INTRODUCTION

The Rackla Gold Property comprises a 1700 km^2 area of highly prospective, platform to basin facies, sedimentary rocks located along the northern edge of the Tintina Gold Belt at the transition from the Selwyn Basin to the Mackenzie Platform in east-central Yukon Territory. Various commodities have been explored for and discovered both presently and historically within the claim block. Past exploration focused on base metal mineralization, while recently the emphasis has been directed towards gold potential. The property is wholly owned by ATAC Resources Ltd. (ATAC) and is informally divided into the Rau and Nadaleen Trends.

This report describes the work completed, methods used and the results obtained from the 2013 exploration program conducted along the Nadaleen Trend portion of the property between May 26th to August 31st, 2013. Management and labour for the project was provided by Archer, Cathro & Associates (1981) Limited (Archer Cathro) on behalf of ATAC. The authors supervised and participated in the program and interpreted all resulting data. The authors' Statements of Qualifications are listed in Appendix I; while Appendix II provides a Statement of Expenditures related to the program.

PROPERTY LOCATION, CLAIM DATA, ACCESS AND INFRASTRUCTURE

The Nadaleen Trend project of the Rackla Gold Property consists of 5508 contiguous mineral claims located from 64°04´N to 64°16´N latitude and stretching from 134°11´W to 131°54´W longitude on NTS map sheets 106C/01, 02, 03, 04, 05, 06,07, 08 106D/01 & 08 (Figure 1). The claims are all registered with the Mayo Mining Recorder in the name of Archer Cathro, who holds them in trust for ATAC. Specifics concerning claim registration are tabulated below while the locations of individual claims are shown on Figures 2-7.

Expiry dates include 2013 work which has been filed for assessment credit but not yet accepted.		

The Nadaleen Trend portion of the property lies 170 km northeast of Mayo, the nearest supply centre. The closest road access is to the community of Keno City, situated 49 km by road northeast of Mayo. Access to the project in 2013 was routed via Mayo to the Stewart airstrip or less commonly the Rackla airstrip 180 km and 150 km respectively from Mayo. Alkan Air provided the project's daily service flights with a Cessna 208B Grand Caravan. Large or bulky supplies were brought to the property on Nomad Air's Skyvan or Alkan Air's DH6 Twin Otter. The locations of airstrips and camps are shown on Figure 8.

Daily access to work areas on the project and between the airstrips and camp was provided by Horizon Helicopters using a Eurocopter AS350 SD2 (A-Star). This machine also transferred all supplies into camp from the airstrip and moved the diamond drills between most drill locations.

Fireweed Helicopters supplied a Bell 204 helicopter for positioning the Kubota KX80 on site from Mayo.

HISTORY AND PREVIOUS WORK

Locations of showings and historical work areas referred to in this report can be found on Figure 8.

The earliest recorded exploration on the eastern side of the Rackla Gold Property in the area of the Nadaleen Trend occurred when McIntyre Mines staked the Birkeland claims, then called Tom and Mom, in 1974 approximately 200 km east of Mayo. Mapping, geochemical soil sampling, trenching and the drilling of 10 BQ and 22 Winkie holes were carried out in 1975. The most significant results achieved were 4.4% zinc, 0.5% lead and 2.7 g/t silver over 1.8 m in DDH75-31 (Shearer, 1975). In 1978 McIntyre Mines entered a joint venture with Canadian Superior Exploration Ltd. No further work was reported and the Birkeland claims expired.

In 1976 the Sian claims were staked approximately 37 km southwest of the Birkeland claims by McIntyre Mines following prospecting of geological targets. Mapping, geochemical soil sampling and EM, mag and SP geophysical surveys were carried out in 1977. Gold was tested for in four grab samples; however, results did not exceed the detection limit for gold (Birkeland, 1978). After entering a joint venture with Canadian Superior Exploration, detailed mapping, trenching and sampling was completed in 1979. Results of this work found low grade lead and zinc throughout a folded dolomite unit. One diamond drill hole was completed in 1980 but did not intersect any mineralization. No further work was recommended and in 1982 the Sian property passed to Serem Ltd, after which the claims were voided and no further exploration was reported.

The Highhawk and Leah showings are situated approximately five and ten kilometres from the Sian showing. They occur within the Leah claims which adjoin the Star, Lee and Nod claims. The Leah claims were staked by a syndicate composed of Highhawk Mines Ltd, Envoy Resources Ltd, Sprott Silver Mines Ltd, Hecate Gold Corporation and Bow River Resources Ltd in 1976. The Star claims, which adjoined to the north, were staked by private prospectors and optioned to Prism Resources Ltd in 1977. Mapping and soil geochemical testing completed by Prism in 1977 returned disappointing results and all claims were dropped. The Lee and Nod claims were staked to the south of the Leah claims in December of 1976 and were optioned to Tay River Mines. No work is on record for these claims and they were allowed to lapse.

McIntyre Mines staked the Jam property in 1977, 4.2 km north of its Sian property. Soil and silt sampling in conjunction with mapping later that year found a favorable dolomite breccia host rock with associated zinc and lead sulphide mineralization. No further work was reported and the Jam claims lapsed.

In 1976, the Black, Ida, Red and Eira claims, located approximately 8 km east of the Sian claims, were staked by the Ortell Syndicate (Precambrian Shield Resources Ltd, Giant Yellowknife Mines Ltd, Nemco Resources Ltd and Highwood Resources Ltd). In 1977, the Black and Ida claims were optioned to a joint venture between DeJour Mines Limited and Nova-Co

Exploration Limited (Thompson, 1977). Mapping and geochemical sampling on the Ida claims later that year returned moderately anomalous zinc values, with erratic lead and silver support.

Also in 1977, prospecting and stream sediment sampling carried out on the Eira property by the Ortell Syndicate returned anomalous silver and zinc results, up to 2.4 ppm and 680 ppm respectively (Curry, 1977). This led to more detailed grid soil sampling and geological mapping. This work returned a number of moderate, non-coincident silver, zinc and lead anomalies.

In 2001, the Geological Survey of Canada completed a regional stream sediment sampling program (Heon, 2003), which included coverage of the current Sten claims, in an area now referred to as the Nadaleen Trend. Creeks draining this area returned weak gold and strong arsenic anomalies.

ATAC's initial interest in the area was to follow up anomalous arsenic silt sample collected by the Geological Survey of Canada in 2001. Over a three day period in 2009, 89 stream sediment, 1 rock and 9 soil samples were collected on the Sten claims. These samples returned a string of moderately to very strongly anomalous results ranging from 12 to 1775 ppb gold and 123 to 155,000 ppm arsenic (Eaton, 2010). As a result, additional claims were staked by ATAC.

