1.0 Executive Summary

Anthill Resources' Einarson Project is located 200 kilometers east of Mayo, Yukon in east-central Yukon. The Einarson Project consists of 11,455 contiguous quartz mining claims totaling 235,000 hectares covering the eastern strike extension of the Rackla Gold Belt. The claims are held by staking and through an option to purchase agreement with Mr. Ron Berdahl providing Anthill Resources 100% ownership of the project. The project was initiated in October, 2010, and exploration work has continued through the end of 2013. The project area continues to receive considerable exploration interest since the October 2010 announcement of Carlin-style gold mineralization on their Rackla Project by ATAC Resources.

A major exploration program was completed in the 2013 field season that further defined eight regional-scale target areas with anomalous gold geochemistry associated with geological settings favorable for Carlin-style, sediment-hosted gold mineralization. Three of the eight target areas were drill tested with significant gold mineralized drill intercepts in the Venus and Mars target zones.

A total of 459 silt, 17,651 soil and 2,203 rock samples were collected in 2013 from the eight regional scale target areas; Venus, Mars, F2, Misty, B Zone, Emer, G Zone and Lansing Trends. These areas contained anomalous gold in stream sediment silt geochemistry with variable pathfinder element arsenic, antimony, mercury and thallium geochemistry. Grid soil and rock chip sampling in 2013 further defined the geochemical anomalies previously known at these eight target areas.

Nine rock chips samples from the Venus area assayed greater than 9.25 g/t gold with a high of 191.00 g/t gold with arsenic values ranging between 1% and 10%. Three of these samples consisted of 3 meter, chip channels which assayed greater than 13.8 g/t gold. A 33.5 meter trench across the Mars Main structural zone assayed 1.65 g/t gold with a high value of 9.25 g/t gold across 2 meters. The hydrothermal systems, in both the Venus and Mars areas, locally deposited gold in sufficient grades and widths to be of economic interest.

In 2013, a total of 4803 meters of HQ core drilling was completed in 21 drill holes in the Venus (10 holes), Mars (3 holes) and F2 (8 holes) target areas. Drilling in the Venus and Mars areas followed up significant 2012 drill results and drilling in the F2 area tested gold in soil anomalies. The results of the 2013 drilling did not expand gold mineralization in either the Venus or Mars target areas and did not encounter significant gold mineralization in the F2 target area.

QA/QC programs were implemented for all silt, soil, rock and drill core sampling, and for all geochemical analysis. The QC data is robust and validates the analytical accuracy of the geochemical data. The Einarson Project is fully authorized for prospecting, drilling and camp-related activities under a Yukon Department of Energy, Mines and Resources Class III permit through May of 2017.

2.0 Introduction

Anthill Resources initiated claim staking in the Einarson Project area in October, 2010 in response to ATAC Resources announcement of Carlin-type gold discoveries on their Rackla Project. By the end of 2011, the Einarson Project consisted of 11,000+ claims covering over 235,000 hectares that are 100% controlled by Anthill Resources through staking and an option agreement with Mr. Ron Berdahl, of Whitehorse, Yukon (Figure 2).

The Einarson Project is an exploration stage gold project located in east-central Yukon, approximately 200 kilometers east of Mayo, Yukon (Figure 1). The project comprises 11,373 contiguous claims, plus an additional 82 claims in two blocks, covering an aggregate area of approximately 235,000 hectares (Figure 2). The Einarson Project covers parts of NTS (1:50,000 scale) map sheets 105N16, 105O13, 105O14, 105O15, 106B02, 106B03, 106B04 and 106C01.

Eight regional-scale gold prospects, at various stages of exploration, are located on the claim block and have been actively explored by Anthill Resources since 2011 (Figure 6). Three of the gold prospects have been drill tested to date and drilling in two of the areas returned significant gold mineralized intercepts.

This assessment report documents the exploration work completed by Anthill Resources in 2013 on the Einarson Project. The report was prepared following the general guidelines set forth by the Canadian Securities Administrators' National Instrument 43-101 and Form 43101F1.

This report covers the following aspects of the projects:

- Topography, landscape and access
- Regional and local geology, and mineralization
- Exploration history
- Review and technical audit of the 2013 work performed by Anthill Resources
- Summary of 2013 exploration expenditures by Anthill Resources

This assessment report builds on previous assessment reports written in 2011 and 2012 by independent contractors working on the Einarson Project (Nass, 2012 and Schultz, 2013).

Authors Ms. Jin and Mr. Cary are independent consultants to Anthill Resources, and author Mr. Yang is employed by Anthill Resources. Authors Cary and Yang spent over 100 days in the field during 2013 exploration program, and between them have inspected all of the Einarson Project target areas in the field and have reviewed all project drill core. The authors have reviewed all of the exploration data collected for the Einarson Project and have reviewed additional information from public domain sources that were pertinent to the Einarson Project. The exploration data presented in this technical report is believed to be reliable, and the authors have no doubt as to the reliability of the historical data present in this report.

The authors of this technical report are considered "qualified persons" as defined by the National Instrument 43-101 standards by the virtue of their education, relevant work experience and professional association. Both Ms. Jin and Mr. Cary are professional geologists recognized by the Association of Engineers and Geoscientists of British Columbia (#37813) and the American Institute of Professional Geologists (CPG-11673), respectively.

3.0 Property Description and Location

3.1 Land Tenure

The Einarson Project claim block consists of 11,455 registered quartz mining claims covering approximately 2350 square kilometers. The boundary of the claim block is shown in Figure 2. The boundaries of the individual claims have not been legally surveyed. A list of the mining claims is given in Table 1 and the claims are graphically presented in Appendix D.1.

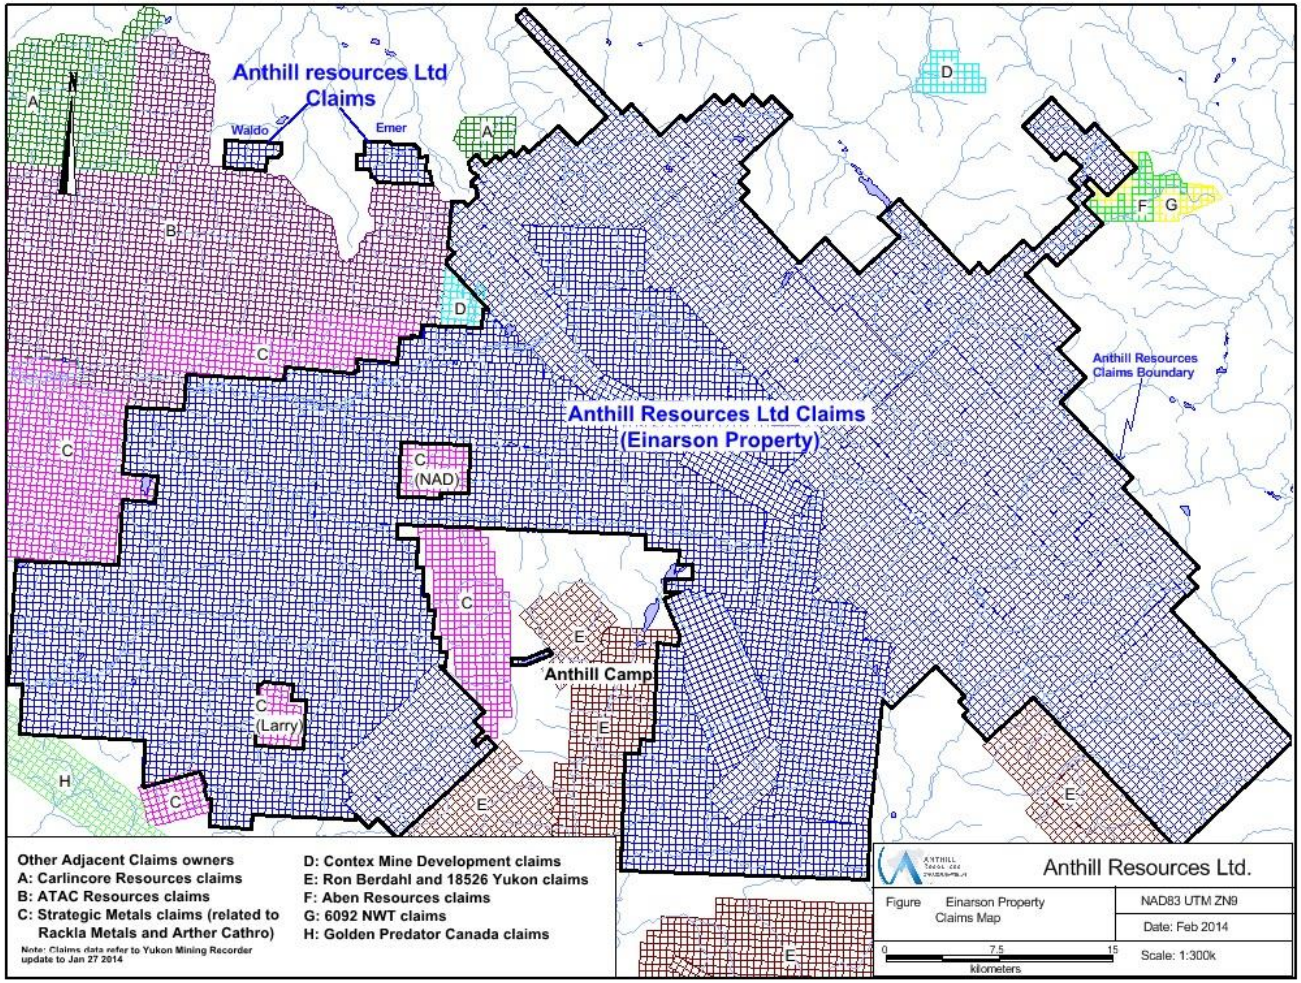
Figure 2. Einarson Project Claim Map with Adjacent Competitor Claims



3.2 Underlying Agreements

Anthill Resources staked 761 quartz mining claims in 2011 that it owns 100%. These claims are registered to Anthill Resources Ltd. and are in good standing with the Yukon Mining Recorder (Table 1).

Anthill Resources has an option agreement to earn 100% ownership to 10,694 additional claims in the project area that was acquired from Mr. Ron Berdahl, of Whitehorse, YT. The property is free and clear of all liens and third party interests. These claims are now registered to Mr. Ron Berdahl or 18526 Yukon 70% and Anthill Resources 30% (Table 1).

3.3 Environmental Considerations

Anthill Resources conducts all exploration activities in a manner to minimize all environmental impacts to land, water, wildlife and cultural resources. All Einarson Project employees and sub-contractors were required to use best practice procedures for minimizing environmental impact due to exploration activities, and to ensure safe working conditions for all persons.

Anthill Resources operates a fifty person camp located adjacent to Anthill Lake (informally named) (Figure 2). A Class 3 Permit (LQ00363a) has been obtained from the Yukon Department of Energy, Mines and Resources, and the permit is valid through May 13, 2017. The Class 3 permit covers all of the exploration and related camp activities at the Einarson Project including fuel storage, waste disposal, trenching and drilling.

Anthill Resources has obtained and complied with any applicable permit requirements to conduct mineral exploration on the Einarson Project claims.

4.0 Accessibility, Climate, Infrastructure and Physiography

The Einarson Project is located within the Hess Mountains, approximately 200 kilometers east of Mayo, Yukon Territory. The claim outline forms an irregular rectangular block situated between the Stewart and Rogue Rivers immediately west of the Yukon/Northwest Territory boundary (Figure 1). The Osiris and Conrad zones, Carlin-style gold mineralized system being explored by ATAC Resources, are located approximately 30 kilometers northeast of the Einarson Project (Figure 6). Access to the property is by float plane to the base camp at Anthill Lake or airplane to the Stewart River airstrip, followed by helicopter to the Anthill Lake base camp.

The project area is glaciated and consists of rugged, steep topography ranging from 900 meters to 2,150 meters in elevation (Figure 2). The majority of the property is above tree line and contains shrubby vegetation. The Einarson Project claims encompass an area draining the Upper Stewart and Lansing River drainages and the northern portion of the Rogue River drainage. Areas below 1,350 meters in elevation are covered by sub-arctic fir mixed with spruce and minor poplar stands along south-facing slopes. White and black spruce is common in the valleys of the Stewart, Rogue and Lansing rivers. Bedrock exposures are extensive above timberline and relatively scarce in the larger river valleys.

Although there are currently no all weather or winter roads connecting camp to any of the major communities in Yukon, access to the Einarson property is considered good. The Stewart River airstrip is located approximately 30 kilometers northeast of the Anthill Lake base camp and the Forks airstrip is located approximately 30 kilometers to the southeast. The 2013 program used both ski and float plane support to the newly constructed Anthill Lake base camp (Figure 2). The 2013 drilling program was helicopter-supported from the Anthill Lake base camp and the drill rigs were de-mobilized from the Stewart airstrip.

The Yukon Territory has a sub-arctic continental climate with a summer mean temperature of 10 degrees Celsius and a winter mean temperature of minus 23 degrees Celsius. Summer and winter temperatures can reach up to 35 and minus 55 degrees Celsius, respectively. Mayo, the nearest access point, has a daily average temperature above freezing for 180 days per year.

5.0 History

Minor historic exploration activity has occurred on the Einarson Property. Only two Yukon Geological Survey Minfile occurrences (Minfile 105O-018 and 106B-024) are documented within property boundary. Both mineral occurrences were staked in 1974 by McIntyre ML exploring for Mississippi Valley-type lead-zinc mineralization.

The Odd prospect was interpreted as a Mississippi Valley-style mineralized system. McIntyre discovered several pods of coarse grained galena and green sphalerite in brecciated “zebra” dolomite. A “typical” trench sample returned a value of 8.0% Pb, 28% Zn and 2.1 g/t Ag across 3.4 meters. McIntyre drilled 4 “Winkie” holes totaling 45.1 meters in 1975 and reported 1.8% Pb, 4.0% Zn and 2.1 g/t Ag over 2.1 meters (Minfile, 2014b). Mineralization is hosted in the Neoproterozoic carbonate rocks of the Algae Formation.

The Birkeland prospect was hosted in Neoproterozoic Hyland Group fine-grained clastic rocks with minor interbedded dolomite. Numerous showings of red to dark green sphalerite occur assaying to 25% combined Pb-Zn. A total of 10 BQ diamond drill holes totaling 900.7 meters and 22 Winkie holes totaling 325.8 meters were completed in 1975. The best

intersection was from Hole 75-31 which assayed 4.4% Zn, 0.5% Pb and 2.7 g/t Ag across 1.8 meters (Minfile, 2014a).

Government sponsored regional geochemical surveys were carried out in the southern portion of the Einarson Project area (NTS 105N and 105O map areas) in 1990 and in the northern portion of the Einarson Project area (NTS 106B and 106C map areas) in 2001 (Heon, 2003). A wide range of elements were analyzed from stream sediments collected over the area.

Interest in the area was rekindled in 2006, with the discovery of gold mineralization by ATAC Resources on their Rau Project located 110 km to the west of the Einarson Project (Theissen, et al., 2012). Continuing exploration by ATAC Resources to the east of their Rau discovery culminated with the 2010 discovery of several zones of gold mineralization informal called the Nadaleen Trend, immediate northeast of the Einarson Project. Two main zones of gold mineralization, Osiris and Conrad, were broadly defined by 2012 with drill intercepts of 42.9 m grading 18.44 g/t Au reported (Tucker, et al., 2013). The style of gold mineralization encountered in the Nadaleen Trend was very similar to well documented gold mineralization present in the Carlin and Battle Mountain-Eureka Trends of north-central Nevada (Arehart, et al., 2013).

Anthill Resources and Mr. Ron Berdahl staked portions of the Einarson Project claims covering prospective regional silt geochemistry and favorable host stratigraphy along the eastward extension of the Nadaleen Trend. Claim staking continued through 2011 under an option agreement to acquire additional quartz mining claims in the area from Mr. Ron Berdahl. The Einarson Project controlled approximately 11,500 claims covering ~2,400 km2 at the end of 2011 covering the eastern extension of the Nadaleen Trend.

The exploration work completed by Anthill Resources in 2013 is discussed in Sections 8, 9 and 10.

6.0 Geologic Setting and Mineralization

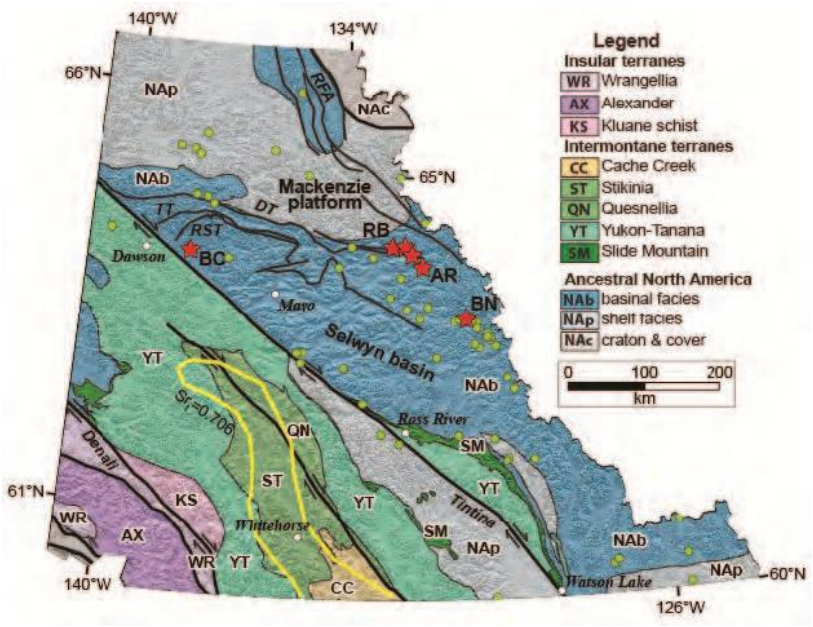
6.1 Regional Geology

The Einarson Project is located on the northeastern margin of the Selwyn Basin which consists of a thick package of Proterozoic through Paleozoic marine sediments extending east-southeast from the Dawson City area to the Yukon-Northwest Territories border. The northwest trending Tintina Fault defines the southwest boundary of the Selwyn Basin while the North American craton defines the northern and eastern boundary (Figure 3). The Selwyn Basin stratigraphy consists of shelf to slope facies, marine clastic and chemical rock units derived from the Ancient North American Platform to the north and northeast. These

carbonate-rich rock units become deep marine facies, clastic and chemical sediments with a significant mafic volcanic and volcaniclastic component to the south. Two major episodes of rifting occurred in the basin; one during deposition of the Proterozoic Hyland Group clastic sediments and the second during deposition of the Devonian-Mississippian Earn Group clastic sediments. These fault zones source coarse grained clastic sediments and mafic volcanic rocks along the basin margins and intra-basin uplifts.

Figure 3. Tecnonic Map of the Yukon Territory

Modified from Colpron, et al., 2013. Red stars show the locations of select gold occurrence; AR = Anthill Resources Einarson Project Venus gold occurrence; RB = ATAC Resources Rackla Belt (Osiris, Conrad, Anubis and Pharaoh gold occurrences).



Significant SEDEX Pb-Zn-Ag, VMS Pb-Zn-Ag+Au and bedded barite mineralization is also developed throughout the Selwyn Basin (Howards Pass, Faro and Wolverine).

The Selwyn Basin represents the northern portion of the regionally extensive, rifted margin of the North American Plate that extends southward over 3000 km to the southwestern United States. The rifted margin was developed by the break-up of the paleo-super continent Rodinia which commenced in the Neoproterozoic and continued through the Middle Triassic (Arehart, et al., 2013). Initial rifting took place along an east-west trending boundary at low latitudes creating the North American and the Australia tectonic plates. Paleozoic fold and thrust orogenic events that are well documented in Nevada (Roberts Mountain and Golconda Thrusts) are not documented in the Selwyn Basin at this time.

Extensive thrust faulting along the entire northern and eastern margin of the Selwyn Basin began during the Late Jurassic and extended through the Early Cretaceous. The regional fold

and thrust belt strikes west-northwest and dips to the southwest. Major regional thrust faults include, from youngest to oldest, the Dawson, Tombstone, and Robert Service from north to south within the Selwyn Basin. This Mesozoic fold and thrust orogenic event correlates with the Sevier and Laramide (?) events in the western United States.

The Mid-Cretaceous Tombstone-Tungsten Magmatic Suite (95-89 Ma) consists of metaluminous, subalkaline, granodioritic to quartz monzonitic magmas emplaced into the Selwyn Basin stratigraphy. The magmatic suite was emplaced along an east-southeast trending belt extending over 500 kilometers from northwest of Dawson City to the Yukon-Northwest Territory border. The intrusions are post-tectonic and post regional metamorphism and are interpreted to represent back-arc magmatism. The intrusions are spatially and temporally associated with world-class tungsten skarn mineralization (Cantung and Mactung) and significant gold mineralization in the Selwyn Basin (Dublin Gulch and Fort Knox, Alaska) (Lang, et al., 2000).

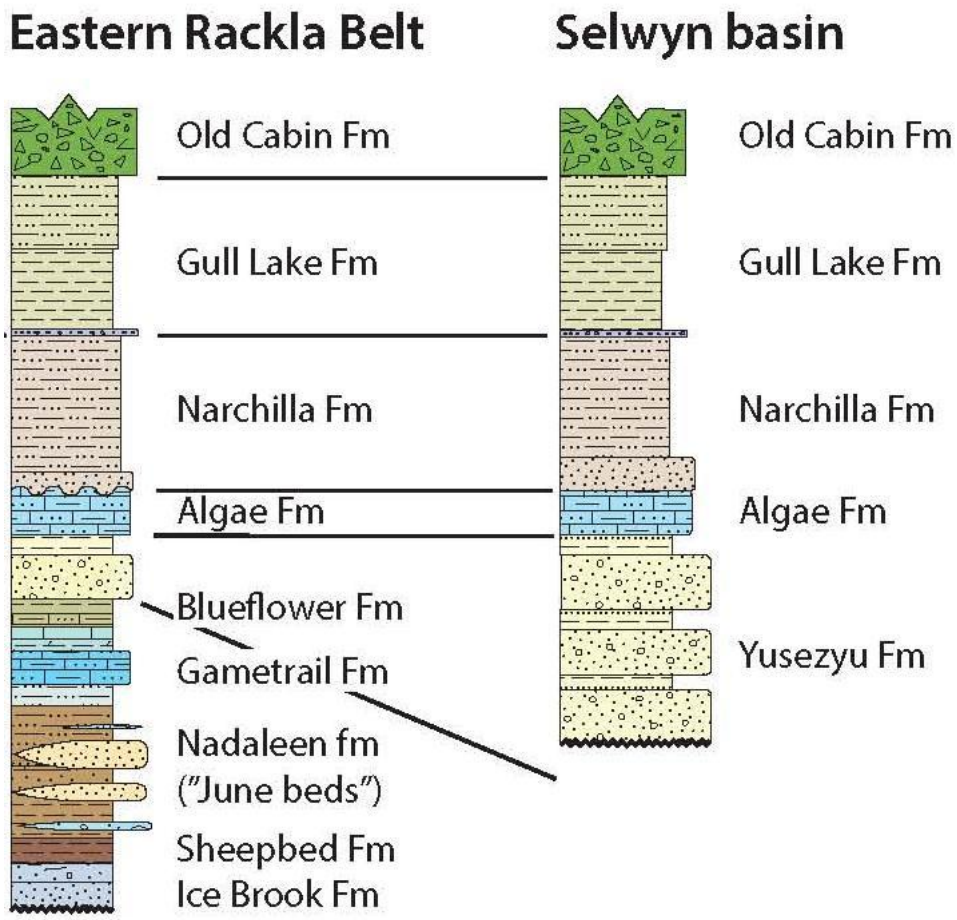
A younger suite of intermediate composition, Late Cretaceous-Paleocene (~60 Ma) magmatic complexes is present in the Selwyn Basin. This intrusive suite is interpreted to be related to gold-rich replacement mineralization at ATAC Resources Rau Project (Theissen, et al., 2012). These intrusions are not well documented and may be volumetrically minor or conversely may not be well exposed at current erosion levels, and their association with gold mineralization elsewhere in the Selwyn Basin remains elusive.

