BMC Minerals LTD

2017 GEOLOGICAL, GEOCHEMCIAL, GEOPHYSICAL, DIAMOND DRILLING AND GEOTECHNICAL PROGRAM REPORT ON THE KUDZ ZE KAYAH (KZK) PROPERTY

Field Work Completed Between June 3rd, 2017 and November 17th, 2017

Located in the Watson Lake Mining District, Yukon
NTS 105G/7, 8, 9 and 10
61˚ 31' N Latitude; 130˚ 33' W Longitude

-prepared for-

SUMMARY

BMC Minerals' Kudz Ze Kayah ("KZK") Property consists of 879 quartz claims that cover 16005 hectares (160 km^2) of south-central Yukon and is centred at 61˚ 31' N latitude and 130˚ 33' W longitude on NTS map sheets 105G/7–10, within the Watson Lake Mining District. It is notable for containing the ABM and GP4F volcanogenic massive sulphide (VMS) deposits, which are located 5 km apart. The ABM deposit comprises an Indicated resource of 18.3 Mt at 0.9% Cu, 1.9% Pb, 6.3% Zn, 1.4 g/t Au and 148 g/t Ag and an Inferred resource of 0.9 Mt at 1.1% Cu, 1.6% Pb, 6.9% Zn, 1.1 g/t Au and 138 g/t Ag (BMC Minerals Ltd., 2016). Also on the KZK property, the GP4F deposit comprises an Indicated resource of 1.0 Mt at 0.2% Cu, 2.7% Pb, 5.7% Zn, 1.0 g/t Au and 83 g/t Ag and an Inferred resource of 0.7 Mt at 0.2% Cu, 2.4% Pb, 4.8% Zn, 2.0 g/t Au and 138 g/t Ag (BMC Minerals Ltd., 2016).

The 2017 field program included earthworks, terrain surveys (ground-based differential global positioning system (DGPS) and terrain hazard mapping), geological outcrop mapping, soil sampling and pH analysis, geophysics (surface fixed-loop transient electromagnetic [FLTEM] surveys and ground-based borehole electromagnetic [BHEM] surveys), exploration drilling (down-dip of ABM and in the ABM zone), geotechnical investigations (in-pit, geotechnical, and test pits), hydrogeological investigations, and environmental baseline surveys (Table 1).

Table 1: Summary of work done and filed for the 2017 KZK Project

Program	Work type/target	Description	Filed?
Earthworks	Construction	5.2 km of trail, 48 drill pads, 14 test pits	Yes
	Reclamation	0.65 ha including 44 drill pads and 14 test pits	Yes
Terrain Surveys	DGPS	41 surveyed points including most 2017 collars	Yes
	Terrain Hazard Mapping	64 km2 study area	Yes
Geological Outcrop Mapping	Phase I	~120 km2 of KZK property	Yes
	Phase II	Detailed mapping and prospecting of 5 prospective targets	Yes
	Limestone Prospecting	Detailed mapping and sampling on the Limy claims	Yes
Soil Sampling	Soil Sampling	2609 samples collected including 97 from orientation surveys, 44 blanks, and 74 field duplicates	Yes
	pH Analysis		Yes
	Geochemical Analysis	2608 samples analyzed	Yes
Geophysical Surveys	Surface EM	32.90 line-km FLTEM	Yes
	Borehole EM	3 holes surveyed for 2175 m	Yes
Exploration Drilling	Down-dip ABM	3 holes for 2269 m, 129 samples assayed, 28 whole rock geochemical samples	Yes
	ABM Zone	1 drill hole for 182 m, 42 samples assayed	Yes
	TerraSpec Study		Yes
	Acoustic Impedance Study		Yes
Geotechnical Investigations	Infrastructure Drilling	36 drill holes for 1389.7 m	Yes
	in-pit Drilling	9 drill holes for 1540 m, 77 samples assayed	Yes
	Test Pits	14 test pits	Yes
	Televiewer Surveys	8 holes surveyed for ~1323 m	Yes
Hydrogeological	Mine site	12 shallow monitoring wells installed	Yes
Environmental	Baseline studies	Water quality, wetland, vegetation and wildlife surveys	No
2017 TOTAL	**All work**	**48 holes for 4928.7 m, ~120 km^2 mapped, 292 samples assayed, 2609 soil samples, 32.9 km FLTEM, 2175 m BHEM, engineering and environmental studies**	

Earthworks done as part of the 2017 work program included drill pad and trail construction, test pit digging, as well as reclamation. During the 2017 report year 0.65 ha of land was reclaimed. The total un-reclaimed disturbance on the KZK Property as of December 2018 is 10.083 ha. The majority of the drill collars for the 2017 drill program were surveyed using a real time kinematic differential GPS. Drill holes, which were not surveyed in 2017 will be surveyed during the 2018 field season.

Terrain stability and hazard mapping was completed for a 64 km^2 area of the KZK project, where mine site and access roads are proposed.

Surface outcrop mapping was conducted across the majority of the KZK property and the Limey claims. More detailed mapping and prospecting was conducted on prospective target areas. These mapping programs investigated the property geology, deformation history, and prospective geology.

A total of 2491 soil samples collected from the southwestern portion of the KZK property were sampled as part of the 2017 soil sampling program. These samples were analyzed on site to characterize the pH conditions of the soil and sent to SGS for multi-element chemical analysis via a combination of aqua-regia digestion with ICP-MS analysis and fire assay for gold.

A total of 32.9 line-km of FLTEM was conducted to the north of the ABM deposit in the area where exploration for a down-dip extension of the ABM deposit and/or stratigraphy occurred. Borehole EM was also conducted in all three exploration drill holes within this area.

Four drill holes, totaling 2451 m, were drilled as a part of an exploration drill program during 2017. Three of the holes targeted the down-dip continuation of the KZK stratigraphy. One drill hole targeted ABM stratigraphy and mineralization within the ABM deposit to characterize the acoustic impedance of these features and determine if seismic reflection profiling is a viable exploration technique at KZK. All core from these drill holes was geotechnically and geologically logged and analyzed with the TerraSpec.

A total of 3629 unique spectral readings from 35 drill holes was collected during the 2017 field program. White mica is the most abundant spectrally identified mineral in the KZK formation due to the felsic nature of the host rocks.

Acoustic impedance testing on drill core was conducted during the 2017 field season. The acoustic impedance characteristics of the lithologies within the KZK formation were determined as part of this program.

Geotechnical work during the 2017 field season included in-pit geotechnical drilling, core recovery and borehole televiewer surveys, infrastructure drilling on proposed mine infrastructure, and soil test pit excavation. The in-pit drilling consisted of nine drill holes targeting proposed open-pit highwalls. In Eight of the nine drill holes, optical and acoustic televiewer surveys were conducted on the open borehole. A total of 35 drill holes were completed during the infrastructure drilling program, using a variety of drilling methods (ODEX, Sonic, and Diamond) to characterize the unconsolidated overburden and bedrock underlying proposed mine infrastructure. The material in many of these drill holes was characterized using Standard Penetration Test (“SPT”) and packer testing. Monitoring installations were put in in many of these drill holes. Fourteen test pits were excavated to characterize the overburden characteristics.

A total of twelve monitoring wells were installed during 2017 in order to characterize groundwater conditions around the proposed mine infrastructure and open-pit.

Ongoing baseline environmental studies continued throughout 2017, including water quality monitoring, wildlife monitoring, wildlife surveys, archaeological surveys, and fish and fish habitat surveys.

Environmental baseline studies are an ongoing part of the KZK work program. The methodology for these studies are summarized in this report but results are not presented, as this is part of an on-going study in the KZK project area. The environmental baseline work has not been filed for assessment.

1.0 INTRODUCTION

This report has been prepared for BMC Minerals LTD ("BMC") in order to document the procedures and results of the 2017 exploration work undertaken on the Kudz Ze Kayah ("KZK") Property and to satisfy assessment reporting requirements for the Yukon Department of Energy, Mines and Resources ("EMR"). Equity Exploration Consultants Ltd. ("Equity") was engaged by BMC to manage the 2017 KZK fieldwork and to prepare this assessment report. The report has been prepared on the basis of personal observations, assessment reports filed with EMR, data and reports supplied by BMC, regional geological publications by EMR, and on the 2017 fieldwork undertaken by Equity or other subcontractors under the direct supervision of the authors. A complete list of references is provided in Appendix A.

