INTRODUCTION

The Klaza property (the Property) lies within the southern part of the Dawson Range Gold Belt in southwestern Yukon. It hosts gold-silver mineralization associated with an extensive system of subparallel vein and breccia zones, which remains open to extension in all directions and to depth. Copper-molybdenum-gold porphyry mineralization has also been discovered on the Property, but has seen little exploration to date. The Property covers an area of 8,620 hectares (86.20 km²) and is owned by Rockhaven Resources Ltd. (Rockhaven).

From May 31 to September 6, 2014, Rockhaven conducted an exploration program involving VLF-EM and magnetic ground geophysical surveys, 880 m of excavator trenching and 19,242 m of diamond drilling in 104 holes. Archer, Cathro & Associates (1981) Limited (Archer Cathro) managed the exploration program. The work was completed from a tent frame camp on the Property. The authors participated in and supervised the program. Their Statements of Qualifications are located in Appendix I and a Statement of Expenditures is in Appendix II.

PROPERTY LOCATION, CLAIM DATA AND ACCESS

The Property is located in southwestern Yukon at latitude 62°08′ north and longitude 137°17′ west on NTS 115I/3 (Figure 1). It comprises 449 contiguous mineral claims registered with the Whitehorse Mining Recorder in the names of Rockhaven or Archer Cathro, which holds them in trust for Rockhaven. A total of 96 claims (Dic, Eagle, Etzel, VG, VIC, J. Bill#, Jon-Wedge and Bull) are subject to a 1.5% Net Smelter Return (NSR) royalty payable to Janet Dickson of Whitehorse. The other 353 claims are not subject to any underlying royalties. Specifics concerning claim registration are tabulated below, while the locations of individual claims are shown on Figure 2.

* Expiry dates include 2014 work which has been filed for assessment credit but not yet accepted.

The Property is located 50 km due west of Carmacks and can be reached from Whitehorse by driving 180 km north on Highway #2 (the Klondike Highway) to Carmacks, then 60 km west on the two-wheel drive Nansen Road to the site of the former Mount Nansen Mine. The Nansen Road is a gravel road maintained by the Yukon Territorial Government. From the mine site, the road deteriorates in quality but continues approximately 14 km north to placer operations in the Klaza River valley. Rockhaven's camp and the main areas of exploration interest on the Property can be reached by a network of four-wheel drive roads and trails that connect to the Nansen Road. By road, the Property is 250 km from Whitehorse and 420 km from the year-round tidewater port at Skagway, Alaska.

HISTORY

Exploration history was mostly compiled from the Yukon Minfile Database (Deklerk, 2008) and assessment reports submitted to the Whitehorse Mining Recorder. The assessment reports were written prior to the implementation of NI 43-101. Nonetheless, they were consistent with professional standards at the time and were accepted by the mining recorder.

Between 1937 and 2012, several operators worked on various claim groups that now lie within the boundaries of the Property. Although strong geochemical and geophysical anomalies were identified by this work, follow-up trenching and drilling produced sporadic results, in part because of physical and technological limitations (early bulldozer trenches rarely reached bedrock, often because of permafrost, and small diameter drill holes typically gave poor core recoveries, especially in the more fractured, mineralized intervals). Table 1 summarizes historical exploration and lists the year of work, owner/operator, claim group name, work performed and highlight results for each exploration program (Tarswell and Turner, 2014).

Table 1 - Exploration History

Year of Work (Report)	Owner/ Operator	Claim Group	Work Performed	Results
1937 (none)	K. Paulson	n/a	Prospecting.	Rumour of high-grade silver-lead float (Eaton, 1986).
1948	G. Dickson	n/a	Bulldozer trenching.	n/a (Eaton, 1986).
1967 (none)	J. Smith	May	Soil sampling and bulldozer trenching.	Anomalous silver and lead soil geochemistry, but no vein was intersected by trenching (Campbell and Guardia, 1969).
1968 (Parker, 1968)	Esansee Explorations Limited	May	Geochemical and geophysical surveys and bulldozer trenching.	Peak soil values were 8,200 ppm lead, 125 ppm silver and 800 ppm arsenic. Specimen samples of "fissure" vein cut in a bulldozer trench returned peak values of 34.3 g/t gold, 2,057.1 g/t silver, 44% lead and less than 1% zinc.
1969 (Campbell and Guardia, 1969)	Esansee Explorations Limited	May	Bulldozer trenching and road building.	A chip sample returned 15.09 g/t gold and 483 g/t silver over 1.83 m. A 14 km road (considered an extension of the Mount Nansen Mine road) was built from the Mount Nansen Mine campsite to the May claims.
1973 (Dickinson and Lewis, 1973)	Area Exploration Company	Betty, Bun and Crow	Percussion (283.5 m) and diamond (776.1 m) drilling.	Two percussion drill holes (283.5 m) and three diamond drill holes (776.1 m) were completed to test a 700 by 900 m copper-in-soil geochemical anomaly.

The best interval from diamond drilling returned 8.64 g/t gold and 25.68 g/t silver over 6.0 m including 24.5 g/t gold and 50.1 g/t silver over 1.5 m (80-6).
1981 (Brownlee, 1981)	BRX Mining & Petroleum Corp.	Tawa	Electromagnetic and proton magnetometer surveys.	Both surveys highlighted coincident, northwesterly trending anomalies.
1985 (Aho et al., 1975)	Kerr Addison Mines Limited	Dic	Geological, geochemical and geophysical surveys.	A total of 216 soil and 45 rock samples were collected for analysis and 4.0 line kilometres of magnetic and 2.8 line kilometres of VLF-EM surveys were conducted.
1986 (Eaton, 1986)	Chevron Minerals Limited	Tawa	Mapping, prospecting, bulldozer trenching and an electromagnetic survey.	Deepening historical trenches returned 5.28 g/t gold and 132.0 g/t silver over 2 m. Geophysical and geochemical anomalies extended to 1,900 and 2,000 m, respectively.
1986 (McClintock, 1986)	Pearl Resources Ltd.	Etzel	Geological mapping and geochemical sampling	Geochemical sampling returning gold-in-soil values up to 310 ppb and silver-in-soil values up to 54.5 ppm. The best chip sample returned 0.99 g/t gold over 1 m.
1987 (Eaton and Walls, 1987)	Chevron Minerals Limited	Tawa	Road building, bulldozer trenching and claim staking.	Trench T-11 at the Klaza Zone returned 4.22 g/t gold and 47.3 g/t silver over 8.0 m including 4.27 g/t gold and 86.7 g/t silver over 1.0 m. Trenching at the BRX Zone intersected 3.12 g/t gold and 46.3 g/t silver over 7.0 m including 6.99 g/t gold and 41.1 g/t silver over 1.5 m (T-14) and 6.86 g/t gold and 160.1 g/t silver over 2.5 m (T-16).

1988 (Eaton and Walls, 1988)	Chevron Minerals Limited	Tawa	Excavator trenching (1924 m) and six diamond drill holes (377 m).	Trenching exposed a vein in T-22 that returned 16.3 g/t gold and 1,289.1 g/t silver over 1.7 m. A drill hole testing the down-dip continuity of this interval returned 6.03 g/t gold and 129.9 g/t silver over 1.36 m (Hole 88-6).
1988 (Sutherland, 1988)	Chesbar Resources Inc.	Dic	Stream sediment sampling, prospecting and trenching.	Silt sampling returned values up to 1050 ppb gold, while 75% of values were less than 10 ppb gold. Prospecting yielded a peak value of 220 ppb gold. Historical trenches (7.8 km) were deepened, but hindered by frozen ground.
1989 (Eaton, 1989)	BYG Natural Resources Inc. and Chevron Minerals Ltd.	Tawa	Road construction and excavator trenching (580 m).	n/a
1996 (Dujakovic et al., 1996)	BYG Natural Resources Inc.	Tawa, KR and Dic	Very low frequency electromagnetic, magnetic and geochemical surveys.	Northwesterly trending VLF-EM and magnetic anomalies and soil geochemical values up to 1,825 ppb gold and 1,049 ppm copper.
1999 (Stroshein, 1999)	BYG Natural Resources Inc.	Gerald and Tawa	Overburden stripping and diamond drilling (307.8 m in 3 holes).	Klaza Zone drilling returned 3.82 g/t gold and 84.7 g/t silver over 5.05 m (TA-98-8). BRX Zone drilling returned 0.24 g/t gold and 1.3 g/t silver over 55.75 m (TA-98-9).
2003 (Stroshein, 2004)	Aurchem Exploration Ltd.	Etzel	Excavator trenching	The best trench result was from a clay-rich zone that graded 6.05 g/t gold and 15.3 g/t silver over 6.0 m.

2010 (Turner and Tarswell, 2011)	Rockhaven Resources Ltd.	Klaza	Claim staking, geophysical surveying, diamond drilling, excavator trenching and soil geochemical sampling.	Best drill intercept returned 3.23 g/t gold and 117.7 g/t silver over 36.50 m. Several additional coincident geochemical and geophysical anomalies were identified. Peak soil geochemical values were 856 ppb gold, 5.8 ppm silver, 494 ppm lead and 349 ppm arsenic.
2011 (Tarswell and Turner, 2012)	Rockhaven Resources Ltd.	Klaza	Geophysical surveying, diamond and reverse circulation drilling, excavator trenching, soil geochemical sampling and air photo surveys.	Best drill intercept returned 5.43 g/t gold and 50 g/t silver over 14.80 m. Peak soil geochemical values were 320 ppb gold, 61.3 ppm silver, 606 ppm lead and 213 ppm arsenic.
2011 (Great Bear Resource, 2012a)	Great Bear Resources Ltd.	Etzel	Diamond drilling, excavator trenching and soil geochemical sampling.	Best drill intercept returned 0.58 g/t gold and 2.4 g/t silver over 40.65 m.
2012 (Great Bear Resource, 2012b)	Great Bear Resources Ltd.	Etzel	Diamond drilling, and soil geochemical sampling.	Best drill intercept returned 2.30 g/t gold and 7.0 g/t silver over 1.16 m.

The main exploration programs and results are described in more detail in the following paragraphs. All work was done in the eastern third of the Property.

In 1968, Esansee Explorations Limited (Esansee) completed geophysical and geochemical surveys on approximately 5,000 m of grid lines. An electromagnetic (EM) survey identified three conductive zones (two major and one minor). Bulldozer trenching across one of these zones reportedly cut a 6 m wide gold-silver-lead bearing fissure vein, which was traced for 760 m. Specimen samples from this vein reportedly returned up to 34.3 g/t gold, 2,057 g/t silver and 44% lead, with less than 1% zinc. Three hundred and fifteen grid soil samples were collected. Soil sample results included peak values of 8,200 ppm lead, 125 ppm silver and 800 ppm arsenic, and showed strong positive correlation with conductive zones (Parker, 1968).

In 1969, Esansee performed trenching to follow up geophysical and geochemical anomalies identified by its earlier program. Three bulldozer cuts were made along the 760 m strike of the vein, and a fourth trench was dug on a weaker parallel structure to the northeast. All trenches across the primary structure intersected wide zones of shearing and alteration, which host irregular and discontinuous vein material with weakly disseminated galena, pyrite and arsenopyrite. Oxidation of sulphide minerals produced limonite, cerussite and anglesite. A chip sample collected from the most northwesterly trench returned 15.09 g/t gold and 483 g/t silver over 1.83 m (Campbell and Guardia, 1969). All claims in the area lapsed following this work.

Between 1971 and 1973, Area Exploration Company (Area Exploration) conducted an extensive program of percussion and diamond drilling on claims belonging to Mount Nansen Mines Ltd. Most of Area Exploration's drilling was done on a porphyry copper target (Cyprus Zone) centred about 1.5 km east of the Property. Two of its percussion drill holes (283.5 m) and three of its diamond drill holes (776.1 m) lie in Kelly Zone within the southeastern part of the Property. These holes partially tested a 700 by 900 m copper-in-soil geochemical anomaly that coincides with a magnetic low (Dickinson and Jilson, 1973). The best result from diamond drilling within the Kelly Zone was 0.10% copper over 6.10 m (1973-CD-17), while the best percussion drilling result was 0.343 g/t gold, 9.94 g/t silver, 0.02% copper and 0.01% lead over 6.10 m (1971-CP-8).

In 1980, BRX Mining and Petroleum Corp. (BRX) staked the Tawa claims to cover the area where Esansee performed its work in the late 1960s. Work done in 1980 included geochemical sampling, bulldozer trenching and seven diamond drill holes (447.3 m). Soil sampling identified linear, northwesterly trending geochemical anomalies with very high values locally. The anomalous geochemical values were not always coincident with electromagnetic anomalies identified earlier by Esansee. The bulldozer trenching program involved re-opening Esansee's trenches. The main mineralized structure exposed in the trenches reportedly strikes 110 to 140° and dips steeply to the northeast. Chip sample values across vein exposures typically ranged from 1.78 g/t gold and 77.8 g/t silver over 0.06 m to 6.0 g/t gold and 54.2 g/t silver over 0.91 m, with the best interval returning 33.0 g/t gold and 607.5 g/t silver over 0.3 m (Saunders, 1980).

Three of the drill holes were collared subparallel to the veins and did not encounter significant mineralization. The other four diamond drill holes intersected fault and vein zones within granitic country rock. Highlight intervals from this drilling were: 8.64 g/t gold and 25.68 g/t silver over 6.0 m including 24.5 g/t gold and 50.1 g/t silver over 1.5 m (80-6); 18.86 g/t gold and 32.0 g/t silver over 0.3 m (80-2); and, 9.26 g/t gold and 65.1 g/t silver over 0.4 m (80-5). Core recovery was poor within areas of strong alteration and gouge, associated with the faults and veins.

In 1981, BRX conducted EM and proton magnetometer surveys on the Tawa claims. The EM survey identified a series of en-echelon, northwesterly trending conductors, while the proton magnetometer survey delineated magnetic anomalies that correlate with the EM conductors (Brownlee, 1981).

