears to continue south of the survey boundary.

In 2010, Strategic Metals expanded the Hidden property to cover the projected extensions of the geochemical and EM anomalies to the south.

In 2012, Strategic Metals conducted a geochemical survey that partially overlapped the historical work area. It was designed to confirm historical geochemical results, obtain multi-element geochemical data and extend geochemical coverage to the east of Cub JV's main work area.

GEOMORPHOLOGY

The Hidden property is located in the Big Salmon Range within the southern part of the Pelly Mountains. It is drained by several creeks that flow into the Big Salmon River, a major tributary of the Yukon River.

The claims cover rugged sub-alpine and alpine terrain on the flanks of Nigel Peak. Local elevations range from about 1200 m on the northwestern edge of the property to 1853 m atop Nigel Peak. Outcrop on the property is mostly restricted to ridge crests, steep slopes and creek cuts.

Tree line is at about 1450 m. Vegetation ranges from thick stands of black spruce with nearly impenetrable buckbrush and alder near the larger creeks, through stunted spruce and buckbrush near tree line, to grassy hillsides and open talus slopes at higher elevations.

Soil profiles vary across the property. Soil below tree line is characterized by more complete soil horizons, including C, B and organic layers, while alpine terrain comprises thin veneers of poorly developed soil and talus. Permafrost is found in treed areas on north-facing slopes. The main glacial ice movement in the area was northwesterly (Duk-Rodkin, 1999). A recent landslide below tree line exposed glacial to glacio-fluvial deposits up to 15 m thick.

REGIONAL GEOLOGY

The Hidden property lies 65 km southwest of the Tintina Fault where components of Cassiar Platform, Yukon-Tanana Terrane and Slide Mountain Terrane are dismembered and rearranged by thrust and high angle faults (Figure 3). Regional-scale folding and faulting occurred in Late Paleozoic and Early Mesozoic times when various island arc, oceanic and continental margin sequences were accreted to the western side of the North American craton. Granitic stocks and batholiths of the Cassiar Suite were emplaced in the region during the Mid Cretaceous (Mortensen et al, 2000).

The oldest unit in the Hidden area comprises siliciclastic and metamorphic rocks of the Upper Proterozoic to Lower Cambrian Ingenika Group. These rocks are discontinuously overlain by Lower Cambrian Rosella Group. Both units contain calcareous beds and are overlain by Ordovician to Lower Devonian Road River Group sooty siltstone, shales and siliciclastics. A regional-scale north-northeasterly-trending fault that crosses the west-central part of the Hidden property juxtaposes Road River Group to the west against a package of interdigitized Upper Devonian to Lower Mississippian Earn Group siliciclastics and Middle Silurian to Middle Devonian Askin Group carbonates to the east. A Mid Cretaceous Cassiar Suite batholith (formally named the Nisutlin Batholith) intrudes Road River Group rocks on and north of the property. It is cut by a northwesterly elongated stock of the Mid Cretaceous Selwyn Suite and younger porphyry dykes that are too small to show at regional-scale. Figure 4 illustrates regional geology as compiled by Gordey and Makepeace (2003) and updated by the Yukon Geological Survey (2013). Table II below describes the regional units in more detail.

Table II – Regional Lithological Units (*Yukon Geological Survey, 2013*)

Unit Name	Map Name	Age	Description
Selwyn Suite	mKqS	Mid Cretaceous	Equigranular to porphyritic (potassium feldspar) biotite ± hornblende ± muscovite granite, quartz monzonite and granodiorite; porphyritic biotite-hornblende granite with large smoky grey quartz phenocrysts and local potassium feldspar phenocrysts.
Cassiar Suite	mKqC	Mid Cretaceous	Medium to coarse grained, equigranular to porphyritic granite and biotite quartz monzonite; biotite-hornblende quartz monzonite and granodiorite.
Earn Group	DMEC1/ DMEC1 ?	Upper Devonian to Lower Mississippian	Recessive, dark grey, thin bedded, black siliceous slate with interbeds and members of quartz-chert greywacke, chert granule grit and chert pebble to cobble conglomerate; may include lenses of intermediate to felsic volcanoclastic rocks.
Road River Group	ODRC2	Upper Silurian to Devonian	Recessive, dark grey to black sooty, limey or dolomitic, thin bedded to platy, graphitic siltstone and fine grained impure quartzite with interbedded graphitic silty shale.