Units and abbreviations used in this report are as follows:

Units:

cm	centimetre
C$	Canadian dollar
g	gram
g/t	grams/tonne
ha	hectare
km	kilometre
kg	kilogram
Koz	thousand troy ounces
Kt	thousand tonnes
kV	kilovolt
kW	kilowatt
m	metre
mGal	milligal
mm	millimetre
Mt	million tonnes
Moz	million troy ounces
nT	nanotesla
ppm	part per million
psi	pounds per square inch
"	inch

Abbreviations:

AAS	atomic absorption spectroscopy
AES	atomic emission spectroscopy
Ag	silver
APS	azimuth pointing system
ARD	acid rock drainage
AWG	American wire gauge
As	arsenic
Au	gold
Ba	barium
BC	British Columbia
BI	biotite
Bi	bismuth
CAN	Canada
CB	carbonate
CI	cordierite
CL	chlorite
CP	chalcopyrite
CPUE	Catch per unit effort
CRM	certified reference material

Cu	copper
DDH	diamond drill hole
DFO	Department of Fisheries and Oceans
DGPS	differential global positioning system
DO	dissolved oxygen
EM	electromagnetic
EDTA	ethylenediaminetetraacetic acid
EMIT	Electromagnetic imaging technology
EMR	Yukon Department of Energy, Mines, and Resources
EOH	End of hole
FLTEM	fixed loop transient electromagnetic
Fe	iron
FP	feldspar
GL	galena
GNSS	global navigation satellite system
GPS	global positioning system
Hg	mercury
HLEM	horizontal loop EM
HQ	drill core measuring 63.6 mm in diameter
HQ3	drill core measuring 61.2 mm in diameter
ICP	inductively coupled plasma
ID	identification
IDH	Inverse difference hydrogen
KSW	Kudz Ze Kayah South West
KZK	Kudz Ze Kayah
LiDAR	light detection and ranging
masl	Metres above sea level
Ma	million years
MG	magnetite
MS	mass spectrometry
MU	muscovite
NAD83	North American datum (1983)
NQ3	drill core measuring 45.2 mm in diameter
NSR	net smelter return
NTS	National topographic system
ODEX	overburden drilling - eccentric
Pb	lead
pH	measure of hydrogen ion concentration (acidity)
PLT	point load testing
PO	pyrrhotite
PVC	polyvinyl chloride
PY	pyrite
QA	quality assurance
QC	quality control
QZ	quartz
ROM	Run of mine
RQD	rock quality designation
RRDC	Ross River Dena Council
RTK	real-time kinetic
S	sulphur
Sb	antimony
Se	selenium
SEPA	socio-economic participation agreement

SP	sphalerite
SPT	standard penetration test
SWIR	Short wave infrared
UCS	unconfined compressive strength
UTEM	University of Toronto electromagnetic
UTM	Universal Transverse Mercator
VMS	volcanogenic massive sulphide
VNIR	Visible-near infrared
VTEM	versatile time-domain electromagnetic
VWP	vibrating wire piezometer
WA	Western Australia
WAAS	wide area augmentation system
WAD	weak acid dissociable
wt%	weight percent
XRF	X-ray diffraction
YESAA	Yukon Environmental and Socio-Economic Assessment Act
YESAB	Yukon Environmental and Socio-Economic Assessment Board
YT	Yukon Territory
Zn	zinc

2.0 RELIANCE ON OTHER EXPERTS

In Section 3.0, the authors have relied entirely upon information provided by BMC concerning their purchase agreement with Teck and the extent of any underlying interests and royalties. Also in Section 3.0, the authors have relied entirely on the Geomatics Yukon website for downloaded shapefile tenure data. Also in Section 3.0, the authors have relied entirely upon information provided by BMC regarding their Socio-Economic Participation Agreement ("SEPA") with the Ross River Dena Council. The authors have not relied upon a report, opinion or statement of another expert concerning legal, political, environmental or tax matters relevant to this assessment report.

3.0 PROPERTY DESCRIPTION AND LOCATION

The KZK Property located in the Finlayson Lake area of the Yukon Territory, and consists of 879 quartz claims that cover an area of approximately 16005 hectares (160 km^2) of south-central Yukon (Figure 1). It is centred at 61˚ 31' N latitude and 130˚ 33' W longitude (416000E 6817000N, NAD83, UTM Zone 9) on NTS map sheets 105G/7–10, within the Watson Lake Mining District.

The KZK Property consists of three separate claim blocks. The main claim block, with 864 contiguous claims, covers an area of about 11 km x 20 km and hosts the ABM and GP4F deposits. A single line of claims extends for 14 km north from the main claim block, roughly coincident with the tote road from where it extends to the Robert Campbell highway. The EL 1–8 and Limy 1–9 claim blocks are not contiguous with the KZK claim block, and lie a few kilometres to the west and east of the tote road respectively (Figure 2, Figure 3). All claims were acquired through staking on the ground. The area covered by each claim is determined by the location of the two claim posts on the ground. Mineral claim data is summarized in Appendix C.

All claims are registered in the name of BMC Minerals (No. 1) Ltd. BMC purchased the KZK Property 100% from Teck Resources Limited ("Teck") on 24 January 2015. A 1.2% NSR Royalty is jointly held by Teck and Nyrstar N.V. over the mineral claims ON20-85, ON87-101, ON104-113, ON116-125 ON162-173 and ON197-198. These claims do not cover the known mineral resources. The KZK Property lies within the traditional territory of the Kaska First Nation. Portions of the KZK Property are covered by a SEPA that includes all Kaska First Nations.

Cominco Ltd. and the Ross River Dena Development Corporation entered into the SEPA in March 1995. In April 2004, RRDC and Teck Cominco Ltd. amended and replaced the SEPA to include all Kaska First Nations and not be limited to RRDC. In accordance with the provisions of the SEPA it was assigned to BMC upon purchase of the project and followed the provisions of the SEPA which states that any third party who wishes to have an Interest in the project must first agree in writing to be bound by the existing SEPA.

The existing SEPA provides a framework for BMC and Kaska (as represented by RRDC) to work together to minimize risks of environmental impact and advance social and economic development of Kaska First Nations. BMC and Kaska have agreed to work together to modernize the 2004 SEPA in order to provide improved certainty and better economic outcomes for the benefit of both parties. These discussions have commenced and are expected to be completed prior to Project development commencing.

Mineral claims confer title to hard rock mineral tenure only. Surface rights are held by the Crown, as administered by the Yukon Territory. Trapping rights over the western portion of the KZK Property are held by the Ross River Dena Council under Group Trapline #405, while trapping rights over the rest of the Property are held under Single Holder Trapline #250. KZK overlaps with part of Outfitter Concession #20, held by Yukon Big Game Outfitters. There are several parcels of land in the vicinity of the KZK Property which have been reserved for a future land claim settlement with the Ross River Dena Council. Currently, staking is not permitted within a large area surrounding the KZK Property due to a government moratorium.

Yukon law requires eligible assessment expenditures of C$100/claim/year on the KZK Property to extend tenure ownership past the current expiry dates. Five claim groupings, containing a maximum of 750 contiguous claims, making up the KZK Property were filed with EMR to allow the representation of work done on one or more claims to be distributed to other claims where work was not done.

Exploration programs in the Yukon are divided into Class 1 (grassroots) through Class 4 (advanced), based on the increasing possibility of the permitted activities causing adverse environmental impacts. The thresholds between the classes are based on levels of camp person-days, fuel storage, and extent of exploration activities. In the KZK project area, exploration activities falling under Classes 1 and 2 require that notification is given to EMR. This notification is sent on to First nations and other stakeholders for comment and returned to the Mining recorder for final approval, denial, or modification. An approved plan of operations and the granting of a Quartz Mining Land Use Permit by EMR is necessary prior to undertaking Class 3 and 4 programs. Of these four classes, Classes 2, 3, and 4 require an assessment under YESSA (Yukon Environmental and Socio-Economic Assessment Act) in order to gather input from government agencies, First Nations, other stakeholders, and the general public. The 2017 KZK exploration work was carried out under Class 3 Quartz Mining Land Use Permit LQ00424b, which is valid to June 28th, 2025. Additional permits, leases and licenses used to complete the exploration activities include: Tote Road and Gatehouse Lease 105G07-001, Type B Water Use License QZ16-085, Approval to Use a Sewage Disposal System 4599, Special Waste Permit 41-289, Storage Tank System Permit 2015-22 and Fuel Tank Registration T-1004 and T-1005.

4.0 HUMAN AND PHYSICAL GEOGRAPHY

4.1 Accessibility

The KZK Property is accessible via a 25 km long, gated, single lane gravel tote road that connects to the Robert Campbell Highway (Highway 4) near Finlayson Lake, at a point 135 road-km east of Ross River and 237 road-km northwest of Watson Lake. Fixed-wing aircraft on pontoons can land on Finlayson Lake. Fixed-wing aircraft on wheels can land on a gravel airstrip located at the northwestern end of the lake.

The mixed-surface Robert Campbell Highway connects the Property to Watson Lake on the paved Alaska Highway and Carmacks on the paved Klondike Highway, giving access to Whitehorse and points south (Figure 1). All highways are maintained by the government for use year-round, but maintenance of the tote road is the responsibility of the KZK Project operator. The ABM deposit on the KZK Property is accessible by the tote road for skid-supported drilling, but helicopters are necessary for access to the remainder of the Property, including the GP4F deposit.