Follow-up prospecting of the anomalous creek in the summer of 2010 led to the discovery of in situ gold mineralization occurring within a folded, deformed carbonate horizon now referred to as the Osiris Zone. A follow up soil grid consisting of 50 m line spacing and 50 m sample spacing was conducted over this carbonate horizon. Results from the soil grid yielded four distinct gold anomalies known as Osiris, Conrad, Isis and Isis East.

Drilling in the fall of 2010 defined three gold bearing zones (Lane, 2011). The Osiris Zone returned the most significant gold grades yielding 65.20 m of 4.65 g/t Au in OS-10-01. Five more holes were drilled within the Osiris Zone with all but one (OS-10-05) intersecting significant gold mineralization. The Conrad Zone, one kilometer to the east was drilled to target a gold bearing trench. Assay results from this hole included 8.03 g/t Au over 21.13 m in OS-10-08. A second hole drilled in the Conrad Zone intersected arsenic sulphide mineralization in a siliciclastic package (OS-10-09) with an average gold grade of 1.61 g/t over 39.76 m. Drilling in the Isis Zone (OS-10-07) one kilometer west of Osiris returned comparatively lower, albeit anomalous, gold grades averaging 0.92 g/t over 17.00 m (Lane, 2011).

In 2011 ATAC carried out an extensive drill program at the Osiris, Isis East and Conrad Zones as well as testing of pathfinder geochemical anomalies at the Isis East, Amon, Dale, Ptah and Pyramid Zones, for a total of 26,675 m of diamond drilling in 89 holes (Lane and Carne, 2012). Mapping during the 2011 season in the Nadaleen trend continued to refine stratigraphic and structural interpretations and correlations, while sampling and prospecting identified geochemically anomalous ground.

In addition to drilling and sampling, an airborne magnetic and radiometric geophysical survey flown over the Pyramid target defined broad, curvilinear lineaments trending east-southeast reflecting the general trend of lithologies and structures in the area. Remote sensing data was also collected over the course of the season to provide property wide, ortho-rectified satellite imagery and high resolution contours with low level aerial photos over the central Osiris area targets.

In 2012, ATAC continued their exploration of the Rackla Gold Project with another extensive drill and regional program. Soil sampling prospecting and mapping identified geochemically anomalous areas which led to the discovery of gold mineralization at the Pharaoh and Anubis Zones, in addition to a strong alteration zone at GT (Lane, et al. 2013). Drilling totaled 36,920 m in 116 holes at the Conrad, Osiris, Isis, Isis East, Sunrise, Pyramid, Anubis and GT zones of which 70 holes returned significantly mineralized intersections.

GEOMORPHOLOGY AND CLIMATE

The Rackla Gold Property stretches 185 km from east to west in the Selwyn and Werneke Mountains and is drained by creeks that flow into the Nadaleen, Rackla, Stewart and Beaver Rivers, all part of the Yukon River watershed. Local topography varies from low forested valleys to alpine terrain and features east-west to northwest trending glaciated valleys and ridges. Elevations range from about 600 to 2000 m above sea level. Outcrop is most abundant near ridge crests and in actively eroding creek beds. Most hillsides are talus covered at slope breaks and are blanketed by glacial till at lower elevations. The region was glaciated in the Late Pleistocene, 22,000 years ago (Duk-Rodkin, 1999) with ice flow from east to west.

Treeline in the vicinity of the project is at about 1500 m. Slopes above that elevation, especially steep north facing slopes are unvegetated. Moderately steep, south facing slopes are well drained and are often lightly forested with poplar. The density and size of vegetation gradually increases on lower slopes, and the valley floors are well treed with mature black spruce. Understory vegetation typically consists of low shrubs and moss.

The climate in the Nadaleen Trend area is typical of northern continental regions with long, cold winters, truncated fall and spring seasons and short, mild summers. Although summers are relatively mild, arctic cold fronts often cover the area and snowfall can occur in any month. The property is mostly snow free from early June through late September.

REGIONAL GEOLOGY

The Geological Survey of Canada performed geological mapping in the vicinity of the Rackla Gold Property at 1:250,000 scale in the early 1970s (Blusson, 1974). In 1999, the Geological Survey of Canada (Gordey and Makepeace, 1999) completed a compilation of Yukon-wide geology and updated the lithological units named in the Rackla area. The Yukon Geological Survey conducted mapping on 106C/03 and 106C/04 1:50,000 map sheets in 2010 and 2011 (Colpron, 2012; Chakungal and Bennett, 2010), completed map sheets 106D1, 106C1-4 in 2012 (Colpron et. al., 2013) and revised map sheet 106B/04 in 2013 (Moynihan, 2014).

The Rackla Gold Property straddles the boundary between deep water dominantly clastic rocks of the Selwyn Basin to the south and shallower water shelf strata of the Mackenzie platform to the north. The Dawson Fault, which juxtaposes rocks of Selwyn Basin against rocks of Mackenzie Platform, is a crustal break that may date back to late Neoproterozoic rifting and was reactivated as a north directed thrust in the Cretaceous (Macdonald et. al, 2010). The tectonic setting of the Rackla Gold Property is shown in Figure 9, while regional relationships and the importance of the Dawson Fault system are presented in Figure 10.

Recent mapping by the Yukon Geological Survey has refined the Proterozoic to Paleozoic sedimentary stratigraphy underlying the Nadaleen Trend (Figure 11). A description of this revised mapping is described below, with Proterozoic to Lower Cambrian rocks described in Table II and Paleozoic rocks in Table III.

NADALEEN TREND - PROPERTY GEOLOGY

Property scale and more detailed, zone specific geologic mapping continued along the Nadaleen Trend during the 2013 field season; with attention focused on areas of interest identified during 2012 geochemical sampling and prospecting. Mapping was also extended to previously unmapped ground to the east of Conrad. The distribution of lithologies and regional scale structures defined during this mapping program are shown on Figure 12.

Lithologies have been divided into three groupings: Paleozoic Rocks, Neoproterozoic - Cambrian rocks and Neoproterozoic Rocks. Descriptions of each of these are provided below.

Paleozoic Rocks – Thought to be equivalent to Earn Group, they are exposed from the Pyramid Zone to just south and west of Nadaleen Camp. This group has been subdivided into four lithologically distinct map units:

- **Pz4:** Thinly bedded, dull grey-brown weathering siltstone interbedded with shale and minor fossiliferous limestone.