In 1985, Kerr Addison Mines Limited (Kerr Addison) staked the Dic 1-50 claims to cover an arsenic and antimony stream geochemical anomaly on the north side of Mount Nansen, south southwest of the Tawa claims. Kerr Addison performed geological, geochemical and geophysical surveys on the Dic claims. A total of 216 soil and 45 rock samples were collected for analysis and 4.0 line kilometres of magnetic and 2.8 line kilometres of VLF-EM surveys were conducted. The best rock sample returned 0.48 g/t gold, 88 g/t silver, 1,600 ppm arsenic and 180 ppm antimony, while soil values peaked at 400 ppb gold, 27 ppm silver, 2,000 ppm arsenic and 46 ppm antimony (Heberlein, 1985).

In 1986, Pearl Resources Ltd. performed geological mapping and geochemical sampling on the Etzel claims. Results from soil samples collected on three separate grids identified linear, northwesterly trending anomalies with maximum values of 310 ppb gold, 54.5 ppm silver, 1,980 ppm lead and 1,160 ppm zinc. A chip sample across a 1.0 m sheared vein zone returned 0.99 g/t gold (McClintock, 1986).

In 1986, Chevron Minerals Ltd. (Chevron) optioned the Tawa claims from BRX. Chevron performed geological mapping, prospecting, grid soil geochemical sampling and EM surveys before staking additional claims to cover extensions of anomalous trends. A 43.2 line kilometre EM survey was conducted and the strike lengths of known EM conductors were extended to 1,900 m. Soil sampling outlined numerous northwesterly trending clusters of anomalous gold values that ranged to a maximum of 6,258 ppb. Individual clusters are continuous for lengths up to 2,000 m. Almost 5,000 m of pre-stripping were done using a bulldozer because permafrost hindered trenching in frozen soil (Eaton, 1986). Where previously stripped trenches were deepened to bedrock, chip samples returned numerous high values including: 5.55 g/t gold and 31.2 g/t silver over 1.4 m (T-4); 3.5 g/t gold and 15.1 g/t silver over 4 m (T-4); and, 5.28 g/t gold and 132.0 g/t silver over 2 m (T-4). Trenching on virgin ground was less successful due to permafrost; however, two significant bedrock intercepts were exposed: 5.28 g/t gold and 242.4 g/t silver over 2.5 m (T-6/7) and 2.33 g/t gold and 3.77 g/t silver over 5.0 m (T-8).

In 1986, Kerr Addison added the Dic 51 to 63 claims to its claim block and conducted line cutting, ground geophysics, soil sampling and prospecting. Results from this work were encouraging and in 1987, Kerr Addison granted Chesbar Resources Inc. (Chesbar) the right to

earn an interest in the Dic claims by contributing to exploration expenditures. Work in 1987 involved pre-stripping trenches of moss and the upper soil layer (Sutherland, 1988).

In 1987, Chevron continued its exploration at the Tawa claims with pre-stripping, bulldozer trenching, road construction and claim staking. The pre-stripping and trenching program comprised 28 trenches totalling 6,385 m, of which 12 trenches totalling 1,939 m were wholly or partially excavated to bedrock. Continuous chip samples collected over 1 to 5 m intervals from trench ribs returned positive results from the Klaza and BRX zones (Walls and Eaton, 1987). The most significant result from the Klaza Zone was 4.22 g/t gold and 47.3 g/t silver over 8.0 m (T-11). The best results from the BRX Zone were 3.12 g/t gold and 46.3 g/t silver over 7.0 m including 6.99 g/t gold and 41.1 g/t silver over 1.5 m (T-14), and 6.86 g/t gold and 160.1 g/t silver over 2.5 m (T-16). Parallel vein structures were identified north and south of the two main zones. The best result from a new structure was 6.82 g/t gold and 17.1 g/t silver over 1 m (T-15). A 1.7 km four-by-four trail was constructed from the Nansen Road to the trenching area on the Tawa claims.

In 1988, Chevron sub-optioned the Tawa claims to BYG Natural Resources Inc. (BYG), under an agreement that allowed BYG to earn an interest in the claims by funding the next phase of exploration, which consisted of road building, pre-stripping, excavator trenching, and six diamond drill holes (377 m). All of the drilling in 1988 was done at the BRX Zone, while the trenching was split between the BRX and Klaza zones (Walls and Eaton, 1988). Results from trenching better defined the known veins and identified a third vein (BYG Zone) approximately half-way between them. The best assay from the BRX Zone was 16.3 g/t gold and 1,289.1 g/t silver over 1.7 m (T-22). The Klaza Zone was delineated over a strike length of 250 m with the best trench exposures grading 43.06 g/t gold and 102 g/t silver over 1.1 m and 4.22 g/t gold and 92 g/t silver over 8.0 m. One trench tested the BYG Zone and it cut three veins about 40 m apart. One of these veins returned 6.03 g/t gold and 24.0 g/t silver over 3.3 m (T-25). Drilling intersected numerous veins that were variably mineralized. The best drill result was 6.03 g/t gold and 129.9 g/t silver over 1.36 m (Hole 88-6), which is down-dip of the vein exposed in T-22 (16.3 g/t gold and 1,289.1 g/t silver over 1.7 m).

In 1988, Chesbar conducted stream sediment sampling, prospecting and excavator trenching on the Dic claims. Forty-four silt samples were collected at 100 m intervals along subparallel drainages. Gold values from this sampling were generally less than 10 ppb, but anomalous values up to 1,050 ppb were reported. Rock geochemical values were background to weakly elevated, with a peak of 220 ppb gold. Although 7.8 km of trenches were pre-stripped, unseasonably high precipitation resulted in less than 20 cm of overburden being removed from each of them (Sutherland, 1988).

BYG's 1989 work program on the Tawa claims comprised road building and three excavator trenches totalling 580 m. Due to frozen ground, none of these trenches reached bedrock (Eaton, 1989).

In 1996, BYG conducted geochemical sampling and VLF-EM and magnetic surveys on the Tawa claims and KR claims, located to the west. The magnetic survey identified northwest-trending linear magnetic highs and lows, which merge to the east into a large magnetic high.

The magnetic lows appear to be related to geological structures or contacts (Dujakovic et al., 1996). The VLF-EM survey delineated three major structures offset by northerly striking faults. In general, the VLF-EM highs and magnetic lows coincide. Four soil grids were sampled. The strongest coincident gold and copper soil geochemical values were obtained along the eastern side of the Tawa claims where peak values were 1,825 ppb gold and 1,049 ppm copper, respectively.

In 1998, BYG performed an exploration program at the Tawa claims that included stripping of overburden from the surface trace of VLF-EM and magnetic anomalies and three diamond drill holes (307.8 m). Two holes (TA-98-7 and 98-8) targeted the Klaza Zone, while the third hole (TA-98-9) tested the BYG Zone. Hole TA-98-7 intersected a weakly altered porphyry dyke with widespread potassic alteration that graded up to 0.9 g/t gold. Hole TA-98-8 intersected an altered porphyry dyke with high-grade gold-silver veins in its footwall. Samples of vein, dyke and breccia averaged 3.82 g/t gold and 84.7 g/t silver over 5.05 m, including a high-grade vein sample that returned 17.1 g/t gold and 159.2 g/t silver over 1.05 m (Stroshein, 1999). Hole TA-98-9 intersected a quartz-sulphide stockwork that averaged 0.24 g/t gold and 1.3 g/t silver over 55.75 m. Subsequent to the 1998 drill program, BYG filed for bankruptcy and all of its claims went into receivership.

In 2003, Aurchem Exploration Ltd. (Aurchem) performed limited excavator trenching on the Etzel claims that now lie in the southeastern part of the Property. These trenches tested altered granodiorite, feldspar porphyry dykes and shear zones. The best results were 1.0 g/t gold and 58 g/t silver over 2.5 m (T-2) and 6.05 g/t gold and 15.3 g/t silver across 6.0 m (T-4). A 21.5 m wide, northwesterly trending clay-rich zone returned 0.85 g/t gold and 4.5 g/t silver over 12.0 m (Stroshein, 2004).

In 2005, ATAC Resources Ltd. (ATAC) staked the Klaza 1-24 claims, which cover much of the old Tawa claim block and form the core of the Property. ATAC subsequently optioned the claims to Bannockburn Resources Limited (Bannockburn).

In 2006, Bannockburn performed line cutting and IP surveying on the Klaza claims. A 1,450 by 1,800 m area was surveyed in the eastern parts of the Klaza and BRX zones. The survey identified two chargeability highs with coincident resistivity lows (Wengzynowski, 2006). In 2008, Bannockburn relinquished its option.
In 2009, Rockhaven purchased the Klaza claims from ATAC.

In 2010, Rockhaven staked additional claims and performed approximately 8,000 m of trenching in 21 trenches, 1,642.08 m of diamond drilling in 11 holes, 326 line kilometres of helicopter-borne geophysical surveys and soil sampling (289 samples) (Turner and Tarswell, 2011). Results from this exploration are discussed in subsequent sections.

In 2011, Rockhaven performed 14,068.45 m of diamond drilling in 52 holes, 2,940 m of reverse circulation percussion drilling in 21 holes, 4,050 m of excavator trenching in 12 trenches, soil geochemical sampling (2,798 samples), petrographic studies and road building (Tarswell and Turner, 2012). Results from this exploration are discussed in subsequent sections.

In June 2011, Ansell Capital Corp. (Ansell) purchased the Etzel claims from Aurchem and then optioned them to Great Bear Resources Ltd. (Great Bear). In 2011, Great Bear completed three diamond drill holes (696.17 m), four excavator trenches (255.70 m) and grid soil sampling (478 samples). Drilling identified multiple narrow, mineralized zones hosted within fresh to strongly limonite altered granodiorite. The best interval returned 1.94 g/t gold and 11.85 g/t silver over 2.60 m (ET-11-01). Trenching yielded a peak result of 2.80 g/t gold and 5.8 g/t silver over 10.4 m (Dadson and Amy, 2012). Great Bear followed up with a three hole diamond drill program (930.25 m) in 2012 to test for the eastern extension of the Klaza Zone. The best result was from ET-2012-06, which returned 1.79 g/t gold, 50.0 g/t silver and 1.409% copper over 1.62 m (Great Bear Resources Ltd, 2012). Great Bear subsequently relinquished its option.

In fall 2011, Rockhaven purchased the Dic and Eagle claims from Aurchem. These claims adjoin the Klaza claims and are the southernmost claims on the Property.

In 2012, Rockhaven purchased the Etzel claims from Ansell and the VG, VIC, J. Bill#, D, Bull, JBF and Jon-Wedge claims from Aurchem. These claims now form the eastern edge of the Property.

From May to September 2012, Rockhaven conducted an exploration program involving: i) 21,719.47 m of diamond drilling; ii) 3,964 m of excavator trenching; and, iii) soil geochemical sampling (Tarswell and Turner, 2013). Results from this exploration are discussed in subsequent sections.

In 2013, Rockhaven completed 5,000 m of excavator trenching in 38 trenches. Highlights from the 2013 trenches include 5.61 g/t gold and 300 g/t silver over 18.79 m in TR-13-51 and 16.20 g/t gold and 158 g/t silver over 6.84 m in TR-13-52.

There have been no historical mineral resource estimates for any mineralized zones on the Property. No lode production has been publically documented on the Property, nor is there any historical evidence of this type of development.

Intermittent placer mining has been documented since 1985 within the headwaters of the Klaza River, immediately northwest of the height of land where the main areas of interest on the Property are located. The closest placer operation is located about 300 m west of the current mineral resource, as shown on Figure 3.

GEOMORPHOLOGY

The Property is situated in the southern part of the Dawson Range, a belt of low mountains, hills and relatively mature river systems. The Property is drained by tributaries of the Klaza River and Nansen Creek, both of which flow into the Nisling River, part of the Yukon River watershed.

The eastern part of the Property covers a broad rounded northwesterly elongated ridge that lies between Mount Nansen and the Klaza River. The rest of the Property is characterized by low hills and valley bottom, flanking the Klaza River. The main areas of interest lie along the

northwesterly elongated ridge in the eastern part of the Property. Elevations on the Property range between 1,200 and 1,500 m above sea level (asl). Tree line is at 1,200 m asl on north-facing slopes and about 1,400 m asl on south facing slopes. Areas above treeline are vegetated with low-lying grass, moss and sparse brush. The density and size of vegetation gradually increases toward lower slopes and valley bottoms, where stunted spruce are surrounded by an understory of dwarf birch and a thick layer of sphagnum moss.

The Klaza area escaped Pleistocene continental glaciation but experienced some local Pleistocene to Holocene valley and alpine glaciation. Outcrop is nonexistent across most of the Property and overburden typically consists of a few centimetres of organics, 0 to 5 cm of volcanic ash and up to 200 cm of loess and immature soil mixed with locally derived rock fragments, over weathered bedrock. At lower elevations, thick layers of fluvial material, glacio-fluvial outwash and till blanket the valley floors. Permafrost is extensive, particularly on north- and west-facing slopes.

The area has a continental climate with low levels of precipitation and a wide temperature range. Summers are normally pleasant with extended daylight hours whereas winters are long and cold. Although summers are relatively warm, snowfall can occur in any month at higher elevations. The Property is mostly snow free from late May to late September. According to Environment Canada, summer temperatures in the nearest community of Carmacks average 18 ºC during the day and 5 ºC at night. Winter temperatures average -12 ºC during the daytime. Total annual precipitation over the 1961 to 1990 period averaged 277 mm, with about 92 cm of snow (Environment Canada, 2015).

GEOLOGICAL SETTING

The area underlain by the Property was visited by J.B. Tyrrell and D.D. Cairnes for the Geological Survey of Canada in 1898 and 1914, respectively, and has been mapped by H.S. Bostock (1936), D.J. Tempelman-Kluit (1974 and 1984) and G.G. Carlson (1987). The geology was revised in a compilation by Gordey and Makepeace (2000). The following discussion is primarily based on maps prepared by Gordey and Makepeace and the Yukon Geological Survey (YGS) website.

The Property lies within the Yukon-Tanana Terrane (YTT) approximately 100 km southwest of the Tintina Fault and 100 km northeast of the Denali Fault (Figure 4). YTT comprises a variety of Proterozoic and Paleozoic metavolcanic, metasedimentary and metaplutonic rocks, and represents both arc and back-arc environments (Colpron et al., 2006; Piercey et al., 2006). The Tintina Fault is a transcurrent structure that experienced about 450 km of dextral strike-slip movement during the Eocene. This movement offset an outlier of YTT in the Finlayson Lake District of southeastern Yukon from the main body of YTT, which lies southwest of the fault. The Denali Fault is another major transcurrent structure that has seen hundreds of kilometres of dextral strike-slip movement.