The Einarson Project is located along the eastern portion of the Rackla gold belt, as defined by mapping by Colpron, et al. (2013) and Moynihan (2014b). The project is located along the northern edge of the Selwyn Basin where Proterozoic to Paleozoic basinal rock is juxtaposed against Proterozoic through Paleozoic shelf/slope rocks along the Dawson Thrust (Figure 5). The area is host to the recently discovered Carlin-type gold mineralization announced by ATAC Resources in 2010 (ATAC Resources, 2010).

The geology of the Rackla belt can be divided into three time equivalent stratigraphy packages which represent different sedimentary depositional facies (Colpron, et al., 2012; Moynihan, 2014a) (Figure 4). South of the Dawson Thrust Fault, the rocks units include the Neoproterozoic to Cambrian Hyland Group and the Cambrian to Ordovician Gull Lake and Ordovician Old Cabin Formations (Figure 5). The Hyland Group includes, from the bottom up, thick sections of coarse-grained sandstones and lesser shales of the Yusezyu Formation carbonate turbidites of the Algae Formations and thick sections of vari-colored shales with lesser siltstone and carbonate turbidites of the Narchilla Formation. The Hyland Group units are overlain by fine to coarse grained lithic sandstones of the Gull Lake Formation and mafic volcanic and volcaniclastics of the Old Cabin Formation (Moynihan, 2014a).

Figure 4. Stratigraphic columns for the Eastern Rackla Belt and Northern Selwyn Basin

Modified from Moynihan (2014a)

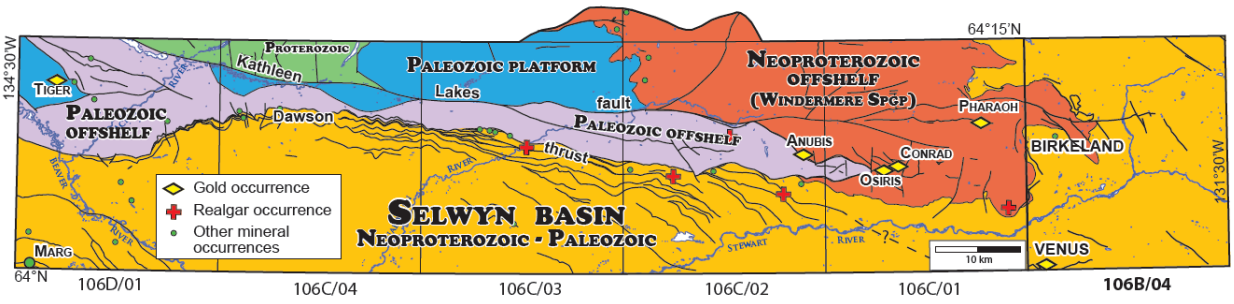


North of the Dawson Thrust Fault, the stratigraphy is correlative with the Selwyn Basin to the south and is interpreted to represent the slope-shelf facies depositional environment with a greater percentage of carbonate lithologies. The lower lithologic units are informally termed the Nadaleen assemblage and the upper lithologic units are termed the Stenbraten assemblage (Moynihan, 2014a). The upper carbonate unit of the Stenbraten assemblage is interpreted to be correlative with the Algae Formation. The slope facies lithologies correlate with well defined shelf carbonate and clastic lithologies of the Windermere Supergroup immediately to the north of the Kathleen Lake Fault (Colpron, et al., 2012; Moynihan, 2014a). The Kathleen Lake Fault is an east trending, high-angle fault with normal displacement that is sub parallel to the Dawson Thrust Fault.

This fault bounded sequence of Proterozoic to Late Paleozoic slope facies carbonate rocks hosts Carlin-type gold mineralization at ATAC Resources' Osiris, Isis, Conrad, Anubis and Pharaoh gold mineralized areas (Colpron, et al., 2013; Tucker, et al., 2013). The Dawson Thrust and Kathleen Lake faults have a long, complex history that involves both reverse and normal offsets and possible strike slip motion. Displacement along both faults appears to decrease to the east (Colpron, et al., 2013).

Figure 5. Regional Geological Map of the Rackla Belt Area

Modified from Moynihan, et al., 2014 showing the location of gold and realgar occurrences in the Rackla Gold Belt. Anthill Resources' Venus gold occurrence is located along the trace of the Dawson Thrust. The Waldo claims are located north of the Pharaoh gold occurrence. Hyland Group rocks are highlighted in tan south of the Dawson Thrust.



6.2 Property Geology

6.2.1 Lithology

The Einarson property is underlain by a thick sequence of Hyland Group stratigraphy. The Hyland Group consists of several kilometers of terrigenous clastic strata with minor carbonate lithologies that span the Precambrian-Cambrian boundary (Gordey and Andersen, 1993). The Hyland Group is subdivided into three main formations, which from oldest to youngest, include the Yusezyu, Algae and Narchilla Formations (Figure 4).

The Yusezyu Formation consists of a thick succession of medium- to coarse-grained quartzose sandstone and grit to quartz-pebble conglomerate with interbedded siltstone and shale. The unit is monotonous and massive no regional marker beds.

The Algae Formation conformably overlies the Yusezyu Formation locally in the Selwyn Basin and the type locality occurs within the Einarson Project in the F2 target area (Figure 6). The Algae Formation can be subdivided into a lower carbonate sequence and an upper calcareous siliciclastic sequence. The carbonate sequences consist of polymict cobble conglomerate, tabular intraclast floatstone and rudstone, flaggy limestone and calcareous turbidite units (Bennett, 2012, 2013). Work by Harry Cook (2011a, 2011b) defined four similar carbonate depositional sequences of Algae Formation in the Einarson Project area and all of these areas host gold in soil geochemical anomalies (Figure 6). Cook (2011a, 2011b) postulated that the Algae Formation forms a marker horizon extending east and south from the Nadaleen Trend through the Einarson Project area.

The siliciclastic units are composed of distinctive angular, poorly sorted, quartz-rich, calcareous and non-calcareous sandstone, siltstone that are locally pyritic. The contact with the lower chemical sediments is transitional.

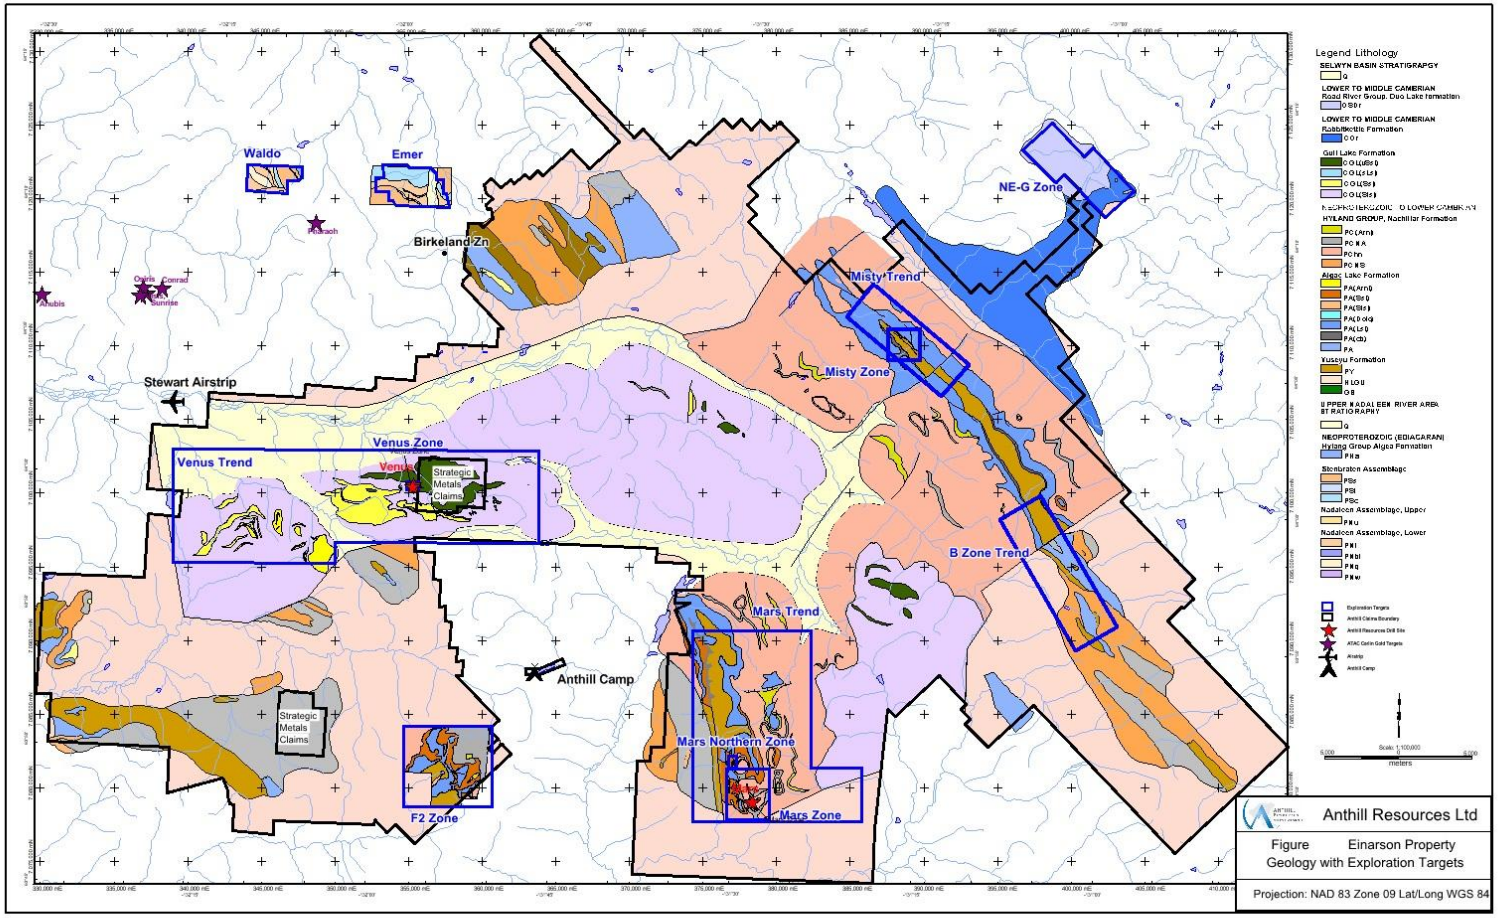
The Narchilla Formation overlies the Algae Formation and is subdivided into Senoah and Arrowhead Lake members. The Senoah Member consists of interbedded siltstone and mudstone while the Arrowhead Lake Member consists of green and maroon shale. Fossil control shows that Narchilla deposition was active into the Early Cambrian.

The Gull Lake Formation conformably overlies the Narchilla formation and is subdivided into three members. A discontinuous limestone conglomerate defines the base of the unit and is overlain by rusty laminated shale, siltstone and fine-grained sandstone. The upper member consists of grey, thick-bedded, variably calcareous and dolomitic siltstone and mudstone. Locally, basaltic sills, flows and dikes, and associated volcaniclastic sediments are interbedded throughout the formation (Bennett, 2012, 2013).

Northeast of the Misty and Cloudy Creek Valleys are massive, thick bedded limestones of the Ordovician Rabbitkettle Formation and black shale and chert with minor limestone of the Ordovician-Devonian Road River Formation.

Notably absent throughout the property is any evidence of Mesozoic or Cenozoic age intrusive rocks or associated hornfels alteration.

Figure 6. Einarson Property Geology with Exploration Targets



6.2.2 Structure

Geological mapping for the entire Einarson project area is available from Gordey and Makepeace (2001) at a scale of 1:1,000,000 (Figure 7). The project area has two distinct regional scale structural domains. The east-west trending Dawson Thrust zone (DTZ) crops out in the western portion of the project area and is spatially associated with mineralization in the Venus area. The informally named, northwest trending Misty Lake (MLFZ) fault zone is exposed along the northeast boundary of the project and is spatially associated with mineralization at the Misty and B Zone areas. Two north-northwest trending anticlinal folds (East Thirteen and Little Lakes) with associated west vergent thrust faults are associated with mineralization in the Mars and F2 areas respectively (Cecile, 1998) (Figure 7). These fold/thrust structures have orientations similar to fold/thrust structures proximal to the MLFZ.

The west-northwest trending DTZ is a regionally extensive zone that is mapped over 300 kilometers from Dawson City, Yukon to the Yukon-NWT border. Early extensional deformation along the DTZ defines the northern margin of the Neoproterozoic to Late Paleozoic Selwyn Basin. In the Mesozoic, the DTZ is re-activated as a compressional thrust structure placing older, basinal Hyland Group rocks on younger shelf carbonate rocks (Colpron, et al., 2013a). Locally the DTZ is interpreted to have left lateral strike-slip motion. Detailed mapping since 2011 in the area immediately to the west of the Einarson Project by Colpron, et al., (2013) has increased the understanding of this geologically complex area. Hydrothermal fluids responsible for the Carlin-style gold mineralization discovered by ATAC Resources are possibly related to the DTZ.

The MLFZ juxtaposes Early Paleozoic shelf carbonates against Neoproterozoic Hyland Group lithologies in the northeast portion of the project area. The MLFZ represents a Late Precambrian, crustal-scale extensional normal fault controlling deposition of several kilometers of Hyland Group sediments southwest of the structure into the Selwyn Basin. The zone was likely re-activated in the Mesozoic as large-scale thrust faults deformed the Selwyn Basin to the southwest and shelf carbonates to the northeast, well into the Northwest Territory. Post Mesozoic strike slip displacement is not well documented. The MLFZ may have a structural history similar to the DTZ, but additional geologic mapping is needed to better understand the structural zone.

Thrust faulting and associated folding interpreted to be Mesozoic in age are the dominant structural features observed in the Einarson Project area. Regional scale, anticline-syncline pairs are present in the Mars, F2, Misty and B Zone areas. The folding is continuous over 10’s of kilometers of strike with fold wavelengths of 10-30 kilometers. Some of the folds are doubly plunging and produce domal outcrop patterns (Cecile, 1998). Folding commonly has closed to tight geometry, and locally overturned beds with recumbent geometry are present

near major thrust faults. Fold geometries and kinematic indicators show both southwest and northeast fold vergence.

Younger, high-angle normal faults are not well documented in the project area to date (Figure 7). In the Venus area, a high-angle fault zone trending 010^{o}, associated with alteration and gold mineralization, was mapped on the surface. There is little structural data to directly interpret the type of offset along the structure, but it is interpreted to have up to the east reverse motion. Mapping by Moynihan (2014b) has also identified northwest trending normal faults in the Venus area.

In the Mars area, the moderately east dipping, 330^{o} trending Mars Fault cuts the western limb of the East Thirteen Anticline with 100's of meters of normal offset (Cecile, 1998). The Mars Fault is cut by two smaller 300^{o} trending normal faults with 10's of meters of normal offset, forming a small graben structure (Figure 7). The graben is spatially associated with a significant gold in soil anomaly in the Mars area.

In the F2 area, two high-angle faults with small displacement and short strike lengths were mapped. Initial mapping in the Misty and B Zone areas defined high-angle faults that were developed sub-parallel to steeply dipping fold limbs or as faults perpendicular to the fold axes. The high-angle structures developed parallel to the older fold axes may locally control gold mineralization.

6.3 Mineralization

Various styles of precious and base-metal mineralization, ranging from SEDEX, MVT, VMS, IRGS and Carlin-type systems, are developed in the Selwyn Basin. Gold mineralization in the Selwyn Basin is generally associated with mid-Mesozoic granitic intrusions and high-angle faulting, although gold-rich Proterozoic-Paleozoic VMS deposits are known. Gold mineralization is predominantly thought to be associated with the Late Mesozoic and younger deformation events.

Carlin-type gold mineralization, documented in the Nadaleen Trend, is bounded to the north by the Kathleen Lake fault and to the south by the Dawson Thrust (Arehart, et al, 2013; Colpron, et al., 2013). The extension of these regionally important faults and related splay faults to the east within the Einarson Project area are currently poorly documented. The Venus, Waldo/Emer and Birkeland target areas are located within this block. The remaining four target areas (Mars, F2, Misty and B Zone) are hosted within the faulted anticlines located to the south and east of the currently defined Nadaleen Trend (Figures 6 and 7).

6.3.1 Venus Trend

The Venus target area is located 20 km northwest of the Anthill Lake camp and 30 km southeast of ATAC Resources Nadaleen Trend gold mineralization (Figure 6). The area was the main focus of the 2012 and 2013 exploration programs. The Venus area was defined in 2011 by stream silt sampling, and prospecting in 2012 identified significant alteration and gold mineralization in soils and rocks in prospective carbonate host rocks. The 2012 drill program by Anthill Resources encountered significant gold mineralization in drill hole D2-12-05 (Table 7). Exploration work in 2013 consisted of rock chip sampling, geological mapping and diamond drillings

The geology consists of a gently southwest-dipping, fault bounded, tabular dolostone unit approximately 150 meters thick that is strongly altered and gold mineralized. This carbonate package has been interpreted as part of the Algae Formation, however alternate interpretations have been proposed Cook (2011a) and Moynihan (2014a). Structurally above the carbonate unit is a sequence of coarse grained, quartz-rich clastics and debris flows with minor limestone of the Narchilla (?) or Gull Lake Formations(?). The clastic-rich sequence is structurally overlain by mafic fragmental volcanics of the Old Cabin Formation. Structurally below the dolostone unit is a thick sequence of mafic flows and volcaniclastics of the Old Cabin Formation. The dolostone unit strikes east onto claims held by Strategic Metals and is down faulted to the west beneath clastic lithologies of the Narchilla Formation (Figure 49).

Three, east-west trending, gently southwest dipping thrust faults bound the different rock units at Venus. Recent mapping by the Yukon Geological Survey suggests these faults are part of the Dawson Thrust (Moynihan, 2014b). Three phases of ductile folding are present with southwest, northeast and northwest-southeast trending fold hinges. The SW and NE trending folds are upright and the NW-SE folds are overturned.

Younger, brittle faults/fractures are present with NW, SE and SW strikes and 70 to 90^{o} dips. The NE trending faults are strongly silicified with hematitic and scoraditic staining and local brecciation. Mineralization includes arsenopyrite, arsenian pyrite, pyrite, realgar, orpiment and cinnabar. Significant gold mineralization is associated with arsenopyrite and arsenian pyrite content and anomalous gold associated with peripheral (?) orpiment / realgar / cinnabar mineralization. Pods of older galena/sphalerite mineralization are present in the area and locally some galena may be associated with the younger gold mineralization.

6.3.2 Mars Trend

The Mars target area is located 20 km southeast of the Anthill Lake camp and 30 km north of Golden Predator Canada's Valley Gold mineralization (Figure 6). The Mars target area was defined by a gold stream silt anomaly in 2012 and was explored by geologic mapping, soil and rock sampling and drilling during the 2013 exploration program. The target area was

defined by a significant gold in soil, rock and trench geochemical anomaly developed along the faulted western margin of the East Thirteen Anticline. The 2012 drill program by Anthill Resources encountered significant gold mineralization in drill hole A2-12-01 (Table 7) at the southern extent of the gold geochemical anomaly.

Gold mineralization is localized along the steep western limb of a north-northwest trending, anticline (Figure 51). The fold limb is cut by a north-northwest trending, moderately east dipping normal fault, and numerous sub-parallel splays and bedding parallel thrust faults. Surface exposures of gold mineralized faults are developed in interbedded sandstone/siltstone of the Narchilla Formation, and minor base metal mineralization is also present in adjacent carbonate lithologies of the Algae Formation.

Gold mineralization is associated with quartz-carbonate-pyrite-arsenopyrite veins developed in both high-angle and low-angle fault/shear zones, and as replacement style mineralization peripheral to the structural zones. Discontinuous, high-angle quartz veins are also developed within low-angle, bedding parallel shear zones. Alteration consists of vein and replacement quartz along the structural zones with thin peripheral clay selvages. Minor, local Cu-Pb-Zn mineralization is present and the geochemistry shows a weak, but consistent Pb-Zn-Cu correlation with gold values. Orpiment or realgar mineralization has not been observed in the Mars area yet. Quartz veins from the Mars Northeast area are chalcedonic and suggestive of an epithermal style of mineralization.

A parallel trend of base metal +/-silver mineralization occurs about 800 meters west of the gold bearing Mars trend, where coarse clastics of the Yusezyu Formation are silicified and clay altered. Several occurrences of galena and sphalerite mineralization occur within the zone.

6.3.3 F2 Trend

The F2 area is located 10 kilometers southwest of the Anthill Lake camp in the Little Lakes Anticline area (Figures 6 and 7). The area has been explored historically for MVT base-metal mineralization (Odd Prospect). Exploration work in 2013 consisted of soil and rock chip geochemistry, geological mapping and diamond drilling.

The geology consists of intercalated units of limestone, sandstone and fine grained clastic rocks of the Yusezyu, Algae and Narchilla Formations (Figure 53). The type section of the Algae Formation is located near the center of the area. The Yesezyu Formation consists of coarse- to medium-grained quartzose sandstones that are conformably overlain by the thick “type-section” of the Algae Formation. The Algae Formation consists of medium- to thin-bedded limestone, limestone conglomerate and debrites with minor black chert that grades upward into quartz-rich sandstone, pebble conglomerate, and debrite units that locally

have a calcareous matrix. Overlying the Algae Formation are siltstone and shale of the Narchilla Formation.

The Little Lakes Anticline is a north-northwest trending domal feature approximate 15 kilometers in length along strike and 5 kilometers wide. Folding is generally upright and open with local zones of tight, overturned to recumbent, southwest and northeast vergent folding. Locally, high-angle normal faults are present with strike lengths of 300-500 meters and offsets of 5-10 meters.

Alteration within the F2 target is present as both silicification and dolomitization. The alteration is developed as both replacement- and vein-style with minor pyrite, arsenopyrite, stibnite, galena and sphalerite mineralization. Stibnite mineralization in the F2 target area appears to be mainly associated with dolomitic veins and in areas with Pb-Zn mineralization. Significant gold and related trace element soil geochemical anomalies are developed in the target area however rock chip sampling has failed to define ore-grade gold mineralization on the surface (Figure 25).