- **Pz3:** Fossiliferous (locally described as 'fossil hash'), medium- to coarse-grained, calcareous and moderately calcareous wackestone interbedded with shale, calcareous siltstone and minor chert. Fossil fragments include shelly bits, crinoids and bryozoa.

- **Pz2:** Well bedded, carbonaceous and argillaceous chert interbedded with carbonaceous shale, siltstone, and lesser amounts of chert pebble conglomerate and minor sandstone that may locally be calcareous. Grades into fossiliferous, micritic limestone.

- **Pz1:** Pale grey weathering, micritic limestone interbedded with thick debrite packages and carbonaceous chert. Includes fossils of favocites, halycites(?) rugose coral, crinoids, brachiopods, bryozoa and possibly sponges. In the Dale target area this unit is silicified and brecciated. Limestone outcroppings at Pyramid, Dale and south of the twin peaked mountains are fossiliferous, medium- to coarse-grained wackestone with fossil fragments including shelly bits crinoids and bryozoa.

Neoproterozoic to Cambrian Rocks - may in part be equivalent to the Hyland Group and Windermere Supergroup. This stratigraphy is exposed across the entire length of the map area. It is divided into ten lithologic map units as follows:

- **phy:** Maroon and turquoise-green phyllites and siltstones interbedded with rosy pink limestone (at the Sian Target), and/or invariably calcareous, green weathering sandstones.

- **dol:** Zebra textured dolostone locally with chert lenses.

- **xlst(a):** Very dark grey/black, coarsely crystalline limestone. Often associated with beds of polymict floatstone containing clasts of orange weathering dolostone, limestone, rounded quartz pebbles and minor shale, particularly near the base of the unit. 'Beef' textured calcite layers are common, particularly in outcrops near the Nadaleen camp. Graded calcite cemented pebble conglomerate to sand layers are very distinctive in the Osiris area. Larger quartz clasts can be quite angular. In drill core the xlst unit is differentiated into three units: O-LST2 and C-LST2 and C-LST1 based on contact and faulted relationships - this variant is equivalent to **O-LST2**

  - **Odmt:** Limestone pebble to boulder conglomerate, predominantly matrix supported with debrite texture. Clasts vary from centimetre to metre scale and comprise limestones that are markedly similar to the limestone and siltstones described below. Matrix composition is variable comprising non to weakly calcareous green siltstone and shale and/or variably crystalline limestone.

  - **Odst**: Fine grained dolostone, texturally similar to Osiris Limestone unit below, with subtle grey-black crackle texture throughout.

  - **Olst**: Well bedded, tan and grey limestone preserving sedimentary structures (ie. climbing ripples, cross bedding). Monolithic, intraclast rudstone layers, averaging 0.5-2 metres thick, are common throughout the unit, particularly in upper sections. They consist of randomly oriented to imbricated, tabular to equant clasts in a carbonate mudstone matrix. Clast composition is almost exclusively the same as the enclosing carbonate mudstones. Where in contact with underlying maroon siltstones, the limestone is characteristically orangey-tan weathering vs. light grey weathering where underlying siltstones are green. Lower in the section, the limestone includes interbedded calcareous and non-calcareous lithic and arkosic sandstones. *Turner, 2012 suggests that this unit and the underlying maroon siltstone may be correlative with Mesoproterozoic, <1.3 Ga; >1.0 Ga, Pinguicula Units B and A respectively.* Total thickness of this limestone/dolostone package at Osiris/Isis East averages 150 m.

  - **Oslt**: Maroon and green siltstone, finely laminated. This unit is generally identified by its proximity to the overlying Osiris limestone. It is referred to as the Osiris maroon siltstone or mudstone in Osiris/Conrad area.

  - **xlst(b):** Very dark grey/black, coarsely crystalline limestone thickly bedded with rare debrite clasts. 'Beef' textured calcite layers are common. In drill core the xlst unit is differentiated into three units: O-LST2 and C-LST2 and C-LST1 based on contact and faulted relationships - this variant is equivalent to **C-LST2.**

  - **Cgl,lst:** Limestone conglomerate that may be more adequately described as a debrite. Clasts vary from centimetre to metre size and are compositionally siliar to the overlying crystalline limestone.

  - **slt:** Green-grey siltstone and shale interbedded with fine- to medium-grained sandstone, lesser calcareous sandstone, minor limestone and limestone debrites.

  - **sst,cgl:** Well sorted, coarse grained, quartz granular sandstone to pebble conglomerate.

- **xlst(c):** light grey weathering, silty laminated clastic micritic limestone. 'Beef' textured calcite layers are common in addition to wispy fine grained quartz layers. In drill core the xlst unit is differentiated into three units: O-LST2 and C-LST2 and C-LST1 based on contact and faulted relationships - this variant is equivalent to **C-LST1.**

<u>Neoproterozoic Rocks</u> - possibly equivalent to Windermere Supergroup as suggested by the Yukon Geological Survey. These rocks are exposed to the north and east of Nadaleen Camp and may also be exposed in the hills immediately east of the Dale target area. In the Osiris area they are locally called Nonad (North of Nadaleen fault). This package is divided into five lithologic map units as follows:

- **N5:** Finely laminated, grey-green limestone interbedded with 'beef' textured calcite and minor siltstone, particularly proximal to the contact with limestone.
- **N4:** Grey weathering shale and minor siltstone.
- **N3:** Grey weathering, fine grained sandstone interbedded with siltstone. This may be part of the coarse-grained sandstone/conglomerate unit described next.
- **N2:** Orange-brown weathering, well bedded, fine-to coarse-grained sandstone interbedded with grey/blue quartz granular sandstone and /or quartz pebble conglomerate. Quartz clasts are most commonly rounded.
- **N1:** Chlorite green siltstone and shale interbedded with orange weathering, coarse-granular quartz and chert pebble sandstone and conglomerate. This unit is polydeformed and has a well-developed cleavage.

It is believed that the Nadaleen Trend area underwent extensive deformation as part of a Mesozoic to early Cretaceous fold and thrust event, followed by a transition into a probable strike slip regime. Two major regional structures transect the property: the Dawson Thrust and the Kathleen Lakes Faults. The Dawson Thrust, historically described as defining the northern edge of Selwyn basin, places Precambrian Hyland Group rocks over Paleozoic shelf carbonates as part of Jurassic to Cretaceous compressional tectonics. This fault is likely a much older structure, possibly dating back to Precambrian rifting that was reactivated during compression.