After Colpron, M. and Nelson, J.L., 2011

Askin Group	SDA2	Middle Silurian to Middle Devonian	Medium grey to buff weathering, medium to thick bedded dolomite, silty and sandy dolomite, limestone; medium to thick bedded, medium grained mature orthoquartzite; dolomitized laminated mudstone and dolomite with vugs and birdseye cavities.
Rosella Formation	ICR	Lower Cambrian	Resistant, thick bedded to massive limestone and argillaceous limestone; local archaeocyathid buildups, trilobite fragments, oolites, and pisolites; pisolitic massive dolomite and limestone; marble, calc-silicate, calcareous phyllite and minor schist.
Ingenika Group	PCI4	Upper Proterozoic to Lower Cambrian	Thin bedded slate, siltstone, quartzite and minor limestone with local medium to coarse grained, feldspathic sandstone to orthoquartzite; muscovite $\pm$ biotite $\pm$ garnet schist, micaceous quartzite, minor amphibolite and marble; rare granodiorite gneiss.

PROPERTY GEOLOGY

Property-scale mapping was performed in 1979 on behalf of Cub JV (Abbott and Cathro, 1979). The total mapped area extends four kilometres west and three kilometres east of the current Hidden property boundary. Detailed geology in the immediate vicinity of the property is shown on Figure 5.

Property stratigraphy is at least 1300 m thick and was sub-divided into six units by Cub JV. These units mostly correlate to regional lithologies and are described from oldest to youngest in the paragraphs below.

Ordovician to Silurian (Askin Group)

OSc: Massive dolomite, characteristically white with black bands. The unit is at least 100 m thick and exposed primarily in drill core and on a few outcrops near the Discovery Showing.

OSsl: Recessively weathered, black, graphitic, calcareous slate with minor fetid limestone that gradationally overlies unit OSc. The Discovery Showing may be hosted by fetid grey limestone near the top of this unit. This horizon is approximately 200 m thick.

OSDqc: Grey to green silty shale interbedded with black graphitic shale and distinct, thinly laminated silty limestone. These rocks undergo marked lateral facies changes and some lithologies are similar to those within other units. This unit is approximately 500 m thick.

Oss: Recessive, rusty weathering, black, non-calcareous slate that gradationally overlies unit OSDqc. A monograptus found in slate on the southeast side of Nigel Peak is probably Silurian in age. This unit is about 100 m thick.

Silurian (Road River Group)

Sd: Massive, light grey, sandy dolomite interbedded with lenses of massive grey quartzite. This unit is about 300 m thick and similar to the dolomite that comprises unit OSc.

Upper Devonian to Mississippian (Earn Group)

uDMs: Black, graphitic, non-calcareous, siliceous slate. These rocks are separated from the other units by a major north-northwest-trending normal strike-slip fault. The exposed section of this unit is at least 300 m thick.

Cretaceous (Cassiar Suite)

Kqm: Porphyritic granodiorite and quartz monzonite. These rocks are part of the Cassiar Suite batholith, the southern margin of which underlies the northwestern corner of the property. The contact is sharp and dips sharply to the southwest.

Cretaceous to Tertiary (?) (Selwyn Suite?)

KTfp: Dark brown feldspar porphyry containing vesicles and calcite filled amygdules. Two north-trending, steeply dipping dykes about 10 m wide cut stratigraphy at a high angle in the central part of the claim block. A small isolated exposure of quartz-biotite-feldspar porphyry located about 800 m due south of Nigel Peak and could be unit Kqm or KTfp (shown on Figure 5 as Kqm).