6.3.4 Misty Trend

The Misty target area is located 40 kilometers northeast of the Anthill Lake camp (Figure 6) and it is defined by a large gold in soil anomaly (Figure 30). Exploration work in 2013 consisted of soil and rock chip geochemistry and geological mapping.

The geology consists of a regional-scale, northwest trending, upright, closed anticline structure in the hanging wall of the Misty Lake Fault Zone. Interbedded shale, siltstone, sandstone with minor limestone exposed in the anticline core are tentatively assigned to the Neoproterozoic Yusezyu Formation, however these unit could also be assigned to the Stenbraten assemblages based on geographic location and slope facies associations. The clastic units are overlain by a thick sequence of cliff forming carbonate lithologies of the Algae Formation with shales and siltstones of the Narchilla Formation along the flanks of the anticline. Locally, the northeastern limb of the anticline is overturned and faulted and numerous reverse faults with 5-10 meters of offset are developed along the fold limbs.

Alteration is subtle consisting of weak bleaching (argillization) of shale and siltstone units and silicification as veins and replacements in quartz-rich clastic units. Mineralization consists of disseminated pyrite in the finer grained clastic sediments in the core of the anticline. Gold mineralization is well defined by grid soil samples from the area, and both soil and rock chip samples have similar gold grades.

6.3.5 B Zone Trend

The B zone target area is the southeastern extension of the Misty anticline and is located 45 kilometers east-northeast of the Anthill Lake Camp (Figure 6). The geologic and structural setting is similar to Misty with anomalous gold soil geochemistry extending over a 30 kilometer strike length (Figure 30). Exploration work in 2013 consisted of soil and rock chip geochemistry and geological mapping.

Alteration is subtle and initial mapping suggests zones of disseminated pyrite associated with silicification alteration as quartz veins, replacements and open-space filling. Locally, the quartz veining is fine grained and chalcedonic in nature.

6.3.6 Emer Trend - G Zone

The Waldo/Emer target areas are located 35 kilometer north of the Anthill Lake camp and 5-10 kilometers from gold mineralization at ATAC Resources Pharaoh, Osiris and Conrad zones (Figure 6). Exploration work consisted of soil and rock chip geochemistry. The two small claim blocks are not contiguous with the main Einarson claim block. They are located on the northern boundary of ATAC Resources extensive Rackla Belt claim group immediately south of the Peel River drainage boundary. Favorable carbonate host rocks of the Stenbratsen Group crop out on both of the claim groups along with interbedded siltstone, sandstone and shale. Mineralization consists of pyrite and minor arsenopyrite as disseminations and associated with both quartz and carbonate veins. Stibnite is also present in quartz veins in the Emer area. Visible gold in quartz veins is reported by ATAC Resources at their Pharaoh gold occurrence immediately south of the Emer area.

The G Zone target area is located 45 kilometers northeast of the Anthill Lake camp on the northeast side the Misty Lake Fault Zone. Exploration work in 2013 consisted of soil and rock chip geochemistry. The geology consists of basinal shale, argillite and chert of the Ordovician-Devonian Road River Group and limestone of the Ordovician Rabbitkettle Formation. The area has a strong base-metal stream sediment signature and weakly anomalous gold in soil values.

7.0 Deposit Types

7.1 Carlin-type Gold

Carlin-type gold deposits are epigenetic, low to moderate temperature, stratabound replacement deposits of gold associated with arsenian bearing pyrite, pyrite, and lesser arsenopyrite and native gold. Associated sulfide gangue minerals include realgar, orpiment,

stibnite, cinnabar and thallium minerals. Non-sulfide gangue minerals include quartz, clay minerals, barite, fluorite and carbonaceous material. The deposits are localized along initially passive, extensional continental margins overprinted by convergent back-arc felsic magmatism and fold and thrust deformational belts. The deposits are enriched in As, Sb, Hg and Tl and in some instances show correlation with W and Mo. The deposits are generally low in silver (10:1 gold/silver).

The gold deposits are commonly hosted in silty or argillaceous carbonate and carbonate-bearing clastic lithologies deposited in the continental slope-basin transition zone. Most of the deposits are found within broad, regional antiform structures in the footwall of regional thrust faults juxtaposing thick, deep water chert-shale lithologies on the carbonate-bearing lithologies. Within the North American Cordillera, the host rocks range in age from Late Proterozoic through the Triassic with the bulk of the gold mineralization hosted in Devonian age carbonates. Many of the deposits are spatially and possibly temporally associated with felsic intrusive rocks which intrude the high-angle feeder structures. They are also associated with larger older to coeval intrusive complexes with associated porphyry and skarn style mineralization. There is Carlin-type gold mineralization with no documented magmatic signature however.

The interaction of high-angle structures with favorable host stratigraphy controls the deposit-scale gold mineralization within regional-scale anticlinal structures. The regional alignment of these anticlinal carbonate-bearing “windows”, as observed in Nevada, produce linear trends of gold mineralization (Carlin and Battle Mountain-Eureka Trends) which suggest a crustal-scale, margin parallel structural control to the gold bearing hydrothermal systems.

Gold mineralization geometry is commonly tabular with both replacement and brecciation textures. Alteration consists of decarbonation with significant volume reduction and collapse brecciation, and silica replacement with associated hydrothermal brecciation. Minor high temperature clay mineral alteration is also present. Gold mineralization commonly consists of gold bearing, arsenic-rich pyrite overgrowths on pre-ore sulfides, and within and on ore-stage gangue minerals.

The current models suggested for Carlin-type gold formation include hydrothermal fluid/metal sources from deep crustal fluid related to mantle/lower crust metamorphic processes and distal magmatic fluid from porphyry/skarn magmatic systems. These gold systems are large, ranging up to 150 MT in size and have significant tonnages of high grade ore ranging between 5 and 10 g/t Au. Where the deposits are oxidized they are amendable to low-cost heap leach production, while the sulfide mineralization is commonly refractory.

7.2 Intrusion-Related Gold

Intrusion-related gold system (IRGS) deposits are epigenetic gold mineralization generated in a proximal magmatic-hydrothermal system. The system classification is relatively new and it differs in tectonic setting, magma chemistry, base-metal content, areal size of the alteration halo and a general association with W and/or Sn mineralization (Lang, et al., 2000).

The intrusions are metaluminous, subalkaline melts of intermediate to felsic composition that are commonly emplaced inboard of defined arc magmatism in a continental setting. Fluids are carbonate-rich with a metal assemblage of Au, Bi, W, As, Mo, Te and Sb with low base-metal values. Alteration is restricted in size and mineralization consists of sheeted to stockwork vein arrays with thin alteration selvages and low total sulfide content. Mineralization can be intrusion hosted or hosted in peripheral, usually hornfelsed sediments. In general, they are relatively low grade (1-2 g/t Au), large tonnage (5-25 Mt) deposits amenable to open-pit, heap-leach mining.

7.3 Mississippi Valley-type Base Metal-Silver

Mississippi Valley-type (MVT) Pb-Zn deposits are epigenetic, low temperature, stratabound deposits of galena, sphalerite and pyrite mineralization with associated dolomite, calcite, quartz, barite and fluorite gangue minerals. The deposits are commonly enriched in Ag and variable amounts of Cd and Ge. The deposits are mostly found in stable interior craton platform or marginal shelf tectonic setting and are also know in foreland thrust belt settings. This style of base-metal mineralization is documented at the Birkeland and Odd prospects located on the Einarson Project (Alldrick and Sangster, 1996).

The deposits are mainly formed in shallow water, carbonate lithologies but are also known in coarse-grained clastic and calcareous fine-grained clastic lithologies. Deposit geometries tend to be irregular and discontinuous with both stratigraphic and local structural control. Collapse breccias textures indicative of dissolution are common.

Sulfide minerals are commonly present filling intra-fragmental void space as massive, irregular intergrowths, or as layered sulfide rich bands. Sulfide mineral grain size varies from coarse- to very fine-grained and the mineral paragenetic sequences is commonly pyrite => sphalerite => galena. Dominant host alteration is coarse-grained dolomitization with “zebra” textures and lesser silicification and clay alteration related to dissolution and concentration of residual mineral phases.

These epigenetic base-metal deposits are formed by low temperature (75^{o} – 200^{o} C), saline hydrothermal fluid migration through sedimentary basins via compaction and/or gravitational flow. Mineral deposition is controlled by fluid mixing, cooling or interaction with additional sources of iron, sulfur or organic compounds. The MTV deposits are in general small (1-10

MT) with combined Pb-Zn grades between 5-10% and are Zn rich (Zn/Zn+Pb=0.8). Silver grades are variable, but can be as high as 30 g/t.

7.4 Epithermal - Low Sulfidation(?)

Quartz veins, stockworks and breccias with gold and silver mineralization and lesser base-metal mineralization. Mineralization commonly shows open-space filling textures and is related to volcanic to geothermal hydrothermal fluid flow. Volcanic island-arc, continental margin magmatic arcs and continental calc-alkaline to bi-modal volcanic fields are common tectonic settings.

Mineralization forms in high-level hydrothermal systems from depths of 1-2 kilometers to surficial hot springs settings. Fluid flow is related to regional-scale fractures systems in extensional grabens, resurgent caldera and flow dome complexes and rarely with maar diatremes settings. Known deposits are mostly Tertiary in age, although older occurrences are known. Mineralization is commonly localized in structures, but mineralization of permeable lithologies peripheral to the structures is common. Open-space vein filling, rhythmic layering and crustiform/colloform textures are common as is brecciation and evidence of multiple fluid pulses. Mineralization is commonly zoned with Au-Ag-As-Sb-Hg at higher levels and increased base-metal content at depth commonly with decreasing Au-Ag tenor (Panteleyev, 1996).

8.0 2013 Exploration Data

8.1 Silt Geochemistry

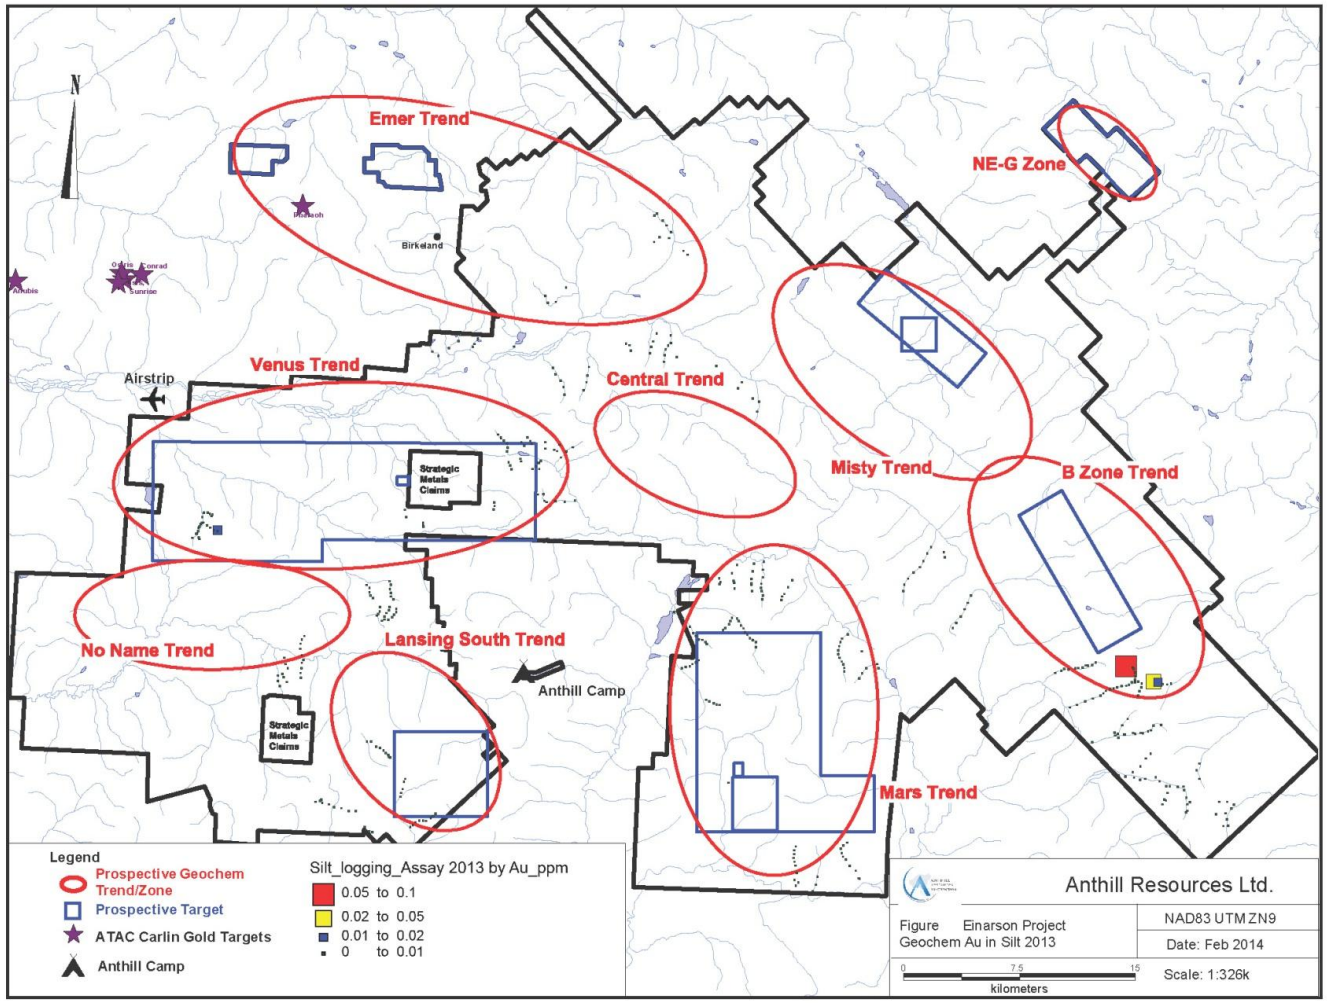
A total of 434 silt samples were collected by Anthill Resources technical staff during the 2013 exploration program (Figure 7). Evaluation and interpretation of the silt geochemical dataset was the primary evaluation tool used to locate and define drainage basins with anomalous gold and associated pathfinder trace elements for continuing prospecting and target definition. All 2013 silt samples were analyzed by AGAT Laboratories. Assay certificates for all silt samples are presented in Appendix A. Sample locations and descriptions are presented in Appendix B. A 100,000 scale map showing silt geochemistry is located in Appendix D.3.

Silt samples were taken during the 2013 field seasons along primary and secondary tributary streams covering drainage catchment basins across the entire project area (Figure 7). The stream sediment dataset represents the only property-wide geochemical database. Areas with low sample density have only single samples collected at main tributary drainages, while higher sample density areas had samples taken every 200-250 meters along the second order

streams. Fine grained silt materials were collected from several places at each sample locations in an attempt to get better sample representation. Stream sediment sample density across the entire Einarson Project averaged approximately 2 samples per square kilometers to a high to 4-5 samples per square kilometers in select areas.

Correlation coefficients were calculated for 12 select trace elements including As, Sb, Hg and Tl which are considered pathfinders elements associated with Carlin type gold systems. The Carlin-type pathfinder elements showed no strong correlative relationship with Au or with the other associated pathfinder elements (the correlation coefficient values are mostly less than 0.1). Elements showing positive correlation coefficient in the stream sediment data included both As-Cu and Ag-Fe-Hg-Te-Tl with values ranging from 0.46 to 0.82 and showing moderate to strong correlation.

Figure 7. Einarson Project Geochemical Au in Silt



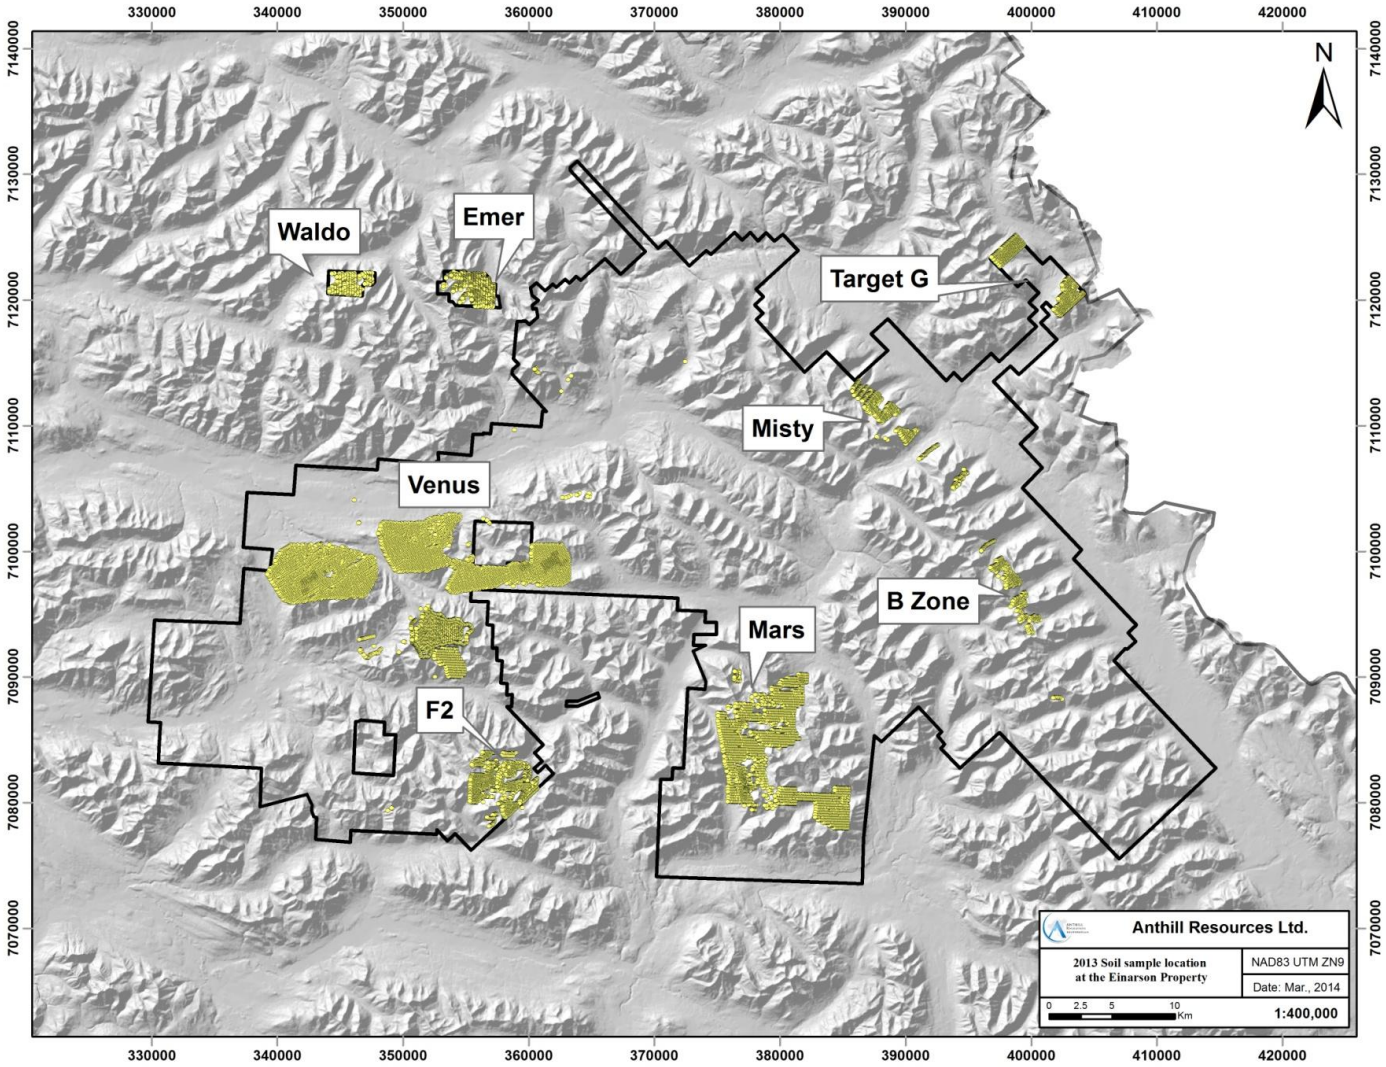
8.2 Soil Geochemistry

In 2013, Anthill Resources carried out soil geochemical surveys in select areas where Au in silt and Au in soil anomalies were identified in the previous year geochemical program. A total of 17,651 soil samples were collected from the various target areas during the 2013 exploration seasons. Assay certificates for all of the samples are presented in Appendix A. The sample locations and sample description are presented in Appendix B.2. The locations of all soil samples are also shown in map format in Appendix C by individual target area.

The 2013 soil sample grids were expanded in the Venus, Mars, F2, Misty and G Zone areas, and new grid soil sampling was initiated on newly identified targets in the B Zone, Waldo and Emer areas. A soil sampling grid of 100 meters by 100 meters was laid out to cover broader areas of the large Venus target. The 2013 soil geochemical surveys in Misty, B zone, F2 zone, Target G zone areas used 100 meter line spacing and 50 meter station spacing for sampling. Soil samples collected at the Waldo and Emer target areas used 200 meter line spacing and 50 meter soil sample station spacing.

Soil samples were analyzed by AGAT Laboratories using Aqua Regia digestion of a 1 gram sub-sample with ICP-MS finish method. Additional gold fire assays were obtained for any samples with gold values above the detection limit (> 5 ppb) of the Aqua Regia-ICP method. Approximately 80% of soil samples returned gold values below 5 ppb and this is considered to be the background gold geochemical value.

Figure 8. Soil Sample Location at the Einarson Property



Venus Zone

Approximately 10,000 soil samples have been collected from the Venus Trend in 2012 and 2013. The central part of the Venus anomaly is characterized by clusters of anomalous Au in soil samples with 45 samples returned values greater than 100 ppb Au. The extent of the anomalous area is 1 kilometer in length and 500 meters in width (Figure 9).

The best arsenic in soil anomaly in the Venus Trend is centered in the Venus Central zone with discrete spot anomalies identifiable in the west and northeast part of Venus as shown in Figure 10. The gold in soil signature is very weak in the Venus West area with several spot anomalies of arsenic in soil identified. These areas warrant additional prospecting, rock sampling and mapping as the geochemical signature could represent a leakage anomaly above deeper mineralization.

Review of the scatter analysis of gold and other key pathfinder elements indicates that gold in soil is mostly associated with arsenic, mercury and thallium, and to a lesser extent with zinc (Figure 11). This Au-As-Sb-Hg-Tl geochemical association is one of the distinct characteristics of Carlin style gold mineralization.

Mars Zone

A total of 4384 soil samples were collected from the Mars Trend with the maximum gold in soil value of 8970 ppb (8.97g/t). The soil surveys have defined three areas of anomalous of gold in soil within the Mars Trend; Mars Main, Mars North and Mars Northeast zones (Figure 12). The most prominent gold in soil anomaly is the Mars Main zone which extends for 3.5 km along the north-south trending Mars Fault zone. The anomaly is defined by six samples with values greater than 1000 ppb gold and an additional 24 samples with gold values above 100 ppb with a high of 8970 ppb gold. The Mars Northeast gold in soil anomaly consisted of 3 samples returning values above 100 ppb and eight samples contain more than 50 ppb with a maximum gold concentration of 1129 ppb. The Mars Northeast zone remains open to the north and possible to the east. The Mars North anomaly is defined by 8 soil samples with values greater than 50 ppb gold.