The Kathleen Lakes Fault marks the contact between Paleozoic platform rocks to the north and Paleozoic shelf to basin rocks to the south in the western part of the property. Both the Dawson Thrust Fault and Kathleen Lakes Faults are more difficult to trace to the east as they move into broad valleys covered by a thick layer of glacial till. The Nadaleen Fault near the eastern end of the property appears to be a splay off the Kathleen Lakes Fault.

The prevalence of debrite and turbidite facies within almost all units, along with the highly variable stratigraphic thicknesses of units provides strong evidence for long lived syn-sedimentary tectonism.

Locally, stratigraphic relationships between the mapped units in the Osiris area have been determined. This stratigraphic column is shown in Figure 13. Detailed geologic maps for the Osiris and Anubis areas are represented in Figures 14 and 15.

MINERALIZATION

The focus of exploration along the Nadaleen Trend is for carlin-style gold mineralization. Carlin-type deposits have been reported around the world, but to date, major economic occurrences have been restricted to the Great Basin of the southwestern United States. Recent discoveries along the Nadaleen Trend have many characteristics of Carlin-type deposits, and hold promise of great potential for new discoveries of economic importance (Arehart et al., 2013).

Carlin-style deposits are characterized as sediment-hosted micron-scale gold hosted within disseminated arsenian pyrite (Arehart, 1996). The deposits are typically found as replacement bodies in silty-carbonates within slope and basinal facies and have both structural and stratigraphic controls with a strong relationship to deep seated crustal-scale structures (Cline et al., 2005; Muntean et al., 2011). Carlin-style fluids are typically weakly acidic, resulting in the dissolution of carbonate which is followed in the mineralization process by precipitation of quartz and gold-bearing arsenian pyrite and trace metal enrichments of As-Sb-Hg-Tl (Muntean et al., 2011). Permeability is the key factor controlling the distribution of alteration and mineralization and features that control it include primary fluid conduits, such as fault and shear zones, as well as stylolites, veinlets and fold hinges (Tucker et. al., 2013).

Along the Nadaleen Trend, carlin-style mineralization has been drill-proven at the Osiris, Conrad, Sunrise, Isis, Isis East, and Anubis Zones. Gold mineralization is best developed within limestone sequences where alteration, characterized by decalcification occurs in association with realgar mineralization peripheral to calcite flooding. Mineralization hosted within non-calcareous rocks generally occurs within brittle fractures and is directly associated with fault breccia and/or intense fracture development.

SOIL, SILT AND ROCK GEOCHEMISTRY

GENERAL

The goal of the 2013 geochemical sampling program along the Nadaleen Trend was to locate new mineralized occurrences and define locations requiring more detailed follow-up work. In total, samplers collected 2123 rock, 9 silt and 7892 soil samples. Soil sampling was mainly focused between the Pyramid and Osiris target areas of the Nadaleen Trend, with some work done in the less explored, low lying ground that lies between the Rau and Nadaleen Trends. Prospecting work focused on following up of geochemical anomalies generated in both during previous sampling programs as well when results of the ongoing work became available. Hand and excavator pit sampling helped to refine these geochemical targets.

Figures outlining the location and results of soil and silt samples are located in Figures 16-52. Rock sample locations are located in Figures 53-64 while rock sample results are located in Figures 65-73. Sampling and analytical procedures are explained in Appendix III; rock sample descriptions are provided in Appendix IV; and certificates of analysis occur in Appendix V.

Background and anomalous values for gold, silver, arsenic, antimony, mercury, thallium, lead and zinc were calculated for all soil samples collected in the Nadaleen Trend between 2011 and 2013. Background, average, weak, moderate, moderately strong and strongly anomalous thresholds approximately correspond to the 80th, 90th, 95th, 98th and 99th percentiles from these samples. The geochemical characteristics of the soil and silt samples are summarized in the following tables.

GENERAL RESULTS

The 2013 sampling program helped to constrain areas of widespread anomalous pathfinder geochemical anomalies. Additionally, widespread transect sampling over previously unsampled ground provided new geochemical information.

Sampling in the Anubis area worked to constrain the widespread pre-existing geochemical anomalies, to refine the targets for follow up prospecting. Further delineation of ten “N series” targets was also conducted. The location of these targets in addition to the defined zones of mineralization is shown on Figure 15 and 16. Table VI, summarizes the mineralized zones discovered or explored along the Nadaleen Trend in 2013, while Table VII outlines the results of the N-series target follow up conducted along the Nadaleen Trend. The results presented for these targets and zones are representative of the culmination of exploration along the Nadaleen Trend between 2010 and 2013.

TABLE VII –N-SERIES TARGET SUMMARY

Target	Location Relative to Osiris (km)	Soil Anomaly Type	Approx Size (m)	Follow up Method	Results of follow up	Future recommended work
N1 south	9.9 km W	Au – intermittent anomaly	850 x 350	Infill soil sampling, hand pitting and prospecting.	Soil sampling confirmed that the anomaly is restricted to the original area defined in 2012. Hand pitting in the location of anomalous soils failed to produce samples with elevated gold.	Better constraint of the geologic contact between argillite and carbonate on the south side of the anomaly could provide a favourable host to mineralization. Additionally follow up work should be completed on the large mercury anomaly ~1500 m south.
N1 north					Soil sampling failed to replicate the original gold values. Prospecting defined an unmapped portion of argillite sediments in the bottom of a gully interpreted to define a syncline. Pitting, focused on the contact between the argillite and carbonate, returning strongly altered carbonate samples that did not contain gold.	Further definition is required of the northern argillite/ carbonate contact with particular attention focused to the intersection of the contact and the north-northeast oriented gold anomaly. Additionally, the linear arsenic anomaly 850m x 50m should be investigated.
N2	13.6 km W	As, Tl – linear anomaly	1600 x 1000	Prospecting and hand pitting at sites anomalous for As.	Hand pitting did not reach below cover, but returned transported clasts of clay altered limestone, similar to those found at Anubis. This suggests that the target may be a result of mechanical dispersion from the Anubis area.	Deeper test pit sampling, utilizing an excavator, would provide information on the thickness of cover and may determine if this anomaly is in fact as result of a mechanical dispersion from the Anubis area.
N3	16.6 km WSW	As, Hg, Sb, Tl – intermittent anomaly	3500 x 1300	Prospecting	Lead and zinc mineralization sources from galena and sphalreite; which supports the historical documentation. Maximum gold value identified at this target is 0.58 g/t Au in soil	Detailed mapping, prospecting and hand pitting could help to determine if rocks sourcing the base metal mineralization have potential to host carlin-type gold mineralization.
N4 *Sian*historic base metal occurrence**	20.2 km WSW	As, Hg, Tl anomaly	2200 x 900	Prospecting	Galenea and sphalerite mineralization observed support the presenence of lead and zinc mineralization from historical documentation.	Prospecting, mapping and hand pitting could determine the potential for carlin-type gold mineralization associated that may be spatially associated with the base metal mineralization.
N5	17.7 km W	Sb, Tl - arcuate anomaly	2000 x 2000	Prospecting	Carbonate samples collected 300 m north of the main soil anomaly showed open space filling by quartz. In rare cases these samples returned gold mineralization up to 0.79 g/t	Focus should be placed on the source of the gold mineralization within the quartz replaced carbonate samples. In addition, refined mapping of the argillite/