Regional stratigraphy in the area of the Property is summarized in Table 2. The basement rocks are mainly schists and gneisses, which include metaplutonic gneisses (Pelly Gneiss), metasedimentary and metavolcanic rocks (Nisling) and enigmatic ultramafic and mafic units (Amphibolite). Basement rocks are cut by weakly foliated plutonic rocks (Long Lake Suite) that

The youngest rocks are unfoliated and are represented by five plutonic/volcanic events that occurred in the Cretaceous and Tertiary (Whitehorse Suite, Mount Nansen, Prospector Mountain Suite, Carmacks and a newly identified, unnamed porphyry dating between 72 to 79 Ma) (Sanchez et al., 2014). The unnamed porphyry suite is of particular significance as it has been shown to be associated with most of the major copper porphyry deposits in the Yukon. Revenue, Nucleus Cash, Casino and Taurus have all been redefined as 72 to 79 Ma in age.

PROPERTY GEOLOGY

Detailed mapping on the Property has been limited by sparse outcrop exposure and extensive vegetation cover. Cursory mapping has been done on the flank of Mount Nansen and from frost boils in the Klaza River valley (Aho et al., 1975). The geology map shown on Figure 5 has been interpreted from regional mapping, trenching, drilling and magnetic data, mostly collected over the past five exploration seasons.

The oldest exposed unit is a pluton of the Early Jurassic Long Lake Suite, which outcrops in the northeast corner on the Property. Most of the Property is underlain by Mid-Cretaceous Whitehorse Suite granodiorite. This granodiorite contains 30% hornblende and biotite. It is coarse-grained and non-foliated.

A moderate size quartz-rich granite to quartz monzonite stock (LKqp) intrudes granodiorite in the southeast corner of the Property and is thought to be the main heat source for hydrothermal cells responsible for mineralization. This pluton and feldspar porphyry dykes (LKqp) related to it are now considered by YGS to be part of an unnamed intrusive suite, that is younger than the Mount Nansen suite but older than Prospector Mountain Suite (S. Isreal, personal communication). Geochronological interpretation is ongoing and results are expected to be published in the coming months.

A series of northwesterly trending feldspar porphyry dykes (LKqp) emanating from the stock in the southeastern part of the Property cut the Whitehorse Suite granodiorite in the main areas of interest. These porphyry dykes are up to 30 m wide and consist of buff aphanitic groundmass containing up to 15% orthoclase phenocrysts (1 to 2 mm) with minor biotite and rare quartz

phenocrysts. Commonly the dykes occupy the same structural zones as the mineralized veins, and they are often strongly fractured. Some veins cross-cut dykes.

Sub-aerial volcanic and volcaniclastic rocks belonging to the Mount Nansen and Carmacks volcanics are found on the periphery of the Property. They include medium green to grey andesite flows and pyroclastic rocks with occasional buff to tan rhyolitic tuff. These rocks are believed to be extrusive equivalents of the mid and late Cretaceous intrusions, respectively.

Two main fault trends (NW and NE) are present on the Property. The first set strikes northwesterly and dips between 60 and 80° to the southwest. Although these faults lack strong topographic expression, they are very important because they host mineralized veins and breccia zones and appear to control the distribution of porphyry dykes. The second set of faults strike northeasterly, almost perpendicular to the primary set, and dip sub-vertically. They form prominent topographic linears and offset the mineralized zones in a number places, creating apparent left lateral displacements of up to 80 m in magnitude. The exact relationship between these structures and the mineralized northwesterly trending structures is still uncertain, but they appear to have been in part coeval and may have played an important role in ground preparation.

A third set of structures are slightly oblique to the main mineralized faults, striking more westerly. They are less continuous and are considered to be Riedel shears. High-grade mineralization is sometimes localized at junctions between these shears and the northwesterly trending structures.

MINERALIZATION

General

The Property lies within the northern part of the Mount Nansen Gold Camp (MNGC), a northwest trending structural belt that hosts more than 30 known mineral occurrences (Figure 6), several of which are categorized as deposits and have produced historically and as recent as 1999 (Hart and Langdon, 1997).

Mineralization within the MNGC is dominated by gold-silver rich structures associated with a zonation model ranging from weak porphyry copper-molybdenum centres, outward to transitional anastomosing sheeted veins, and lastly to more cohesive and continuous base and precious metal veins. The age of the mineralizing events within the MNGC is now interpreted to be Late Cretaceous.

The hydrothermal system interpreted to have deposited mineralization at the Property is centred on two porphyry centres (Cyprus and Kelly zones) related to Late Cretaceous plutonism. Mineralized zones identified on and adjacent to the Property, and the generalized metal zonation model are shown on Figure 7. The larger and better defined porphyry centre (Cyprus Zone) lies southeast of the Property. It was explored in the late 1960s and early 1970s with approximately 4,500 m of drilling in 26 holes. Average hypogene grades of 0.12% copper and 0.01% molybdenum were reported at depths exceeding 60 to 90 m below surface. Hypogene copper grades are approximately double those in the overlying leached cap. There is no significant

supergene enrichment zone. Locally higher grade zones (0.6% copper and 0.06% molybdenum) and elevated precious metal values are associated with intensive fracturing (Sawyer and Dickinson, 1976). These metal enriched zones are found in weakly potassic altered areas within the dominantly phyllic altered porphyry system. The potassic altered areas often feature tourmaline breccias, abundant quartz veining and/or secondary biotite.

The western porphyry centre (Kelly Zone) is located on the Property and was explored as early as 1973. The Kelly Zone is defined by coincident geochemical and geophysical anomalies, including: 1) strongly elevated gold, copper and molybdenum soil geochemical response; 2) high chargeabilities with moderate resistivities; and, 3) a large area of low magnetic susceptibility observed in both ground and airborne surveys. The coincident anomalies cover a semicircular area approximately 2,500 m across. Trenching and diamond drilling done in 2012 by Rockhaven on the western edge of the Kelly Zone, discovered minor chalcopyrite, chalcocite and molybdenum, with rare bornite. The mineralization is hosted in several, 25 to 100 m wide bands of strongly phyllic altered and heavily quartz veined granodiorite, which are separated by barren porphyry dykes.

Structurally controlled gold-silver mineralization on the Property is interpreted to be related to the hydrothermal system that is cored by the Cyprus and Kelly zones. Re-Os dating of the Cyprus Zone has established Late Cretaceous age for the pluton and the associated mineralization (Mortensen et al., 2003).

The majority of Rockhaven's exploration activities have been conducted in the distal part of the local hydrothermal system where copper-deficient precious metal-rich veins predominate. This work has identified nine main mineralized structural zones that are developed northwest of the porphyry targets. The structural zones collectively from a 2 km wide corridor that cuts northwesterly through Mid-Cretaceous granodiorite country rocks. Individual zones exhibit exceptional lateral and down-dip continuity, and all of them remain open for extension along strike and to depth. From south to north, the zones are named Chevron, Dickson, AEX, BRX, Pika, Herc, BYG, Klaza and Pearl. Rockhaven's exploration has focused mainly on the Klaza and BRX zones, which have been subdivided into the Western BRX, Central BRX, Western Klaza and Central Klaza zones. The current mineral resource estimate contains mineralization from parts of these four sub-zones.

The main mineralized structural zones range from 1 to 100 m wide and are usually associated with feldspar porphyry dykes. Mineralization occurs within veins, sheeted veinlets and some tabular breccia bodies. The host granodiorite exhibits pervasive weak argillic alteration immediately adjacent to and up to 30 m peripherally to them. Sericitization and potassic alteration are developed directly adjacent to hydrothermal channel ways. The granodiorite is magnetite-bearing except where it is destroyed around mineralized structures. Details of the alteration facies proximal to the structural zones are discussed later in this Section.

Depth of surface oxidation ranges from 5 to 100 m below surface, depending on fracture intensity, the type of mineralization and local geomorphology. The deepest weathering occurs in wide, pyritic veins located along ridge tops or on south facing slopes.

Detailed evaluation of oriented drill core and measurements taken from trench exposures has identified two main structural orientations that control mineralization. The primary structural set strikes between 135˚ and 155˚ and dips 60˚ to 80˚ to the southwest. The secondary mineralized trend strikes between 110˚ and 130˚ and dips 60˚ to 70˚ to the south. The secondary structures may represent either Riedel shears of the primary structural set or a separate structural event altogether. The best gold mineralization is sometimes localized in areas where the two structural trends converge. The plunge of these structural intersections is towards the southeast.

Petrographic analysis completed in 2011 by John Payne, Ph.D., P.Geo. of Vancouver Petrographics reported veins, veinlets and breccia material hosting disseminated to semi-massive pyrite, arsenopyrite, galena, sphalerite, stibnite and jamesonite in quartz, carbonate and barite gangue (Payne, 2012). The sulphide minerals typically comprise 1 to 10% of the sample, often increasing to between 20 and 80% over 25 to 200 cm intervals. The petrographic work also identified native gold/electrum (Tarswell and Turner, 2012).

Quartz is the dominant gangue mineral in veins on the Property. It occurs in a variety of textures including chalcedonic, comb, banded, speckled and vuggy. Smoky quartz is the most common colour variation, but milky and clear quartz are locally abundant. Carbonate occurs mainly as ankerite and rhodochrosite and typically ranges between 5 and 20% of the veins by volume.

Breccias form tabular bodies consisting of heterolithic wallrock clasts, which include granodiorite and various volcanic or sub-volcanic lithologies. Matrices are enriched with fine-grained, disseminated to blebby pyrite, arsenopyrite, sphalerite and galena. Breccias are mostly observed within drill core from the Klaza Zone where they range up to 2 m in width.

Mineralization within most structures is interpreted to be spatially and genetically related to porphyry dykes, which strike northwesterly and dip steeply to moderately toward the south. The dykes pinch and swell in three dimensions and are usually unmineralized. Some movement on the related faults likely post-dates emplacement of the dykes as they are occasionally cut by mineralized veins.

Two parallel, northeast trending faults have been observed to cut across the northwestern portion of the Klaza and BRX zones. The easterly cross-fault appears to offset the western sections of the mineralized zones about 80 m to the south; however, the exact sense of motion is uncertain. Detailed exploration has not been conducted yet on the western side of the westerly cross-fault, so displacement on it has not been determined. The westerly cross-fault appears to be a stronger structure. The relative timing of movement on these faults has not yet been determined, but they are thought to be coeval to, or slightly younger than, the vein structures. Some of the better mineralized sections of the vein structures occur in what appear to be dilatant zones immediately east of the cross-faults. Drill holes and trenches are aligned subparallel to the orientation of the cross-faults – therefore only a few holes have intersected them. The extent to which the northeast trending faults are mineralized is not yet known. In the Klaza Zone, the easterly cross-fault marks a sharp change in mineralogy with increasing arsenopyrite and sulphosalt contents coupled with higher silver:gold ratios in the Western Klaza Zone relative to the Central Klaza Zone. At the BRX Zone, the same cross-fault separates bonanza-grade rhodochrosite-facies

mineralization in the Western BRX Zone from lower-grade, iron-carbonate facies mineralization in the Central BRX Zone.

Mineralization Paragenesis

Interpretation of vein paragenesis is based on observations made from drill intersections at the Western BRX, Central BRX, Western Klaza and Central Klaza zones. The general sequence of mineralizing events for the veins is postulated as follows:

Phase I:	Early barren quartz veining associated with brecciation and alteration (phyllic and argillic) of the host granodiorite.
Phase II:	Smoky quartz veining hosting disseminated to semi-massive pyrite, arsenopyrite, +/- sulphosalt mineralization.
Phase III:	Carbonate veining (calcite, rhodochrosite, ankerite and siderite) accompanied by sphalerite and galena.
Phase IV:	Single to multi-stage brecciation of veins by late hydrothermal fluids.

Mineral assemblages and precious metal abundance associated with the four phases varies based on the spatial relationships of each zone to the primary heat source and the localized structural controls involved in vein emplacement. The following paragraphs describe the paragenetic features observed in the four sub-zones defining the mineral resource.

The Western BRX Zone hosts mineralization styles that appear to be relatively consistent over the entire 500 m strike length and through 520 m of down-dip vertical extent. Mineralizing phases include an initial grey to white quartz phase +/- pyrite followed by a smoky quartz phase hosting pyrite, arsenopyrite and sulphosalts. The first two phases are cut and/or brecciated by ankerite or rhodochrosite that typically host galena and sphalerite. Tetrahedrite and chalcopyrite have also been observed in this phase. A final explosive phase is commonly present, brecciating the sulphide veins, injecting breccia veinlets, and creating micro-fractures. Paragenetic phases observed in drill core from the Western BRX Zone are shown in Plate 1.

KL-14-156 114.20 m

Plate 1: Western BRX Zone intersect highlighting Phases I through IV. Sphalerite and galena are clearly seen in proximity to tan ankerite.

Veins within the Central BRX Zone are mainly dominated by quartz and pyrite with locally abundant galena and sphalerite. These veins host the same mineralizing phases observed in the Western BRX Zone, except that rhodochrosite is not present, arsenopyrite and sulphosalts are less abundant, and gold:silver ratios are generally lower. A typical vein intercept from the Central BRX Zone is shown in Plate 2.

KL-14-197 79.97 m

Plate 2: Central BRX Zone drill core highlighting Phases I through III. Quartz and pyrite generally dominate these veins.

Veins in the Western Klaza Zone generally host the highest grade silver found on the Property. Unlike the other zones, these veins are not spatially associated with feldspar porphyry dykes. Initial alteration of the host granodiorite is a result of the emplacement of early barren grey to white quartz. This is followed by one or two mineralizing events consisting of smoky quartz/sulphide (pyrite +/- arsenopyrite) and smoky quartz hosting high concentrations of pervasive acicular sulphosalt minerals, which is unique to Western Klaza. These two events are typically observed together in the Western Klaza Zone veins but can occur individually. Common late-stage tan ankerite with associated sphalerite and galena fill breccias and fractures cutting earlier quartz phases. Representative vein intercepts from the Western Klaza Zone are shown in Plates 3 and 4.