The arsenic values in the soil are also anomalous in all three Mars target areas with a high value of 250 ppm arsenic, and a total of 24 soil samples contain more than 250 ppb arsenic. The spatial distribution of arsenic and antimony in the soil anomalies corresponds well with the gold anomalies, but there are only weak geochemical signatures for mercury and thallium.

Figure 9. Au in Soil at Venus Zone

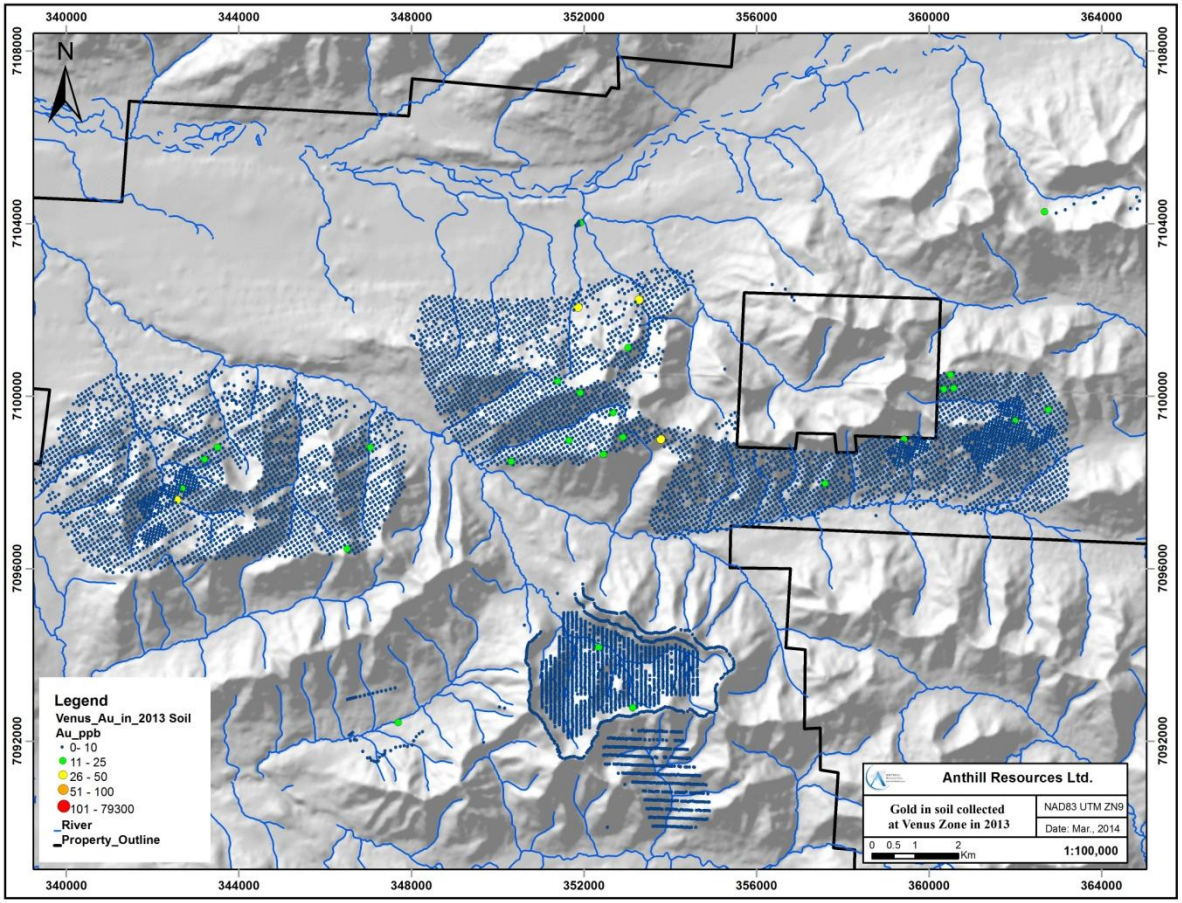


Figure 10. As in Soil at Venus Zone

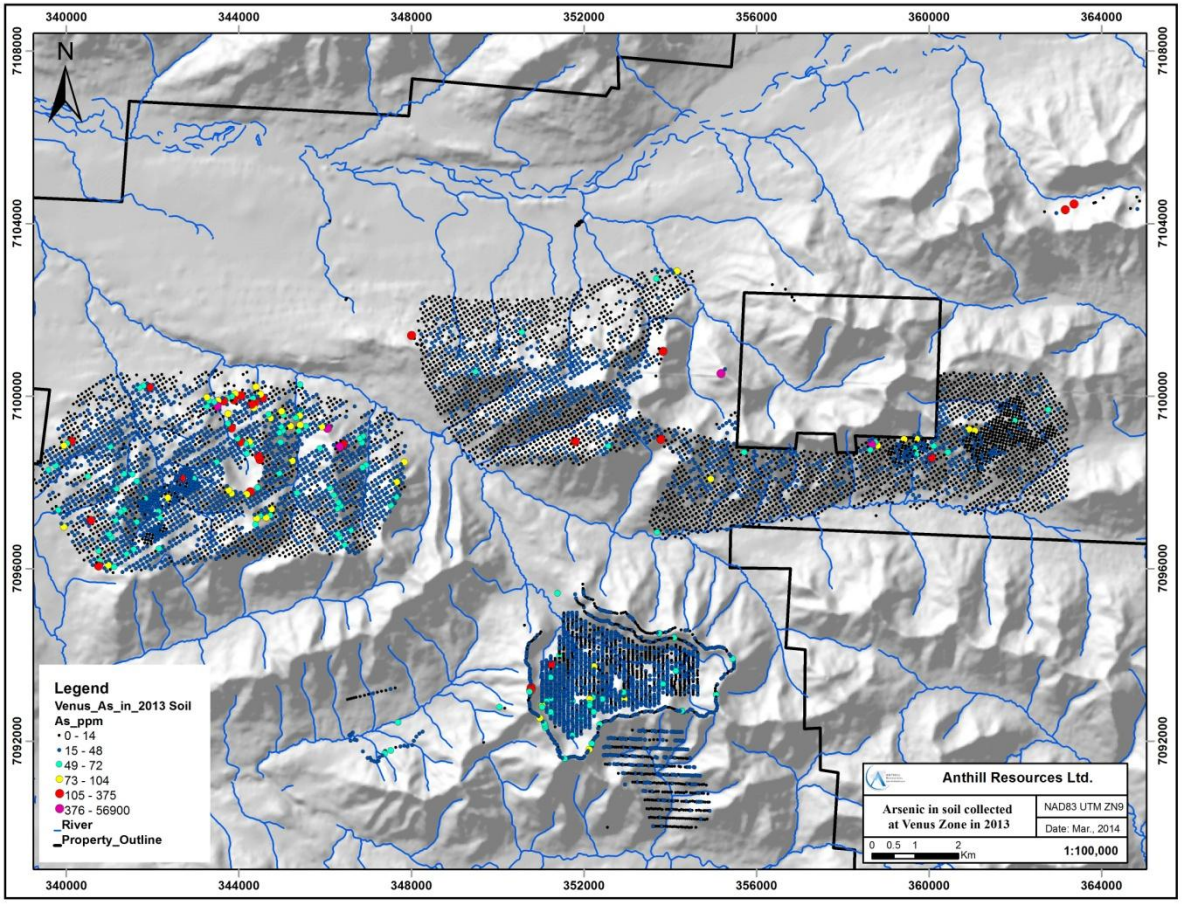

Figure 11. Scatter plots between Au and As, Sb, Hg and Zn Values in Soil - Venus Zone

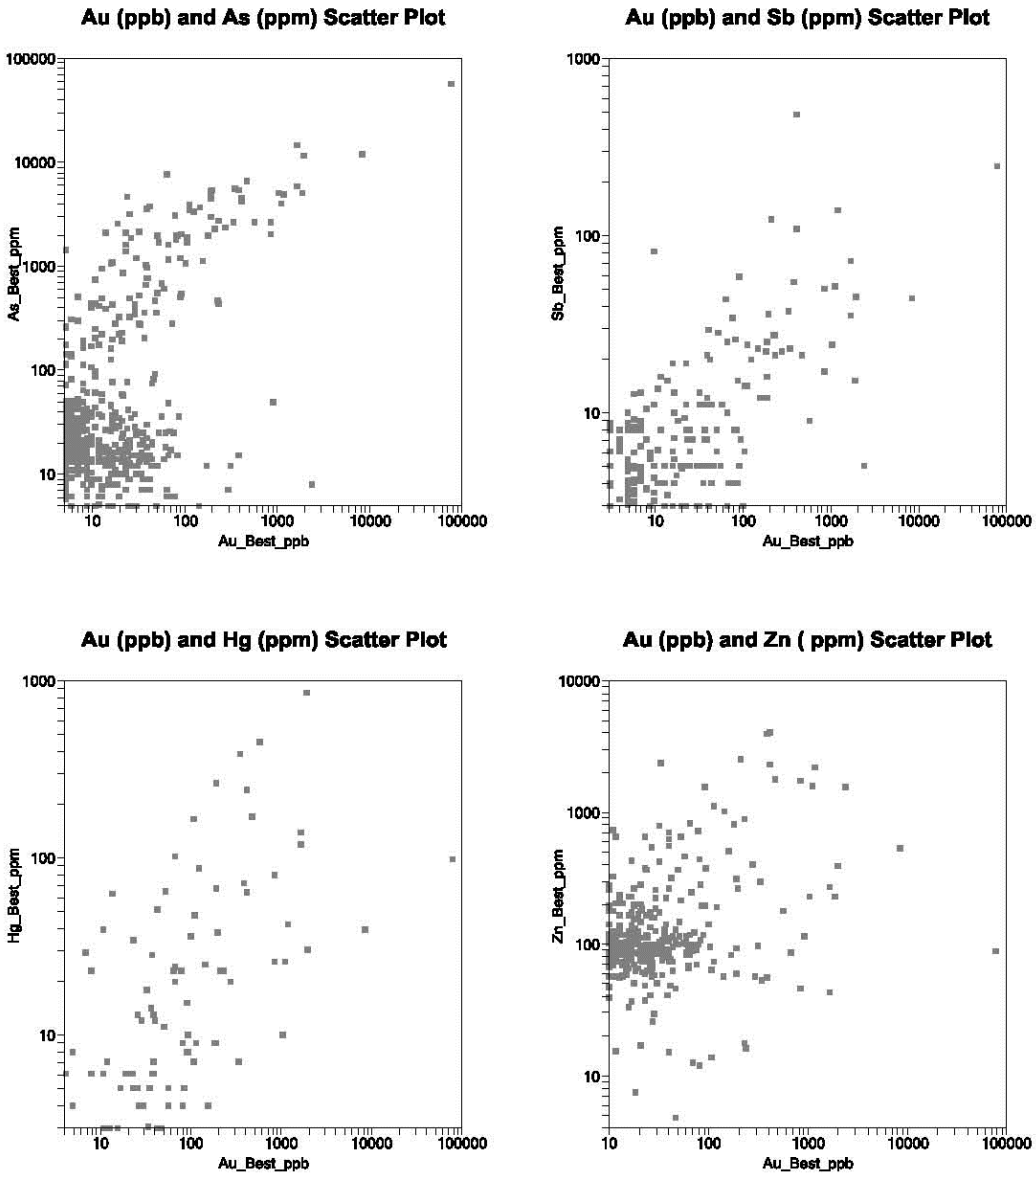

Figure 12. Au in soil at Mars Zone

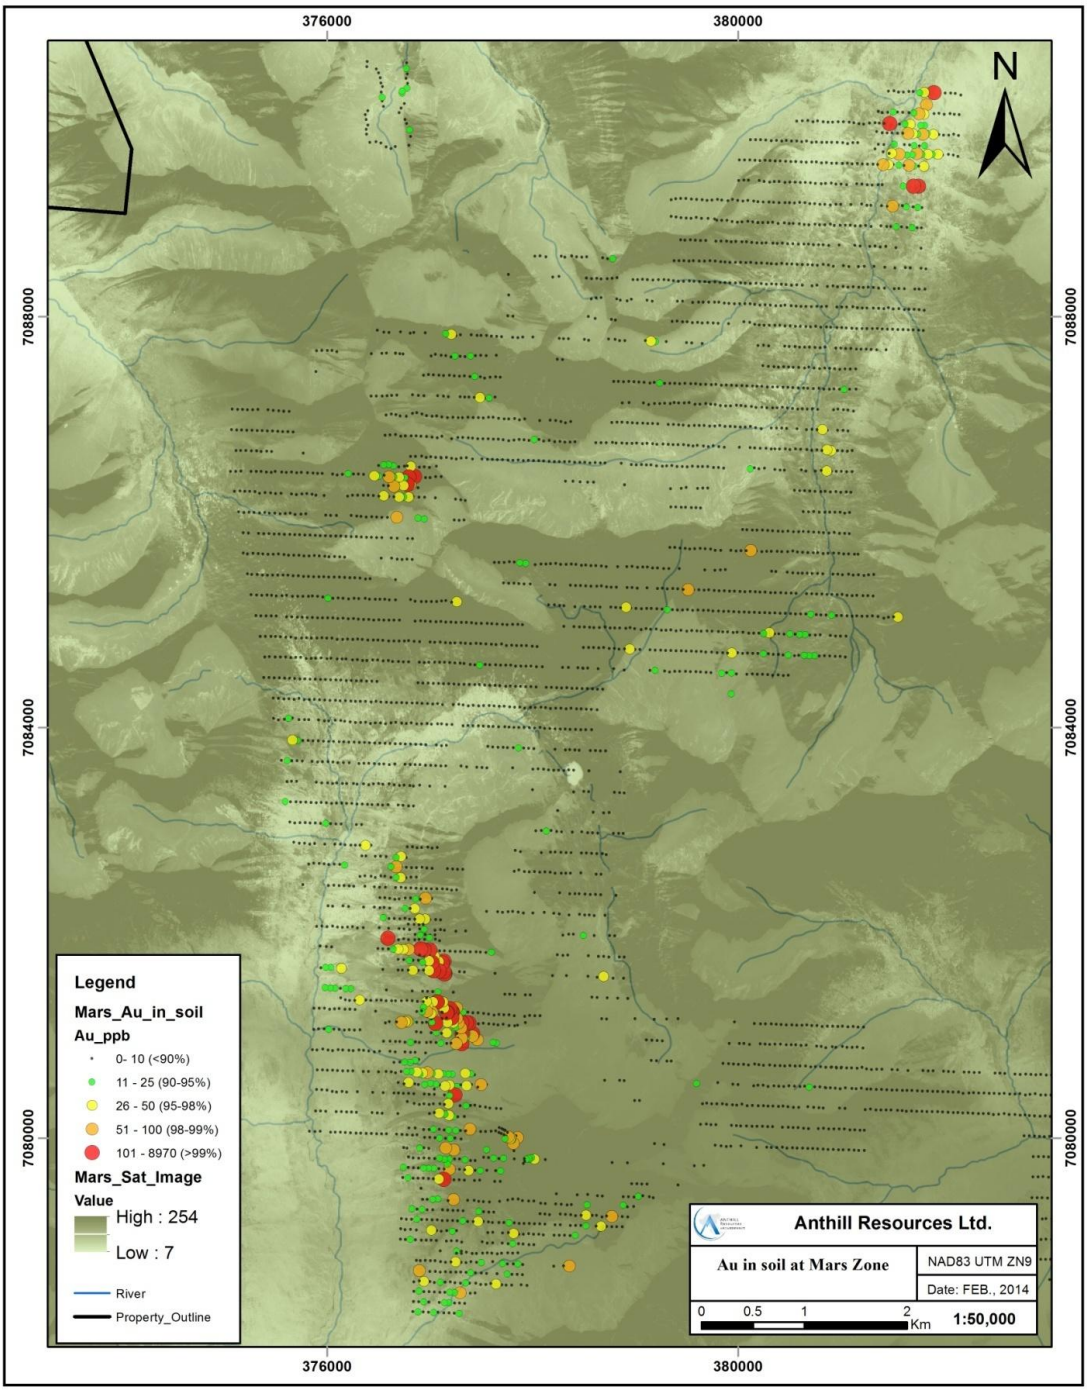

F2 Zone

In 2012 and 2013, over 2600 soil samples were collected from the F2 zone. The gold in soil assay results returned 36 soil samples having greater than 100 ppb gold with a high of 2150 ppb.

The gold in soil anomaly is situated in the south-central and central part of the F2 zone. The anomaly observed in the central of the F2 zone is located proximal to the north-south oriented creek (Figure 13). The other anomalous area in the south sits on top of the ridge and extends to the eastern and western flanks of the ridge. The Au in soil anomaly at F2 zone is spatially correlated with arsenic and antimony anomalies. However, the geochemical signature of gold, arsenic and antimony is in sharp contrast with the mercury and thallium signature in the area. The samples with elevated mercury and thallium do not coincide with the areas with high concentrations in gold and arsenic.

Misty Zone

Approximately 1000 soil samples were collected from the Misty zone located in the northeast portion of the Einarson property. A total of 36 samples returned Au in soil values greater than 100 ppb forming a distinct continuous northwest trend anomaly. The northwest trending Au in soil anomaly is 4.5 km in length and the central part of the anomaly widens to 1.3 km to northeast as shown in Figure 14.

The Au in soil anomaly area is also characterized by increased arsenic and antimony concentration in soil. The mercury and thallium in soil values in the Misty Zone are consistently low compared with other target zones in the Einarson property. The highest mercury in soil value at Misty zone is around 1 ppm and highest thallium is 7.22 ppm with majority ranging between 0-3 ppm.

The gold, arsenic and antimony in soil anomaly are localized in the core of a regionally extensive, upright anticline and have not been drill tested.