4.2 Local Resources and Infrastructure

Ross River, the nearest settlement to the KZK Property, has a population of about 300 and provides some services (groceries, fuel, accommodation and meals) and labour. Whitehorse (population 25000), which is located 260 km west of KZK, offers a full range of services and supplies for mineral exploration and mining, including skilled and unskilled labour, bulk fuel, freight, heavy equipment, groceries, hardware and daily scheduled flights to Vancouver (Figure 1).

The Yukon electrical grid supplies 138 kV electrical power to Faro, located 170 km northwest of the KZK Property and 25 kV electricity to Ross River. Concentrates from the Wolverine Mine, located 25 kilometres to the east of KZK, were trucked 900 kilometres south to port facilities at Stewart, BC prior to the mine's shutdown in early 2015.

4.3 Physiography and Climate

The KZK Property lies in the Pelly Mountains and covers portions of several creeks which ultimately drain north-east into the Finlayson River. The ABM deposit lies near the head of Geona creek, which drains into Finlayson Creek near where the tote road intersects the Robert Campbell Highway. The topography is moderately rugged, and typical of mountainous terrain. Elevations range from 1000 m near Finlayson Lake to over 2000 m at the peaks of the mountains southwest of the ABM deposit. The surface elevations in the ABM and GP4F deposit area range between 1300 and 1500 m.

Below the tree line (1350–1500 m), white and black spruce are the most common tree types. Black spruce is usually dominant in wetter areas whereas white spruce predominates in drier areas. Paper birch, aspen, balsam and lodgepole pine are also present. Alpine fir grows near the tree line. In dense coniferous

stands, feather moss dominates the understory, but in more open areas willows and heath-like shrubs become prevalent.

Sedge or sphagnum tussocks are common in wetlands and under black spruce. Shrub birch and willow occur in the subalpine and extend well above the tree line. The region has intermittent permafrost with moist depressions comprising peat plateaus, patterned fen and bog complexes.

The climate is cold continental with a mean daily summer temperature of 15˚C and a mean daily winter temperature of -25˚C. Precipitation falls fairly evenly throughout the year, predominantly as rain from May through September, and snow for the balance of the year. The mean annual precipitation is 655 mm. Groundwork on the Property is possible from May until October; however, snow may cover parts of higher elevations late into the summer. Drilling can be conducted year-round by using heated water for drilling.

During the last glacial period, ice moved across the eastern part of the area in a northwesterly to westerly direction and extended to approximately 1525 m elevation (Ritson, 2000).

5.0 HISTORY

The following description of pre-2004 exploration history of the KZK Property has been adapted from MacRobbie and Holroyd (2005b).

Little work had been reported in the KZK area prior to 1992, when Cominco Ltd. (Cominco, later Teck-Cominco Ltd., and ultimately, Teck Resources Ltd.), confirmed and expanded an anomalous regional silt sample from earlier work (Hornbrook and Friske, 1988). The following year, prospector A. B. Mawer discovered a well-mineralized, layered sulphide cobble in the anomalous drainage area. This was followed by a reconnaissance UTEM geophysical survey over the projected trace of the suspected host stratigraphy, which outlined an EM conductor. Staking of the first TAG claims over the conductor was accompanied by a ground magnetic survey. Further magnetic and horizontal loop EM and soil surveys completed later that fall defined a compelling drill target (Schultze, 1993).

The target was drilled in April 1994, with the first hole intersecting 22.5 m of massive sulphide in two sections (Schultze, 1995). Three additional holes were drilled in April, and each of them intersected sulphide mineralization over significant widths. The weighted average grade of sulphide in the discovery hole was 0.5% Cu, 2.8% Pb, 10.0% Zn, 278 g/t Ag and 2.9 g/t Au over 22.5 m. The sulphide body was named ABM after the long-time Cominco prospector who made the initial float discovery, A. B. Mawer. In total, 52 diamond drill holes (DDHs) (8485 m) were drilled in 1994 along with ground and airborne geophysical surveys, detailed mapping in the vicinity of the deposit, regional and detailed exploration geochemistry and baseline environmental sampling (Schultze, 1996).

In 1995 an additional 133 DDHs (16178 m), were completed at the ABM deposit and on regional targets. Additional soil sampling, minor geological mapping and ground geophysical surveys were also completed (Schultze, 1996). Engineering and environmental work included geotechnical investigations, bulk metallurgical sampling, construction of the tote road, environmental baseline studies, and archaeological studies (Stacey, 1996). A pre-feasibility engineering study was completed by Cominco in July 1995 (Brown, 1995).

The 1996 program involved regional, 1:20,000 scale geological mapping outside the immediate ABM deposit area, minor line cutting, ground geophysical surveys, and soil geochemistry over the northeastern part of the TAG Property. Diamond drilling (99 m) was completed in the southwest corner of the current KZK Property. Minor structural mapping and core logging were completed at the ABM deposit.

The 1997 program consisted of ground geophysical surveys and diamond drilling. An extensive UTEM and magnetic survey was completed east of the ABM deposit and additional gravity and magnetic surveys were completed over several coincident EM-magnetic anomalies proximal to ABM. A total of 17 drill holes were completed for 3566 m, with seven aimed at expanding the ABM deposit, two testing regional targets, and eight holes testing the Fault Creek target. Drilling at Fault Creek intercepted 6.4 m of Cu-rich sulphide in K97-181, which assayed 5.2% Cu, 1.0% Pb, 5.6% Zn, 141 g/t Ag and 2.4 g/t Au. This poorly defined occurrence represented the first discovery of significant sulphide mineralization south of the Fault Creek Fault (MacRobbie

and Bannister, 1998). By the end of 1997, 168 geological and 15 metallurgical drill holes had been completed in the immediate ABM deposit area, and another 20 drill holes had been completed elsewhere on the Property (including the eight on the Fault Creek target). Environmental studies, metallurgical testing and permitting activities were ongoing.

In 1998 additional line cutting, soil sampling and limited ground geophysical surveys were completed in several areas. A further 11 DDHs (K98-188 to 198; 1755 m) were completed, nine of which tested the GP4F area and two testing a coincident magnetic-EM feature northeast of GP4F (MacRobbie and Holroyd, 1999). The most significant result was the discovery of the GP4F deposit located 5 km southeast of ABM, which was estimated by Cominco to comprise a (non 43-101 compliant) resource of 1.5 Mt grading 0.1% Cu, 3.1% Pb, 6.4% Zn, 89.7 g/t Ag and 2.0 g/t Au (MacRobbie and Holroyd, 2000).

In 1999 a small geophysical program was completed, including an in-loop UTEM survey HLEM survey, and magnetic survey over the GP4F deposit (MacRobbie and Holroyd, 2000).

In 2000 the KZK Property was optioned to Expatriate Resources Ltd. (“Expatriate”) (Schultze, 2001). Expatriate carried out ground geophysical surveys (UTEM, magnetics) in the area south of the ABM deposit, extending their survey south of the Fault Creek target (Klein, 2000). Expatriate allowed the option to lapse in late 2001.

In 2004 Teck optioned the R-15 block, immediately south of the KZK Property, from Kaska Minerals Corporation, an entity controlled by the Kaska First Nation in Ross River. That summer, Teck discovered the R-15 deposit, through mapping, ground geophysical (UTEM and magnetic) surveying and drilling (7 DDHs, 1481 m) on the R-15 block. The program extended north, with 6.8 line-km of UTEM, 0.4 line-km of magnetics and one drill hole (K04-199; 246 m) on the KZK Property (MacRobbie and Holroyd, 2005a).

The R-15 option was subsequently terminated, and no further exploration was done on the KZK Property until 2015, after BMC purchased it from Teck. Following approval of exploration permits in July 2015 BMC began an ambitious exploration program that included building exploration infrastructure, data compilation, re-logging historical drill core, LiDAR and ground-based differential GPS surveys, geophysics (airborne VTEM, ground-based gravity and borehole EM), resource and exploration drilling, metallurgical drilling, geotechnical drilling, hydrogeological drilling and environmental baseline studies (Hughes et al., 2016). The most significant result of this program was the discovery of the Krakatoa Zone immediately southeast of the ABM Zone, which (at the time) added 5.1 Mt (2.1 Mt indicated, 3.0 Mt inferred) to the ABM deposit resource inventory (Green et al., 2016).

The 2016 BMC exploration program continued much of the work that was begun in 2015. Historical core logging continued and additional LiDAR, DGPS, and geophysical surveys (airborne magnetics and VTEM, borehole EM) were undertaken. Resource and exploration drilling, metallurgical drilling, geotechnical investigations, hydrological investigations, and environmental baseline studies were continued.