					Au. The arcuate shape of the Sb anomaly corresponds with the mapped location of siliciclastic rocks of the locally defined Pz2 unit, well exposed at surface. The elevated Sb and Tl but lack of Au, As and Hg suggest the anomaly is a result of the natural elevation of Sb and Tl within this well exposed package of rocks.	carbonate contact could be used in combination with the soil data to separate Sb and Tl anomalies within the carbonate unit. This process could assist with vectoring possible sources of gold mineralization within the carbonate.
N6	16.2 km WSW	As – Hg anomaly	2300 x 1000	Infill soil sampling, prospecting and hand pitting	Infill soil sampling successfully reproduced 2012 results, better defining the limits of the anomaly. This work did not however return samples elevated in gold. Hand pitting at anomalous soil sites returned argillite with strong coatings of arsenic oxide.	Constraining the contact between the argillite and carbonate in addition to further pitting in the vicinity of anomalous samples should be the focus of follow-up at this target.
N7	13.4 km NW	Au, As, Tl – linear anomaly	900 x 600	Infill soil sampling, prospecting and hand pitting.	Soil sampling successfully reproduced elevated As and Tl but not Au values. Hand pitting, hindered by frozen ground, encountered only a laterally continuous blanket of cover. Samples of this cover material did not yield elevated gold.	Further pit sampling is recommended up slope at the southern terminus of the elevated As and Tl anomaly.
N8 *also known as the Dale target in 2011*	10.7 km WNW	As, Sb, Tl – linear anomaly	5800 x 700	Prospecting	Prospecting focused along two parallel northwest trending faults that showed strong alteration and realgar mineralization in drill core from 2011.	Detailed mapping along the NW oriented linears could determine prospective areas to host mineralization. As well, prospecting should be conducted on the along the previously unworked northwest portion of the linear arsenic anomaly.
N9	8.4 km SE	As, Hg – anomaly	1300 x 500	Prospecting	Sampling of a gossan returned limonitic samples associated with botryoidal calcite containing elevated arsenic but no gold.	Focus should be placed on finding the hypothesised upslope source of the limonitic precipitate. Additionally, grid soil sampling should be extended to the west and east to fully define the limits of the arsenic anomaly.
N10	10.1 km NE	Au, As, Sb Hg – arcuate anomaly	2300 x 800	Prospecting	Prospecting determined that mineralization has a strong structural control. The siliciclastic rocks that dominate the area limit the potential for lateral mineralization.	Further prospecting of the soil anomaly to the northwest and into the drainage is necessary as there are yet to be unexplained silt samples elevated in gold collected

						within this drainage. In addition, sampling should be biased to carbonate horizons, particularly where they are projected to intersect the known fertile structures.

EXCAVATOR SAMPLING PROGRAM

GENERAL

Excavator assisted pit sampling was conducted in the Anubis area between July 17th and August 27th, utilizing a Kubota KX80 operated by 15317 Yukon Inc. This sampling program was designed to test the soil geochemical anomalies in the vicinity of the Northern and Anubis faults, to vector the source of the mineralization. This work also helped to refine the location of the faults and broad geologic contacts. The program was completed in an area that extended from the eastern terminus of the Anubis Fault on a gentle ridge top down into a valley where cover quickly thickens. Pit locations with respect to these faults are shown on Figure 74.

A total of 252 pits and 2 trenches were dug in an attempt to reach bedrock in the vicinity of areas of anomalous soil geochemical response that occur proximal to faults cutting favourable stratigraphy. A total of 1217 rock samples were taken over the course of the program. Pits dimensions were largely determined by ground conditions and excavator capabilities but on average were 3x2x3 metres reaching a maximum depth of 4.6 metres. The failure to reach bedrock was due to a combination of site specific and machine limitations, frozen ground, and exceptionally thick cover in places.

Pits were generally located 10-50 metres apart and completed on lines spaced 50 to 100 m oriented perpendicular to the trace of the fault. Once dug the pits were logged, sampled, and photographed they were backfilled. The locations of the pits were recorded with a handheld GPS and marked with a flagged piece of 0.5 metre tall wooden lath. The pit identification number was inscribed on an aluminum tag affixed to the lathe.

Key information pertaining to the pits is listed in Table VIII while Figures 75-81 thematically highlight the results of the work. Appendix II provides a detailed description of the Sampling and Analytical Procedures used, while Appendix VI details descriptions of the rock samples collected, with assay results of these samples provided in Appendix VII.

PITTING RESULTS

Pitting in the Anubis area revealed a widespread layer of transported cover ranging from one to more than four metres thick. The cover was generally thickest in drainages and valley bottoms where it consists of colluvium, alluvium, or glacial till overlain by a layer of variably frozen organic material. Bedrock was best exposed in pits along ridgetops and midslope elevations where cover is relatively thin.

The pitting program not only tested the geochemical potential of the Anubis area, but helped to define the location of faults as well as the footwall and hanging wall stratigraphy. Lithologies observed in samples and pit walls were consistent with broad observations on surface and included the following lithologies: micritic or crystalline limestone showing varying degrees of oxidation, hydrothermal alteration and/or dolomitization; fine grained, black argillite with pervasive weathering and fracturing, and/or oxidation along fracture planes; and, fault rock including fault breccias, oxidized clay or gouge. Hydrothermal alteration, where observed, is typical of Carlin-style systems and includes moderate to strong “sandy” decarbonitization, and less commonly, silicification. Clay alteration was most typically associated with arsenic±antimony±iron±lead oxide and occurred within fault zones or altered lithologies as thin (<2 m), light grey to green or red-brown bands. Gold-, silver- and base metal-mineralized samples were typically associated with moderate to intense oxidation and/or hydrothermal alteration of limestone or argillite.

In total, 47 pits returned results considered significant for gold, silver, lead and/or zinc based on trend-wide geochemical thresholds of those elements. Observations from each zone returning significant results in pitting are described below. A summary of pits and trenches significantly mineralized for gold is presented in Table IX while geological pit logs occur in Appendix VIII.