In general, the sedimentary units are mildly deformed by open, upright, northwest-trending folds with amplitudes ranging up to 100 m. The most significant folding is located near Nigel Peak and extends northwesterly. Penetrative cleavage within the sedimentary units dips southwesterly, sub-parallel to bedding in fine grained clastic rocks, but there is no evidence that it is accompanied by large-scale folds.

The dominant structural elements on the property are north-trending normal faults, but similarities between some rock types and limited bedrock exposures makes recognition of these structures difficult. The largest displacement occurs along the western-most fault where more than 1000 m of normal offset is inferred. Some movement on the faults appears to postdate emplacement of the batholith as evidenced by offsets on its margin and the presence of air photo lineaments that can be traced from the wallrocks into the batholith (Main and Cathro, 1981). The porphyry dykes strike sub-parallel to the faults, suggesting that the two may be related.

MINERALIZATION

Historical prospecting and trenching discovered two main styles of tungsten mineralization on the Hidden property (Figure 6):

- 1) Diopside-garnet-quartz±pyrrhotite skarn where angular to subhedral grains of scheelite, diopside and minor garnet occur in a quartz groundmass with irregular interstitial sulphide blebs; and,
- 2) Stockwork quartz-scheelite veining with pervasive diopside and bleached envelopes that are two to five times the width of the vein.

The **Discovery Showing** covers an area of scheelite rich talus, which is 40 m long and 30 m wide. The mineralized skarn blocks are typically 0.3 to 1 m in diameter with a few slabs up to 1 m thick and 5 m across. The showing was originally interpreted as frost-heaved outcrop; however, trenching showed that the mineralized blocks are rotated and mixed with unmineralized talus.

Mineralized skarn blocks at the Discovery Showing comprise massive to weakly banded, dark to medium green, fine grained diopside-garnet-quartz skarn with up to 5% disseminated pyrrhotite and about 1% chalcopyrite. This skarn has dark brown weathering surfaces. Scheelite forms subhedral grains ranging from one to five millimetres across. These grains are fairly evenly disseminated throughout the skarn, but occasionally form poorly defined bands. A chip sample across one of the larger slabs graded 1.32% WO₃ over 1.5 m. A specimen taken in 2003 from Trench 78-1 returned 1.57 % WO₃, 79.6 bismuth, and 12 ppb gold, and a specimen from Trench 78-2 returned 3.70% WO₃, 167 ppm bismuth and 24 ppb gold (Figure 6).

A second type of mineralized rock, which was given the field name “altered skarn,” is moderately abundant in talus at the Discovery Showing. The altered skarn occurs as both concordant and discordant bands up to several centimetres thick within diopside-garnet-quartz skarn. In hand specimen it is soft, crumbly and intensely fractured. White laths of pyroxene up to one centimetre long give the rock an igneous appearance, but thin sections from the 1981 petrographic study show that the rock is skarn composed of scheelite and pyroxene in a quartz groundmass. A composite chip sample taken across the talus train that included both skarn types reportedly averaged 1.2% WO₃.

Prospecting in the early 1980s located several other areas of interesting mineralization including: additional areas of mineralized skarn and a broad stockwork vein zone consisting of scheelite bearing quartz veinlets and dry fractures with bleached selvages. Skarn is developed along faults and adjacent to porphyry dykes in silty limestone and dolomite. The exposed skarns typically grade less than 0.2% WO₃ and contain little or no magnetite or sulphide mineralization. Dry fractures and scheelite bearing quartz veinlets form a stockwork zone in an approximately 850 by 350 m area between the Discovery Showing and Nigel Peak (Figure 6). The dry fractures are flanked by 0.5 cm wide bleached selvages occasionally containing calc-silicate minerals, pyrrhotite and scheelite. The stockwork vein zone is hosted within sedimentary rocks that exhibits two to three mineralized fractures per metre on most outcrops. The mineralized fracture system has not been systematically sampled to establish its average grade.

Hand trenching in 1984 exposed tungsten-rich skarn that graded between 0.3 and 2.8% WO₃ in bedrock or float samples.

Night lamping conducted during CUB JV exploration programs showed that the dominant tungsten mineral on the property is scheelite – fluorescence blue to white – with only traces of molyscheelite – fluorescence yellowish (Main, 1984). No wolframite has been observed on the property.