Several mineral resource estimates have been completed for the ABM and GP4F deposits by Cominco and Teck (Cominco, 1995; Teck-Cominco, 2007), and also by CSA Global Pty Ltd (“CSA”) on behalf of BMC (Green, 2015a, b; Green et al., 2016). The most recent estimate (Table 2) was completed by CSA in November 2016, (BMC Minerals Ltd., 2016) and incorporates all of the data up to the end of the 2016 exploration program.

Table 2: Mineral resource estimates for the ABM and GP4F deposits

Deposit	Date	Category	Mt	Cu (wt%)	Pb (wt%)	Zn (wt%)	Au (g/t)	Ag (g/t)	Reference

6.0 2017 WORK PROGRAM DESIGN

Work at KZK during 2017 comprised a multifaceted geological and engineering program that included construction and rehabilitation of new and historical exploration trails, terrain surveying, geological mapping, soil sampling, ground and downhole geophysics (EM), exploration and geotechnical drilling (diamond, ODEX, and Sonic drilling), test pitting, borehole optical and acoustic televiewer surveying, geochemical assay, hyperspectral imaging of drill core, and environmental baseline studies

6.1 Earthworks

Construction work related to the 2017 drilling program included building of new drill sites and trails, reclamation of drill pads and trails following their last use, and the construction of a temporary building for core display.

Construction and reclamation earthworks were completed by Tim Moon Construction Ltd, of Ross River (referred to here as “heavy machine operators”), and René Darveau (light excavator operator). Heavy machinery used included a Hitachi 270 and Link-Belt 290 excavators, Caterpillar D6R and D7 bulldozers, and a Western Star dump truck. A CanDig CD21 light excavator was used in locations without road access.

Trails to be constructed were laid out by Equity staff and/or machine operators, with an emphasis on avoiding tree stands (primarily spruce). A bulldozer and/or excavator were used to clear the trail, after which the excavator would cut ditches and place bars/culverts across the trail to guide runoff. Where possible, soft spots were filled with till material sourced from the 18-km mark on the tote road.

6.2 Terrain Surveys

Terrain surveys included ground-based differential GPS (DGPS) surveys and terrain hazard mapping. Contractors, procedures and methods used for these programs are summarized below.

6.2.1 DGPS survey

Ground-based DGPS surveys were completed by Challenger Geomatics Ltd of Whitehorse, Yukon (“Challenger”), over the course of the 2017 field program. All surveying was completed in NAD83 UTM Zone 9 with Leica Real Time Kinematic (RTK) DGPS survey equipment and Leica Viva Global Navigation Satellite Systems (GNSS). Radio base stations were set up in proximity to the survey sites providing RTK corrections when radio contact was possible.

Two surveys were conducted, a survey of drill hole collars (See section 6.6.1) and a topographic survey of the material stockpile sites and open pit area.

All surveyed coordinates for the 2017 drill holes are included in Appendix D.

6.2.2 Terrain hazard mapping

Terrain stability and hazard mapping was undertaken by Core Geoscience Services Ltd. (Coregeo) with the objective of characterizing the types and distribution of terrain hazards within the proposed mine site area, and along the access road corridor. Mapping and assessment work was completed in accordance with the hazard assessment guidelines of Yukon Environmental and Socio-economic Assessment Board ("YESAB").

The program's objectives were to delineate and characterize the distinct terrain units and geomorphological processes within the study area; identify potential hazards posed by the environment on the project, and by the project on the environment (terrain stability effects); and to evaluate risks to the project infrastructure considering the implications of climate change.

Initial terrain stability and hazard mapping methodology consisted of background review and consultation with BMC, review of maps, terrain analysis reports, and other pertinent data sources. Field investigations were undertaken by two of Coregeo's staff consisting of a senior geomorphologist, and senior environmental geoscientist under favourable field conditions. A comprehensive review of the methods used in this survey is available in Appendix E, Terrain and Hazard Mapping (McKillop et al., 2017).

6.3 Geological Outcrop Mapping

The 2017 geological mapping program on the KZK Property was subdivided into three programs; (1) phase I property-scale mapping, (2) phase II follow up on a series of geological-geophysical-geochemical targets, and (3) limestone prospecting on the Limy claim block, which lies east of the KZK Property.

6.3.1 Mapping procedures

Phase I geological mapping was done by a two- to four-person crew between 22 July and 16 August 2017, with daily helicopter set-outs and pick-ups along pre-planned traverse routes. Mapping was conducted on ruggedized, GPS-enabled Panasonic Toughbook computers using QGIS software. Structural data was collected using a combination of Silva and Brunton compasses, and the Fieldmove Clino iPhone application. Mapping data was compiled daily into *.TAB files using MapInfo on a central computer at the KZK Camp. Interpretation and the final property geology map was completed using a combination of MapInfo (2D) and Micromine (3D). Geological data for the property map was aggregated from 2017 and historical outcrop mapping, drill hole logs, and geophysical data, to constrain our interpretation of surface geology, presented in Appendix F. Field notes from the traverses that informed this mapping are available in Appendix G.

The Phase II mapping program involved detailed outcrop and subcrop mapping on four high priority target areas that were initially referred to as Fault Creek, GP4F, Tour Cirque and GP3L (Figure 22) (Voordouw, 2017). Mappers were set out by helicopter and then completed traverses through each of these areas. Mapping was done on ruggedized Panasonic Toughbook computers equipped with a GPS that has an accuracy of approximately ±5 m. Mapping data was entered into QGIS software where it was collected as polygons (outcrops), lines (structure) and points (alteration, mineralization, rock samples, points of interest). Codes used for geological features (e.g. lithology, structure, alteration, mineralization) are the same as those used for the KZK drilling program (Hughes and Baknes, 2015b).

The Limy claims are considered part of the Kudz Ze Kayah (KZK) project and comprise a satellite claim block located ~15 km north of BMC's ABM project, east of the tote road. Rocks comprising the claims were previously mapped as Lower Mississippian mafic volcaniclastic rocks and Upper Mississippian to Mid-Pennsylvanian bioclastic limestone of the Nasina Assemblage (e.g. Murphy et al., 2001).

A one-day detailed mapping exercise in the Limy claims was completed by two geologists to assess the following objectives:

- Map the rocks and possible contacts with other rock units in the existing claims and determine any textural heterogeneities in the limestone unit;
- Collect representative grab samples to be submitted for whole rock geochemical analysis.

6.3.2 Sampling and Geochemical assay

Rock samples were collected from mineralized and/or altered outcrops, but also from unmineralized and unaltered exposures to help establish consistency between geological mappers. Sample descriptions are available in Appendix H. Those samples designated for geochemical assay were first analysed by hyperspectral imaging (see Section 6.9 Hyperspectral Imaging Study, Appendix J), then placed in a polyethylene bag with a unique sample tag and packed, together with 6-7 other rock samples, into rice bags for shipment to the lab. Each of these rice bags was sealed with a uniquely numbered security tag and was transported to SGS Mineral Services Geochemistry Vancouver ("SGS") in Burnaby, BC, through a series of transport companies, including Tu-Lidlini Petroleum (KZK Camp → Ross River), Small's Expediting (Ross River → Whitehorse) and Canadian Freightways (Whitehorse → Burnaby).

Rock samples sent to SGS were analysed for whole rock oxides and trace elements. SGS Vancouver is an ISO 9001:2008 certified laboratory (accredited laboratory No. 744) that also conforms to the requirements of CAN-P-1579, CAN-P-1578 and CAN-P-4E (ISO/IEC 17025-2005) for the analytical methods used on the 2017 KZK Project. Accreditation details were provided in the 2015 QA/QC review (Voordouw, 2016a). Rock sample certificates of analysis are presented in Appendix I. Methods of analysis are presented in Table 3 below.