Columba Zone
Pit sampling in the Columba Zone tested an area along the Anubis Fault anomalous for gold in soil. Pitting was focused on a northwestern facing hillside immediately upslope of the soil anomaly with pits dug on north-easterly oriented lines spaced approximately 50 metres apart having pits spaced 20 to 50 metres along them. Many of the pits did not reach bedrock due to exceptionally thick overburden with a frozen layer of organic cover. Samples from the pits at Columba generally consisted of altered argillite, variably dolomitized and hydrothermally altered limestone and oxidized fault rock. The spatial relationship of these rock types is poorly understood. Samples taken immediately beneath the highest gold-in-soil values exhibit the strongest gold enrichment with grades up to 0.52 g/t Au occurring in altered argillite. Moderately anomalous silver and zinc grades were returned from fault rock and transported cover in pits on the periphery of the Columba Zone. In these pits, peak grades of 36.00 g/t Ag and 1.51% Zn were returned from samples of oxidized fault rock.

Draco Zone
Transect and grid pitting was conducted at the Draco Zone. Two roughly parallel north-northeast oriented transect lines oriented perpendicular to a fault were followed, along which pits spaced 20 to 50 metres apart were dug. Grid pitting was conducted 350 metres to the northeast of the transect pitting over an area anomalous for gold in soil associated with multiple recessive linears.

Transported cover, up to 2 metres thick, overlies the footwall limestone unit in this area which is well exposed upslope of the gold anomaly. The limestone intersected in the pits is variably dolomitized with thin horizons of arsenic-antimony-iron oxide associated with moderate clay alteration of the rock. Transect pits returning samples of transported cover, clay altered oxidized limestone from the bottom of AnEx13-232 returned encouraging gold values ranging from 1.04 to 1.57 g/t Au. Samples from the gridded pits did not return significant gold mineralization suggesting that the lower Draco Zone and upper gold-in-soil anomaly are genetically distinct.

Ana Zone
The Ana Zone received minimal pit sampling as it was hand pitted in 2012. Several excavator pits slightly northwest of Ana were placed along the Anubis Fault. Deep cover greatly inhibited evaluation of this area, with only two of the six pits reaching bedrock. Material retrieved from near pit bottoms comprised oxidized argillite fragments with oxidized clay suggestive of fault gouge. Pit AnEx13-171, returned samples of argillite with up to 0.43 g/t Au.

Additional pitting targeted the argillite-limestone contact directly south the main zone in pits dug 10-50 metres apart along transect lines spaced 40 metres apart. Although cover was relatively thin in this area, the presence of limestone boulders greatly inhibited excavation. Bedrock and subcrop material consisting of unaltered to weakly oxidized argillite was encountered in the southern pits while limestone was encountered to the north. Oxide and clay alteration intensity increased in both units towards the contact. Massive crystalline calcite was observed near the contact in the eastern-most transect. One pit dug within the Auubis fault near its intersection with an orthogonal cutting structure returned three samples between 0.22 g/t and 0.43 g/t Au.

Hydra Zone
Pit sampling in the around the Hydra Zone consisted of three roughly north-northeast trending lines. The western line targeted a northeast-trending topographic feature coincident with a vegetative kill zone. The central line explored the extent of alteration to the north of that intersected in drillhole AN-12-006. While the eastern line tested an arsenic soil geochemical anomaly. Infill pit sampling and follow up trenching were conducted selectively between the western edges of each line.

Transported cover was generally two to three metres thick, extending to over four metres deep in topographic lows. Lithologies observed generally consisted of crystalline to micritic, dolomitized, and locally fossiliferous limestone. Streaky oxidation in addition to clay alteration are common in gold, silver and zinc-enriched samples. These were collected within a cluster of pits clustered immediately northeast of the An-12-006 drill collar. Within this cluster, trench AnEx13-252 showed strataform clay alteration with 0.7 g/t Au. Highlight samples of base metal mineralization from the Hydra area returned peak values of 151.00 g/t Ag, 0.20% Pb and 2.65% Zn.

Corona Zone
Pit testing in the vicinity of the Corona zone was focused along the Northern Fault, beginning north of the Anubis Fault terminus where anomalous gold, lead, zinc and pathfinder geochemical anomalies form a broad northwest-trend, coincident with a recessive gully. Transect lines spaced 50 to 100 m apart were dug with follow-up pitting and trenching filling in gaps between anomalous pits.

Only one to two metres of cover was encountered in the eastern pit area while it thickened to over four metres towards the drainage at the base of slope. Above this elevation, samples of argillite, fault rock and limestone were retrieved from the pits. Oxidation and hydrothermal alteration ranged from weak to intense with the strongest alteration observed in the argillite unit. Zinc enrichment is most prevalent immediately north of the Corona Zone in samples of argillite and transported cover. Significant zinc values in this area range between 1.0 and 2.5% with a peak value of 10.1%. Strong Carlin-type pathfinder mineralization (arsenic, antimony, mercury and thallium) follows the Northern Fault down the drainage to the northwest and is lost downslope below drill collar An-Ex-004. Approximately 65% of pits dug along the Northern Fault returned values above the 95th percentile for at least one of the pathfinder elements. Peak values for these elements at the Corona zone were 4.00% As, 476 ppm Hg, 7990 ppm Sb, and 1090 ppm Tl.

Pitting at the eastern most terminus of the known extent of the Northern Fault returned samples of argillite-hosted base metal mineralization with gold enrichment. Significant gold-silver-lead mineralization was first discovered in AnEx13-13 with grades of individual samples up to 1.15 g/t Au, 434 g/t Ag, 15.3% Pb, 0.75% Zn, 2.58% As, 446 ppm Hg, 1895 ppm Sb and 89.80 ppm Tl. Mineralization in this pit consists of intensely altered and variably silicified argillite defined by a light grey band with a parallel oxide horizon oriented approximately 060˚ dipping 25SE. This orientation corresponds to the strike of a southeast trending fault that intersects the Northern Fault proximal to pitted area. Pit AnEx13-13 was extended into a northwest oriented trench (AnEx13-251) later in the season. Abundant galena was discovered in lenses associated with "sandy" decarbonitization and silicification of suspected carbonate layers within the argillite. Samples taken in these alteration zones returned values up to 2910 g/t Ag and 73.15 % lead. Arsenic-lead-antimony-iron oxides in association with clay alteration of argillite were observed within the trench.