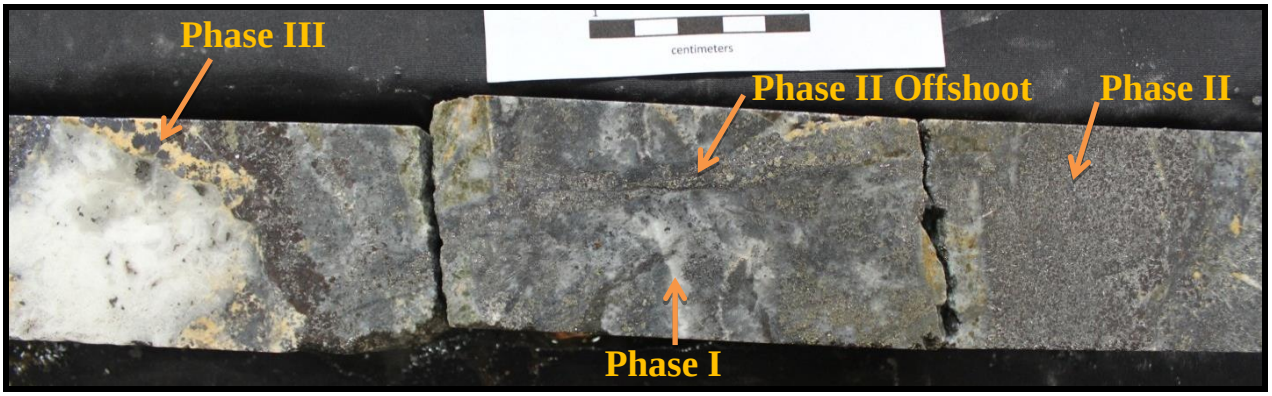

Plate 4: Western Klaza Zone drill core highlighting relationship between Phases I through III.

The Central Klaza Zone is a sheeted vein complex hosted in a feldspar porphyry dyke swarm. The strongest veins are often found along dyke contacts, but they are not limited to these areas. Sheeted vein emplacement is common and, in some instances, mineralized veins cross-cut the dykes. Typical vein composition in Central Klaza Zone consists of initial barren quartz veining, smoky quartz/pyrite/arsenopyrite veining, and further brecciation by tan-white ankerite with sphalerite and galena, as shown on Plate 5.

Alteration Facies

Alteration facies described in this section are developed around veins. Where a mineralized zone consists of multiple, closely spaced veins, the areas of alteration can coalesce. Extensive areas of pervasive alteration characterize the Cental Klaza Zone, and this type of alteration appears to be increasing toward the east in several of the mineralized structural zones, as they approach the porphyry centres. Where only a few veins are present, or they are widely separated, the alteration zones are quite discrete and are surrounded by unaltered wallrocks.

Four significant alteration facies are observed on the Property in drill core and trench exposures. These phases are propylitic, argillic, phyllic and potassic alteration. The alteration facies and intensities vary, based principally on the spatial relationships of each zone with respect to the primary heat source. Further controls on alteration include mineral zonation, proximity to feldspar porphyry dykes, and presence of multiple phases of mineralization. Generally, propylitic alteration represents the most distal alteration facies, followed by weak argillic and advanced argillic alteration, then phyllic alteration and finally, the most proximal, potassic alteration. The following paragraphs describe the alteration facies observed at the Property.

Propylitic facies alteration in the host granodiorite is mainly represented by the assemblage calcite, chlorite and sericite. Weak sericitization of feldspar imparts a dark greenish grey colour to the granodiorite. Calcite usually develops as coatings within microfractures. Chlorite content is modest at about 3 to 5% of the rock. Epidote, another propylitic index mineral, is rarely observed.

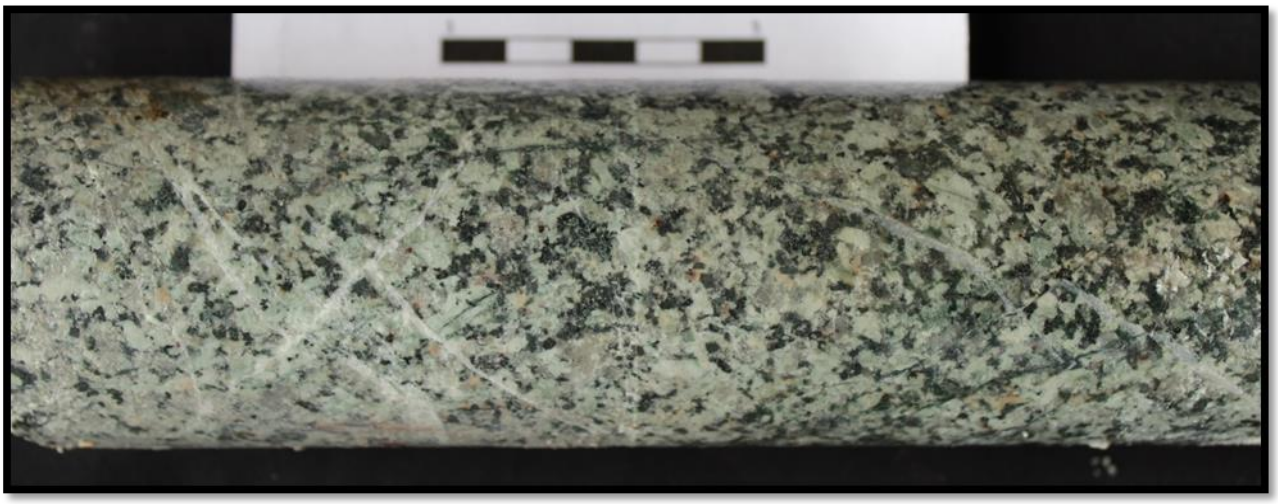

Plate 6: Moderate propylitic alteration.

KL-14-231 190.6 m

Plate 7: Strong propylitic alteration with weak potassic overprinting.

Argillic facies alteration has two sub-facies, montmorillonitic and kaolinitic, with each sub-facies defined by the type of clay replacing plagioclase feldspar. Montmorillonitic alteration (Weak Argillic) is characterized by a pale green colour that develops when clay altered plagioclase oxidizes on exposure to air. Montmorillonite alterated rocks swell when the clays absorb water, making them highly friable. This sub-facies is generally less than 50 m wide and occurs outward of the Kaolinite sub-facies.

KL-14-138 138.86 – 141.76 m

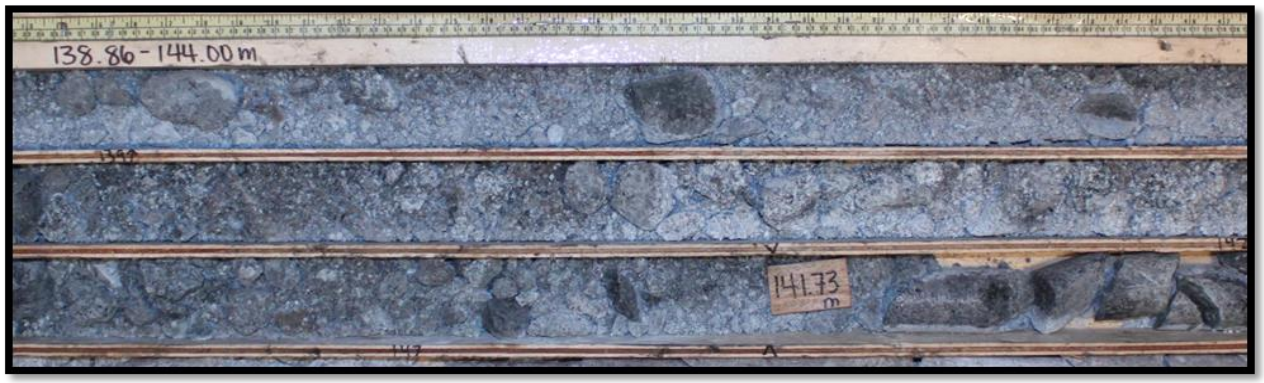

Plate 8: Highly friable montmorillonite alteration.

Kaolinitic alteration (Advanced Argillic) has a strong bleached appearance and is often cut by weak sericite veinlets with narrow alteration envelopes. Typical kaolinitic alteration grades to phyllic alteration, as sericite dominates over kaolinite. The kaolinite sub-facies has been classified into weak, moderate and strong, depending upon the presence or absence of biotite, K-feldspar, calcite, sericite, pyrite and hematite. The contacts between these three classifications are gradational.

Weak kaolinitic alteration is characterized by plagioclase feldspar and hornblende altering to a chalky and/or dull white clay. Biotite is present as fresh to weakly altered books. Pink orthoclase (K-feldspar) may also be present. Calcite is rarely observed. Magnetite is generally oxidized to hematite, and disseminated pyrite is usually absent.

KL-14-220 182.30 m

Plate 9: Weak kaolinitic alteration.

Moderate kaolinitic alteration is noted where biotite, calcite and K-feldspar are destroyed, as the intensity of alteration increases. Pale green sericite becomes common; however, it is not

pervasive. Hematite is common and chlorite, a relic of biotite alteration, may be present. Pyrite is generally absent or very weak.

KL-14-234 63.10 m

Plate 10: Moderate kaolinitic alteration.

Strong kaolinitic alteration occurs where kaolinite is largely replaced by white to pale green sericite. Pyrite veinlets up to 1 mm are common and wider veinlets sometimes have narrow white, intense sericite envelopes. The pyrite results from sulphidization of hematite.

KL-14-235 89.10 m

Plate 11: Strong kaolinitic alteration.

Argillic facies alteration occurs more proximal to mineralized zones than the propylitic facies and can sometimes be present within 50 cm of mineralized veins.

Phyllic facies alteration is characterized by sericite, quartz and pyrite and is seen immediately adjacent to mineralized zones inside the propylitic and argillic alteration halos. Typical phyllic alteration consists of quartz±sulphide veinlets enveloped by pervasive sericite and pyrite. With an increase in veinlet density, the original rock texture is destroyed and converted to a dark gray, very fine-grained mixture of sericite, pyrite and quartz. The quartz is a product of the alteration and accumulates as blebs or migrates to form veinlets and veins. The strongest phyllic alteration observed to date on the Property is within the Klaza Zone. Clasts in the breccias that are typically found in the Klaza Zone are often strongly phyllic altered.

KL-14-229 310.70 m

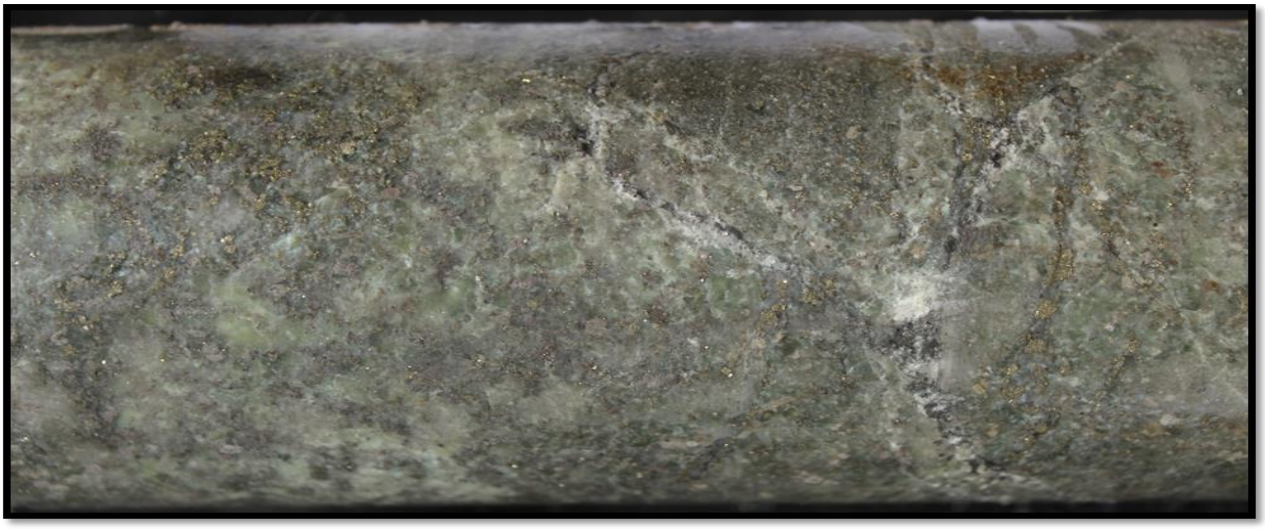

Plate 12: Strong phyllic alteration.

Potassic facies alteration features fine-grained interstitial white feldspars that may be K-feldspar and euhedral books of biotite. Besides the diagnostic alteration minerals, biotite and K-feldspar, potassic alteration may contain secondary magnetite, anhydrite, tourmaline and ankerite.

Carbonate Gangue Facies

Gold-silver mineralization occurs on the Property in veins containing quartz, various carbonate minerals and iron and base metal sulphide minerals. The gold-rich Western BRX Zone has the highest abundance of manganiferous carbonate (rhodochrosite) discovered to date on the Property. Iron-rich carbonates (ankerite and siderite) are the dominant carbonate minerals in the remainder of the BRX Zone and in the Klaza Zone.

Deposit Style Classification

Textures and mineralogy observed at the Property share a number of key similarities with Carbonate Base Metal (CBM) deposits. This class of deposits has not been identified elsewhere in Yukon, but some researchers have recognized that mineralization on the Property resembles mineralization at what are now categorized as CBM deposits (Smuk, 1999, and J. Richards, personal communication). CBM deposits have mainly been discovered around the Pacific Rim and include multi-million ounce gold deposits such as Porgera (New Guinea), Buritica (Colombia) and Kelian (Indonesia).