Figure 13. Au in Soil at F2 Zone

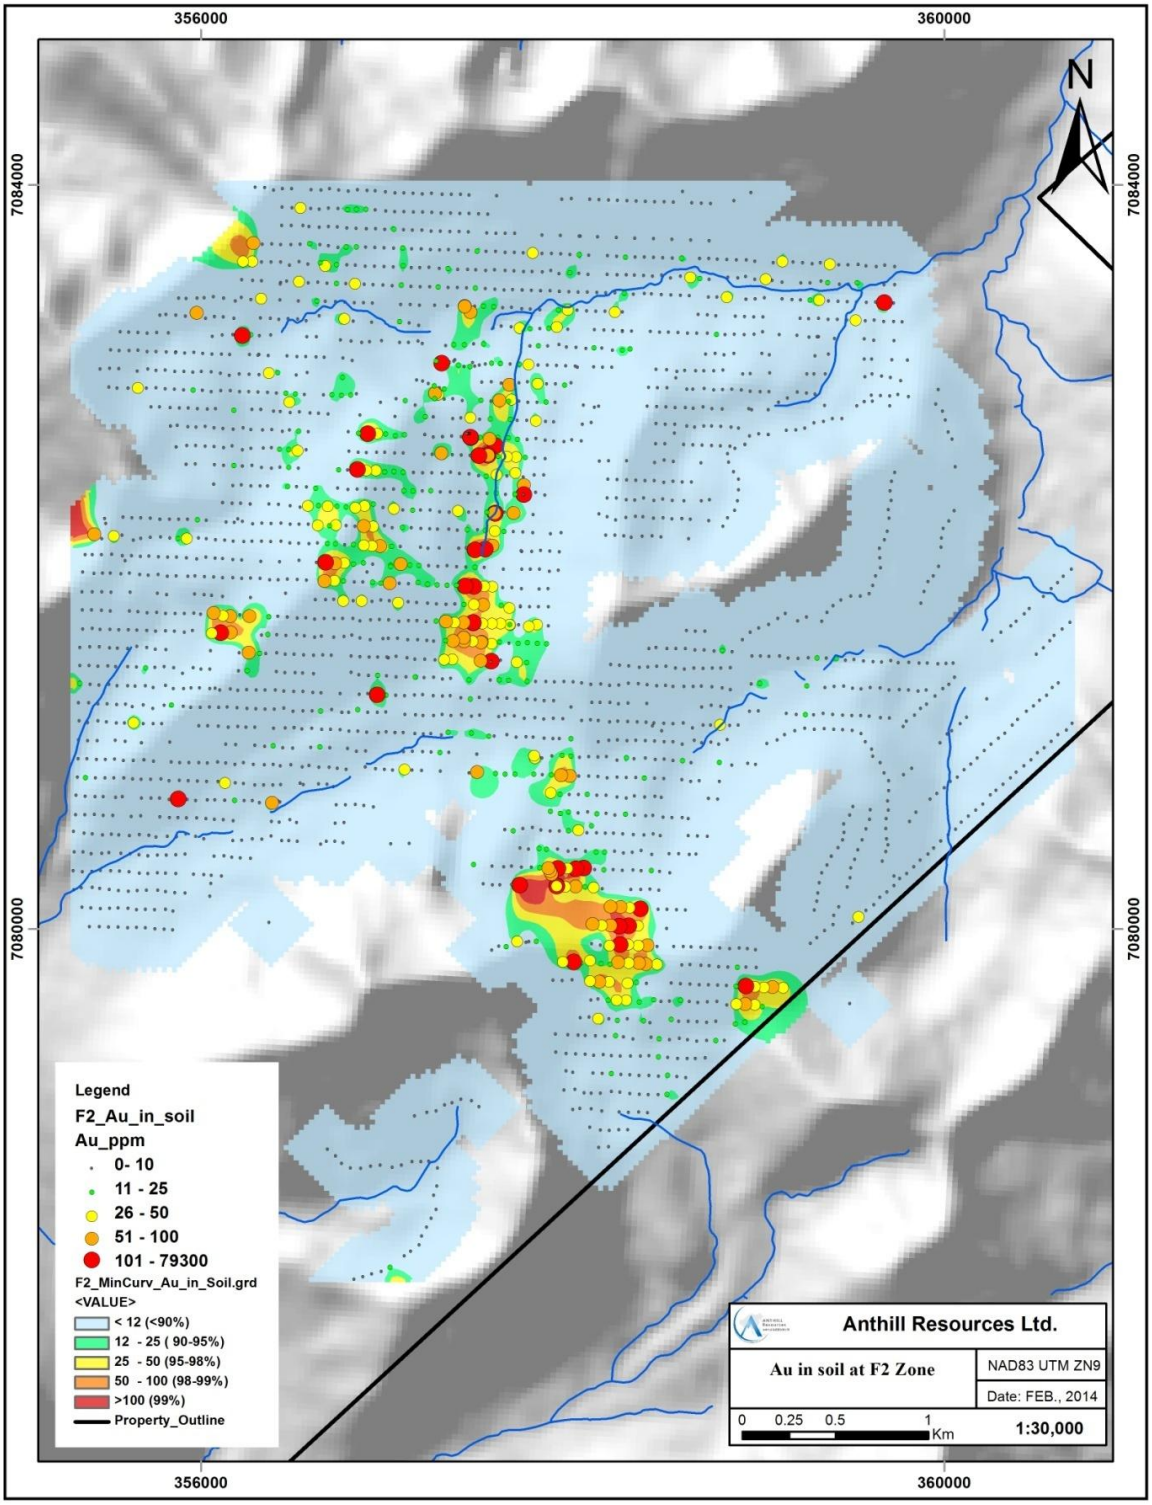

Figure 14. Au in soil at Misty Zone

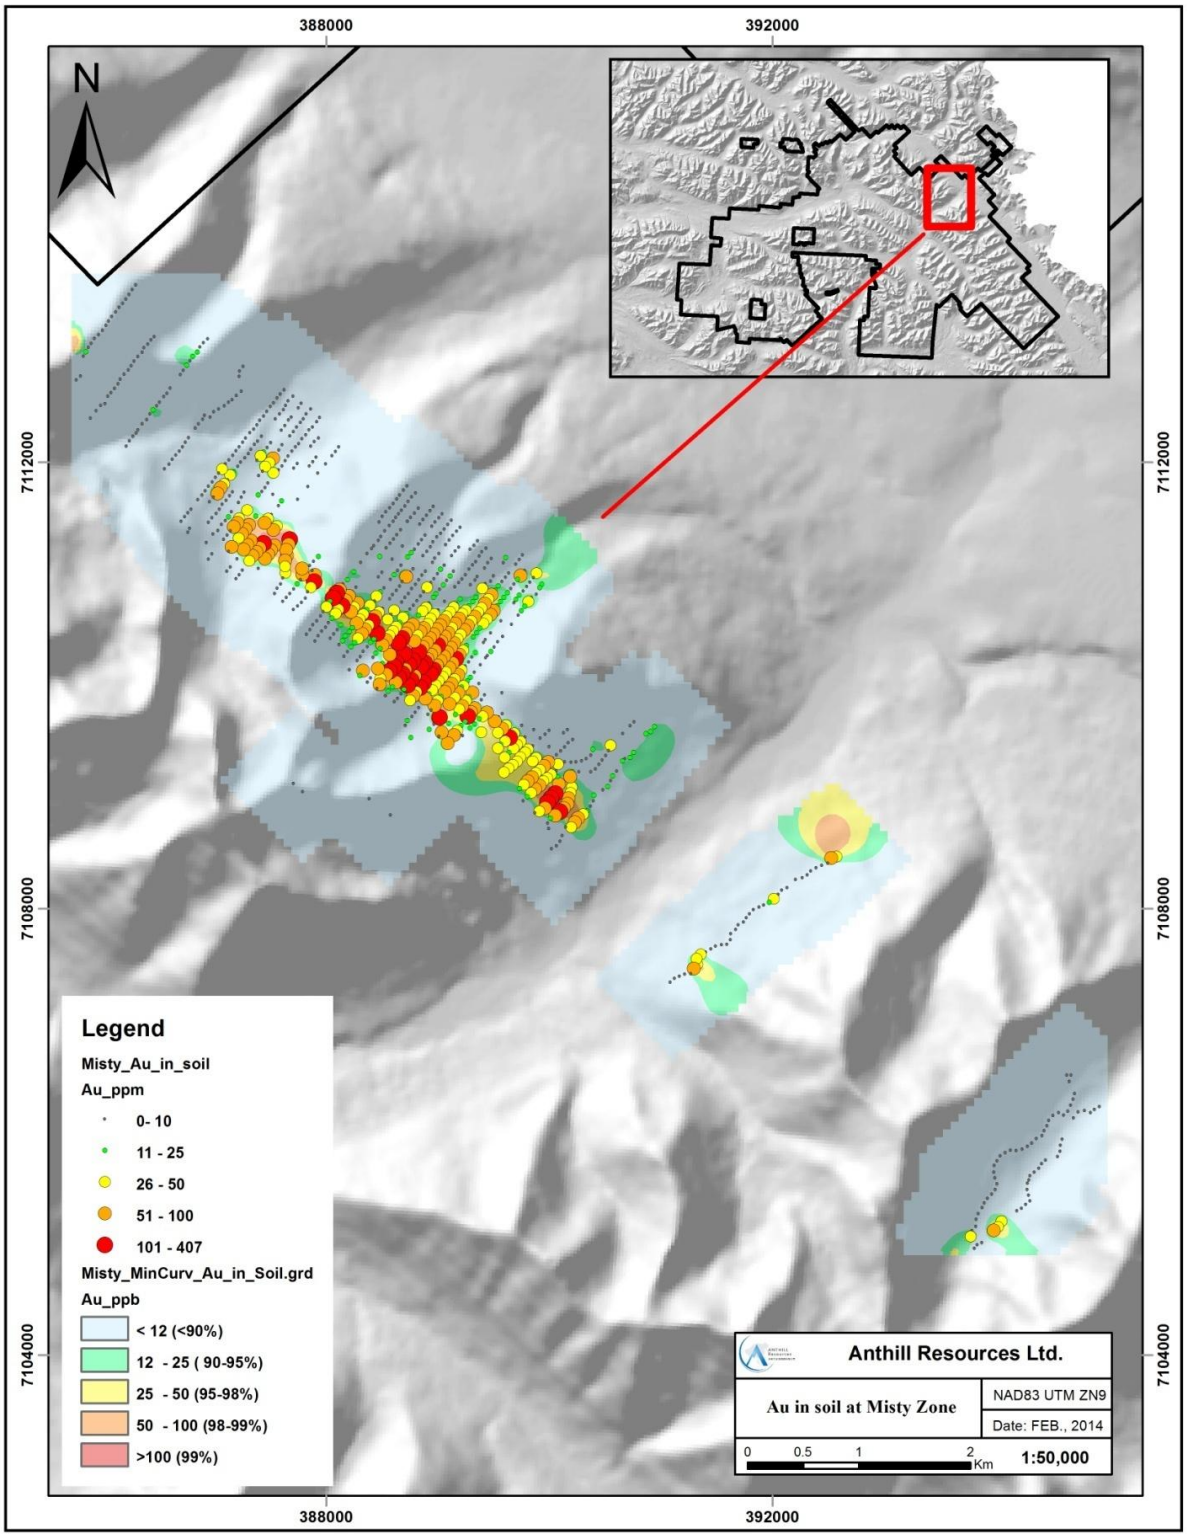

B Zone

Over 1700 soil samples were collected from the B zone target area with 33 samples returning values above 100 ppb gold in soil. The locations of the soil samples as well as the gold in soil anomalies at the B Zone are shown in Figure 15.

The soil sampling grid is oriented sub-parallel to the northwest trending fold axes. The gold in soil values defines four individual anomalies within the greater B Zone trend, which is 10 km in length. These anomalies are developed in a structural setting similar to Misty, but here the folding is more open in nature and axial plane cleavage within the fold hinge is not well developed.

The gold anomalies are spatially associated with arsenic and antimony in soil values. The strongest arsenic in soil values are located in the northwest and southeast areas of the greater B Zone target area. These As in soil anomalies cover 2 kilometer by 2 kilometer drainage basins which warrant additional prospecting and detailed sampling to understand the sources of these anomalies.

The locally elevated mercury and thallium in soil are only identified in the areas relatively low in gold, arsenic and antimony.

Waldo/Emer/G Target

Soil grid sampling was also carried out at Target G situated in the northeast corner of the property, as well as at the Waldo and Emer areas which are non-contiguous claim blocks located north of Atac Resources Rackla claim block. Over 4100 soil samples were collected from the three areas. The gold in soil values at Waldo, Emer and Target G are shown in Figure 16. A total of eight soils returned values greater than 100 ppb Au with the highest values of 930 ppb and 630 ppb identified in the northeastern and central areas of Target G. The gold values define broad areas with sporadic elevated values. The elevated Au in soil is spatial associated with increased arsenic concentration ranged between 100 ppm to 278 ppm in soil and show several zones with clusters of elevated values.

Strongly elevated mercury and thallium in soil is present at Target G with two areas of elevated Hg/Tl associated with Au-As-Sb in soil and a second Hg/Tl in soil anomaly developed in the southeastern area of the zone. The spatial distribution of these high Hg/Tl values suggests the data needs additional evaluation regarding sample collection/sample analysis to confirm the anomaly.

Figure 15. Au in Soil at B Zone

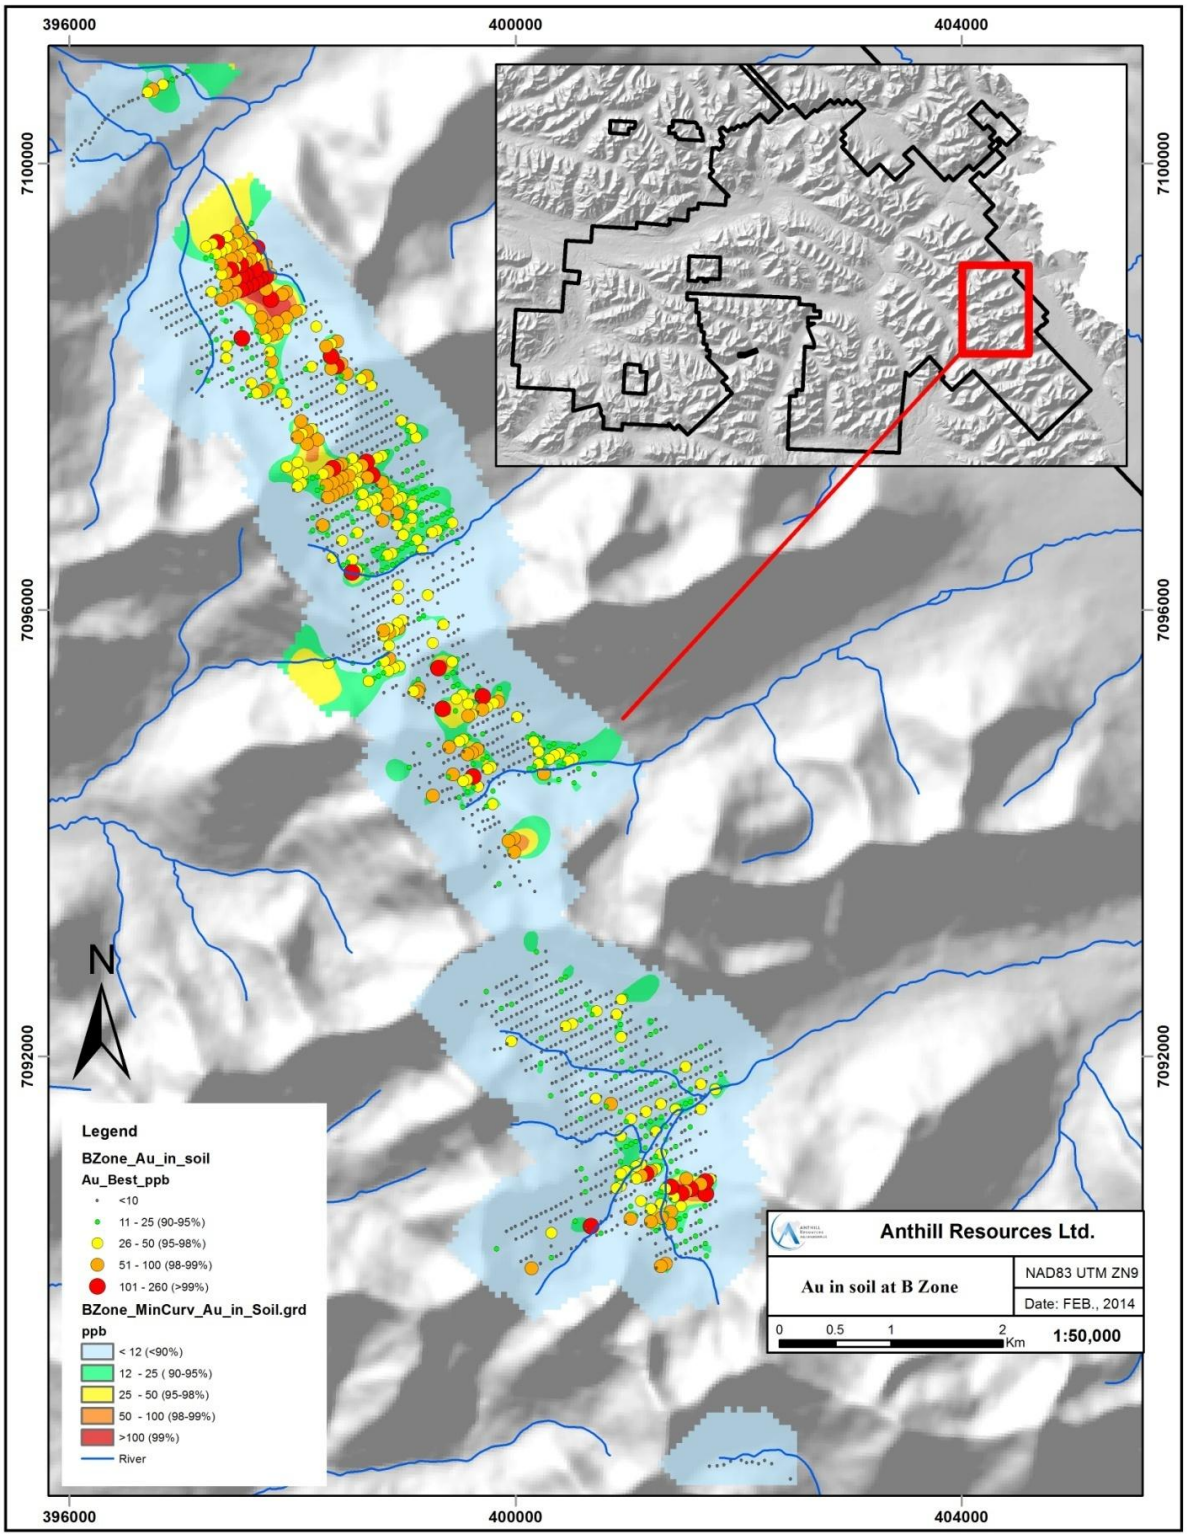

Figure 16. Au in soil at Waldo/Emer and Target G

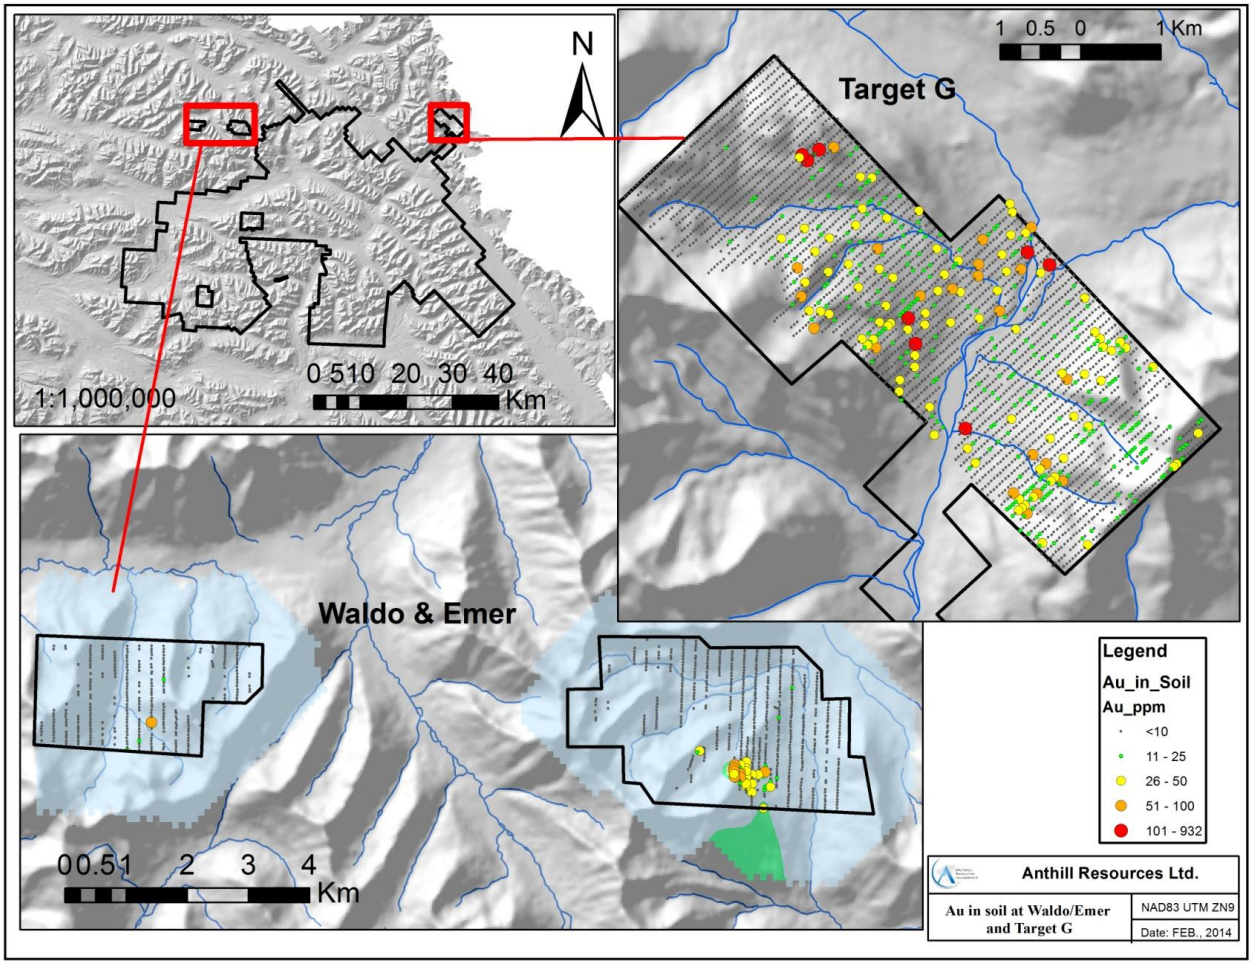


8.3 Rock Geochemistry

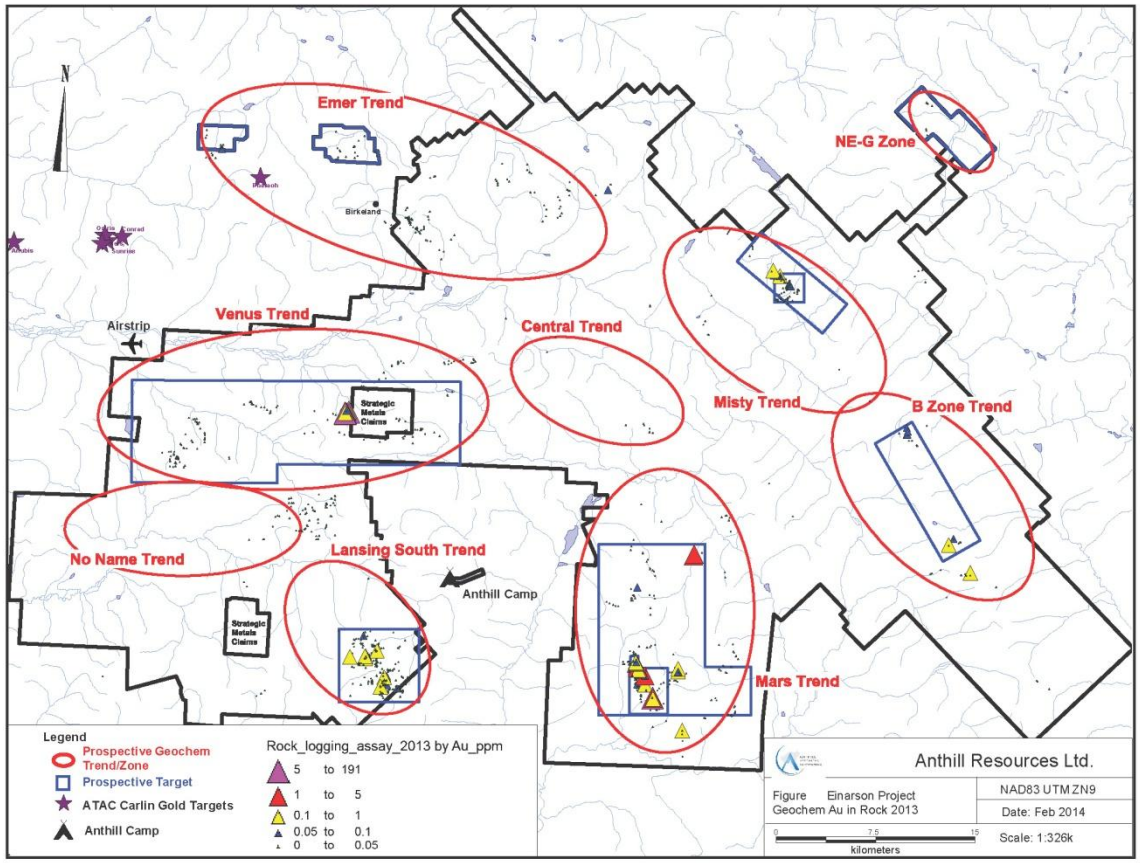
Rock samples were collected by Anthill Resources technical staff and geotechnical contractors during the 2013 exploration programs to prospect for significant gold mineralization. All rock chip sampling was focused within areas defined by anomalous gold and trace element geochemistry previously outlined by silt, soil and rock samples, and by lithologic and alteration mapping. Rock samples types included float, subcrop/talus, outcrop and channel samples. All rock samples were analyzed for gold plus 51 trace elements. A total of 2203 rock samples were collected in 2013. All of the 2013 rock samples were analyzed by Agat Laboratories in Mississauga, Ontario.

A total of 434 rock samples (~6.5%) returned Au values greater than 0.099 ppm and of these 92 samples assayed higher than 0.999 ppm Au. Correlation coefficients calculated from the entire dataset show only a weak correlation of gold with arsenic (0.26) and thallium (0.16), however correlation coefficients from high gold sample populations show significant As (0.59), Sb (0.16) and Tl (0.50) correlation. The data also define a sample population of samples with Zn, Pb, Ag and Hg geochemistry. Correlation coefficients from the +0.999 ppm Au samples show the same As, Sb, Tl association along with Pb.

Nine rock chips samples from the Venus area assayed greater than 9.25 g/t gold with a high of 191.00 g/t gold with arsenic values ranging between 1% and 10%. Three of these samples consisted of 3 meter, chip channels which assayed greater than 13.8 g/t gold. A 33.5 meter trench across the Mars Main structural zone assayed 1.65 g/t gold with a high value of 9.25 g/t gold across 2 meters. The hydrothermal systems, in both the Venus and Mars areas, locally deposited gold in sufficient grades and widths to be of economic interest.

Rock chip sampling in the Misty, F2, B Zone and Waldo/Emer target areas has not defined surface rock mineralization with consistent gold values greater than 1.0 g/t gold.

Figure 17. Einarson Project Geochemical - Au in Rock



8.4 Trenching

In 2013, hand trenching was completed at both the Venus and Mars zone target areas following up anomalous gold in soil and reconnaissance rock chip geochemistry. A total of four trenches were completed in the Mars area totaling approximately 45 meters. These trenches were completed in areas of steep topographic relief with thin soil cover along the Mars structural zone. A single trench was constructed and channel sampled in the Venus area in the vicinity of the orpiment/realgar surface showings. The geochemical analysis of rock chip channel sampling of the Mars zone trench is summarized in Table 2 and plan maps showing gold assays, geology and alteration/mineralization are shown in Figure 18.