Table 3: Analyses performed on categories of sample submitted for analysis

Sample Type	Prep	Elements Analysed	Analysis
Core Assay	Weighed, dried and crushed to 75% passing 2 mm, with a 250 g split pulverized to 85% passing 75 microns	Au	High-temperature cupellation / aqua-regia digest / atomic absorption spectroscopy
		Ba, Cu, Fe, Pb, S, Zn	Sodium peroxide fusion / inductively-coupled plasma-atomic emission spectroscopy
		As, Sb, Bi, Hg, Se	Aqua-regia digestion / inductively-coupled plasma-atomic emission spectroscopy
		As, Sb, Bi, Hg, Se	Aqua-regia digestion / inductively-coupled plasma-mass spectrometry
		Ag	Aqua-regia digestion / atomic absorption spectroscopy
Soil	Weighed	Au	High-temperature cupellation / aqua-regia digest / atomic absorption spectroscopy
		Multi-element	Aqua-regia digestion / inductively-coupled plasma-mass spectrometry
		H^+	Determination of the pH of the soil-water paste
Rock	Weighed, dried and crushed to 75% passing 2 mm, with a 250 g split pulverized to 85% passing 75 microns	Au	High-temperature cupellation / aqua-regia digest / atomic absorption spectroscopy
		Major/Minor Oxides	Borate fusion / X-ray fluorescence spectroscopy
		Multi-element	Aqua-regia digestion / inductively-coupled plasma-mass spectrometry
Limestone	Weighed, dried and crushed to 75% passing 2 mm, with a 250 g split pulverized to 85% passing 75 microns	Major/Minor Oxides	Borate fusion / X-ray fluorescence spectroscopy
		Multi-element	Four-acid digest / inductively-coupled plasma-atomic emission spectroscopy
		Multi-element	Four-acid digestion / inductively-coupled plasma-mass spectrometry
Whole Rock	Weighed, dried and crushed to 75% passing 2 mm, with a 250 g split pulverized to 85% passing 75 microns	Major/Minor Oxides	Borate fusion / X-ray fluorescence spectroscopy
		Multi-element	Four-acid digestion / inductively-coupled plasma-mass spectrometry
		Multi-element	Four-acid digest / inductively-coupled plasma-atomic emission spectroscopy

6.4 Soil Sampling

The 2017 exploration program included the collection of 2394 soils samples from the "KZK southwest" ("KSW") grid, along with 97 from orientation lines over the ABM and GP4F deposits, and another 118 for QA/QC (Table 4). Methods for soil sampling, pH measurements and geochemical analysis are described below.

Table 4: Overview of samples collected as part of 2017 KZK soil sampling program

Sample Type	Grid	Line km	Samples	Sample/line-km	Assays	Comments
Exploration soil	KSW Grid	245	2394	10	2393	One sample lost
Orientation soil	ABM Central	1.80	51	28	51	
	ABM West	0.59	16	27	16	
	GP4F	0.96	30	31	30	
QA/QC	Blanks	n/a	44	n/a	44	
	Field Duplicates	n/a	74	n/a	74	
Total			2609		2608	

6.4.1 Field sampling

The KSW grid covers approximately 4 x 6 km^2 at 100 x 100 m sample spacing, extending from just west of the ABM deposit to the western and southern boundaries of the Property (Figure 4). Orientation lines were run north-south and sampled at 25 or 50 m spacing. One of these lines crosses both the ABM and Krakatoa zones of the ABM deposit, the 2nd crosses the western end of the ABM Zone (Figure 5) and the 3rd line runs across the GP4F deposit (Figure 6).

The soil sampling crew averaged four workers for most of the program. Samplers exposed the contact between the A- and B-horizons, and sampled silty B below the base of A. Each soil sampler had their own Garmin GPSmap® 62 unit with the planned sample coordinates, which were uploaded with GPS TrackMaker® software. Field data was captured on Rite-In-The-Rain® sheets and then transferred daily into an Excel spreadsheet, along with the uploaded GPS sampling coordinates. Data captured at each sampling station includes the soil horizon, colour, texture and moisture content, as well as the station ID, sample depth and vegetation. Each station ID matches the sample ID corresponding to the bar-coded sample tags provided by SGS. The soil horizons were classified as either Ah, B or C, with instructions to collect, in preferential order, B then C then A. Colour codes were restricted to orange, red brown, yellow brown, brown, grey, black. Texture was described by allocating proportions of organic, clay, silt, sand and pebbles to total 100%. Moisture content was captured as moist or wet. The sampling depth was measured (in cm) from the ground surface to the base of the sampling pit. Vegetation was recorded as one of either alpine, brush, swamp or talus. All soil sampling field notes are provided in Appendix K. Samples collected for QA/QC monitoring included field duplicates and blanks. Field duplicates comprise a second soil sample taken from the same general sampling site, but from its own pit. One of these daughter samples was taken every 20 to 40 samples for a total of 74 field duplicates. Blank samples consist of silica powder that was inserted at a rate of 1 for every 40 samples, for a total of 44. These 118 QA/QC samples comprise 4.5% of geochemical analyses.

6.4.1 Soil pH measurements

The pH of each soil sample was measured at KZK Camp. For each sample, 15 g of 180 mesh sieved soil sample was agitated with 40 mL of de-ionized water. This soil-water paste was then analyzed with a handheld Ultrapen™ PT2 pH and temperature pen. After the first analysis, the mixture was acidified with a single drop of 10% HCl, stirred and re-analyzed with the PT2. Captured data for each soil sample ID included pH original (i.e. before acid), pH with acid, temperature, date and the pH meter used, as some measurements were also done with an Oakton pH meter. Glassware and pH meters were rinsed with de-ionized water between each analysis.

The pH meters were calibrated at the start of each work day using a set of calibration solutions for pH: 4, 7 and 10. In addition, measurements were made on a “gravel pit standard” that was collected from road improvement material stored at KZK Camp.

The original and acidified pH measurements were used to calculate the inverse difference hydrogen (IDH) factor (Smee, 2013) for each sample:

$$IDH = 1/(\text{acidified } H^+ - \text{original } H^+)$$

where $H^+ = 10^{-pH}$. The IDH factor helps to outline the calcite peak on either side of a H+ (or low pH) anomaly, which is the definitive signal for a body undergoing oxidation (Smee, 2013). All pH sampling data is provided in Appendix L.

A subset of 92 soil samples were also analyzed by SGS for pH as a QA/QC check of the onsite pH analyses. The SGS method (GE_ISE15V) also involves measurement on a soil-water paste.

6.4.2 Soil sample geochemical assay

After pH analyses were done, groups of 5-10 soil Kraft bags were placed into a polyethylene bag, taped up and placed with 4-5 other polyethylene bags into a single rice bag for shipment. Each rice bag was sealed with a uniquely numbered security tag and then shipped to Whitehorse, YT, via Ross River-based Tu-Lidlini Petroleum and Whitehorse-based Small’s Expediting, and then to SGS Canada in Burnaby, BC, with Canadian Freightways.

At the SGS lab in Burnaby, BC, soil samples were received, logged in, oven dried at 60°C and then sieved at 80 mesh (180µm). Samples were digested in aqua regia and then analysed by ICP-MS for 36 elements (SGS code GE_IMS14B). In addition, gold was analyzed by fire assay fusion of a 30 g aliquot followed by atomic absorption spectroscopy (AAS) analysis (SGS code GE_FAA313). All soil sample certificates of assay and QA/QC reports are presented in Appendices M and N, respectively.

6.5 Geophysical Surveys

Geophysical work done in 2017 includes a surface EM survey, a borehole EM survey, and an acoustic impedance testing program. The EM surveys were conducted as part of a target generation project north of the ABM deposit while the acoustic impedance testing program was performed to determine the effectiveness of seismic reflection profiling as an exploration tool at the KZK property.

6.5.1 Surface EM

A Fixed Loop Transient Electro-Magnetic (FLTEM) survey was conducted at the KZK property between 2 September and 31 September 2017. The purpose of this survey was to target potential mineralization postulated to exist north of and down dip from the ABM deposit.

The survey was conducted by Discovery Geophysics International and consisted of two adjacent but slightly offset loops (Loop 1 and Loop 2) (Table 5), both of which had dimensions of 2000 m x 1500 m. Loop 1 was accompanied by 10 survey lines, most of which were 2.20 km in length, but which ranged from 1.90 km to 3.00 km, for a total survey length of 22.40 line-km. Loop 2 was accompanied by 7 survey lines, all of which were 2.50 km long for a total survey length of 17.50 line-km. All of the survey lines were oriented north-south across the long axis of the loops with stations spaced 100 m apart, with 50 m infill stations placed at the operator's discretion. In order to help merge the data between the two loops, a 1 km section of overlap was included on lines that were common to both loops. Accounting for the overlap, the total survey length was therefore 32.90 line-km across both loops and encompassed a total of 373 reading stations (268 on Loop 1, 182 on Loop 2, 77 overlap). Figure 7 shows a map of the EM Loops and survey lines while Table 5 summarizes the lengths and number of stations on each survey line.

Table 5: FLTEM survey line lengths and number of stations

	Loop 1		Loop 2		Overlap		Total	
Line	Line-km	Stations	Line-km	Stations	Line-km	Stations	Line-km	Stations
4050E	2.20	23	2.5	26	1.0	11	3.70	38
4350E	2.20	23	2.5	26	1.0	11	3.70	38
4650E	2.10	26	2.5	26	1.0	11	3.60	41
4750E	3.00	33	0	0	0	0	3.00	33
4950E	2.20	30	2.5	26	1.0	11	3.70	45
5250E	2.20	27	2.5	26	1.0	11	3.70	42
5550E	2.20	27	2.5	26	1.0	11	3.70	45
5850E	2.20	31	2.5	26	1.0	11	3.70	46
6150E	2.20	28	0	0	0	0	2.20	28
6450E	1.90	20	0	0	0	0	1.90	20
Total	22.40	271	17.50	182	7.00	77	32.90	376

The instrument for this survey was an Electromagnetic Imaging Technology (EMIT) SMART Fluxgate sensor coupled with an EMIT SMARTem24 Receiver unit and involved measurements of the X, Y, and Z components of the secondary EM field (B-field). The current source for the EM loops was provided by a Phoenix TXU-30 30kW transmitter, upgraded from a 20kW transmitter in order to produce greater depth projections of the EM field. Power for the transmitter was supplied by a Subaru RGV13100T (13kW) 3-phase generator and the loop wire consisted of 10 AWG EM tracer wire. The base frequency for Loop 1 was 5 Hz and involved 29 time-gates ranging from 0.0995 to 42.68 ms after shut-off, except for line 4750E, which had a base frequency of 1 Hz and involved 36 time-gates ranging from 0.0995 to 194.0 ms after shut-off. Loop 2 had a base frequency of 2.5 Hz and included 32 time-gates ranging from 0.0995 to 81.67 ms after shut-off. The current in both loops was 20 A and the turn-off time was 700 µs.