CBM deposits are formed by the mixing of rising mineralized fluids with bicarbonate waters (Corbett and Leach, 1998). Mineralization styles are highly zoned, depending on the crustal level of the system, with silver-rich CBMs formed at higher levels. Characteristic zonation of carbonate compositions develop when upwelling mineralizing fluids are progressively cooled as they mix with descending bicarbonate groundwater. These carbonate compositions vary from proximal (hot) calcium (Ca) through magnesium (Mg) and manganese (Mn) to distal (cool) iron (Fe) facies. Gold mineralization is believed to be preferentially distributed within veins containing Mn/Mg carbonate facies. Key diagnostic features of CBM deposits are compared to features observed at the Property in Table 3:

Table 3 - CBM Comparison with Klaza

Diagnostic Features of CBM Deposits	Diagnostic Features of Klaza Mineralization
Mineralization hosted in veins and breccias	Mineralization hosted in veins and breccias
Large vertical extent of mineralization (> 1,000 m)	Large vertical extent of mineralization (520 m and open to depth)

Carbonate (dominant), quartz, pyrite, sphalerite and galena gangue	Quartz (dominant), carbonate, pyrite, sphalerite and galena gangue
Multiple mineralized structures with long strike lengths (> 700 m)	Multiple (nine) mineralized structures with long strike lengths (>2,400 m)

Although more studies are required at the Property to definitively classify the deposit type, key characteristics of mineralization on the Property are generally consistent with the CBM model and it is used in making recommendations concerning future exploration.

SOIL GEOCHEMICAL SAMPLING

From 1967 to present, various operators collected soil geochemical samples from the eastern part of the Property. Historical samples were taken on baseline-controlled grids established using hip-chain and compass. Baselines were marked with one metre high wooden lath and sample sites were marked with 0.5 m wooden lath; however, very few of these markers are currently standing and legible. Early soil sampling identified linear gold±silver±lead anomalies, which correspond to some of the known mineralized structural zones, and a large (2,000 by 3,000 m) area of moderately to strongly anomalous copper-in-soil response, which partially defines the Kelly porphyry target in the southeastern corner of the Property.

From 2010 to 2012, Rockhaven expanded grid sample coverage to the west and north of the earlier grids, and collected samples on a few contour-controlled lines in the northwestern part of the Property. Soil sampling methods and analytical techniques are described in Appendix III. No additional soil sampling was completed in 2014.

Effectiveness of soil sampling is often limited by thick layers of organic material and overburden, and in many areas, by permafrost. Despite these limitations, soil sampling has been one of the most effective surface exploration techniques for identifying trenching or drilling targets on the Property.

Results for gold, silver, lead, arsenic and copper from historical surveys and Rockhaven's sampling are illustrated together on Figures 8 to 12, respectively using gradient contour techniques. Table 4 lists the anomalous thresholds and peak values obtained by Rockhaven's surveys, for these elements.

The Property exhibits distinct copper zonation from east to west. Copper is strongest in the southeastern part of the Property in proximity to the intrusive centre at the Kelly Zone. Response across the remainder of the gridded area is more subdued. The more southerly BRX, AEX, Dickson and Chevron zones have weakly elevated copper-in-soil signatures, while the other zones, further to the north, show only background copper response.

The structural corridor hosting the nine known mineralized zones is defined by linear trends of moderately to strongly anomalous values for gold, silver, lead and arsenic. Similar but more discontinuous anomalies have been identified southwest and northeast of the structural corridor, where no zones have been discovered to date. Northwest along strike of the known mineralized zones, elevated soil values occur as isolated samples or in small clusters. The lack of continuity in these outlying anomalies may be due in part to more difficult sampling conditions resulting from lower elevations and increased overburden depths.

GEOPHYSICAL SURVEYS

To date, four types of geophysical surveys have been completed on the Property: (1) SJ Geophysics Ltd. of Delta, British Columbia conducted two ground-based VLF-EM and magnetic surveys on behalf of BYG Natural Resources in 1996 (Visser et al., 1996) and Rockhaven in 2014; (2) Aurora Geosciences Ltd. of Whitehorse, Yukon conducted a gradient array induced polarization survey on behalf of Bannockburn Resources in 2006 (Wengzynowski, 2006); (3) New-Sense Geophysics Ltd. (NSG) of Markham, Ontario conducted two high sensitivity helicopter-borne magnetic and gamma-ray spectrometric surveys for Rockhaven during the 2010 (Turner and Tarswell, 2011) and 2011 (Tarswell and Turner, 2012) field seasons; and (4) Ground Truth Exploration of Dawson City, Yukon conducted high resolution induced polarization surveys along two experimental lines in the Cental Klaza and Central BRX zones for Rockhaven during the 2013 field season.

The **SJ Geophysics** VLF-EM and ground-based magnetic surveys were completed during two programs and covered a total of 330 line kilometres on a 4.5 by 8 km grid in the eastern and central parts of the Property. The first work program was completed on behalf of BYG in 1996 and covered 250 line kilometres. In 2014 Rockhaven added an additional 80 line kilometres to the earlier survey. SJ Geophysics integrated and interpreted the data from both programs and produced images relating to it. These surveys delineated numerous linear magnetic lows and VLF-EM conductors that coincide with known mineralized zones. Northerly trending breaks in the VLF-EM conductors correspond to known or suspected cross-faults. Figure 13 shows the

VLF-EM results overlain with the interpreted surface traces of the mineralized structural zones and their possible extensions along strike.

The gradient array and pole-dipole IP survey conducted by **Aurora Geosciences** covered an 1,800 by 1,450 m area in the east-central part of the Property. Readings were collected at 25 m intervals along lines spaced 100 m apart. This survey identified two main anomalies, both of which feature elevated chargeability with coincident resistivity lows.

The most prominent anomaly is located in the southeastern corner of the grid. It is only partially defined and currently comprises a 1,000 m diameter, semicircular area characterized by moderate chargeability and low resistivity, which remains open to the south and east. This anomaly coincides with an area of weak to strong gold-in-soil geochemistry (25 to 100 ppb) and strong copper geochemistry (>200 ppm) as well as porphyry style mineralization that is part of the Kelly Zone. To date, only two trenches and one drill hole have tested the northern edge of the anomaly with the best result coming from hole KL-12-115, which averaged 0.15% copper, 0.14 g/t gold, 2.70 g/t silver and 0.010% molybdenum over 93.15 m.

The second IP anomaly includes three westerly trending chargeability features of weak to moderate intensity. These chargeability features are 710 to 1,200 m long and are offset 30 to 190 m to the south from parallel resistivity lows. The IP anomaly also includes three other, smaller chargeability highs that directly coincide with resistivity lows. These latter features correspond with parts of the BRX, AEX and BYG zones.

The **NSG** surveys resulted in 326 line kilometres being flown on a grid that covered most of the Property (Klaza 1 to 319 claims). Condor Consulting, Inc. of Lakewood, Colorado was retained to ensure quality control and produced a 3D model of the total field magnetics as well as various vertical derivatives.

The magnetic surveys identified a number of prominent, linear magnetic lows on the Property. Subsequent trenching and drilling have shown that many of the northwesterly trending lows coincide with mineralized structural zones, while northeasterly trending breaks in the magnetic data correspond to cross-faults. These relationships are consistent with the low magnetic susceptibility results returned from core samples within the altered structural zones compared to higher values from surrounding unaltered wallrocks. Several of the magnetic lows extend outside the main areas of exploration and have not yet been tested by drilling or trenching. Figure 14 shows the first vertical derivative of the magnetic data overlain with the interpreted surface traces of the structural zones.

Elevated potassic radioactivity is evident in the general area of the main zones in the eastern part of the Property, but does not specifically coincide with individual mineralized zones. Numerous porphyry dykes and frost boils containing porphyry fragments lie within this area and are the probable source of this radioactivity. The Klaza River valley generally has subdued radiometric response, which is likely due to thick vegetation and water saturation in the flats adjacent to the river. Elevated radioactivity that directly correlates with the bed of the Klaza River may be caused by exposed gravels, which include abundant potassium feldspar bearing, intrusive material.

The experimental IP survey conducted by **Ground Truth Exploration** collected dipole-dipole extended, inverse Schlumberger and strong gradient array data on section lines 10+050 mE and 10+600 mE at the Klaza and BRX zones. Each of these lines was 415 m long (a single spread length for the arrays). Transceivers were placed 5 m apart along the lines, resulting in a very high signal to noise ratio and thus providing high quality resistivity data. The mineralized vein and breccia zones tested by the two lines show up as resistivity lows that coincide with chargeability highs.

EXCAVATOR TRENCHING

Rockhaven performed about 21,050 m of trenching in 82 trenches between 2010 and 2013. In 2014, another 5 trenches totalling approximately 880 m were completed using a Hitachi 450 excavator, owned and operated by 15317 Yukon Ltd. of Whitehorse.

A total of 334 chip samples were collected in 2014 from bedrock exposed in trenches. Chip samples were taken along the west rib of each trench or where bedrock was the most stable. Sample Handling and Analytical Procedures are described in Appendix III, while Certificates of Analysis can be found in Appendix IV.

Historically, excavator trenching in geochemically anomalous areas has been the most effective tool for identifying near surface but non-outcropping, mineralized zones. Within the main areas of exploration, overburden generally consists of 5 to 20 cm of vegetation and soil organics covering a discontinuous layer of white volcanic ash and 50 to 125 cm of loess and/or residual soil, which cap decomposed bedrock.

Typical trench exposures within the mineralized vein zones exhibit strong limonite and clay alteration that is often water saturated and more deeply weathered than the surrounding wallrocks. These zones are more intensely fractured and have higher porosity as a result of near surface oxidation. Residual sulphide minerals are rarely present in trenches and, where seen, they are usually encapsulated in silica. The locations and orientations of lithological contacts in trenches correspond very well with those predicted from nearby drill holes, indicating little solifluction has occurred. Outside of the mineralized zones, trench exposures are dominated by blocky, weakly oxidized granodiorite.

Table 5 lists the total number and combined lengths of trenches completed by Rockhaven each year since 2010.

The majority of Rockhaven's trench locations were selected based on results from historical programs. Where possible, trenches were excavated in areas that had previously been stripped of soil and vegetation. The trenches were aligned at about 030°, which is perpendicular to the trends of the main veins and soil geochemical and geophysical anomalies. Figure 15 is a plan view map showing trench locations and approximate surface traces of the nine main mineralized structural zones.

Highlights from the 2014 trenches include 5.83 g/t gold with 390 g/t silver over 1.3 m and 3.78 g/t gold with 9.85 g/t silver in TR-14-13 and 1.13 g/t gold and 12.22 g/t silver over 5.9 m in TR-14-79.

Individual zones and their key trench results are discussed from north to south in the following paragraphs, based on descriptions in Tarswell and Turner, 2014. All widths reported are sampled widths, which are considered to represent 80 to 90 % of true widths.

The **Pearl Zone** is the most northerly mineralized structure identified on the Property. It was exposed in two excavator trenches located 450 m apart along a recessive linear. The best interval was exposed in TR-13-41S, which averaged 2.85 g/t gold and 20.04 g/t silver across 10.72 m. This interval included 1.25 m grading 19.75 g/t gold and 148.00 g/t silver.

The **Klaza Zone** is a historical zone that has been traced for a strike length of 2,400 m. The zone is made up of numerous individual veins that range between 0.2 to 4.5 m wide.

Mineralization in the ***Central Klaza Zone*** is hosted within a laterally extensive complex of steeply dipping veins, breccias and sheeted veinlets that are associated with a swarm of feldspar porphyry dykes. The strongest veins are typically found along dyke margins. The best result returned from this part of the Klaza Zone was 5.61 g/t gold and 300 g/t silver over 18.79 m in TR-13-51.

Mineralization in the ***Eastern Klaza Zone*** comprises broad zones of quartz-pyrite stringers and veinlets hosting disseminated galena, sphalerite and rare molybdenum and chalcopyrite. Up to 70 m wide barren feldspar porphyry dykes crosscut zones of mineralization. The strongest vein zones are typically associated with broad areas of disseminated pyrite and trace molybdenum centered on phyllic and weak potassic alteration. The best result returned from this part of the Klaza Zone was 0.69 g/t gold and 3.43 g/t silver over 53.95 m in TR-13-42.

Main mineralized structures

Narrow, high-grade silver-gold enriched veins in the ***Western Klaza Zone*** are believed to represent a more distal style of mineralization. A strong vein and a nearby weaker vein; both with good lateral continuity, have been traced along this segment of the zone. These veins are not emplaced alongside a feldspar porphyry dyke, nor are they flanked by the type of sheeted veining seen elsewhere in the Klaza Zone. The mineral assemblages contain higher proportions of arsenopyrite and sulphosalts than are common further east in the zone, and silver to gold ratios are higher. The best trench result from this part of the Klaza Zone was 16.76 g/t gold and 1,052 g/t silver over 3.03 m in TR-13-70.

While individual mineralized exposures within the Klaza Zone are generally comparable to those at other zones on the Property, the Central and Eastern Klaza Zones are distinguished by the presence of multiple subparallel veins, which are relatively closely spaced within a structural corridor that is up to 100 m wide.

In 2013, two trenches tested the projected extension of the Klaza Zone 1,300 m east of the main trenching area. The best of these trenches (TR-13-41S) yielded multiple mineralized intervals, including 1.91 m grading 2.38 g/t gold and 18.25 g/t silver. The area between this trench and the known Klaza Zone has not yet been drilled or trenched and the continuity between these areas has not been established.

The **BYG Zone** splays south off the east-central part of the Klaza Zone. It has been traced by excavator trenches for 650 m and hosts veins developed along the selvages of two dyke swarms. Trench TR-11-26 returned 2.13 g/t gold and 7.94 g/t silver across 14.68 m.

The **Herc Zone** also appears to splay off the Klaza Zone, approximately 300 m east of the BYG Zone. The Herc Zone was discovered in 2010 by following up historical soil geochemical results and has been traced over a 460 m strike length. The best exposure was in TR-10-12, which yielded 3.06 g/t gold and 48.66 g/t silver over 7.60 m. Trenching along the projected strike to the west failed to identify significant mineralization, although strong alteration was exposed along the inferred trend.

The **Pika Zone** was also discovered in 2010 and lies 650 m south of the Klaza Zone. It hosts one or two discrete veins that have been tested by four trenches along a 740 m strike length. This zone has a relatively weak soil geochemical signature compared to the other known zones. The best interval obtained to date yielded 2.94 g/t gold and 190.06 g/t silver over 3.20 m (TR-12-04).

The **BRX Zone** was the original historical discovery on the Property and has now been traced for 2,400 m by 37 trenches. This total strike length includes fault offset segments. Mineralization within the BRX Zone is associated with a laterally extensive feldspar porphyry dyke. Veins occur on the margins of that dyke and, where the dyke splits into two or more 'fingers,' the number of veins increases, which sometimes results in wider mineralized intervals. All of the vein exposures in this zone host abundant sulphide and quartz veinlets. The best results are from the 500 m long section, called the ***Western BRX Zone***, which is situated between two northeast trending cross-faults. Highlights from this section include 87.0 g/t gold and 768 g/t silver over 1.15 m in TR-13-47 and 71.4 g/t gold and 1,310 g/t silver over 2.25 m in TR-13-58.