SOIL GEOCHEMISTRY

A number of soil geochemical surveys have been performed within the area now covered by the Hidden property. Pre-2000 samples were analyzed using varying techniques that provided incomplete digestion and were not taken to “final values.” Post-2000 samples were analyzed by multi-element techniques that involved complete digestion and yielded “final values” for all elements including tungsten. Soil sample locations for samples analyzed using multi-element techniques are illustrated on Figure 7, while thematic results for tungsten, bismuth, molybdenum, copper and silver are illustrated on Figures 8 through 12.

In the late 1970s, Cub JV conducted systematic soil sampling along the southern margin of the Cassiar Suite batholith. This work outlined a broad tungsten anomaly (Hidden Anomaly) encompassing a 1300 by 1000 m area centred between the Discovery Showing and Nigel Peak.

In 2003 and 2012, soil sampling was completed within the known tungsten soil anomaly and to the east of it.

In 2013, a total of 332 grid and trench floor soil samples were collected. A 50 by 50 m soil grid comprising 321 soil samples overlies the core of the historical soil anomaly, while 11 samples were taken from historical trenches within the anomaly. All soil sample locations were recorded using hand-held GPS units. Sample sites are marked by aluminum tags inscribed with the sample numbers and affixed to 0.5 m wooden lath that were driven into the ground. A hand-held soil auger was used to collect material from as deep in the soil profile as ground conditions allowed, which typically ranged from 20 to 50 cm depth. Samples were placed into individually pre-numbered Kraft paper bags. The soil samples were sent to ALS Minerals in Whitehorse, where they were dried, screened to -180 microns, then sent to ALS Minerals in North Vancouver, where they were dissolved by four acid digestion and analyzed for 48 elements by inductively coupled plasma combined with mass spectroscopy and atomic emission spectroscopy (ME-MS61). Certificates of Analysis are provided in Appendix III. Anomalous thresholds and peak values for post-2000 samples are listed in Table III.

Table III – Soil Geochemical Threshold and Peak Values

Metal	Anomalous Thresholds			Peak Values
	Weak	Moderate	Strong	
W (ppm)	$\geq 100 < 200$	$\geq 200 < 500$	≥ 500	6,820
Mo (ppm)	$\geq 5 < 10$	$\geq 10 < 20$	≥ 20	44
Cu (ppm)	$\geq 50 < 100$	$\geq 100 < 200$	≥ 200	533
Bi (ppm)	$\geq 10 < 20$	$\geq 20 < 50$	≥ 50	1,035
Ag (ppm)	$\geq 1 < 2$	$\geq 2 < 5$	≥ 5	11.6

Complete digestion results from 2013 sampling showed good contrast between background and anomalous tungsten values. Using moderately anomalous values (>200 ppm) as the cut off threshold, the Hidden Anomaly covers a 1300 by 1000 m area.

The Hidden Anomaly is defined by nearly coincident moderately to very strongly anomalous tungsten and bismuth values. The anomaly covers an area with complex geology – including numerous faults, porphyry dykes, skarn zones and stockwork veins. The host stratigraphy varies from limestone to sandy dolomite and shale.

A 550 by 350 m core of moderately to strongly anomalous copper and silver values lie within the northern part of the Hidden Anomaly in an area riddled with faults and porphyry dykes. Molybdenum values are relatively subdued within the Hidden Anomaly; however, a few strongly anomalous values are scattered throughout.

In 2013, eleven soil samples were taken from beneath the floors of historical trenches using a hand-held soil auger. These values cannot be directly compared to other soil samples because they represent a deeper soil horizon. Peak values from trench floor samples are listed in Table IV.

Table IV –2013 Peak Soil Values from Historical Trenches

Trench	Peak Values				
	W (ppm)	Mo (ppm)	Cu (ppm)	Bi (ppm)	Ag (ppm)
TR-78-2	3,100	21.4	195	316	0.97
TR-84-1	1,460	38.7	586	192	2.9
TR-84-2	1,310	24.5	616	197	3.01
TR-03-1	480	4.75	91.1	38.5	0.58
TR-03-2	311	8.53	178.5	308	8.39

Contrary to expectations, values from soil samples collected beneath historical trenches mostly returned lower values than conventional soil sampling.