QA/QC of the FLTEM survey data was performed on-site by Discovery International Geophysics' personnel. The full TEM waveform was recorded at a high sample rate for each individual stack (256 stacks per measurement) to allow for post-survey processing such as stacking and windowing of the secondary TEM

data. Post-survey processing was carried out using the EMIT SMARTem24 software. This software was also used to quality-check the readings at each station by examining the secondary decay plots for each component. Readings with decays that were either not smoothly varying with time, or that were significantly outside the range of the majority of decays at that station, were deleted from the stack. The final edited data was written to a final EMIT format (*.TEM) data file for each line surveyed. These *.TEM data files were then imported in to another EMIT processing program (Maxwell) which plotted and modelled the EM data. The final profile plots for each line, as well as additional information regarding the survey parameters, are included in the Discovery International Geophysics Logistics Report attached in Appendix O.

6.5.2 Borehole EM (BHEM)

Discovery International Geophysics completed a Borehole EM (BHEM) survey at the KZK property in 2017. This survey was conducted in tandem with the surface FLTEM survey and was designed to target the same postulated northern extension of the ABM deposit between 2 September and 31 September 2017.

Three drill holes (K17-447, K17-448, K17-449) were drilled in the northern extension target area in order to test for potential down dip mineralization. The BHEM survey was conducted on these holes to detect off-hole EM conductors in the area. The three holes were drilled approximately perpendicular to local stratigraphy and ranged in length from 452.00 m to 1017.00 m, for a total surveyed length of approximately 2,175 m. Two of the BHEM holes (K17-447, K17-448) used Loop 1. The third BHEM survey (K17-449) used FLTEM transmitter Loop 3. A map of the drill hole locations in relation to the FLTEM survey loops is included in Figure 7.

The BHEM surveys were all conducted using the same transmitter, receiver, and generator as the surface EM survey (see previous section). Measurements were captured using an EMIT DigiAtlantis borehole probe which measured all three components of the primary EM (B) field; A (axial down hole), U (orthogonal to A parallel to the azimuth of the drill hole), and V (orthogonal to A and U). The probe was lowered through the hole using a Discovery Winch Frame and borehole cable reel. Measurements were made at 20 m intervals throughout the hole with additional infill readings made at 5 and 10 m increments at the operator's discretion. A base frequency of 5 Hz coupled with 29 time-gates ranging from 0.0995 to 42.683 ms was used for each survey. The transmitter current and turn-off time however varied from 10.0 to 28.0 A and 700 to 1200 µs respectively. Similar to the surface EM survey, QA/QC of the BHEM survey data was performed on site by Discovery International Geophysics' personnel and data processing, plotting, and modelling was completed using EMIT Maxwell software. A summary of the BHEM survey parameters are presented in Table 6 and additional information as well as the final profile plots for each hole are included in the contractor report attached in Appendix O.

Table 6: BHEM survey parameters

Hole ID	Loop	Frequency (Hz)	Loop Dimensions (m)	Current (A)	Turn-Off Time (µs)	Hole Length (m)	Surveyed Interval (m)	Total Surveyed (m)
K17-447	1	5.0	2000 x 1500	10.0 - 20.0	700 - 1200	452.00	20 - 445	425.00
K17-448	1	5.0	2000 x 1500	10.0 - 20.0	700 - 1200	1017.00	20 - 1000	980.00
K17-449	3	5.0	900 x 900	28.0	700	800.00	20 - 790	770.00

6.5.3 Acoustic impedance study

An acoustic impedance (AI) testing program was carried out on drill core from 9 KZK drill holes during 2017. The program was managed by HiSeis Pty Ltd., a Perth-based seismic services company. The purpose of the program was to test their seismic reflection method for sub-surface exploration and modelling at KZK. The program was the first phase of a proposed three-phase approach to complete a 3D seismic survey. HiSeis personnel conducted acoustic impedance testing and trained Equity staff on the procedures, between 21 July and 25 July 2017. Majority of the acoustic impedance testing was performed during this time, with additional supplementary data collected during the remainder of the drill program.

Acoustic impedance measurements were performed at approximately 1 m intervals in drill core, where core pieces were greater than 15 cm. Velocity measurements were conducted using a UK1401 Ultrasonic

Tester on dry consolidated core over 15 cm in length. 3 velocity measurements, 15 seconds each, were conducted in a single sample interval and averaged. The density of the sample was measured, using the same method described in section 6.6.2. HiSeis processed this data along with notes on the geology to determine the acoustic impedances of certain lithological and stratigraphic units. A full description of the methods used during the 2017 program can be found in Appendix P.

6.6 Drilling

The 2017 drilling program included exploration drilling in and north of the ABM Zone (N = 4), infill drilling at the ABM Zone (N = 1), drilling for in-pit geotechnical investigations (N = 9), and infrastructure related geotechnical drilling (N = 35), for a total of 48 drill holes and 4928.7 m (Table 7, Figure 8).

Table 7: Summary of 2017 drilling

Program	Purpose	DHs	Metres	Comments
Exploration	Exploration and Downhole Geophysics	4	2451	
In-pit Geotechnical	Geotechnical investigation, hydraulic conductivity testing, televiewer	9	1540	
Infrastructure Geotechnical	Geotechnical Investigation, water monitoring installation	35	937.7	Includes one abandoned hole
2017 Total		48	4928.7	

*Includes dual purpose infill and metallurgical drill holes

New Age Drilling Solutions (“New Age”) and Midnight Sun Drilling Inc. (“Midnight Sun”) completed the 2017 KZK drilling program. New Age drilled from 23rd of June to the 3rd of October using a skid-mounted Zinex A5 diamond drill rig, which was converted to be helicopter-portable part way through the drill program. All New Age drilling was done using triple tube HQ3, with inner splits used to maximize core recovery. Midnight Sun drilled during two periods between June 28th to October 23rd using a MultiPower Prospector P1 track mounted drill and a TerraSonic CC150 track mounted drill. Midnight Sun drilling used a combination of drilling techniques, including ODEX and Sonic drilling through overburden and diamond drilling with triple tube HQ3, with inner splits in bedrock.

Trans North Helicopters Ltd of Whitehorse, Yukon, (“Trans North”) provided helicopter support for drill moves and logistical support. Yukon-based contractors hired through Equity built lumber drill pads for helicopter-supported drilling, with sites cleared by the pad builders using a CanDig Mini Excavator.

Figure 8

6.6.1 Collar and downhole surveys

Drill hole collars were spotted with either a handheld GPS or were laid out by Challenger using an RTK DGPS. Prior to drilling, drill rigs were aligned using a Brunton Pocket Transit Compass set to a declination of 20.3° in order to correct to true north azimuth (Figure 9). Short, vertically oriented drill holes were not aligned along any particular azimuth. After completion of the drill hole, drill collars were marked with a wooden stake and surveyed with an RTK DGPS. Surveyed drill collar locations are presented in Appendix D.

Downhole orientation surveys were completed using both a Reflex EZ-shot system and Reflex EZ-Gyro downhole probe. Short, vertical drill holes were not surveyed for azimuth drift.

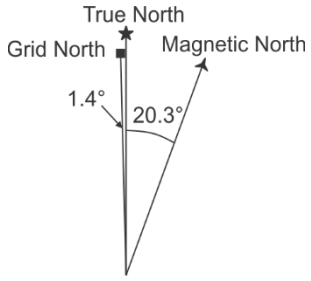

Figure 9: A diagram representing the angles between grid north, true north, and magnetic north at the KZK property, June 14th, 2017

The Reflex EZ-Shot measures drill hole azimuth relative to magnetic north, as well as dip and magnetic field strength. Magnetic north azimuth readings were converted to UTM grid north by adding 21.7°. The shallowest EZ-shot surveys were typically completed 12–18 m into bedrock, followed by tests at 24 m intervals as the hole progressed. Survey results were not used if the measured azimuth deviated significantly from those above and below, which is typically due magnetic interference (i.e. magnetic bedrock, drill string). Such interference can often be confirmed by magnetic field strength readings that deviate from between 5600 nT and 6000 nT.