The **AEX Zone** was discovered in 2012, lies 850 m south of the Klaza Zone and has been traced for 1,650 m. The best trench exposure was in TR-10-03 and returned 10.90 g/t gold and 56.41 g/t silver over 1.25 m.

The **Dickson Zone** was also discovered in 2012 and lies 1,050 m south of the BRX Zone. It has been exposed in two areas, located approximately 1,500 m apart within a 3,000 m long geophysical and multi-element geochemical anomaly. The best exposure from this zone came from TR-12-02 and returned 10.85 g/t gold and 93.60 g/t silver over 1.60 m.

The **Chevron Zone** was another 2012 discovery, which lies 1,150 m south of the BRX Zone. It hosts multiple vein structures that have only been tested by two trenches. The best trench results were 3.79 g/t gold and 190.48 g/t silver over 9.20 m and 6.25 g/t gold and 319 g/t silver over 4.80 m, both from TR-12-36.

Table 6 lists the most significant mineralized intervals from trenching programs between 2010 and 2014.

DIAMOND DRILLING

This section summarizes drill programs completed from 2010 to 2012 and in 2014.

In 2010, diamond drilling on the Property was contracted to Top Rank Diamond Drilling Ltd. of Ste Rose du Lac, Manitoba, and was done with two, skid-mounted, diesel-powered JKS-300 drills using NTW and BTW equipment.

In 2011, diamond drilling on the Property was contracted to three companies: Swiftsure Diamond Drilling Ltd. of Nanaimo, British Columbia; Strike Diamond Drilling of Kelowna, British Columbia; and, Elite Diamond Drilling of Vernon, British Columbia. The work was done using two, skid-mounted, diesel-powered A-5 drills and one, skid-mounted, diesel-powered JKS-300 drill. The A-5 drills used HQ equipment while the JKS-300 used BTW equipment. Percussion drilling was completed by Midnight Sun Drilling Ltd. of Whitehorse, Yukon. This drilling was done using a track-mounted, diesel-powered reverse circulation percussion drill.

In 2012, diamond drilling on the Property was contracted to four companies: Swiftsure Diamond Drilling Ltd. of Nanaimo, British Columbia; Strike Diamond Drilling of Kelowna, British Columbia; Elite Diamond Drilling of Vernon, British Columbia; and, Platinum Diamond Drilling Inc. of Winnipegosis, Manitoba. The work was done using three skid-mounted, diesel-powered A-5 drills and one skid-mounted, diesel-powered JKS-300 drill. The A-5 drills used HQ and NQ equipment while the JKS-300 used BTW equipment.

Diamond drilling in 2014 was contracted to Platinum Diamond Drilling Inc. of Winnipegosis, Manitoba. The work was done using two A-5 diamond drills and one Discovery II diamond drill. The A-5 drills used HQ and NQ equipment while the Discovery II used NQ equipment.

A total of 240 diamond drill holes (56,673 m) were drilled on the Property between 2010 and 2014, as summarized in Table 7. A total of 6,199 samples were collected from drill core in 2014. Sample Handling and Analytical Procedures are described in Appendix III, while Certificates of Analysis are in Appendix IV. Geological and geotechnical logs can be found in Appendix VII.

Table 7 - 2010 to 2014 Diamond Drilling Summary

Year	Holes Drilled	Total Drilled (m)
2010	11	1,642.08
2011	52	14,068.45
2012	73	21,719.47
2013	0	0.00
2014	104	19,242.35

All diamond drill holes were collared at dips of -50° and most of the holes had azimuths of 030° to 035° (north-northeast) as shown on Figure 16. Drilling was completed on section lines spaced roughly 50 m apart along much of the lengths of both the Klaza and BRX zones. The majority of drill holes completed in 2014 were located along the Western BRX and Western Klaza zones. This drilling targeted areas of known high-grade mineralization and was designed to infill around existing drill holes in order to complete resource calculations.

The recent diamond drill programs completed by Rockhaven have successfully expanded zones of gold and silver mineralization identified by previous operators and discovered new zones elsewhere on the Property. The various zones have been traced for a cumulative mineralized strike length of more than nine kilometres.

Table 8 shows the drill confirmed strike length of each of the main zones, the maximum down-dip intercept depth in each zone and a select gold-biased drill intercept from each of the zones.

Table 8 - Data for Main Mineralized Zones

Zone	Mineralized Strike Length (m)	Maximum Down-dip Drill Intercept (m)	Best Drill Intercept (2010 to 2014 Diamond Drilling)
Western Klaza	400	250	13.75 g/t gold and 357 g/t silver over 2.11m (KL-12-115)
Central Klaza	800	325	7.20 g/t gold and 260 g/t silver over 15.30 m (KL-10-07)
Eastern Klaza	1100	180	34.10 g/t gold and 47.5 g/t silver over 1.00m (KL-12-68)
Western BRX	500	520	5.78 g/t gold and 111 g/t silver over 15.62m (KL-12-96)
Central BRX	1900	400	11.30 g/t gold and 233 g/t silver over 1.52m (KL-12-114)
Pika	740	250	32.52 g/t gold and 34.3 g/t silver over 3.36 m (KL-10-06)
AEX	1650	310	9.03 g/t gold and 27.7 g/t silver over 1.00 m (KL-12-125)
BYG	650	310	6.29 g/t gold and 342 g/t silver over 1.43 m (KL-11-63)
Dickson	450	100	7.08 g/t gold and 127 g/t silver over 1.00 m (KL-12-86)
HERC	460	310	3.39 g/t gold and 205 g/t silver over 2.28 m (KL-12-95)
Chevron	250	90	3.97 g/t gold and 95.4 g/t silver over 1.26 m (KL-12-120)
Pearl	450	100	2.09 g/t gold and 5.68 g/t silver over 2.57 m (KL-14-234)

All of the mineralized zones listed above begin at surface and are open to expansion along strike and to depth.

The **BRX Zone** has been traced for approximately 2,400 m along strike and been tested to a maximum depth of 520 m down-dip. Mineralization is associated with a laterally extensive northwest striking and moderately to steeply southwest dipping feldspar porphyry dyke. Veins occur on the margins of that dyke and, where the dyke bifurcates, the number of veins increases, which sometimes results in wider mineralized intervals.

The ***Central BRX Zone*** features veins and vein zones that are dominated by quartz, pyrite and iron-rich carbonates (ankerite and siderite). Pyrite, sphalerite and galena are the main sulphide minerals, while arsenopyrite and sulphosalts are absent, or present in only minor quantities. A type section depicting the geometry of the mineralized veining relative to the dyke is shown in Figure 17. The best intervals from the Central BRX Zone came from KL-14-197, which graded 6.76 g/t gold and 978 g/t silver over 0.73 m and KL-11-29, which returned 3.29 g/t gold and 407 g/t silver over 3.00 m.

The ***Western BRX Zone*** consists of quartz veins and vein zones that contain pyrite, arsenopyrite, galena, sphalerite, chalcopyrite and sulphosalts. Carbonate gangue facies in these veins largely

comprises manganiferous carbonates. Figure 18 illustrates the geometry of the mineralization defining this zone.

The two best intercepts in the Western BRX Zone were in the deepest holes, KL-12-96 and KL-14-238. KL-12-96 intersected two veins grading 25.1 g/t gold and 621 g/t silver over 2.32 m and 10.55 g/t gold and 92.7 g/t silver over 2.90 m. When composited together with adjoining samples, the boarder interval averaged 5.78 g/t gold and 111 g/t silver over 15.62 m. KL-14-238 intersected multiple veins within an 18.5 m interval that averaged 2.19 g/t gold and 120 g/t silver. The best of the veins in that interval graded 16.29 g/t gold and 1,435 g/t silver over 1.37 m. KL-14-238 intersected the zone 200 m down-dip from the closest hole.

The mineralogical differences between the Western BRX and Central BRX zones suggest some degree of vertical off-set along a major cross-fault, which separates the two segments of the zone. Figure 19 is an inclined longitudinal section illustrating gold equivalent distribution using grade-thickness normalization of gold and silver values from diamond drill holes and excavator trenches located along the BRX Zone. The longitudinal section does not include significant results returned from secondary veins found in the hanging wall or footwall of the main structure. Inclined longitudinal sections illustrating separate gold and silver grade-thickness along the BRX Zone are presented on Figures 20 and 21, respectively.

The **Klaza Zone** is located about 800 m northeast of the BRX Zone. Drill holes tested along the zone on section lines spaced approximately 50 m apart. The Klaza Zone has been subdivided into three sub-zones – Eastern Klaza Zone, Central Klaza Zone and Western Klaza Zone. Each sub-zone has a distinct style of mineralization that is believed to reflect their respective distances from the hydrothermal centre. The Central and Western Klaza zones are off-set by the same cross-fault that separates the corresponding sections of the BRX Zone.

The ***Eastern Klaza Zone*** (extending east from section KL 10+500) lies closest to the hydrothermal centre and is characterized by broad gold-silver bearing veins that form a sheeted complex, possibly suitable for bulk mining methods. The mineral assemblages and precious metal contents in this area are distinguished from those of the Central Klaza zone in two ways: 1) sulphide veins are dominated by pyrite with significantly less galena and arsenopyrite; and 2) the silver-to-gold ratios are lower. The best drill result from the Eastern Klaza zone was from an interval in KL-12-121, which graded 1.43 g/t gold and 2.69 g/t silver over 18.03 m.

Mineralization in the ***Central Klaza* Zone** (east of section KL 9+900 m and west of section KL 10+500 m) is hosted within a laterally extensive complex of steeply dipping veins, breccias and sheeted veinlets, which are associated with a swarm of feldspar porphyry dykes. The strongest veins are typically found along dyke margins. Pyrite, arsenopyrite, galena and sphalerite are the main sulphide minerals in this sub-zone. Excellent results from this part of the Klaza Zone were reported from an interval in KL-10-07, which graded 7.20 g/t gold and 260 g/t silver over 15.30 m and an interval in KL-12-133, which graded 11.90 g/t gold and 5.23 g/t silver across 6.70 m. KL-12-133 is the deepest hole at the Klaza Zone.

The ***Western Klaza Zone*** is defined by two narrow high-grade silver-gold veins (extending west from section KL 9+900). Unlike other zones, these veins are not emplaced alongside a feldspar

porphyry dyke and they are not flanked by the type of sheeted veining seen elsewhere in the Klaza Zone. The mineral assemblages in the Western Klaza Zone contain higher proportions of arsenopyrite and sulphosalts than are common further east in the Klaza Zone, and silver to gold ratios are higher. Some of the best drill results from this area were cut in KL-12-115 and KL-14-220. KL-12-115 returned 4.51 g/t gold and 332 g/t silver across 7.12 m, including 13.75 g/t gold and 357 g/t silver across 2.11 m. An interval in KL-14-220 graded 15.38 g/t gold and 741 g/t silver across 1.46 m.

Type sections for the Central Klaza and Western Klaza zones are shown on Figures 22 and 23, respectively.

Figure 24 is an inclined longitudinal section demonstrating the gold equivalent distribution using grade-thickness normalization from diamond drill holes and excavator trenches located along the Klaza Zone. The longitudinal section does not include significant results returned from secondary veins found in the hanging wall or footwall of the main structure. Inclined longitudinal sections illustrating separate gold and silver grade-thicknesses along the Klaza Zone are presented on Figures 25 and 26, respectively.

The **BYG** zone is parallel to the Klaza Zone, 125 m to the south. The central portion parallels the Central Klaza Zone and has been traced for 650 m before it converges into the Eastern Klaza zone. No work has been done along the possible eastern extension of this zone to determine if the BYG structure coalesces with the Klaza structure or cuts through it and continues to the east. The western portion of the BYG zone parallels the Western Klaza Zone. It was discovered in 2014 and has been traced for 650 m along strike.

The ***Central BYG Zone*** is associated with a series of siliceous, brown feldspar porphyry dykes. Sixteen diamond drill holes intersected the zone between 2010 and 2012, and all cut significant mineralization. The best intercepts graded 4.57 g/t gold with 51.6 g/t silver across 3.97 m and 6.29 g/t gold with 342 g/t silver across 1.43 m. Only two diamond drill holes have intersected the ***Western BYG Zone***. The best intercept graded 11.22 g/t gold with 10.6 g/t silver over 1.68 m in hole KL-14-224. This zone is open for extension along strike and at depth.

The **Herc** zone has only been tested by two diamond drill holes spaced 300 m apart. These holes were originally designed to intersect the Pika zone but after crossing it were extended to reach the Herc zone. Both holes cut vein style mineralization, approximately 300 m downdip of trench exposures. The best result from drilling was an interval that graded 3.39 g/t gold and 205 g/t silver over 2.28 m.

In 2012, exploration around the **Pika** zone expanded an area of mineralization intersected in KL-10-006 and KL-10-09 during the 2010 program. Eight diamond drill holes were completed in 2012, seven of which intersected significant mineralization. The Pika zone has demonstrated good continuity in widely-spaced drilling, over a strike length of 740 m and to a depth of 250 m. The best mineralization intersected came from an interval in KL-12-114, which graded 2.25 g/t gold and 40 g/t silver across 12.58 m, including sub-intervals of 9.55 g/t gold and 137 g/t silver over 1.00 m and 11.3 g/t gold and 233 g/t silver over 1.52 m.

The **AEX** zone is located approximately 150 to 200 m south of the BRX zone. It is one of the largest zones on the property with a drill indicated strike length of 1,650 m. The best drill intercept from the AEX zone came from KL-12-091, which graded 9.03 g/t gold and 27.7 g/t silver over 1.00 m.

The **Dickson** zone has been tested by eight holes in two areas located approximately 1,500 m apart. These drilled areas lie within the same 3,000 m long, geophysical and multi-element soil geochemical anomaly. The deepest intercept on the Dickson zone is 100 m downdip of surface and returned 7.08 g/t gold and 127 g/t silver over 1.00 m. Additional drilling needs to be done between the two areas of mineralization to confirm continuity along the anomalous trend.