DIAMOND DRILLING

In 1979, eight holes totaling 915 m were completed (Figure 6). Three holes (DDH-79-1, DDH-79-2 and DDH-79-3) were drilled at different dip angles from a pad located uphill from the Discovery Showing. These holes tested the apparent host stratigraphy down-dip from mineralized talus. Hole (DDH-79-5) was positioned such that it scissored beneath the showing.

Figure 13 illustrates three possible cross section interpretations for the Discovery Showing drill results. Holes DDH-79-1, DDH-79-2 and DDH-79-3 intersected black limestone and weakly developed siliceous diopside skarn containing only traces of scheelite. Bedding angles in the holes suggest that the stratigraphy is nearly horizontal. Therefore, assuming the mineralization is stratigraphically controlled, it has limited lateral extent (Interpretation A), or it is derived from a source located uphill from the drill holes (Interpretation B). Hole DDH-79-5 intersected a fault zone that assayed 0.95% WO_3 across 2.13 m. Rocks within and adjacent to the fault are described as veined and brecciated skarn; however, no skarn was noted in the remainder of the hole. Thus, the skarn mineralization could be developed in a narrow band within and along the margins of a vein fault (Interpretation C). Assuming Interpretation C is correct, the fault would likely strike northeasterly and dip about 60° to the northwest. It would extend up-dip from the intersection in DDH-79-5 to a point immediately uphill of the Discovery Showing talus train, but downhill from the collars of DDH-79-1, DDH-79-2, DDH-79-3. Mineralogical variations between the skarn observed in the drill hole and the majority of the mineralized boulders may be due to differing wallrock chemistry.

The remaining four holes were drilled near the Discovery Showing to test panning anomalies and to obtain geological information. The holes intersected minor dark green, siliceous skarn and infrequent grains of scheelite. No core from these holes was assayed.

GEOPHYSICS

In 1978, Cub JV carried out preliminary ground magnetic and EM surveys in an area approximately 1300 by 900 m within the current property boundary. The magnetic survey outlined six anomalies, which ranged from 80 to 980 nT above background. These anomalies are not closely correlated to panning or soil geochemical anomalies. The Discovery Showing exhibited a low magnetic response of 50 nT below background. The EM survey identified four very low frequency electromagnetic conductors. Most of these conductors are not directly correlated to mineralization; however, one anomaly lies 40 m east of the Discovery Showing.

In 1981, W.A. Barclay Exploration Services conducted a proton magnetometer survey across the core of the scheelite panning anomaly. Well defined magnetic highs were found to correlate to faults and dacite dykes associated with localized skarn zones; however, the data was not professionally interpreted (Main and Cathro, 1981).

In 2007, Geotech Ltd. flew magnetic and versatile-time domain electromagnetics (VTEM) geophysical surveys over the Hid 1-12 claims. Figure 14 illustrates electromagnetics, while Figure 15 shows interpreted magnetic data. The VTEM survey outlined two moderate conductors that have been tentatively interpreted as sulphide bearing skarn zones. The northern

conductor is located 300 to 500 m south of the Cassiar Suite batholith. It is 750 m long, trends northeast, and responds as a thick plate dipping shallowly to the southeast. An area of low conductivity within the northern conductor correlates to a major fault that juxtaposes limestone and shale. The southern conductor is 500 m long and has been interpreted as a thick plate dipping northwest. This conductor appears to be underlain by limestone and its trace parallels a nearby folded contact. This anomaly lies in an area that has only been soil sampled at a reconnaissance level.

The magnetic survey produced total magnetic field values with only 50 nT variation, which is characterized as quiet behavior. The Discovery Showing is marked by a subtle moderate magnetic low, which lies peripheral to a cluster of large magnetic highs. A number of other scattered magnetic highs coincides with the stockwork vein zone. In some areas, linear trends (faults?) are marked by sharp changes in magnetic patterns.