The Reflex EZ-Gyro gyrocompass tool uses a north-seeking micro-electromechanical system (MEMS) to measure drill hole azimuth and dip deviation relative to true north. Measurements are unaffected by ferromagnetic materials therefore the tool can be used inside the drill string and are not affected by magnetic bedrock. True north azimuth readings were corrected to UTM grid north by adding 1.4° (Figure 9). Gyro surveys were typically recorded at 15 m intervals downhole during drilling. Single-measurement readings were recorded as “Standard” and multi-measurement readings were recorded as “Optimized”.

All in-pit drill holes were surveyed down-hole with the EZ-shot system. K17-447 was surveyed with both the EZ-shot and EZ-gyro systems. K17-448, 449, and 450 were surveyed with the EZ-gyro system.

6.6.2 Core orientation

Drill core was oriented in every exploration drill hole in 2017 from the base of overburden until the end of hole (EOH). The bottom-of-hole orientation mark was placed by the drill crew using a Reflex ACTIII RD core orientation system. Following transport to the core shack, geotechnicians would realign the core and draw a blue orientation line if the bottom of hole mark could be accurately related to the rest of the drill run. Orientation lines were transposed onto adjacent runs if the start or end of the runs could accurately fit together. Alpha and beta angles of structural features were recorded along with a confidence rating on a scale of 1 to 3 as follows: (1) not certain of orientation and measurement, (2) moderate confidence since core matches well with orientation mark, and (3) high confidence because orientation line matches well for entire drill run. Additionally, lock angles were recorded between drill runs which fit together throughout the runs. Lock angles measure the beta angle between orientation marks of different runs, allowing to quantify variations in the orientation of the downhole mark.

6.6.3 Geological core logging

Geological logging was completed by the onsite geologists, who collectively logged 100% of the core drilled in 2017. Core logging focused on lithology, mineralization, alteration, structure, veining, oxidation intensity and geodomain classification, with data captured in GeoSpark database software. All drill core was photographed and is stored on pallets at the KZK Camp, along with relocated historical core. Drill logs are attached as Appendix Q.

Lithology was logged with the same coding system defined in 2016 (Hughes and Voordouw, 2017). Mineralized intervals are recorded in the mineralization table and, above 20% modal sulphide, the lithology table as massive sulphide (e.g. OA, OB) and semi-massive sulphide (e.g. OI, OJ).

Alteration was logged in the alteration table of the GeoSpark database, with features recorded including mineral type (e.g. MU for muscovite, CL for chlorite) and an interpreted origin as either “original” (OR, syngenetic hydrothermal) or “overprint” (OP, regional metamorphic) alteration. Alteration types associated with syngenetic hydrothermal alteration at the ABM deposit include muscovite (MU, OR), chlorite (CL, OR), and cordierite (CI, OR).

Structures were characterized (i.e. fault, foliation), attributed an intensity on a scale of 1 to 7 (1 = trace, 7 = intense) and, if possible, measured relative to core axis (alpha angle). Orientations measured on oriented core were also given a beta angle and orientation confidence on a scale of 1 to 3, where 1 is lower certainty and 3 is highest. Approximately 90% of all structural records (N = 3362) are for the dominant foliation, or joint, foliation (DFOL, FOL) and fault zones (FLT).

Veins were logged as sets characterized by a core depth range, vein mineralogy, core axis angle and percent abundance within the defined interval. Oxidation was logged on an intensity scale of 0 to 4, where 0 is unoxidized and 4 is completely oxidized. The geodomain classification was typically applied by the project geologist after core logging was complete and the drill trace plus data was imported into Micromine. Classifications include three metallurgical domains for ore and nine metallurgical domains for waste rock, and used the codes developed in 2015 (Baker, 2015a; Duncan, 2015).

6.6.4 Geotechnical core logging

All drill core (100%) was geotechnically logged, either by Equity geotechnicians, Knight-Piésold engineering personnel, and/or Dempers and Seymour personnel. Data from the drill core logged by Equity was captured in GeoSpark software, an Access-based database management system. Geotechnical core logging was done by geotechnicians and involved measuring recovery, rock quality designation (RQD), magnetic susceptibility and bulk density. Results are captured within data tables named “Geotech” (recovery, RQD), “Geophysics” (magnetic susceptibility) and “Specific Gravity” (bulk density).

Recovery was measured to the nearest centimetre, from core block to core block and from the base of overburden to the end of hole. The total recovery for the 2017 drilling program was 91.8%, which is calculated by summing all of the core recovered and then dividing by the difference of drilled metres minus overburden. Overall, the 2017 recovery is equivalent with the 2016 program (91.7%).

Rock quality designation (RQD) was also measured from core block to core block, comprising the sum of all naturally fractured core lengths >10 cm in length divided by the run length. Natural fractures include breaks that are inherent to the lithology (e.g. joints) but not mechanical breaks generated by drilling. Average RQD is significantly lower for the 2017 program (32.7%) than for the 2016 program (51.6%) programs. This is likely due to both the high number of faults drilled in 2017 for geotechnical investigation and also the high number of short holes, which did not intersect significant unweathered rock.

Magnetic susceptibility for all holes were measured with a multi-parameter (MPP) probe from Instrumentation GDD Inc. Magnetic susceptibility measurements were taken at 0.5 m intervals, starting from below the base of overburden to the end of hole. Statistics for magnetic susceptibility are presented in Table 8.

Table 8: Magnetic susceptibility data collected as part of all BMC KZK drill programs

Campaign	Instrument	Readings	Mean	Std dev	Skew	Min	25th %ile	Median	75th %ile	Max
2017	MPP probe	7004	1.92	8.37	29.64	0.0	0.19	0.66	1.82	411
2016	KT-10	846	1.7	12.9	13.5	0.0	0.0	0.2	0.3	248
2016	MPP probe	31484	2.4	21.4	21.7	0.0	0.0	0.3	1.1	796
2015	KT-10	17160	7.79	46.76	10.1	0	0.27	0.63	1.43	937

A total of 657 bulk density (BD) measurements were completed, mostly on representative 10–15 cm long whole core samples of various hanging wall and footwall lithologies (N = 466) as well entire half- or quarter-core sample submitted for analysis (N = 102) and SG standards (N = 89). Each of these samples was twice weighed in a basket suspended below a digital metric balance, once in air and a second time in water (i.e. “water immersion method”). Measuring directly on the scale was avoided due to magnetic interference concerns. No measurements were taken on excessively friable or broken samples.

The two standards used to monitor BD measurements were each calibrated by averaging 50 measurements, which returned bulk densities of 4.60 ± 0.10 g/cm^3 for a piece of NQ-sized massive sulphide (SG MXSX standard) and 2.65 ± 0.05 g/cm^3 for a BQ-sized piece of porphyritic rhyolite (SG RHY standard). Weights of these standards overlap with core samples. One standard was weighed for every nine bulk density measurements. Geotechnical drill data is available as Appendix R

6.6.5 Geochemical sampling and assay

A total of 250 samples were submitted for geochemical assay, comprising 223 HQ3 half-core samples, 13 blanks and 14 certified reference material (CRM) samples. Each of the core samples was marked with a unique sample tag in the core box. All mineralized intersections were sampled along with 1–10 m of the immediate hanging wall and footwall rock to characterize waste rock dilution. Core samples were constrained by lithological contacts, with the exception of very short lithologies. If possible, sampling was constrained by alteration and mineralization features as well. Mineralized samples had a nominal sample length of 1.0 m and a minimum length of 0.3 m whereas barren or weakly mineralized samples have typical nominal and minimum sample lengths of 1.5 m and 0.5 m respectively.

Half core samples were cut parallel to the core axis with an open circulation rock saw. Split core was consistently sampled from the same side, then placed into labelled plastic sample bags that were sealed with a plastic zip tie. Samples were then packed into rice bags together with QA/QC samples (i.e. certified reference materials, blanks), sealed with security tags and then shipped to SGS Mineral Services Geochemistry Vancouver in Burnaby, BC, (“SGS”) for geochemical assay. A list of required quartz washes to follow suspected high-grade samples was also submitted to SGS, in order to avoid contaminating adjacent lower grade samples. These quartz washes were completed at the crush and pulveriser stage of sample preparation.

Each core sample was analyzed for selected base metals (Cu, Fe, Pb, Zn), precious metals (Ag, Au) and trace elements (As, Ba, Bi, Hg, S, Sb, Se), with all analytical certificates attached in Appendix S. Quality assurance and quality control (QA/QC) of these analyses was monitored through the insertion of certified reference materials (CRMs) and blanks alternately every 10 samples into the sample sequence, and through two check assay programs. A review of the QA/QC program is attached as Appendix T.