The **Chevron** zone hosts multiple vein structures that have only been tested by two diamond drill holes and one excavator trench over a 250 m strike length in the western part of the zone, and one trench 1600 m to the east. The best drill intercept returned 3.97 g/t gold and 95.4 g/t silver across 1.26 m.

Significant diamond drill hole intersections from the 2010 to 2012 and 2014 diamond drill programs are shown in Appendix VIII.

MINERAL PROCESSING AND METALLURGICAL TESTING

Preliminary mineralogical and metallurgical testwork has been conducted on samples from parts of the Klaza Deposit. This testwork has occurred in two phases, with the first phase examining material from four composites assembled from coarse rejects of drill core collected from the BRX and Klaza zones during the 2012 drill program, and the second phase focusing on a single composite sample consisting from coarse rejects of drill core from 2014 drilling at the Western BRX Zone. Figure 27 shows the location of drill holes that were used to create the 2014 composite.

Work has been primarily conducted by SGS Canada Ltd. (GSC) and has been overseen by Archer Cathro or Blue Coast Metallurgy Ltd. (Blue Coast). The two test programs have included quantitative mineralogical examination, gravity recovery, cyanide leaching, and flotation testing.

Mineralogical information gleaned from a Quantitative Evaluation of Minerals by Scanning Electron Microscopy (QEMSCAN) study indicates that gold is present as discrete mineralization, both free and locked in sulphides, and in solid solution in arsenopyrite and pyrite. A Dynamic Secondary Ion Mass Spectrometry (D-SIMS) study found that sub-microscopic gold occurs at elevated grades in the arsenopyrite mineral lattice, suggesting arsenopyrite is the primary host of the refractory gold component. Silver appears to be mostly present as coarse-grained and well liberated tetrahedrite.

Gold recoveries by gravity ranged from 13 to 30% in testwork conducted down to 100 microns. The remaining discrete gold in these samples is either too fine for gravity recovery, or mostly associated with sulphides.

Preliminary cyanide leach tests on material from the area delineated by the current mineral resource yielded gold recoveries ranging from 21% to 42%. Silver extractions by cyanide ranged from 10% to 32%.

The mineralization responded very well to flotation concentration. Flotation testing has focused on recovery of base metal concentrates. Work conducted in the second phase of testing, on a composite sample from the Western BRX Zone, has led to development of a promising preliminary flowsheet. Batch cleaner tests have produced a lead concentrate grading 45% lead, 5,650 g/t silver, and 308 g/t gold with recoveries of 79%, 67% and 46% respectively. Zinc flotation has yielded a concentrate grading 45% zinc, 27 g/t gold, and 617 g/t silver, with recoveries of 76%, 6% and 10% respectively.

Significant amounts of gold, silver, and base metals report to middling products, including an arsenopyrite-rich concentrate with elevated gold grades. Overall recoveries would be expected to improve in future locked cycle tests. Based on the testwork conducted to date, it is projected that overall gold recoveries would be in the range of 75% to 85%. Silver recovery to the lead concentrate would be in the range of 65% to 80%, while up to 10% to 20% may report to the zinc concentrate. Lead recoveries would be in the order of 80% to 90%, and zinc recoveries are projected to be 75% to 85%.

Further details pertaining to the metallurgical testwork can be found in the technical report entitled "Geology, Mineralization, Geochemical Surveys, Geophysical Surveys, Diamond and Percussion Drilling, Metallurgical Testing and Mineral Resources" prepared by W.A. Wengzynowski, P.Eng., of Skivik Holding Co. Ltd., G.H. Giroux, M.A.Sc., P.Eng., of Giroux Consultants Ltd. and C.J. Martin, C.Eng., of Blue Coast Metallurgy Ltd.

MINERAL RESOURCE ESTIMATE

The inferred mineral resource for the western and central portions of the Klaza and BRX zones total 7,040,000 t grading 4.19 g/t gold, 96.23 g/t silver, 0.78% lead, 0.93% zinc and 0.09% copper. This mineral resource is stated above a 1.5 g/t gold cut-off grade. A summary of inferred mineral resources at various cut-off grades is provided in Table 9.

The mineral resource estimation was completed by Gary Giroux, P.Eng., M.A.Sc. (Giroux Consultants Ltd.) who is a Qualified Person (QP) and independent of Rockhaven, based on the criteria defined by National Instrument 43-101.

Data generated during drill programs conducted between 2010 and 2014 at the Property by Rockhaven were independently reviewed by Giroux Consultants Ltd. as part of the resource study. The mineral resource estimate was initiated by constructing a wire-frame 3D solid model in "GEMS". Solids were manually digitized from the available drill data and were used to constrain the interpolation of mineralization. The model was constructed based upon structural controls, lithological boundaries and mineralogical domains. Twelve solids were created, each representing a separate mineralogical domain and defining high-grade vein mineralization in each zone.

Drill holes were "passed through" these geologic solids with the entry and exit points recorded. Using this information, the assays were "back tagged" with different codes, representing which solid they were within. Of the 240 diamond drill holes completed to date, 178 intersected one or more mineralized solids and were used to calculate the resource.

A rotated block model with blocks 5 x 10 x 5 m in dimension was superimposed over the mineralized solids. For each block, the percentage below surface topography within overburden and within each of the mineralized solids were recorded.

The bulk density of individual blocks was determined using 1,639 assay intervals with corresponding density data. Mineralized portions of blocks were assigned a bulk density based on the combined estimated grades of lead, zinc, copper and iron.

Uniform two metre long, down-hole composites were produced to honor the mineralized solids. Grades for the elements of interest were interpolated into blocks containing mineralized solids using Ordinary Kriging. The kriging exercise was completed in a series of four passes. Appropriate block model validation techniques for resource estimation at this stage of project development were applied.

Tables 10 through 13 present the grade-tonnage results at a series of gold cut-offs for the material within the Western BRX, Central BRX, Western Klaza and Central Klaza mineralized domains. These results assume one could mine to the limits of the solid with no external dilution.

A detailed description of the methodology used to calculate the current mineral resource can be found in the technical report entitled "Geology, Mineralization, Geochemical Surveys, Geophysical Surveys, Diamond and Percussion Drilling, Metallurgical Testing and Mineral Resources" prepared by W.A. Wengzynowski, P.Eng., of Skivik Holding Co. Ltd., G.H. Giroux, M.A.Sc., P.Eng., of Giroux Consultants Ltd. and C.J. Martin, C.Eng., of Blue Coast Metallurgy Ltd.

DISCUSSION AND CONCLUSIONS

The Property is situated in an active placer gold mining camp and historical hard rock gold and silver mining district, which lie within the southern portion of the Dawson Range Gold Belt. Other important areas within this belt include the prolific Klondike Goldfields, the Casino porphyry copper-gold-molybdenum deposit and the recently discovered Coffee and Whitegold gold deposits.

The Property hosts a significant gold-silver deposit within a 100% owned road-accessible claim block. The current mineral resource is defined within the central and western portions of the BRX and Klaza zones, which are two of nine main mineralized structures identified on the Property to date.

Although mineralization at the Property appears to be quite complex, the continuity of the BRX and Klaza zones is remarkably planar and cohesive both laterally and vertically. Gold and silver distribution varies throughout the system, with the highest values for both metals mostly clustered within the western parts of the BRX and Klaza zones.

Mineralogical and metallurgical work on samples of sulphide material taken from the various zones comprising this resource has shown that gold occurs in multiple forms: as discrete (free) grains, as electrum, and as refractory gold predominantly in arsenopyrite. Silver occurs primarily as tetrahedrite, but is also found as electrum and other silver sulphide compounds. Base metal mineralogy appears to be straightforward, being dominated by galena, sphalerite and chalcopyrite.

Metallurgical work has included conventional gravity separation, cyanide leaching and flotation tests. Recovery of gold and silver by gravity varied between zones, but was generally low. Cyanide leaching recoveries were also low for composites representing the areas comprising the mineral resource. Flotation work has focused on producing base metal sulphide concentrates, and yielded promising recoveries of base metals to reasonably high-grade cleaner concentrates. Silver reports primarily to the lead concentrate, with minor amounts to the zinc concentrate. A significant portion of the gold reports to the lead concentrate and another large fraction appears to report to a relatively high-grade arsenopyrite concentrate. The gold reporting to the arsenopyrite concentrate is refractory in nature and will require further work to either produce a concentrate with high-enough grades for direct shipping, or determine an appropriate oxidation and leaching process. Flotation work completed to date is preliminary in nature, and optimization work will need to be conducted to determine optimal recoveries and product grades.

Mineralization at the Property shares a number of key similarities with Carbonate Base-Metal Gold (CBM)-style deposits, renown for hosting multi-million ounce gold resources such as Barrick Gold's Porgera Mine (Papua New Guinea), Rio Tinto's formerly producing Kelian Mine (Indonesia) and Continental Gold's Buritica project (Colombia).

Klaza and known CBM deposits feature multiple precious metal-rich structures that are formed peripheral to mineralized porphyry systems. The presence of carbon dioxide gas within the mineralizing hydrothermal fluids is a key factor in facilitating precious metal deposition over large vertical extents, often in excess of one kilometre. Lead, zinc and copper are also common in this type of deposit.

The current mineral resource and unquantified mineralized zones elsewhere on the Property are open for expansion along strike and to depth. The mineralized system is known to have a vertical extent of at least 520 m down-dip, and this could reasonably expand because most CBM deposits are mineralized in a vertical range exceeding 1,000 m. There is excellent potential to significantly increase the current mineral resource through continued low-cost drilling. In addition, many geochemical and geophysical anomalies, outside of those associated with the known mineralized structures, have yet to be explored.

Ongoing exploration at the Property has largely been directed by geochemical and geophysical results. Multi-element soil geochemical anomalies mark the known mineralized zones and similar, mostly untested anomalies have been identified along strike and parallel to the known zones. Hydrothermal fluids that flowed through the mineralized structures have locally destroyed magnetite in the host rocks, precipitated sulphide minerals in fractures, veins and breccias, and altered some minerals comprising wallrocks in and around the zones. Magnetic susceptibility measurements of drill core confirm that the mineralized zones are considerably less magnetic than the surrounding, unaltered granodiorite, and helicopter-borne surveys have outlined magnetic lows along the known zones. There are numerous untested linear magnetic lows on the Property, which parallel the orientation of the known structural zones. Results of ground-based VLF-EM surveys generally support the magnetic data. An induced polarization survey completed in 2006 identified areas of high chargeability on the western edge of the Kelly zone, which are only partially tested by drilling and trenching. These anomalies are open to the south and east onto recently acquired ground. A second, tighter array induced polarization

survey was done in 2013 across the central parts of the Klaza and BRX zones and showed that broad chargeability highs and resistivity lows mark the main zone and flanking structures. The untested soil geochemical and geophysical anomalies are considered priority targets for future exploration. The ground-based VLF-EM survey completed in 2014 outlined many new and untested anomalies that require follow up work in the future.

The geophysical surveys have also been successful in outlining cross-faults, which offset mineralization. The sense of movement along these faults is poorly understood, but analysis of the geophysical data has led to a number of hypotheses in regards to displacement of the mineralized zones. Determining the exact orientations and probable offsets of these cross-faults should be a priority for future work programs.

Additional drilling should be designed to extend the bounds of the current mineral resource to greater depths. This work should be considered high priority, specifically within the western portions of the BRX and Klaza zones, because the tenor of mineralization in the deepest holes is well above the deposit average grades and there are no indications that mineralization is waning at depth. Both these areas have much higher grades than are typically found in the central portions of the BRX and Klaza zones and the mineral resource estimates for these areas are the least affected by cut-off grade sensitivity.

Areas immediately southeast along strike of the current mineral resource require further delineation drilling to determine if that mineralization can be included in future resource estimates. These portions of the mineralizing system differ from their western and central counterparts as they represent more dispersed sheeted vein complexes and are probably lower grade bulk tonnage targets.

Northwesterly extensions of the BRX and Klaza zones are inferred by anomalous multi-element grid soil geochemical samples, and linear, airborne magnetic low and ground very low frequency electromagnetic (VLF-EM) conductors. A series of widely spaced holes that attempted to trace the Western BRX Zone further to the northwest across a major cross-fault intersected vein zones, but it is unclear whether these zones are part of the BRX structure. Work is certainly warranted northwest of the cross-fault to assess potential along strike of the BRX, Klaza and other mineralized zones.

Continued deposit studies are recommended and should include fluid inclusion analyses to verify the deposit model classification. An in-depth analysis of metal and associated element ratios within the mineralized zones should also be done in order to establish vertical and lateral vectoring tools for continued deposit expansion and discovery of new mineralization elsewhere on the Property.

Metallurgical work conducted to date has been preliminary in nature. Follow-up work should be conducted to better develop the current flowsheet and investigate optimal gold recovery methods, including a focus on refractory gold recovery and processing. The majority of metallurgical work completed to date has focused on samples from the Western BRX Zone. Follow-up work should examine material from the other three sub-zones included in the current resource estimate to determine if variability of mineralization in these areas will impact

metallurgical performance. Test work should also be conducted to determine the crushing and grinding work indexes of the deposit, as well as to evaluate the environmental impact of tailings products.

A preliminary economic assessment is recommended for the Klaza Deposit, after metallurgical work is completed, to better understand potential mining methods and other economic factors.

SAMPLE HANDLING AND ANALYTICAL PROCEDURES

SAMPLING METHODS AND APPROACH

Soil Sampling

Soil samples collected in 1986 and 1998 were taken from a 1400 by 2500 m northwest trending grid that covers most of the southeastern part of the Property. Soil samples were collected at 50 m intervals on lines spaced 100 m apart using two northwest trending base lines for grid control. The base lines are approximately 800 m apart and marked at 50 m intervals with one metre high wooden lath, while the sample sites on cross lines were marked with 0.5 m lath. All lath bear aluminum tags inscribed with the grid coordinates and sample numbers. The grids were established with hip-chain and compass, but later survey control was provided by hard-chain and transit. The soil samples were taken 20 to 50 centimeters below surface from B horizon material. They were placed in pre-numbered heavy gauge paper bags. A total of 1405 soil samples were collected in 1986 and 776 in 1998.