Anubis Zone

Pitting directly surrounding the Anubis zone targeted three areas: the Anubis fault southeast of the Anubis discovery, a gold-in-soil anomaly northwest of the showing that is coincident with the Anubis fault trace, and a linear feature within the broad drainage northwest of the showing between the Anubis and Northern faults that is associated with a gold, arsenic and mercury anomaly.

Selection of pit locations was limited by the mobility of the excavator in the steep terrain. Cover on the higher ground was generally thin, allowing for the exposure of bedrock and subcrop, while in the valley it was considerably thicker limiting access below cover.

Transect lines placed along the Anubis fault southeast of the showing included pits spaced 15-30 metres apart; while northwest of the showing isolated pits were dug at accessible sites directly within the fault trace. Many of these pits encountered a frozen layer of fractured argillite that became less prevalent as pitting continued downslope. Lithologically the pits returned highly fractured, pervasively weathered argillite with locally strong to intense hydrothermal alteration. The alteration intensity was represented as clay development and an arsenic, antimony, and iron oxidize horizon running subvertically through the pits. This alteration and oxidation increased in intensity towards the fault trace. Gold, in addition to lead and zinc mineralization returned values considered background to weakly anomalous, though elevated silver values were encountered in four pits. Three of these pits, located northwest of the showing at the faulted contact between footwall limestone and hanging wall argillite returned maximum silver values between 5.92 to 10.40 g/t Ag.

Pitting in the broad northwest-facing drainage centred between the Anubis and Northern Faults was conducted in a broad grid covering a 500 by 150 metre wide area with pits spaced approximately every 50 metres. Nearly all pits reached their maximum depth in cover made up of rounded polytithic fragments and large limestone boulders. Pits located slightly upslope of the valley bottom in the margin of the grid area, reached subcrop consisting of argillite with variably weak to strong arsenic, antimony and iron oxidation. Evidence of folding within the argillite unit was present in AnEx13-153 located on the eastern side grid area. Here an upright open fold, plunging 30 to 50° to the south occurs in association with the oxidation described above. High background geochemical values (<90th percentile) of gold and base metals were returned from samples of transported cover – mainly consisting of rounded polylithic fragments and loose dirt. These anomalous samples returned from pits on the east boundary of the grid reached 17.40 g/t Ag and 0.83% Pb.

DIAMOND DRILLING

GENERAL

Diamond drilling was carried out on the Conrad, Isis, Isis East and Sunrise Zones between June 11 and August 25th by Superior Diamond Drilling Ltd. of Peachland, BC. The work was completed using HQ and NQ equipment on two heli-portable Discovery II drills. One drill was mounted on tracks for 32 days, completing 7 holes at Sunrise. A total of 7,303 m of diamond drilling was completed in 26 holes.

When not on tracks, drills were set up on an approximately 16 foot square platforms built of 8” x 8” timbers covered with 2” x 8” planks or on an earth filled log structure of approximately the same size. Each of these pad types were prepared by hand. Drill sites on which the track equipment was positioned were constructed directly on or built on a spur of the main access road at Sunrise. The road segment used for drilling was roughly flattened and widened where necessary to position the drill. All road building and site modifications were done using either a Kubota KX80 or KX041 excavator. All drill collars were marked with a piece of drill rod cemented into the hole and labeled with the basic drill hole information. All drill core was assayed for gold and multi-element data for the entirety of their length.

Drill collar locations are plotted on Figures 82-85, and key data for the holes is listed in Table X. Geologic cross sections are presented in Figures 86-104. Geological and sample logs are given in Appendix IX, sampling and analytical procedures data verification and QAQC results are provided in Appendix X, and certificates of analysis are shown in Appendix XI.

Sunrise Zone

The Sunrise Zone occurs within a suite of limestone and dolostone (O-LST1 and O-DST) rocks underlain by a maroon and green to variably grey mudstone (O-MST1) collectively known as the Osiris Stratigraphy. This stratigraphy, which is also host to mineralization at the Osiris Zone, 300 m to the east, is synformally folded at the Sunrise Zone. This folded package of sediments is in fault contact with a dark grey crystalline limestone unit (C-LST2) which is stratigraphically overlain by the grey to maroon variants of the fault repeated O-MST1 unit of the Isis Stratigraphy. A moderately-strong ductile fabric defines the fault zone at Sunrise and is around 5 metres true thickness. Unlike the Osiris Zone where the O-LST1 and O-DST units are easily distinguishable and define a clear stratigraphic marker, at Sunrise intense folding and deformation of the carbonate package makes definition of this contact unachievable.

Gold mineralization at the Sunrise Zone is confined to the carbonates of the undifferentiated O-LST1 and O-DST units and is most commonly controlled by a steeply south dipping corridor that roughly parallels the fault plane. This corridor likely represents an area of increased fluid flow associated with axial planar cleavage development at the axis of the Sunrise synform. Additionally, mineralization at the Sunrise Zone is associated with metre-scale zones of tight folding, which are interpreted as parasitic folds on the limb of the Sunrise synform.

Within the mineralized intervals, drill core shows a darkening in colour to near black, representing the addition of sooty-sulphides. Original bedding textures are faint and at times unrecognisable due in part to decalcification and silicification of the carbonates. Realgar both fills fractures and occurs as disseminations within porous beds within and peripheral to gold mineralized zones.

Conrad Zone

The Conrad Zone consists of a package of carbonates (C-LST1) and overlying siltstones to conglomerates (C-SLC) that are folded into a broad east-west trending doubly plunging anticline. This anticline has been re-folded in the centre causing the eastern and western limbs to curve back towards the north. This poly-deformed rock package is in fault contact with a mudstone unit (C-NONAD) along the steeply north dipping Nadaleen Fault Zone. This fault zone is up to 50 m wide and shows brittle to ductile cataclastic textures of all three rock units imbricated together.

Drilling has defined two areas of significant mineralization known as the Upper and Lower Conrad Zone. In the Upper Conrad Zone, gold mineralization occurs along the stratigraphic contact between C-LST1 and the overlying C-SLC package with the best mineralized areas at the crest of the east and west plunging anticlinal fold. Mineralization at the Lower Conrad Zone occurs within C-LST1 adjacent to the intersection of a relatively flat-lying fault with a near-vertical, east-west trending fracture system.

All mineralized intervals are accompanied by decalcification and deposition of sooty pyrite, giving the mineralized core a darker appearance than unmineralized intervals. This darkening of the core is very subtle to non-recognizable within C-SLC. Realgar is commonly associated with gold bearing zones, existing mainly in veins and fracture fill, but also as disseminations within the mineralized zone. Not all occurrences of realgar have associated gold.