DEPOSIT TYPE

The most analogous deposit to the Hidden property is Largo Resources Limited's Northern Dancer (Logtung) Deposit, which is located about 240 km to the southeast. Northern Dancer hosts widespread tungsten and molybdenum porphyry-style mineralization and has a measured resource of 30.8 million tonnes grading 0.114% WO₃ and 0.030% Mo and an indicated resource of 192.6 million tonnes grading 0.100% WO₃ and 0.029% Mo. The total mineable tonnes are estimated to be 545,236,000 tonnes at a grade of 0.076% WO₃ and 0.024% Mo. In 2011, a preliminary economic assessment indicated a positive net present value of \$918 million at the price of \$275 metric tonne unit of ammonium paratungstate (Largo Resources – Press Release, 2011).

The Hidden and Northern Dancer properties both lie within the Cassiar Terrane and in the same belt of intrusions. Mineralization at Northern Dancer is centred on a small Cretaceous to Tertiary feldspar porphyry dyke swarm that cuts a Cretaceous quartz monzonite stock. At Northern Dancer, two partially overlapping zones host fracture and vein mineralization associated with northeast-trending sheeted vein structures. The core of the deposit is a higher grade molybdenum (as molybdenite) porphyry zone developed within and adjacent to the felsic dyke swarm. The much more extensive tungsten (scheelite) zone is hosted by the northeast-trending sheeted quartz veins (Largo Resources – Properties, 2011). The recessively weathered, steeply dipping, sheeted veins cut the dykes and porphyry zone. The veins contain significantly higher grade tungsten mineralization than the porphyry zone.

Beryllium and bismuth minerals are often present in the veins at Northern Dancer, especially in the more distal part of the system. Skarn zones contain only a small percentage of mineralization at Northern Dancer but, where intersected, often grade between 0.3 and 1% WO₃ (Wengznowski, 2004). The ore mineral assemblage at Northern Dancer comprises scheelite, molybdenite and molyscheelite (powellite). Figure 16 illustrates the intensity of the tungsten-in-soil anomalies on the Hidden and Northern Dancer properties.

TUNGSTEN GEOCHEMISTRY COMPARISON

HIDDEN PROPERTY

DISCUSSION AND CONCLUSIONS

The Hidden property covers calc-silicate altered carbonate and siliciclastic rocks of Cassiar Platform, which are cut by Mid Cretaceous to Tertiary intrusions. Reconnaissance- and detailed-scale exploration on the property has identified well mineralized skarn blocks in talus (Discovery Showing) and an extensive stockwork quartz-scheelite vein zone. Both types of mineralization lie within a broad area (1300 by 1000 m) of strongly to very strongly anomalous tungsten-in-soil geochemistry.

A number of similarities exist between the Northern Dancer Deposit and Hidden property including:

- 1) calc-silicate altered wall rocks intruded by Mid Cretaceous plutons and younger porphyry dykes;
- 2) extensive vein-hosted mineralization;
- 3) skarn mineralization;
- 4) mineral assemblage including scheelite with bismuth and beryllium; and
- 5) tungsten-in-soil anomalies that are comparable in size and intensity.

There are two significant differences between the Hidden property and Northern Dancer Deposit:

1) Northern Dancer has mineralized quartz-feldspar porphyry dykes, while feldspar porphyry dykes at Hidden are unmineralized, and 2) there is little or no molybdenite or molybscheelite at the Hidden property. The positive implication of the low molybdenum content is that a clean tungsten concentrate should be easier to produce at the Hidden property than at Northern Dancer.

Most of the known mineralization on the Hidden property lies within the Hidden Anomaly. Limited hand trenching and drilling have returned variable tungsten results, which do not adequately explain the large, very strong tungsten-in-soil anomaly.

The presence of widespread scheelite bearing veins and narrow skarn zones developed as envelopes along steeply dipping faults suggests that the main controls on mineralization are probably structural. Based on observed lithologies, styles of mineralization and soil geochemical response, it is possible that the Hidden property represents a shallow level of erosion within a very large hydrothermal system.