Soil samples collected in 2010 and 2011 extended sample coverage to the west and north of the earlier grids, while 2012 sampling was mostly done in the southeast corner of the Property. The samples were taken using soil augers, between 30 cm and 130 cm below surface. Soil samples were collected at 50 m intervals along lines spaced between 100 to 200 m apart. Sample sites are marked by aluminum tags inscribed with the sample numbers and affixed to 0.5 m wooden lath that were driven into the ground. Soil samples were placed into individually pre-numbered Kraft paper bags. All soil sample locations were recorded using hand-held GPS units. Sampling was often hindered by permafrost on moss-covered, north-facing slopes. Samples were not collected from some of these locations due to poor sample quality.

Trenching

Chip samples were collected from bulldozer and excavator trenches in several parts of the Property during programs conducted between 1986 and 1989 and from 2010 to 2014. Bedrock exposed in trenches was sampled on a continuous basis.

Continuous chip samples were collected from bulldozer and excavator trenches in several parts of the Property during programs conducted between 1986 and 1989 and from 2010 to 2014. The collection protocol for channel samples was as follows:

1) Trenches were excavated.
2) The walls of trenches were cleaned, where necessary, with a shovel.
3) Trenches were mapped and sample intervals marked at geological breaks or at 1 to 10 m intervals depending on the intensity of alteration and mineralization.
4) Continuous chip samples were collected along one wall of the trench as close to the floor of the trench as slumping would allow using a geological hammer. The chips were collected either in a tub or on a sample sheet. Sample sizes averaged approximately two kilograms per linear meter sampled for intervals containing veins and about 7 kg per sample for intervals comprised primarily of altered wallrock.

5) Samples were placed in doubled 6 mm plastic bags along with a pre-numbered sample tag, then two or three samples were placed in a fiberglass bag sealed with a metal clasp and sample numbers were written on the outside of that bag with permanent felt pen.
6) In 2011 to 2014, one blank and one standard samples were randomly inserted into every batch. No quality control samples were inserted into batches in 2010.
7) In 2013, samples collected from trenches within the core of the BRX and Klaza Zones were divided into batches comprising 31 trench samples plus one blank sample, one assay standard and one coarse reject duplicate sample.

Diamond Drilling

Geotechnical and geological logging was performed on all drill core from the 2010 to 2014 programs. A geotechnical log was filled out prior to geological logging of drill core and included the conversion of drill marker blocks from imperial to metric plus determinations of core, rock quality designations (RQD), hardness and weathering. Wetted core photographs were taken and catalogued prior to logging. Magnetic susceptibility measurements were taken at one metre intervals along core from each hole.

During the 2010 to 2012 programs, core recovery was good, averaging 97%. The holes from these programs were mostly sampled top to bottom (about 99% of core was sampled). In 2014, core recoveries averaged approximately 94%, excluding the near surface portions of the holes where core recovery was poor. Only vein zones and associated peripheral alteration were sampled in 2014. Care was taken during all drill programs to ensure that the sample split was not biased to sulphide content and, therefore, the sampling should be reliable and representative of the mineralization.

Drill core samples were collected using the following procedures:

1) Core was reassembled, lightly washed and measured.
2) Core was wet photographed.
3) Core was geotechnically logged.
4) Core was geologically logged and sample intervals were designated. Sample intervals were set at geological boundaries, drill blocks or sharp changes in sulphide content.
5) Core recovery was calculated for each sample interval.
6) From 2010 and 2011, visually promising core intervals were sawn in half using a rock saw and the remainder of the core was split with an impact core splitter. In 2012, all visually promising core intervals were saw in half using a rock saw, while selected specimens of altered country rock were split using an impact core splitter. In 2014 all marked samples were cut using a rock saw. In each case, one half of the core sampled and the remaining half was placed back in the core box.
7) All samples were double bagged in 6 mm plastic bags, a pre-numbered sample tag was placed in each sample bag, then two or three samples were placed in a fiberglass bag sealed with a metal clasp and sample numbers were written on the outside of that bag with permanent felt pen. In 2012 and 2014 the fibreglass bag was sealed with a numbered security tag.

8) Two blank and two assay standard samples were randomly included in every batch of 30 or 31 core samples (in 2012 and 2014, batches comprised 30 core samples).
9) One duplicate sample consisting of quarter-split core was included in every batch of 30 or 31 core samples (in 2012 and 2014 batches comprised 30 core samples).
10) In 2012 and 2014 one coarse reject duplicate sample was also included in every batch of 30 core samples.

Density measurements were systematically taken on core, throughout the 2011, 2012 and 2014 drill programs with a total of 1,823 density measurements from a variety of holes and lithologies. Measurements are mostly from vein, porphyry dyke, fresh granodiorite and mineralized granodiorite but also include aplite and mafic dyke material. Sample densities were determined by cutting a 10 cm long section of core and then determining its weight dry and its weight in water. That data was applied to the following formula to establish the density of each of these samples:

Density = weight in air ÷ [Pi x (diameter of core ÷ 2)^2 x length of core]

For samples that could not be cut, a graduated cylinder (filled with water) was used to calculate the volume of the core sample and in turn the sample's density. Employing this technique, each sample was first weighed in air, and then its displacement was calculated using a volumetric cylinder. A second formula was then used to determine the density of each sample:

Density = weight in air ÷ (Final Volume – Initial Volume)

In addition to density, the specific gravity was calculated using the following formula for each sample wherever possible. As a cross check, density and specific gravity values were compared. Any significant discrepancies were investigated and corrected.

Specific Gravity = weight in air ÷ (weight in air – weight in water)

All logging data was recorded as a hardcopy during the day and transcribed to digital format during the evenings.

HISTORICAL SAMPLE PREPARATION, ANALYSIS AND SECURITY

This section describes the sample handling procedures followed during the 1986 to 1989 and 2010 to 2012 exploration programs managed by Archer Cathro and the 1998 program conducted by BYG. The procedures followed during earlier exploration programs are not known.

During the 1986 to 1989 programs all samples were transported from the Property to Whitehorse by truck, escorted by a member of the geological crew, and then shipped via Canadian Airlines or a commercial trucking company to Chemex Labs (now ALS Minerals) in North Vancouver, B.C. Soil geochemical samples were dry sieved through a -35 mesh screen and ring pulverized to approximately -100 mesh before being analyzed for gold by neutron activation and inductively coupled plasma (ICP) analyses. Channel samples were fire assayed for gold and silver. The 1988 drill core samples were also fire assayed for gold and silver.

Drill core samples collected in 1998 were shipped directly from the site by company vehicle to the laboratory operated by Little Salmon Analytical in Carmacks. That laboratory was primarily established to process samples from the former Mount Nansen mine. The samples were assayed for gold and silver. The analyses were by the one ton fire assay method.

Samples collected in 2006 were submitted to ALS Chemex in North Vancouver, B.C. Analyses were done using industry-standard fire assay and ICP techniques. The ALS Chemex (now ALS Minerals) laboratory in North Vancouver carries ISO 9001:2000 registration and is accredited to ISO 17025 by Standards Council of Canada for a number of specific test procedures including fire assay Au by AA, ICP and gravimetric finish, and multi-element ICP and AA assays for Ag, Cu, Pb and Zn.

SAMPLE SECURITY

In 2010, all drill core was trucked to the Archer Cathro yard in Whitehorse for logging and splitting. In 2011, 2012 and 2014, drill core was logged and sawn or split at a processing facility on the Property. Chip samples taken between 2010 and 2014 were collected and labelled at the trenches on the Property.

In 2010, Archer Cathro personnel were responsible for transporting all samples from Archer Cathro's Whitehorse yard to ALS Minerals' Whitehorse preparation facility. In 2011, 2012, 2013 and 2014, Archer Cathro personnel were responsible for transporting all samples from the Property by truck to ALS Minerals' facility in Whitehorse for preparation. ALS Minerals was responsible for shipping the prepared sample splits from Whitehorse to its North Vancouver laboratory, where they were analyzed. All samples were controlled by employees of Archer Cathro until they were delivered directly to ALS Minerals in Whitehorse.

In 2012 and 2014, Archer Cathro ensured that a Chain of Custody form accompanied all batches of drill core during transportation from the Property to the preparation facility. A unique security tag was attached to each individual fibreglass bag when the bag was sealed. The bags and security tags had to be intact in order to be delivered to ALS Minerals. If a security tag arrived at the laboratory damaged, an investigation into the sample bag was undertaken by ALS Minerals and Archer Cathro and any affected samples were not processed until a resolution had been reached on the security of the samples.

SAMPLE PREPARATION AND ANALYSIS

All samples were sent to ALS Minerals' laboratory in Whitehorse for preparation and then on to its laboratory in North Vancouver for analysis. ALS Minerals, a wholly owned subsidiary of ALS Limited, is an independent commercial laboratory specializing in analytical geochemistry services. Both ALS Minerals' Whitehorse and North Vancouver laboratories are individually certified to standards within ISO 9001:2008.

All 2010 to 2012 soil samples were dried and screened to -180 microns. All 2010 to 2014 rock, core and trench samples were dried, fine crushed to better than 70% passing -2 mm and then a 250 g split was pulverized to better than 85% passing 75 microns. In 2014, visually mineralized

intervals and adjoining samples were prepared using a technique designed for coarse gold and silver. The sample is dried and crushed to better than 90% passing 2 mm. A 1,000 g split is then taken and pulverized to better than 95% passing 106 microns.

In 2010 and 2011, all core and trench samples were initially analyzed for gold by fire assay followed by atomic absorption (Au-AA24) and 35 other elements by inductively coupled plasma-atomic emission spectroscopy (ME-ICP41). Overlimit values for gold were determined by fire assay and gravimetric finish (Au-GRA22) and silver values were determined using Ag-OG46. Sample pulps from mineralized intervals of drill core from 2011 were later reanalyzed for lead and zinc as well as 46 other elements using four acid digestion followed by inductively coupled plasma-atomic emission spectrometry (ME-MS61). Overlimit values for silver, lead and zinc were determined by inductively coupled plasma-atomic emission spectroscopy (Ag/Pb/Zn-OG62).

In 2012 and 2014, rock samples were routinely analyzed for gold by fire assay followed by atomic absorption (Au-AA24) and 48 other elements by four acid digestion (ME-MS61). All overlimit values were determined for gold by fire assay and gravimetric finish (Au-GRA22) and for silver using Ag-OG62.

Soil samples collected in 2010 were analyzed for gold by fire assay with inductively coupled plasma-atomic emissions spectroscopy finish (Au-ICP21) and for 35 other elements using aqua regia digestion and inductively coupled plasma-atomic emission spectrometry. Soil samples collected in 2011 and 2012, were analysed for gold by fire assay fusion and atomic absorption spectroscopy (Au-AA24) and for 35 other elements using aqua regia digestion and inductively coupled plasma-atomic emission spectrometry.

All 2010 to 2014 assay standard, blank and duplicate samples passed QA/QC reviews. It is the Author's opinion that the sample preparation, security and analytical procedures used for this project are adequate.

DATA VERIFICATION

Database

Prior to 2014, geological and geotechnical logging was initially recorded as a hardcopy and then transcribed into MS Excel®. In 2014, logging was recorded as hardcopy and then entered into a MS-SQL Server® database. All of the pre-2014 data have been transferred to the database.
Visual comparison of hardcopy data and digital data was conducted on select holes to ensure accuracy. Any discrepancies identified by this process were investigated, by examining the core stored on the Property, and corrected.

Collar Location

All drill hole collars were re-surveyed in 2012 using a Trimble RTK GPS system and, where necessary, survey data collected in previous years was corrected. The differences between this most recent survey and the earlier surveys can be explained by the poorer accuracy of the hand held GPS devices used in previous years.

Elevation data obtained during the RTK GPS survey was compared to elevation data calculated from low level orthophotos. Any discrepancies identified were investigated and corrected, if possible. If no resolution to a discrepancy was immediately apparent, an additional survey was conducted.

Down-hole Orientation

Prior to 2011, no down-hole azimuth measurements were made and dip deviations were measured using an acid test at the bottom of each hole. This practice does not follow industry standards, but due to the limited number of holes (11), shallow depths (up to 273.12 m) and good ground conditions, this is not considered to be a significant issue.

Original 2011, 2012 and 2014 survey data was obtained from the survey tools in CSV format and was visually inspected. Erroneous data was not used during the interpretation process.

Assays

Sample intervals from all 2010 through 2014 drilling were imported into a MS SQL Server ® database. Assay certificates, for all of the drilling done to date, were obtained from ALS Minerals in CSV format and imported directly into this database.

Internal algorithms built into the database ensure that the correct assay data is matched with the correct sampling data. Errors detected by the database were inspected and corrected. Spot checking of data within the database to hard copy certificates issued by ALS Minerals was also implemented and did not revealed any issues.

Samples from the 2010 to 2014 diamond drilling programs were subjected to a quality assurance and quality control (QA/QC) program designed by Archer Cathro for Rockhaven. The QA/QC program consisted of:

1) Sequentially numbered sample tags: to identify each sample with a unique number to minimize the possibility of sample numbering errors and to ensure uniform collection of sample data.
2) Sealed sample bags: to secure individual sample bags in order to reduce the possibility of sample contamination, spilling or tampering.
3) Chain of custody: samples were stored in a secure preparation area and delivered to the laboratory directly by Archer Cathro personnel.
4) Sample duplicates: select samples were quartered and re-submitted for assay. In addition, duplicates of coarse reject material of select 2012 samples were re-submitted for assay.

5) Sample blanks: commercial samples were purchased and inserted in the sample sequence. to test for "smear effect" during the sample preparation process. These blanks were assigned unique sample numbers within the sample sequence and were randomly inserted into each batch, so as to be "blind" to the laboratory.
6) Reference standard samples: commercially available assay standard samples for gold and silver were purchased for the 2010 and 2011 drill program. Six batches of assay standards were prepared from coarse reject material from the 2011 and 2012 core samples for use during the 2012, 2013 and 2014 programs. These assay standards were prepared, homogenized and packaged by CDN Resource Laboratories Ltd. of Delta, British Columbia. All assay standards were certified by Smee & Associates Consulting Ltd. of North Vancouver, British Columbia assay standards were assigned a unique sample number within the sample sequence and were randomly inserted into each batch.

All of the samples have passed this quality assurance and quality control program.