Table 2. Mars Trench Channel Sample Assay

Channel Samples ID	NAD83 Zone 09		Elevation	Azimuth	From	To	Au	As	Sb	Hg	Tl	Ag	Pb	Zn

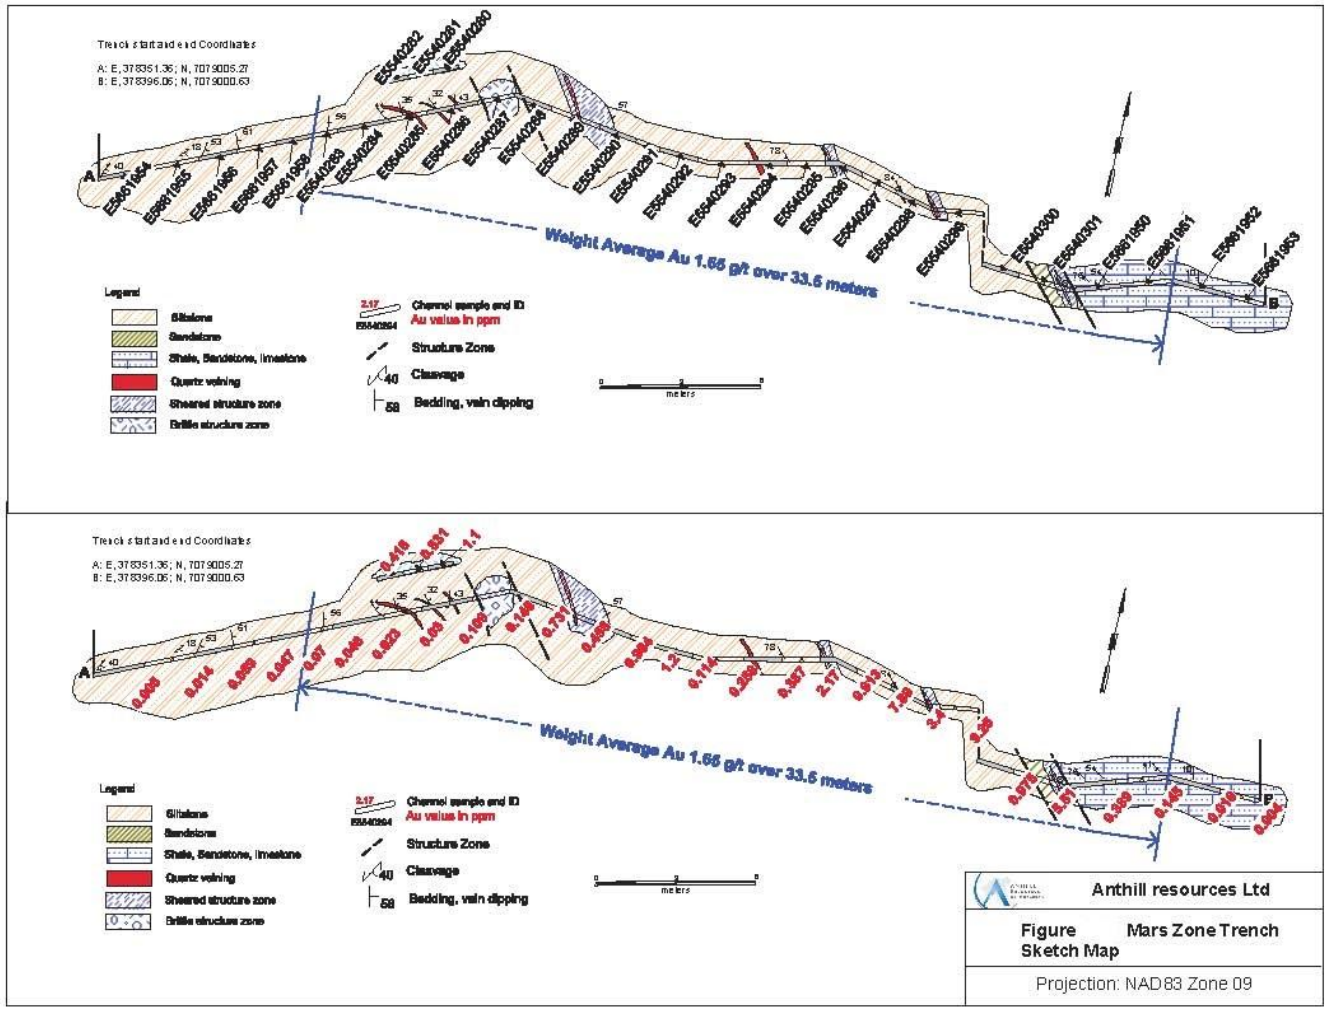
Figure 18. Mars Zone Trench Sketch Map



8.5 Geological Mapping

Regional scale geological mapping is available for the entire Einarson project area at a scale of 1:1,000,000. Cecile (2008) completed 50,000 scale geologic mapping in the F2 and portions of the Mars target areas. The mapping by Cecile (2008) covered the type stratigraphic section of the Algae Formation and defined two regional scale anticlinal fold/thrust structures within the Mars and F2 target areas. The Misty Lakes and 13 North anticlines host anomalous gold geochemistry in silts, soils and rocks in the F2, Mars and B Zone target areas.

Colpron, et al., (2012, 2013) completed an extensive 50,000 scale mapping project of five quadrangles (NTS 106C/1-4 and 106D/1) in the Rackla belt and the mapping covers the new Carlin-style gold mineralization discovered by ATAC Resources in 2010. This detailed mapping defines the shelf-slope transition along the northern boundary of the Selwyn Basin, and defines the lithologic and structural architecture of the Rackla gold belt. The mapping incorporates much of the geological mapping completed by ATAC Resources. These geologic maps cover the Waldo/Emer target areas.

Additional work by the Yukon Geological Survey in 2013 continued the Colpron, et al., (2013) mapping to the east onto the main Einarson Project claim block and covered portions of the Venus target area and the eastern portion of the Waldo/Emer target area (Moynihan, 2014b).

Anthill Resources' technical team continued mapping at 50,000 scales throughout the 2013 field season. 50,000 scale geologic mapping was completed for the Venus, Mars, F2, Misty, B Zone and Waldo/Emer target areas. The geologic mapping for each target area is presented in Appendix D.2 and in Appendix E.

Detailed geologic mapping has been completed at both the Venus and Mars target areas at a scale of 1:1000. The 1000 scale map areas cover hydrothermal alteration and surface gold mineralization that was drill tested in 2013 in the Venus target area. The 1000 scale mapping in the Mars target area focused on the northern section of the Mars structural zone that hosts a significant gold in soil anomaly.

9.0 Drilling

Drilling programs in 2013 have initially tested three target areas; Venus, Mars and F2 (Figure 6). A total of 21 core boreholes were completed during the 2013 field season totaling 4803 meters. The drilling was completed between June and September by Peak Drilling of Courtenay, British Columbia in 2013. Drilling in 2013 was completed using HQ steel recovering core seventy five millimeters in diameter. All drill rig and core was transported by helicopter on the project.

The 2013 drilling program was designed to expand gold mineralization encountered in the Venus and Mars areas in 2012, and to initially test a third target area defined by anomalous gold in soil geochemistry in the F2 area.

Borehole locations were planned and marked in the field by Anthill Resources geologists using hand held GPS units for locations and hand held compasses to orient borehole azimuth and inclination. All boreholes were drilled at angles between -80^{o} to -45^{o} from horizontal and multiple holes were typically collared from single drill pad. The deviation in borehole azimuth and inclination was determined using a Reflex EZ-Shot electronic single shot (magnetic) device.

Core was transferred from the various drill areas to the main camp at Anthill Lake by helicopter. The core boxes were checked for hole and box numbering, and drill meterage labeling at camp. Initial logging includes determination of core recovery, rock quality determination, magnetic susceptibility, HCl reaction and hardness. The core was then described by a geologist and sampling intervals were determined and marked. All descriptive information was captured digitally using Geospark Core software. The logging data was transferred to a local server daily and to Geospark Consulting, in Victoria, BC, weekly to be compiled in the Einarson Project master Geospark database.

The location and borehole orientation data is summarized in Table 3 and significant assay results are summarized in Table 4. The locations of boreholes for each area are shown in Appendix E and in Figures 19, 20 and 21.

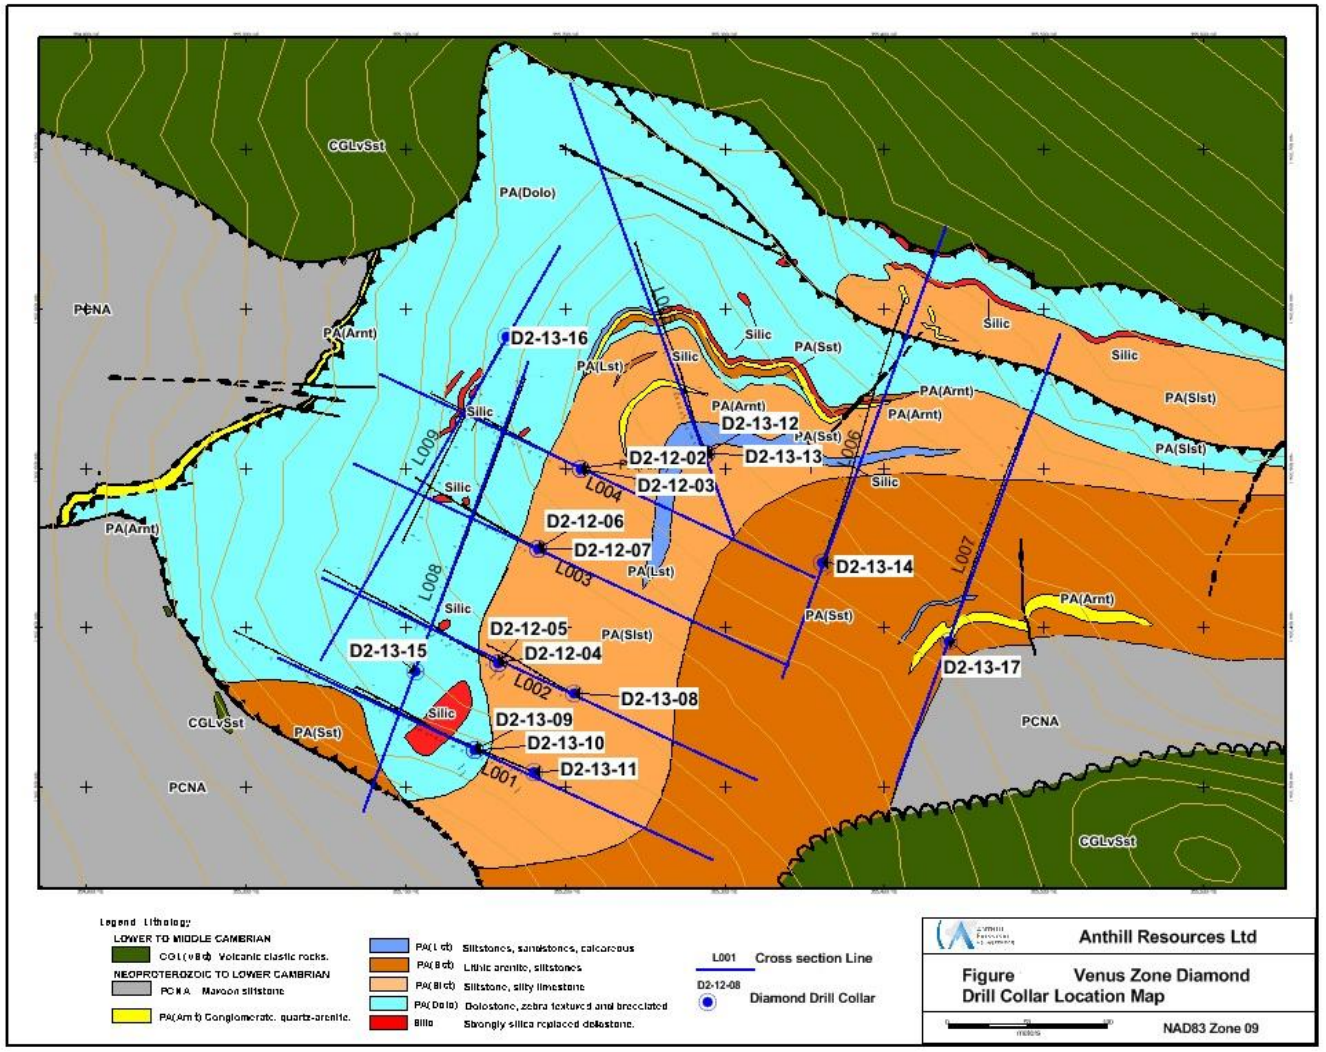
Figure 19. Venus Zone Diamond Drill Collar Location Map



9.1 Venus Zone 2013

Ten diamond core drill holes, totaling 2444.17 meters, tested the Venus target area in 2013. A summary of drill hole collar locations and drill orientations is shown in Table 3. The 2013 Venus drill program tested strike extensions of the 020 trending gold mineralized drill intercepts from the 2012 drill program (D2-12-04, D2-12-05), and also tested the hinge zone of the 340 trending Venus anticline and structural/stratigraphic target in the NE limb of the Venus anticline (Figure 19).

The "discovery zone" of the Venus target area is located along the westerly limb of the Venus anticline with surface gold mineralization localized along a steeply dipping, 020 trending fracture zone. Drill holes D2-13-08, -09 and -10 tested the down-dip extension of gold mineralization defined in 2012, and the southern strike extension of the mineralized zone. Drill hole D2-13-08 was lost due to bad ground conditions and was completed 70 meters short of the proposed depth. These drill holes encountered altered and mineralized host rock, however gold values were low with the best interval in D2-13-10 which assayed 0.974 g/t Au over 6.37 meters starting at a depth of 66.95 meters. The grade of gold mineralization in these drill holes was similar to 2012 drill results from drill holes D2-12-02, D2-12-06 and D2-12-07 which were located 100-150 meters northeast along strike. All of these drill holes intersected thick zones of strataform (?) orpiment-realgar mineralization below the upper gold intercepts.

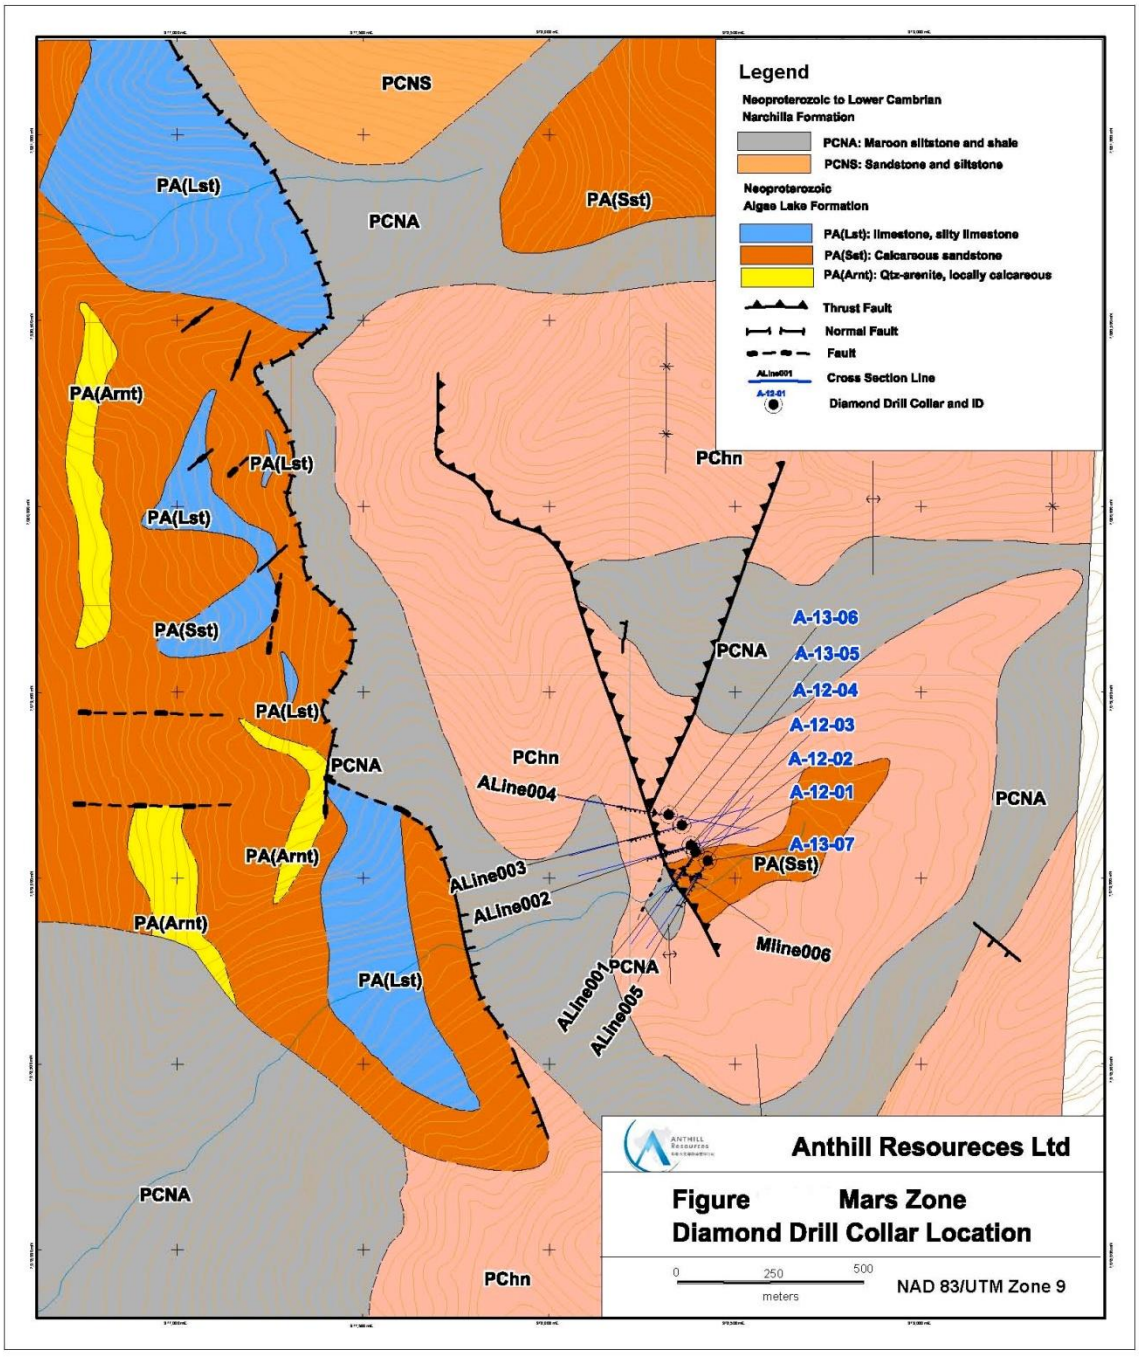
Drill holes D2-13-15 and D2-13-16 were drilled parallel to the 020 strike to the northeast (D2-13-15) and to the southwest (D2-13-16) to test for cross-structures that could have controlled the higher grade gold mineralization present in D2-12-03 and D2-12-05. Neither of the drill holes intersected significant gold mineralization, and both drill holes are interpreted to have drilled both the hanging wall and footwall margins of the 020 mineralized structure.

Drill holes D2-13-12, D2-13-13 tested the hinge zone of the Venus anticline beneath gold anomalous surface rock and soil geochemistry. Drill holes D2-13-14 and D2-13-17 tested low angle thrust faults and isoclinals fold hinges that also hosted anomalous surface rock and soil geochemistry. These drill hole encountered thin, low-grade gold mineralization along high-angle fractures zones and significant orpiment and realgar mineralization with 50-100 ppb gold values that appears to be stratiform in geometry. Significant mercury mineralization in the form of cinnabar was also present in the arsenic rich zones.

9.2 Mars 2013

Three drill holes were completed in the Mars zone in 2013 totaling 670 meters. Two of the drill holes tested the zone 50 and 100 meters north of the 2012 drilling, and one drill hole tested the zone 40 meters south of the 2012 drilling (Figure 20).

Figure 20. Mars Zone Diamond Drill Collar Location



Rock types, alteration and mineralization encountered in the 2013 drilling were similar to the 2012 drill results. Interbedded siltstone and sandstone lithologies with minor shale are cut by both high- and low-angle shear/fracture zones localizing vein and replacement silica alteration with arsenopyrite and pyrite mineralization. Drill intercepts include 0.18 g/t Au over 8.41 meters starting at 73.15 meters in A-13-05 and 0.693 g/t Au across 5.55 meters starting at 86.13 meters. Drill hole A-13-07, which was drilled to test encouraging trench results (Figure 18), returned six gold mineralized intercepts ranging in thickness from 1.25 to 10.69 meters with grades ranging from 1.280 to 0.267 g/t gold (Table 7). Drilling in the southernmost portion of the Mars zone has encountered plus one gram gold mineralization from individual samples however the continuity of the gold mineralization is sporadic to date. Two drill holes, A-12-01 and A-13-07, have both tested the down-dip projection of the structural zone defined in the Mars discovery trench. Neither drill hole encounter gold grades or mineralization continuity observed in the surface trench. Additional geological work to define targets (both structural and lithologic) which could host more consistent mineralization with higher gold grades is needed.