The Hidden property definitely warrants additional work to better assess the character and scope of the known mineralization, particularly the stockwork zone. Future exploration should consist of hand trenching or hand pitting at the sites of strongly anomalous tungsten-in-soil values. Trenching and pitting should be designed to provide additional data concerning the styles of mineralization, stratigraphic affinities and structural orientations. Drill sites should be selected after this data is available to further test at depth beneath the Discovery Showing and stockwork quartz-scheelite veined zone.

Respectfully submitted,

ARCHER, CATHRO & ASSOCIATES (1981) LIMITED

APPENDIX I
STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS

I, Andrew Mitchell, geoscientist in training, with business addresses in Whitehorse, Yukon Territory and Vancouver, British Columbia and residential address in Vancouver, British Columbia, hereby certify that:

1. I graduated from the University of British Columbia in 2010 with a B.Sc. in Earth and Environmental Sciences.
2. From 2010 to present, I have been actively engaged in mineral exploration in Yukon Territory.
3. I am a Geoscientist in Training (GIT) with the Association of Professional Engineers and Geoscientists of British Columbia.
4. I have interpreted all data resulting from this work.

A. Mitchell, B.Sc. GIT

APPENDIX II
STATEMENT OF EXPENDITURES

Statement of Expenditures
Hid 1-22 Mineral Claims
September 10, 2013

Labour

A. Mitchell – geologist – 6 days July at \$595/day	3,748.50
J. Thomson-Gladish – field assistant – 6 days July at \$425/day	2,550.00
L. Vinnedge – field assistant – 6 days July at \$374/day	<u>2,244.00</u>
	8,542.50

Expenses (incl. management)

Field room and board – 18 mandays at \$130/day	2,457.00
Trans North – 6.7 hours Bell 206B at \$990/hour plus fuel	7,826.49
ALS Chemex	<u>7,377.77</u>
	17,661.26

Total	<u>\$26,203.76</u>

CERTIFICATE OF ANALYSIS WH13131711

CERTIFICATE COMMENTS

ANALYTICAL COMMENTS

Applies to Method: REE's may not be totally soluble in this method.
ME-MS61

LABORATORY ADDRESSES

Applies to Method: Processed at ALS Whitehorse located at 78 Mt. Sima Rd, Whitehorse, YT, Canada.
LOG - 22 SCR - 41 WEI - 21

Applies to Method: Processed at ALS Vancouver located at 2103 Dollarton Hwy, North Vancouver, BC, Canada.

CERTIFICATE WH13131712

Project: **HIDDEN**

P.O. No.:

This report is for 209 Soil samples submitted to our lab in Whitehorse, YT, Canada on 22-JUL-2013.

The following have access to data associated with this certificate:

HEATHER BURRELL

SARAH DRECHSLER

JOAN MARIACHER

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI - 21	Received Sample Weight
LOG - 22	Sample login - Rcd w/o BarCode
SCR - 41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION
ME-MS61	48 element four acid ICP-MS

To: **STRATEGIC METALS LTD.
ATTN: JOAN MARIACHER
C/O ARCHER, CATHRO & ASSOCIATES (1981) LIMITED
1016 - 510 W HASTINGS ST
VANCOUVER BC V6B 1L8**

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE OF ANALYSIS WH13131712

CERTIFICATE COMMENTS

ANALYTICAL COMMENTS

Applies to Method: REE's may not be totally soluble in this method.
ME-MS61

Applies to Method: Interference: Samples with Ca>10% on ICP-MS As. ICP-AES As results reported (5 ppm DL)
ME-MS61

LABORATORY ADDRESSES

Applies to Method: Processed at ALS Whitehorse located at 78 Mt. Sima Rd, Whitehorse, YT, Canada.
LOG-22 SCR-41 WEI-21

Applies to Method: Processed at ALS Vancouver located at 2103 Dollarton Hwy, North Vancouver, BC, Canada.
ME-MS61