Isis East Zone

The Isis East Zone is hosted in the Isis Carbonate Horizon, a faulted repeat of the Osiris Horizon rocks at Sunrise. The stratigraphy at Isis East is folded into an anticline that plunges steeply to the south becoming overturned at depth. Gold mineralization at Isis East is hosted in both O-LST1 and O-DST units, most commonly controlled along the limestone-dolostone contact with mineralized intervals thickest in the direct vicinity of the anticlinal hinge. Decalcification and silicification are the main alteration features in addition to realgar deposition, all of which are associated with gold mineralized zones.

Isis Zone

The Isis Zone is defined by a broad gold-in-soil anomaly, downslope from the western extension of the Osiris Fault. Holes drilled in previous years have returned anomalous, but non-significant results for gold. Detailed mapping of the Isis area in 2013 suggested the faulted contact between a block of zebra banded dolostone with a package of variably limy siliciclastic rocks may source the mineralized anomaly. Three drill holes targeting this faulted contact were completed in 2013. All three holes encountered extremely rubbly faulted intervals, of which hole OS-13-215 returned the highest grade interval of 1.31 g/t Au over 3.05 m.

DISCUSSION AND CONCLUSIONS

The Rackla Gold Property lies at the boundary between Mackenzie Platform and Selwyn Basin, within geomorphological and geological settings similar to those at the Carlin gold district in northeast Nevada. At the eastern end of the 185 km long Rackla Gold Property, the Nadaleen Trend represents the first discovery of Carlin type gold mineralization in this belt of rocks. Encouraging new Carlin type mineralization encountered along the Nadaleen Trend during the 2013 exploration season promote continued exploration of the property and across the district.

Silt and soil sampling, prospecting and pit sampling surveys conducted in 2013 defined six new Carlin-type gold discoveries and three new base metal occurrences. Focused exploration along the structures within the geochemically anomalous trend at Anubis may result in further discoveries of Carlin type gold mineralization. Detailed mapping should be continued around all geochemical anomalies with particular attention paid to the recognition of folds, faults and favourable carbonate strata, as they are the principal controls on the location of mineralization in gold-rich, carbonate-hosted replacement deposits.

Pitting, designed to test the fertility of faults and geochemical anomalies in the Anubis area resulted in the definition of new showings surrounding Anubis. High grade silver-lead mineralization with gold enrichment was discovered at the Corona Zone. Gold and pathfinder mineralization was encountered at the Columba, Draco and Hydra Zones. Further work should extend mineralized pits into trenches, allowing for more detailed observations and sampling. Additionally, the coverage of subsurface sampling via, pitting, trenching and auger sampling should be completed.

Diamond drilling during 2013 focused on the Osiris Area. This drilling refined the controls of mineralization at the Conrad Zone through the definition of the Upper and Lower mineralized zones. Both these mineralized zones remain open along strike and at depth. The Lower Zone in particular needs more drilling to define its limits. Drilling at the Isis East Zone confirmed that mineralization is strongly stratigraphically controlled near the hinge of a south plunging anticlinal structure, but that this anticline is becoming very steep to overturned at depth. Surface work at the Isis Zone suggested a new control to mineralization, but drilling did not return significant gold values. The source of elevated gold-in-soil values at the Isis Zone may not be a feature that contains consistent grade but rather, the anomaly is representative of the absolute value of mineralization. More work is required to determine this.

The mapping, prospecting and pitting in the Anubis area, resulted in new discoveries of not only gold but silver, lead and zinc mineralization that occurs within or proximal to large scale faults. The success of using a systematic approach to evaluate the 12 km^2 pathfinder soil geochemical anomaly defining the Anubis area warrants continuation of this style of follow-up. In addition, carefully targeted drilling would help to evaluate mineral potential of the targets and structures at depth.

It is likely that undiscovered gold occurrences within the Rackla Gold Property occur at depth and may have relatively subdued surface signatures. Further exploration techniques should focus on the coincident presence of favourable indicator elements in soils occurring in association with favourable stratigraphy and structural features which facilitate auriferous fluid transport deposition.

ROCK, SOIL, SILT - SAMPLING AND ANALYTICAL PROCEDURES

2013 Prospecting and Excavator Pit Rock Samples

Rock geochemical sample sites on the property were marked with orange flagging tape labelled with the sample number. The location of each sample was determined using a handheld GPS unit. Rock sample descriptions are presented in Appendix III.

Excavator pit rock samples were collected in where deemed mineralogically or geologically relevant. Excavator pit rock sample descriptions are noted in Appendix VI.

All rock samples were submitted to ALS in Whitehorse, Yukon where they were dried and fine crushed to 70% passing 2 mm. A 250 g split of the crushed material was then pulverized to better than 85% passing 75 microns. Separate splits of the pulverized fraction were analyzed for gold by fire assay and atomic absorption spectroscopy (Au-AA26) and for 49 other elements using a four acid near total digestion technique (ME-MS61m) at ALS in North Vancouver, British Columbia. Mercury was analyzed for using HG-CV41 methods by aqua regia digestion and atomic adsorption spectroscopy.

2013 Soil Samples

Soil sample types ranged from grid samples taken at lines along a constant bearing, to contour and ridge and spur samples targeting constant elevations and high elevations respectively. Soil samples were taken using an auger, targeting `C` horizon soils below organic cover; sample depths ranging from 10-90 cm dependent on local soil development, vegetation and frozen ground conditions. Samples were placed in kraft soil sample bags, and sample sites were flagged and marked with stakes etched with assay tag number, line or point number and grid name. The soil samples were sent to ALS where they were dried and screened to 180 microns. Soils samples were sent for 51 element, aqua regia digestion using ICP-MS and ICP-AES assay analysis (ME-MS41). Gold values in soil samples were determined using a 30 gram nominal sample weight. The analytical process for quantitative determination of gold values was a fire assay fusion with an ICP-AES finish (Au-ICP21).

2013 Silt Samples

Silt samples were taken from in-stream silt-rich sediment or from silty accumulation within the roots of overhanging moss at the creek edge where stream conditions did not allow for sufficient silt build-up. Flagging marked with the assay sample number was used to mark silt sample locations. The stream sediment samples were sent to ALS, where they were dried, screened to 180 microns, dissolved in aqua regia solution and then analyzed for 51 elements using an aqua regia digestion and a combination of ICP-MS and ICP-AES for analysis (ME-MS41). Gold values in silt samples were determined using a 30 gram nominal sample weight. The analytical process for quantitative determination of gold values was a fire assay fusion with an ICP-AES finish (Au-ICP21).