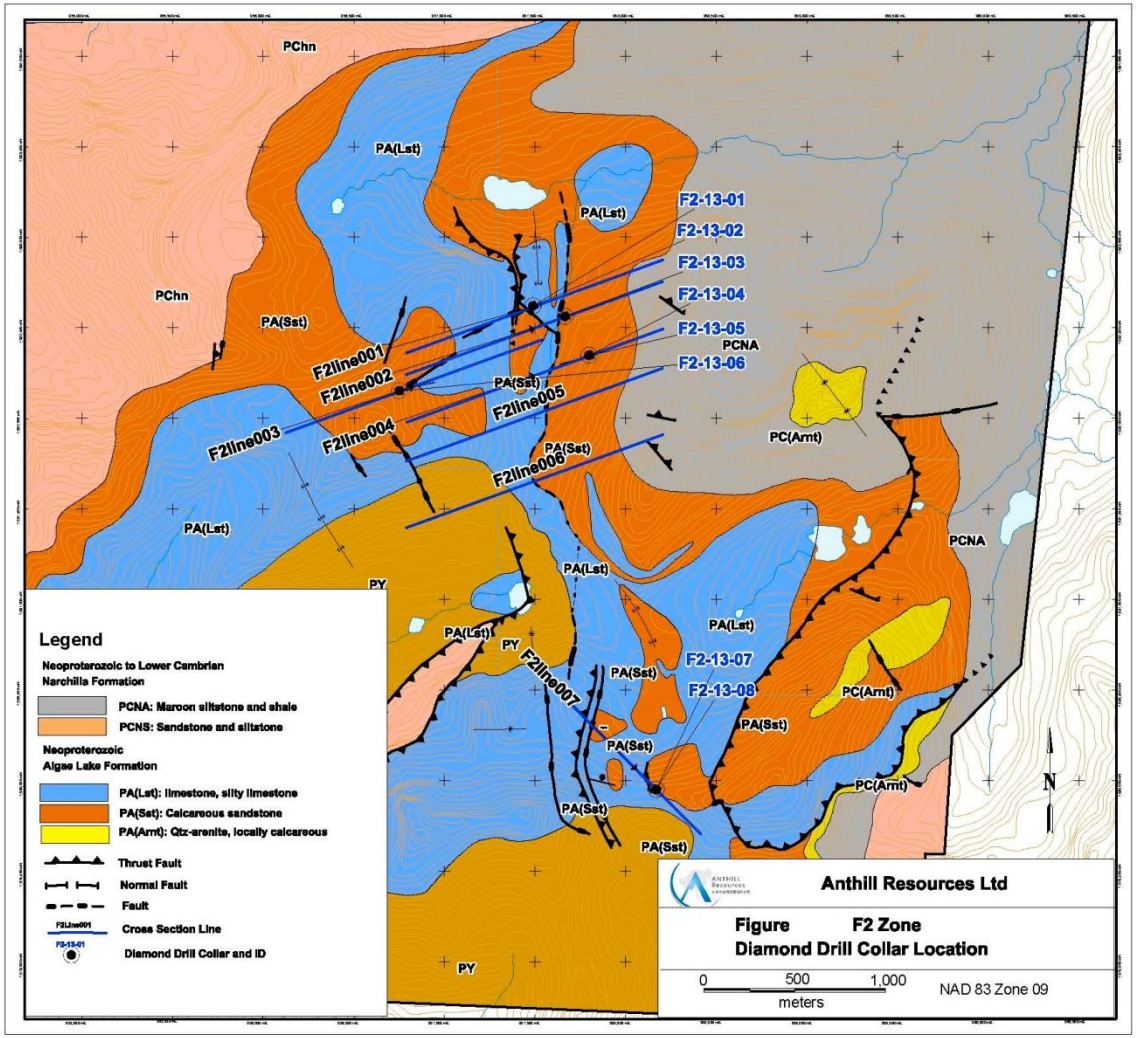
9.3 F2 Zone 2013

Eight drill holes totaling 1,688 meters were drilled to test the F2 target in 2013 (Table 3). A five hole fence from three drill pads tested a 400 meter wide, northerly trending gold in soil anomaly at the Main zone (Figure 21). A single drill hole, one kilometer to the southwest, tested an arsenic/weak gold in soil anomaly at the Ridge zone with a similar northerly trend. Two drill holes from single pad tested a northerly trending gold/arsenic in soil anomaly at the Border zone located 2.5 kilometers south of the Main and Ridge zones.

The Main zone drill holes were oriented at $250^{o}/-50^{o}$ and $/-70^{o}$ to intersect an inferred northerly trending fault zone. The Ridge zone drill hole was oriented $80^{o}/-50^{o}$ and the Border zone drill holes were oriented at $310^{o}/-50^{o}$ and $310^{o}/-75^{o}$ to test across northerly trending fault zones. The drill program was designed to test northerly trending, high-angle structural zones associated with anomalous gold, arsenic and thallium geochemistry in carbonate and calcareous clastic host rocks of the Algae Formation.

Four of the drill holes intersected, sporadic weakly anomalous gold and arsenic geochemistry with a high of 238 ppb gold and 9600 ppm arsenic. Observed alteration included patchy dolomite and replacement silicification with trace amounts of pyrite and arsenopyrite mineralization in the drill core (Table 4). Additional geological work is needed to better understand the nature of the surface soil geochemical anomalies.

Figure 21. F2 Zone Diamond Drill Collar Location



10.0 Sampling Preparation, Analysis and Security

10.1 Historical Sampling

Only minor historic geochemical sampling has taken place on the Einarson property and Anthill Resources does not include any pre-2011 geochemical results in their database.

10.2 Sampling by Anthill Resources

Sampling of geological materials (silt, soil, rock and core samples), completed by Anthill Resources and Anthill Resources contractors, during the 2013 exploration program was performed by trained technicians under the supervision of appropriately qualified consulting geologists and company geologists.

10.2.1 Silt Sampling

The purpose of the silt sampling program was to define the gold and trace element geochemical signature of primary, secondary and tertiary drainage basins in the Einarson Project area. The silt geochemical data allows for initial evaluation of relative mineral potential over a large area with little historic prospecting or exploration data.

The 2013 silt sampling program was carried out by Anthill Resources personnel to better define gold and arsenic anomalous silt samples from the 2011 and 2012 exploration programs and to infill areas with no previous silt sampling. Silt samples were taken from several locations at a particular site focusing on fine grained sediment within the active stream drainage. Sample locations, in UTM NAD-83 format, were recorded in the field using a non-differential handheld GPS. Samples were described as to percent fines, color, stream grade and width, date, sampler and comments. Samples were placed in Kraft paper bags with a sample tag showing a unique sample number, and the bags were labeled and marked in the field. The QA/QC samples were inserted into the sample stream.

Samples were submitted to AGAT Laboratories in Whitehorse, Yukon and Mississauga, Ontario for 30 g FA/ICP gold plus 51 elements geochemical analysis. Sample location data, field description data and geochemical analytical data were uploaded into Anthill Resources Geospark database.

10.2.2 Soil Sampling

The 2013 soil sampling program was performed by All-In Exploration Solutions of Whitehorse, Yukon, and by Anthill Resources technical staff. Soil samples were collected from pre-determined grid locations along easterly and northeasterly trending lines with 100 and 200 meter line spacing, and 50 meter sample spacing. At the Venus target area sample spacing was 100 meters.

Samples were collected using a hand auger or a hand pick with samples taken at various depths depending on the soil profile. Soil profiles are quite variable depending on area, slope aspect, slope steepness, vegetation types and permafrost. Maximum sampling depths were limited to 125 centimeters (auger length), and all samples were collected as close as possible to the weathered bedrock surface. All A horizon organic material was discarded and the sample materials ranged from B horizon to C horizon (talus fines) based on location and commonly represented 50-70 centimeter intervals. Sample number, handheld GPS location co-ordinates, depth and several geologic/geomorphologic parameters were collected on data sheets- and later transferred to digital spreadsheets. All sample locations were marked with flagging in the field and a portion were also marked with aluminum tags.

Samples were submitted to AGAT Laboratories in Whitehorse, Yukon and Mississauga, Ontario for 30 g FA/ICP gold plus 51 elements geochemical analysis. Sample location data, field description data and geochemical analytical data were uploaded into Anthill Resources Geospark database.

Field duplicate, assay standard and assay blank samples were inserted to the sample stream as part of the 2013 QA/QC program.

10.2.3 Drill Core Sampling

In 2012, Anthill Resources completed the first drilling program on the Einarson Project. This program tested anomalous gold geochemistry in soils and rock samples with associated hydrothermal alteration in both the Venus and Mars target areas. The 2013 drill program tested the strike and depth potential of significant 2012 drill intercepts from the Venus and Mars target areas, and tested anomalous gold and arsenic geochemistry in soils from the F2 target area.

The approach was to target structural/geochemical trends with fences of one or more core drill holes oriented perpendicular to the strike of the inferred trend. Many of the fences have two drill holes that intersect the target zone at depths of 50 to 150 meters below the ground surface. A two drill hole fence provides multiple geological and geochemical profiles which allows for a better interpretation of structural and stratigraphic feature orientations, and the continuity of hydrothermal alteration and gold mineralization.

Drill core was transported daily by helicopter from the drill sites to the logging facility at Anthill Resources main camp. All drill core was initially logged for alteration and mineralization when it arrived in camp and initial summary drill hole information was entered into the logging database. All core box numbering and footage measurements were checked for accuracy and readability, and down hole depths were converted to meters. Core recovery and rock quality determinations were measured and recorded, and the core was oriented (Reflex ACT III tool) when possible by both geotechnicians and geologists. The core was logged by a geologist for lithology, structure, oriented structure, alteration and mineralogy directly into a "Geospark" database using a laptop computer. All geotechnical and geological data was downloaded daily to the camp server and transferred weekly to the Vancouver office to be incorporated in the master "Geospark" database.

Assay sample intervals were selected by the geologist based on geological parameters with a nominal 1.5-2.0 meter sample interval. Sample interval lengths vary based on geological parameters. Sequential drill sample identification numbers with matching barcodes, supplied by AGAT Laboratories, were used for the 2013 drill programs. Sample intervals were labeled on the core boxes with the matching paper barcode tag and an aluminum sample tag being stapled to the core box. All core boxes were then "dry" photographed and then readied for sampling. Sample assay number and sample interval data was also entered to the "Geospark" database using a laptop computer with daily downloads to the camp server and weekly downloads to the corporate database in Vancouver. All original sample tag books are stored in the Vancouver corporate office. The quality assurance/quality control program included the insertion of assay standards, assay blanks, ¼ core duplicate samples and pulp duplicate samples into the sample stream.

Core assay samples consisted of half-core sawed length-wise with a diamond saw. Cut lines were drawn on the core by the logging geologist defining the half-core to be sampled. The drill core samples were collected in labeled poly bags with a matching, internal paper barcode sample tag, and the sample bag was secured using plastic zip tie fasteners. The remaining half- core was replaced in the core boxes and the core boxes were photography "wet". All 2012 and 2013 drill core is stored onsite at the Anthill base camp (Figure 6).

All drill core samples from 2013 were analyzed by AGAT Laboratories with sample preparation facilities in Whitehorse, Yukon and analytical facilities in Mississauga, Ontario. All drill core samples were transported from the field by fixed wing airplane to the Black Sheep Aviation headquarters in Mayo, YT. Drill core samples were transported to the AGAT Whitehorse sample preparation facility by contract courier or by employees of Anthill Resources. Umpire check analyzes were performed by ALS Chemex Labs and Acme Labs with facilities in Whitehorse, YT and Vancouver, BC.

10.3 Quality Assurance and Quality Control Programs

10.3.1 QAQC program for the surface geochemistry samples

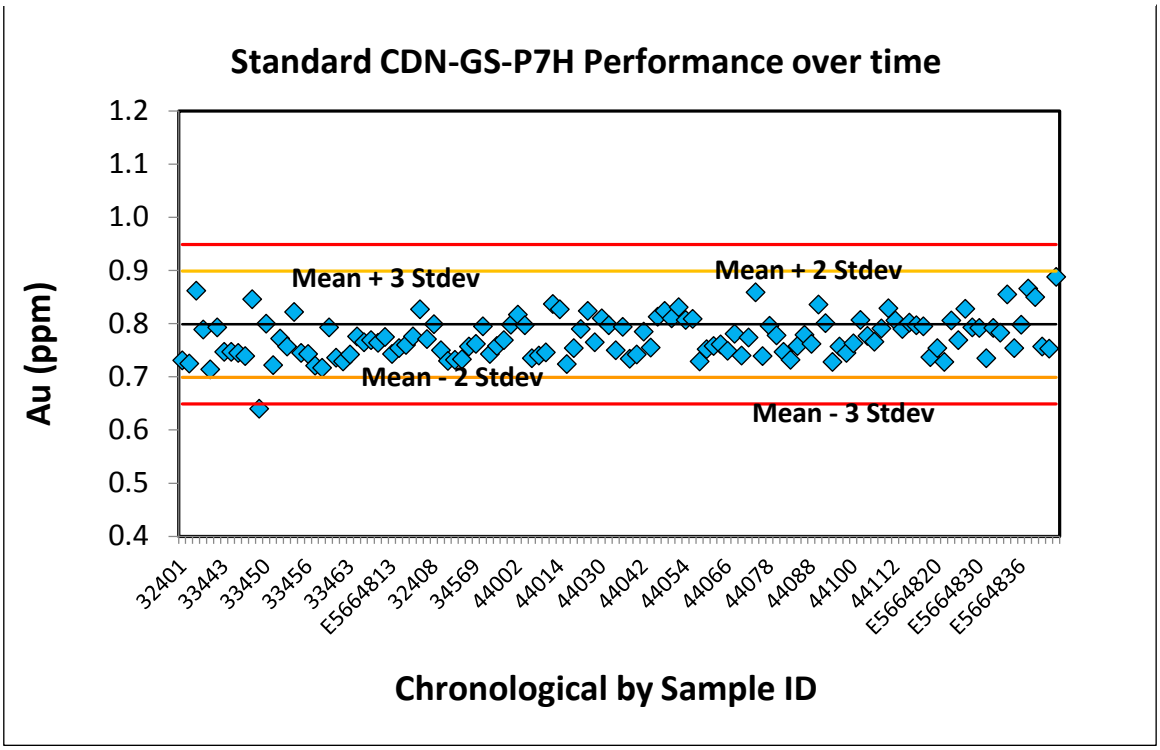
Approximately 240 standards and 165 blanks of known gold concentration value were inserted into the sample stream during the 2012-2013 geochemical sampling programs (silt, soil and rock). The standards were inserted for every sample dispatch to ensure at least one type of QC sample was included for every lab work order to monitor the quality of lab assay results.

Assay standards with three different gold concentration values were inserted into the sample stream of the surface geochemical samples collected in the 2012-2013 field seasons.

A review of the assay results from all of the QC samples indicates all of the standard samples returned results that are within the statistically acceptable value range. The mean value is close to the expected statistical mean and deviation from the mean is less than 2 standard deviations. A graphical representation of the assay performance of over time for one of the standards is presented in Figure 22.

The gold assay results from 126 samples of standard CDN-GS-P7H along with the expected mean, +/- 2 standard deviation lines, +/- 3 standard deviation lines are shown in Figure 22. All of the sample population returned gold results within the acceptable mean +/- 2 standard deviations with one sample result deviating 3 standard deviation from the expected statistical mean. Based on statistical review of the standard performance in light of the industry acceptable QA/QC standard, authors believe the standard CDN-GS-P7H passes the QC test and the data is acceptable.

Figure 22. QC sample CDN-GS-P2A analysis - silt, soil, and rock samples



10.3.2 QA/QC program for the drill core samples

The quality assurance and quality control (QA/QC) program implemented for the 2012 and 2013 drilling campaigns consisted of inserting certified reference materials (standards), blanks and duplicates in the drill core sample stream. Another part of QA/QC program, implemented by the company, was to use umpire assay laboratories to check the primary AGAT Laboratories results. A number of coarse rejects, pulps and quarter core samples were submitted to the ACME Laboratories and ALS Chemex Laboratories, both based in Vancouver, BC, for secondary check assays.

During the 2012 drilling program, QC samples included one duplicate after every 37th core samples, followed by one standard and one blank to ensure each type of QC for every 40 samples. Two certified reference materials from the CDN Laboratories were used as standards, CDN-GS-P2A and CDN-GS-2L.

During the 2013 drill program, the frequency of QC sample insertion was increased to one QC samples after every 10 core samples following the sequence of blank, duplicate and standard. Specifically, sample numbers ending in 11 (XXXX11) were reserved for blanks, sample numbers ending in 22 (XXXX22) were reserved for a duplicates of the previous samples, and sample ID ending in 33 (XXXX33) were for insertion of standards. The certified reference materials used in 2013 are listed below.

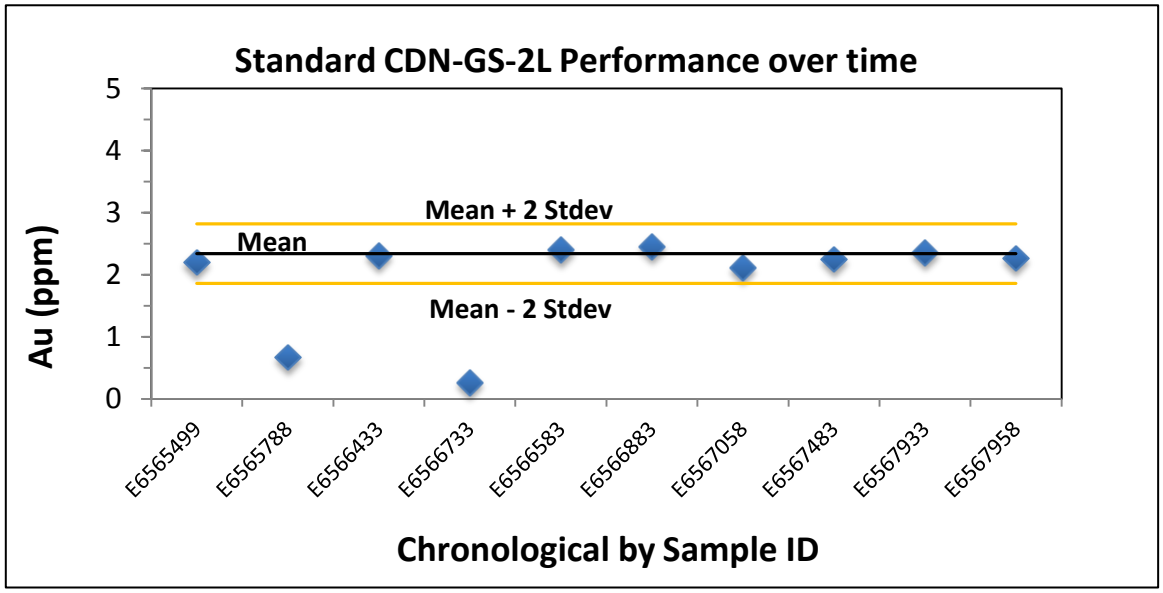
Blank materials used in 2012 and 2013 were taken from barren dolomitic sand and limestone purchased from a commercial store in order to check the sample contamination by improper cleaning of the analytical equipment by the lab.

Standards

The analytical performance of a select standard is displayed in Figure 23. The graphs show the expected Au concentration mean, +/- 2 standard deviation lines of the Au values for CDN-GS-2L.

Out of ten standard CDN-GS-2L inserted, eight control samples returned Au values very close to the expected concentration mean with little deviation in results. One outlier from the two failed standard appears to be a mis-labeled blank material.

Figure 23. QC sample CDN-GS-2L analysis – drill core samples 2012-2013

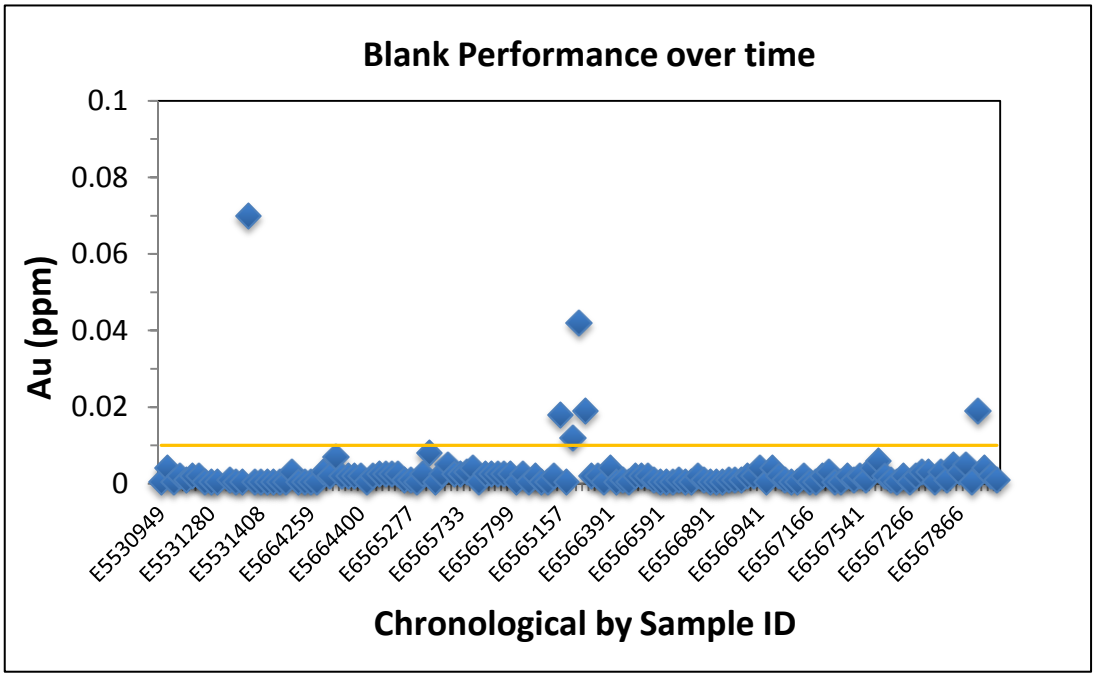


Blanks

Figure 24 shows the results from 135 blanks inserted from the start of the August 2012 drill program to the end of September 2013 drill program. As the detection limit for the fire assay analytical method used for drill core sample analysis was 0.001 ppm, the results of the blank samples were reviewed against 10 times the detection limit - 0.01 ppm. The graph shows five outliers above the blank performance test values with the remaining 96.3% of the blank samples below 0.01 ppm passing the blank performance test.

Overall, the performance of blank QC samples was very good and demonstrates that cross contamination from the sample preparation, sample mixing or mis-labeling and fire assay oven contamination were not a concern.

Figure 24. QC Sample - Blank sample analysis – drill core samples 2012-2013



Quarter Core Duplicate analysis

A total of 56 quarter core samples from the 2012 and 2013 drill core, along with 12 QC samples, were analyzed by ACME Laboratories for comparison to the original assay results from the AGAT Laboratories. The samples were analyzed using a 50g fire assay/ICP technique and overlimit (>10 g/t) samples were re-analyzed using a gravimetric finish (Table 5).

The QC samples included duplicate, standard and blanks and all of the QC samples returned acceptable assay results with the exception of one QC sample Au 8039 which failed. The duplicate samples in the batch showed relative value difference of approximately 1% and a single sample showing variance of 8.6%. All of the standards, except sample Au 8039, fall within 2 standard deviation of the mean expected gold value for the standards.

As eleven out of twelve QC samples passing the test, the umpire assay lab check batch is considered to have passed the generally accepted QC rules. The assay results from Acme Laboratories provide confidence in the original assay data reported by AGAT Laboratories.

Table 5. QC Quarter core samples - umpire analysis by Acme

QC sample performance of Au (g/t)						
sampleNo	QC Type	original	Original Assay	Check Assay	RD(%)	
Au8009	Duplicate	Au8008	0.07	0.064	8.6%	QC Pass
Au8020	Duplicate	Au8018	0.107	0.108	0.9%	QC Pass
Au8041	Duplicate	Au8040	0.018	0.018	0.0%	QC Pass
Au8058	Duplicate	Au8057	0.101	0.102	1.0%	QC Pass
sampleNo	QC Type	StandardID	Expected Value	2 Stdev	Returned Assay	
Au8010	standard	CDN-GS-15B	15.98	1.42	16.1	QC Pass
Au8029	standard	CDN-GS-P7H	0.799	0.1	0.82	QC Pass
Au8030	Blank		0		0.005	QC Pass
Au8039	standard	CDN-GS-2L	2.34	0.48	0.294	QC Fail
Au8048	standard	CDN-GS-15B	15.98	1.42	16.6	QC Pass
Au8049	Blank		0		0.04	QC Pass
Au8059	standard	CDN-GS-2L	2.34	0.48	2.448	QC Pass
Au8067	standard	CDN-GS-P7H	0.799	0.1	0.809	QC Pass

The duplicate analysis of the quarter core samples taken in 2013 illustrates strong correlation with tight tolerance between the original Au assay value by AGAT Laboratories and the check Au assay value from the ACME Laboratories. The results of the original and check Au assay values are shown in Figure 65 with plus 10% and minus 10% of relative difference lines.

Figure 25. Quarter Core Duplicate Assays

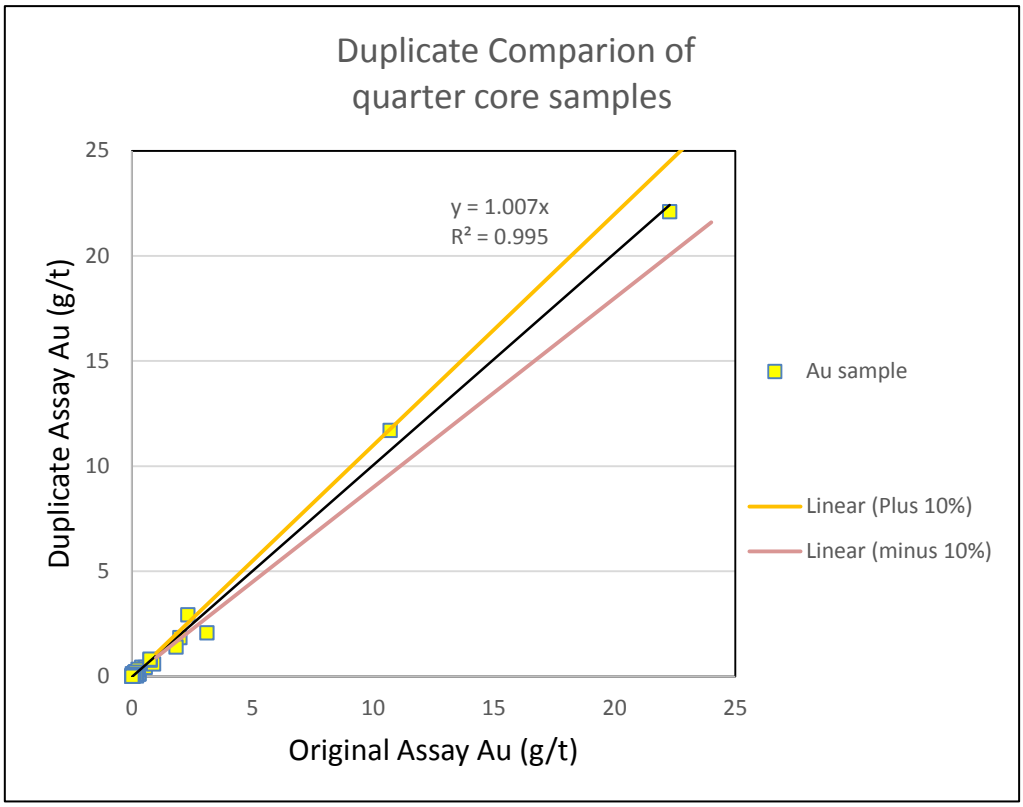


Table 6. QC Gold standard pulp samples – umpire analysis by ALS Chemsx

Sample ID	Standard ID	Returned Au value from ALS	Mean Au value for CRM	Stdev of CRM
AHR09	CDN-GS-2K	2.12	1.97	0.18
AHR18	CDN-GS-10D	9.98	9.5	0.56
AHR27	CDN-GS-2K	2.08	1.97	0.18
AHR36	CDN-GS-P7H	0.826	0.799	0.05
AHR45	CDN-GS-2K	1.92	1.97	0.18
AHR54	CDN-GS-P7H	0.823	0.799	0.05

11.0 Data Verification

In 2013, exploration work consisting of diamond drilling, geological mapping, silt sampling, soil sampling and rock sampling was supervised by qualified Anthill Resources personnel.

Quality Assurance/Quality Control (QA/QC) programs were implemented continuously from the start of the exploration program in 2013 and they included standard, blank and duplicate samples in every laboratory work order to monitor the accuracy and consistency of the analytical labs. Geological and geochemical data collected by subcontractors were examined by the qualified subcontractors and further reviewed by Anthill personnel. The data collected between 2011 and 2013 have all been compiled and merged into a master customized Access database developed by Geospark and has been verified and managed by Anthill personnel.

Additionally, secondary umpire check assays were obtained from Acme Laboratories and ALS Chemex Laboratories on quarter-core duplicate, coarse reject duplicate and pulp duplicate samples to verify primary laboratory results by AGAT Laboratories. Paired data analysis showed a strong correlation between samples with minimal deviation between the original assay result and the check sample assay result.

In preparation for the assessment report, systematic data verification work has been completed by the authors of the report. The data verification work consisted of:

- Comparing assay certificates with assays residing in the master Access database;
- Comparing the original geological logging data with the data in the Access database;
- Comparing soil geochemistry data on the original paper sample card to the digital data in the Access database;
- Comparing sample IDs on the submission form with the sample IDs reported on the assay certificate;
- Reviewing and analyzing the assay results of all of the standards, blanks, duplicate samples inserted into geochemistry sampling program and diamond drilling program;
- Reviewing and analyzing the assay results of paired data between the primary lab AGAT Laboratories, and ALS Chemex and ACME Laboratories;

In the opinion of the authors of the report, the data collected from the exploration program, as well as the analytical results reported by the AGAT Laboratories are reliable and satisfy the requirements of generally accepted industry standards.

No mineral resource or mineral reserve estimates have been made for the Einarson Property.

12.0 Adjacent Properties

12.1 ATAC Resources - Rackla Project

Anthill Resources Einarson claim block is adjacent to the eastern edge of ATAC Resources Rackla Gold project. Anthill's Venus gold prospect is located 30 km southeast of ATAC's Conrad and Osiris, Carlin-type gold discoveries (Figure 2). All of the following description is modified from the ATAC Resources website as of December 11, 2013.

The Rackla Gold Project is located 55 km northeast of Keno City in Central Yukon and is 100% owned by ATAC Resources Ltd. with no underlying royalties. The project covers 1,700 sq. km and is situated between the regional-scale Dawson Thrust and Kathleen Lakes Fault in the Selwyn Basin tectonic province.

The Rackla Gold Project was a grassroots discovery made by ATAC in 2006 and since then, the Company has acquired over 160 km of favorable structure and stratigraphy through staking. Exploration was initially focused along a 15 km ridge system, called the Rau Trend, where more than a dozen gold and/or silver exploration targets have been identified. Detailed work has been centered on the Tiger Zone, which has received 132 diamond drill holes totaling 25,900 meters from 2008-2010. In 2010, exploration efforts focused along the Nadaleen Trend where five areas of significant Carlin-Type gold mineralization have been outlined by surface sampling and 65,598 m of diamond drilling along a 50 km east-west trend. No resources estimates are available for the Nadaleen Trend gold mineralized zones.

The 2013 Nadaleen Trend exploration program continued to expand gold mineralization at in the Osiris zone and suggests continuity of the Osiris Zone with the Sunrise Zone to the west. It also identified several new zones surrounding the Anubis discovery area.

12.2 Strategic Metals Ltd. – Golden Midas Project

Strategic Metals has four projects adjacent to Anthill Resources Einarson project. Two small claim blocks (Nad and Larry) are inliers surrounded by Anthill Resources claims and the other two projects (Scarlet East and Lolita) are peripheral to the project claims (Figure 2). One of the projects, Scarlett East is under option from Rackla Metals (Strategic Metals Ltd., 2012a) and the other three are wholly owned by Strategic Metals. Exploration data is available from the Strategic Metals website for the Scarlet East and Nad projects.

The Scarlett East project is located on the northwest margin of the Anthill Resources claim block and immediately south of the ATAC Resources Nadaleen area claims. Strategic Metals

is earning a 60% interest in the property by staged exploration expenditures totaling $5 MM by December 16, 2016 which includes 1,000 m of drilling by December 31, 2013.
Grid soil geochemical data defined a coherent Au and As soil anomaly in carbonate stratigraphy of the Neoproterozoic Hyland Group with gold values ranging from 20-221 ppb and arsenic values ranging from 100 to 8467 ppm. The soil geochemical values trend northwest and are spatially associated with anticlinal fold hinges. Five drill holes totaling 1167.68 m were completed on the project in 2012 and none returned significant assay values (Strategic Metals Ltd, 2012b).

The NAD project is located immediately east of Anthill Resources Venus target area (Strategic Metals Ltd., 2013). Grid soil sampling returned values to 90 ppb Au and 2,990 ppm As from carbonate stratigraphy that extends onto the Anthill Resource claims. Orpiment-realgar showings are reported and a proposed 2013 drilling program was not undertaken and the prospect remains untested.

12.3 Americas Bullion Royalty Corp. – Rogue Project

Americas Bullion Royalty Corp (fka Golden Predator Canada Corp) reported positive exploration results from their Rogue B project located 22 km south-southeast of the Anthill Resources Mars target area (Golden Predator Corp., 2013) (Figure 2). The alteration and mineralization reported are typical of an IRGS system with gold mineralization present as veins, stockworks and replacements in both Paleozoic fine-grained clastic rocks and in Mid-Cretaceous, Tombstone suite felsic igneous rocks. Rock chip assay values are reported with a high of 152.0 g/t Au from a grab sample and chip channel assays of 3.42 m @ 4.32 g/t Au and 3.99 m @ 3.6 g/t Au.

12.4 18526 Yukon, Inc.

18526 Yukon, Inc. is a private company owned by local Whitehorse, Yukon prospectors Ron and Scott Berdahl. Anthill Resources optioned ~95% of the claims in the Einarson Project from 18526 Yukon and Mr. Ron Berdahl. The company controls two large claims blocks adjacent to the project. One block covers the southeast extension of the B Zone target area and the other covers prospective ground between the Mars and F2 target areas along the Einarson Creek drainage. There is no published data from their data, but an orpiment/realgar showing is reported west of Einarson Creek near the F2 target area.

13.0 Interpretation and Conclusions

The exploration work to date on the Einarson Project has identified gold and base-metal mineralization associated with folded and fractured, hydrothermally altered rocks. Significant

surface gold mineralization has been identified in six areas (Venus, Mars, Misty, B Zone, F2 and Emer Trends) and initial drill testing of surface gold anomalies in two areas (Venus and Mars) has returned significant intercepts of gold mineralization. The project area covers the eastward strike extension of gold mineralization currently being defined in the Rackla gold belt by ATAC Resources.

13.1 Venus

The gold mineralization in the Venus target area exhibits many characteristics associated with Carlin-style gold systems; carbonate host rock; gold association with arsenical sulfide mineralization and silica replacement hydrothermal alteration. High-grade gold drill intercepts at Venus indicates that the hydrothermal system has the potential to create gold-grades of economic interest (+5 g/t Au). Geological mapping of the Venus area suggests that exploration along strike to the east and west will need to target carbonate host lithologies at depth beneath “upper plate” siliciclastics, and identify additional host rock lithologies in the “upper plate” stratigraphy. A similar geological setting hosts gold mineralization at ATAC Resources Rackla Project 30 kilometers to the northwest.

The Venus target area represents a significant discovery of surface and sub-surface Carlin-style gold mineralization with the Rackla Gold Belt. The drainage basins are defined by anomalous gold, arsenic and mercury silt geochemistry, and grid soil samples defined a 300 meter by 100 meter gold-arsenic soil geochemical anomaly assaying greater than 500 ppb gold. Sixteen rock chips samples assayed greater than 9.25 g/t gold with a high of 191.00 g/t gold with arsenic values ranging between 1% and 10%. Three, 3 meter, chip channel rock samples assayed greater than 20.00 g/t gold. Similar high-grade gold mineralization was encountered in drill holes D2-12-05 and D2-12-03 which intersected 38.7 meters grading 9.67 g/t gold and 3.1 meters grading 15.16 g/t gold respectively. Gold mineralization of this tenor associated with large-scale hydrothermal alteration and widespread arsenic sulfide mineralization suggests that the greater Venus target area warrants additional geological and geophysical exploration to better understand the mineralizing gold system and to define additional drill targets.

13.2 Mars

Gold mineralization in the Mars area, as defined by silt, soil, rock and drill core geochemistry, was defined in three areas; Mars Main, Mars Northwest and Mars Northeast. Gold mineralization observed, to date, has been associated with quartz veins/stockworks and silica replacement alteration containing pyrite and arsenopyrite mineralization. The gold bearing mineralization is localized in both high-angle and low-angle fault/fracture zones developed in siltstone/sandstone lithologies of the Narchilla Formation. Carbonate host rocks of the Algae Formation are present in the target areas; however these carbonate lithologies have not been tested at depth in proximity to the gold mineralized structures.

The Mars Fault zone controls gold mineralization at both the Mars Main and Mars Northwest target areas with anomalous gold values in soils and rocks to a high of 9.11 and 9.25 g/t, respectively. The gold in soil anomaly is developed over a 4.0 kilometer strike length. The extreme southern portion (~150 m strike length) of the Mars Main target was trenched and drill tested in 2012 and 2013, with a trench returning gold values of 1.65 g/t over 33.5 meters with a high of 9.25 g/t across 2 meters. The best drill intercept, from seven drill holes, in the Mars Main zone was 0.571 g/t Au over 21.16 meters in drill hole A-12-01.

The Mars Northwest gold in soil anomaly is developed on the Mars Fault zone, approximately 2.0 kilometers north of the Mars Main zone. The gold in soil anomaly is 1.1 kilometers long with gold values to 9.11 g/t and it has not been drill tested. Initial geological mapping suggests the gold mineralization is hosted in east dipping, low-angle fault/fractures zones in siliciclastic lithologies of the Narchilla Formation that are cut north and northwest trending normal faults. The northwest trending normal faults are interpreted to be post mineral while the north trending normal faults are locally associated with gold mineralization. The Mars Northwest target has not been drill tested.

The Mars Northeast target was defined by soil and rock geochemistry in 2013. The gold in soil anomaly is northerly trending with a strike length of 900 meters and the anomaly remains open to the north. Soil and float rock chip samples have returned gold values up to 1.13 g/t and 2.44 g/t from the zone, respectively. Gold anomalous silt samples are present in the same drainage basin up to 5.0 kilometers north of the target area.

Gold mineralization in the Mars Trend has geological characteristics that are highly favorable for sediment-hosted gold mineralization. Gold mineralization is associated with pathfinder elements As, Sb, Hg and Tl within a package of siliciclastic, calcareous siliciclastic and carbonate lithologies of the Narchilla and Algae Formations. The mineralization is hosted in a regional-scale, anticlinal fold/thrust structural setting with local areas of post-thrusting high-angle normal faulting. Initial prospecting of the Mars Northeast target identified, fine-grained, chalcedonic quartz vein (?) float containing +2 g/t gold mineralization which initially appears different from the quartz vein mineralization at the Mars Main and Mars Northwest areas and could represent a “classic” epithermal quartz vein target.

13.3 F2

The F2 target area still has the potential to host significant gold mineralization, in spite, of the disappointing 2013 drill results. The target area is defined by anomalous gold-arsenic silt geochemical responses from multiple drainage basins. The well defined gold in soil anomaly is developed along 2 kilometers of strike length and it has only been drill tested in two areas. A total of 36 soil samples assayed greater than 100 ppb gold with a high of 2150 ppb gold. Strongly anomalous arsenic, mercury and thallium in soil geochemistry are well developed in carbonate rocks peripheral to the gold anomaly. The source of the gold/arsenic soil

geochemical anomalies is still not well understood. The target area contains significant volumes of Algae Formation carbonate rocks that are the preferred host rocks in the Rackla Gold Belt within a regional anticlinal fold/thrust structural setting with strongly anomalous trace element geochemistry. Additional geological and possibly geophysical work is needed to better understand the nature of the anomalous gold and arsenic geochemistry and the structural framework of the zone.

13.4 Misty and B Zone

The Misty and B zone targets are early-stage exploration targets with significant, well defined gold in soil anomalies developed along a northwest trending fold/thrust structural corridor. The large, relatively low-grade gold in soil anomalies are developed in interbedded shale, siltstone and limestone lithologies in the Yesezyu Formation below the favorable carbonate host lithologies of the Algae Formation. The possibility of carbonate host rock beneath the gold in soil anomalies will need additional geological mapping to refine whether the stratigraphy in the Misty-B Zone areas is related to the Rackla belt stratigraphy, as defined by Colpron, et al. (2013) and Moynihan (2014b), or part of the Selwyn Basin stratigraphy. The Rackla belt stratigraphy has carbonate lithologies beneath the "Algae Formation equivalent" lithologies (Figure 4), and these deeper carbonate rocks could be potential host units at both the Misty and B Zone targets.

The gold, arsenic and antimony in soil geochemical anomalies are developed in a fold/thrust structural corridor in the hanging wall of the Misty Lake Fault zone (MLFZ). The MLFZ is interpreted to be similar to the Dawson Thrust with early crustal-scale extensional followed by Mesozoic thrust fault and possible strike-slip faulting. Surface outcrops exhibit subtle alteration including weak argillic alteration of fine-grained clastics containing disseminated pyrite and minor arsenopyrite. Rock samples from the Misty zone assayed between 0.1 – 0.5 g/t gold and higher gold grades up to 2.3 g/t were collected in the B Zone target areas. The Misty mineralized zone has a strongly developed axial plane cleavage that may represent the high-angle "conduit" for hydrothermal fluid flow.

A better understanding of the structural controls on gold mineralization is needed for both the Misty and B Zone targets. Additional geological mapping and geophysical surveys would enhance the structural controls and mineralization and aid in initial drill targeting.

13.5 Additional Gold Targets

Silt and soil sampling of the Emer Trend (Waldo, Emer and Birkeland area claims) have defined areas of anomalous gold and trace element geochemistry, however initial reconnaissance rock sampling did not identify the source of the anomalies. The geologic setting of these areas is favorable for Carlin-type gold mineralization and the areas warrant additional exploration. Stibnite bearing quartz vein float was observed on the Waldo claims,

however the samples were only weakly gold mineralized. Two rock samples collected from limestone outcrops on the Emer claims returned gold values of 0.542 and 0.508 g/t gold respectively which need follow up prospecting.

13.6 Base-Metal Targets

Although exploring for base-metal mineralization was not the focus of the exploration work on the Einarson Project several areas returned interesting base-metal mineralization in silts, soils and rocks. North of the Misty Lake Fault Zone, the NE-G Zone base-metal target is defined by strongly anomalous silt, soil and rock chip geochemistry. The lead-zinc±silver target is developed near the stratigraphic/structural contact between the shale-chert lithologies of the Road River Group and the massive limestone of the Rabbitkettle Formation. Reconnaissance rock chip sampling from the area returned values to 18.7% Zn and 4.95% Pb with 97.6 g/t Ag from a quartz-carbonate vein in the area.

Older, Mississippi-Valley type (MVT) lead-zinc±silver mineralization is associated with the carbonate lithologies of the Algae Formation. This style of mineralization is present in the Emer, Mars, and F2 Trend areas as small, discontinuous areas of anomalous base-metal geochemistry not spatially associated with the younger gold mineralization. Two historic MVT prospects, Odd and Birkeland, were described in Section 6.0 and they typify this style of mineralization. Locally, this style of older mineralization is overprinted by younger gold systems as at Venus and possibly F2. A similar overprint of younger gold mineralization on older base-metal mineralization is reported in the Nadaleen gold trend by ATAC Resources.

Reconnaissance rock chip sampling in the eastern Emer Trend returned two samples assaying +30% Zn. Rock chip samples from the Mars base-metal zone returned assays to 4.44% Zn, 3.78% Pb and 69.1 g/t Ag from poddy replacement mineralization hosted in Algae Formation carbonates.

14.0 Expenditures

The 2013 exploration program at the Einarson Project has defined large areas of gold anomalous silt, soil and rock geochemistry in geological settings favorable for Carlin-style gold systems. The results of the exploration work by Anthill Resources over the 2013 field season are of sufficient merit to continue exploration expenditures on the Einarson Project in 2014.

Table 7. 2013 Exploration Expenditures

Item	SubContractor	Cost	Sub-Totals	Comments
Labor Cost	Anthill Resources Labor	$300,963.52		Labor
	All-Terrane Geological	$5,770.97		Geological Consulting
	Animas Exploration Services	$85,700.00		Geological Consulting
	Dun-Right Staffing	$55,335.00		Geological Consulting
	All In Exploration Services	$429,476.25		Soil Survey
	Venessa Bennett	$59,259.06	**$936,504.80**	Geological Consulting
Camp Cost	Mayo Bigway Foods	$102,581.12		Food
	Raymac Environmental Service	$114,887.26		Fuel Tanks
	Rugged Edge Holdings	$28,553.44		Camp Mob/Demob
	Northwest Shelters	$45,377.00		Camp Supplies
	Industrial Electrical	$62,764.94	**$354,163.76**	Generator - Power Infra.
Transportation	Alpine Aviation	$6,251.18		Fixed Wing
	Horizon Helicopters	$1,297,977.00		Helicopter
	Alcan Air	$46,533.00		Fixed Wing
	Nomad Air	$316,231.00		Fixed Wing
	Black Sheep Aviation	$444,155.73	**$2,111,147.91**	Float Plane
Fuel	Pacesetter	$252,203.62		Jet A & Diesel
	Mayo Fuel Services	$2,049.24	**$254,252.86**	Propane
Assay	Agat Laboratory	$513,360.00		Geochem
	ALS Chemex Labs	$4,707.00		Geochem
	Acme Laboratory	$2,077.00	**$520,144.00**	Geochem
Drilling	Peak Drilling	$793,751.60		Drilling
	ALX Exploration Services	$54,857.09		Core Boxes - Lumber
	Arctic Inland Building Suppli	$6,174.53		Drill Pad Lumber
	Rafex Exploration Services	$71,247.44		Drill Pad Building
	Reflex Instrument Services	$30,895.26	**$956,925.92**	Downhole Survey Tools
Expediting	Smalls Expediting	$90,575.79		Whitehorse Service
	Rick Cocks Expediting	$7,043.50	**$97,619.29**	Mayo Service
Communications	Total North	$31,044.51		Satellite Communication
	BC Communications	$9,742.77	**$40,787.28**	Radios
IT Services	McElhanney Consultants	$32,478.83		IT Services
	Blackbridge Geomatics	$33,349.05		Aerial Photography
	Geospark Consultants	$18,129.31	**$83,957.19**	Database Management
	Total Expenditures	**$5,355,503.01**

Method Summary

CLIENT NAME: ANTHILL RESOURCES (YUKON)

AGAT WORK ORDER: 13Y731533

PROJECT NO:

ATTENTION TO: Yinghua Chen

PARAMETER	AGAT S.O.P	LITERATURE REFERENCE	ANALYTICAL TECHNIQUE
Y	MIN-200-12017		ICP-MS
Zr	MIN-200-12017		ICP-MS
Sample Login Weight	MIN-12009		BALANCE
Au	MIN-200-12006		ICP/OES

Results relate only to the items tested and to all the items tested