All CRMs were manufactured from sulphide ores and are the same as those used during the 2015 drill program (Hughes et al., 2016; Voordouw, 2016b). The CRMs are certified for Cu, Pb, Zn at the % level, as well as Au and Ag at the ppm level, and were originally selected to match low-, medium- and high-grade mineralization. During sampling, CRM selection was based on the tenor of surrounding mineralization, with CDN-ME-1311 used for low-grade, OREAS 621 and 623 used sequentially for medium-grade, and OREAS 113, GBM310-16 and G312-4 used for high-grade. A minimum weight of 100 g was used for CRM samples so that reanalyses could be completed if required. Blank material comprised the same barren landscaping stone that was calibrated in 2015 (Hughes et al., 2016; Voordouw, 2016b). The CRM suite was more widely used in 2015 with three CRMs preferentially used in 2016 and GBM310-16 only used once (Table 9).

Table 9: CRM usage during BMC KZK drilling programs

CRM Type	Number of times used		
	2015	***2016***	***2017***
CDN-ME-1311	109	65	11
OREAS 621	63	34	1
OREAS 623	62	34	1
OREAS 113	14	0	1
GBM310-16	15	1	0
G312-4	9	0	0

6.7 Geotechnical Investigations

Geotechnical investigations completed in 2017 included diamond drilling for in-pit geotechnical investigations (N = 9), and infrastructure related geotechnical drilling (N = 35), test pitting, geotechnical logging as well as field and laboratory testing of geological materials. Drilling methods are reported in section 6.6 Drilling.

The majority of the 2017 geotechnical investigation program was focused on the infrastructure geotechnical investigation, including 35 of 44 geotechnical drill holes (937.7 m) and all 14 test pits. This portion of the 2017 geotechnical program was conducted by Knight Piésold Consulting of Vancouver, BC ("Knight Piésold"). The other portion of the geotechnical investigation program was focused on the in-pit geotechnical investigation, including the remaining nine drill holes (1540 m) and the optical-acoustic televiewer program. This program was directed by Dempers and Seymour Pty Ltd. of Perth, WA ("Dempers and Seymour").

6.7.1 Infrastructure geotechnical program

Infrastructure-focused drilling and test pitting was conducted at the proposed sites for classified materials storage, stockpiles, mill site and paste plant. The program was completed over two phases, with drill holes K17-421 through K17-426 competed between June 28 to August 13, 2017 (phase one), and drill holes K17-451 through K17-466 completed from October 4 through October 23, 2017 (phase two).

The geotechnical program conducted on the geotechnical drill holes included geotechnical logging of standard penetration testing (SPT) of surficial materials, uniaxial compressive stress (UCS) testing on representative core samples. Geotechnical logging data from this program is available in Appendix R.

SPTs were performed at approximately 1.5 m intervals until bedrock was encountered to estimate the state (compactness) of the material and to obtain samples for laboratory testing. Tests were conducted with an automatic hammer equipped with a 610 mm AWJ split spoon sampler. Blow counts were recorded at four continuous 150 mm intervals for a maximum sampling length of 600 mm. The N-value was determined as the sum of the blow counts for the second and third interval and can be related to the compactness of the soil. The tests were terminated prior to reaching the maximum sampling length when less than 150 mm penetration per 50 blows was achieved. The length of the incomplete test was recorded when early refusal occurred.

A total of 10 Rock samples were taken from the 2017 geotechnical drilling for laboratory testing in order to characterize their strength. The rock samples were subjected to uniaxial compressive stress (UCS) tests at the Norman B. Keevil Institute of Mining Engineering at the University of British Columbia.

Hydrogeological monitoring equipment was installed in ten of the infrastructure drill holes. Packer testing for hydraulic conductivity was completed in 12 infrastructure drill holes during the 2017 infrastructure program. Further information can be found in section 6.10 Hydrogeological Investigations.

Overburden test pits were located with a handheld GPS and dug to refusal at the top of bedrock, barring technical or environmental issues such as insufficient machine capability, excessive groundwater ingress, poor wall stability and/or permafrost. Test pit walls and stockpiles were geotechnically logged and samples were collected for additional laboratory testing. Pits were accessed using existing trails and roads where possible,

however some locations required making new trails. Each test pit was reclaimed through backfilling and recontoured to match the pre-excavation ground profile.

6.7.2 In pit geotechnical program

The purpose of the in-pit geotechnical investigation program was to study the geotechnical properties of the proposed open pit high-wall. The program comprised the geotechnical logging of historic and 2017 drill holes, hydraulic conductivity testing, and optical and acoustic televiewer surveys performed on open boreholes upon completion of each drill hole.

Geotechnical logging of historical and new drill holes was conducted by D&S personnel. Hydraulic conductivity testing was conducted on 2017 drill holes during drilling.

Downhole optical and acoustic televiewer surveys were completed by Equity geologists. These surveys provide in-situ imaging of the bore hole walls in order to collect structural measurements and characterize the nature of the rock mass at the proposed pit wall. Drill holes were planned to intersect the proposed pit wall at a right angle. Upon completion of a drill hole, the drill rods were removed, and the borehole was flushed with water. A dummy probe was used to test the integrity of the bore hole walls prior to sending the televiewer instrument down the hole. Two surveys were conducted using the optical and acoustic televiewer probes to capture optical and acoustic data along the length of the hole.

The optical televiewer produces a true colour image of the bore hole wall while the acoustic televiewer produces an acoustic image of the internal wall. The acoustic image is a sonar image based on the amplitude and travel time of acoustic beams emitted by the probe and reflected off the drill hole wall. Both the optical and the acoustic survey methods produce 360° images of the drill hole wall and both utilize a built-in fluxgate magnetometer to orient the image with respect to magnetic north. Rock structure can be interpreted from both images to give dip and dip direction for each feature down the hole, as well as to identify fractures and zones of broken ground.

The data produced from the televiewer survey was interpreted by D&S engineers to inform a 3D geotechnical structural model of the pit area and determine design parameters of the pit wall. Downhole logs from the televiewer program can be found in Appendix U.

6.8 Hyperspectral Imaging Study

Over the course of the 2017 field season, spectra were measured on cut and whole drill core at 3-5 metre intervals over 35 holes. In addition to the spectral capture, sample location depths were measured, marked with a grease pencil on the core, described, and photographed. In total, 4101 rock spectra were captured over 3330 unique locations. Samples were captured in the field using a field portable TerraSpec® VIS-NIR Spectrometer (“TerraSpec”). The system collects spectra in the visible and near infrared (VNIR, 350-1000 nm) and short-wave infrared (SWIR, 1000-2500 nm) wavelength ranges (Danner et al., 2015). Measurement procedures followed those recommended by the manufacturer (ASD Inc., 2008).

Processing of the TerraSpec data was performed in The Spectral Geologist™ (“TSG”), a dedicated and geologically-focused program for processing spectral analyses. Spliced spectrum files (.sco files) were imported into TSG, and de-stepped between 440 and 2240 nm to remove any artefacts from the splicing process. The final correction spectrum was set to “Spectralon Absolute Reflectance” in order to match with the white reference that was used. SWIR data was the focus of this exercise due to the abundance of hydroxyl group (OH) bearing minerals in the study area. VNIR spectra from 350 to 1300 nm were also processed however there were very few valid analyses in the VNIR range and this data was not used in our analysis.

After processing the spectra in TSG, mineral IDs are matched by The Spectral Assistant® “TSA” (a routine within TSG) and various scalar data are extracted from the spectra and exported to .csv for further analysis.

Scalar data were exported to .csv and matched with their corresponding depths. The resulting table was then filtered to remove redundant data and imported to Micromine. Scalar data was attached to their corresponding drill holes as event data, and X-Y-Z coordinates were generated from these event data to plot

the scalar data as points. Data was then filtered in Micromine to generate useful subsets of data for interpretation. Drill core TerraSpec data is included as Appendix V.

6.9 Hydrogeological Investigations

The 2017 hydrogeological work program was undertaken as a part of the infrastructure drilling program (Section 6.7.1). The program involved hydraulic conductivity testing and the installation of vibrating wire piezometers, stand pipe piezometers, and thermistor strings. The locations of these drill holes can be found in Figure 8.

6.9.1 Hydraulic conductivity testing

The hydraulic conductivity testing (packer testing) for the infrastructure geotechnical investigation was conducted by Knight Piésold engineers. Packer testing was completed at 7–16 m intervals with a nitrogen-inflated single-packer system manufactured by RST Instruments Ltd of Maple Ridge, BC or water-inflated packer system manufactured by Inflatable Packers International. The procedure involved injecting water at a constant pressure into a flushed and sealed drill hole for 20 minutes in order to measure the volume of injected water with a flow meter. The injection pressure and volume of water pumped into the bedrock are used to calculate the hydraulic conductivity of the rock mass.

Drilling contractors and methods were the same as those used in infrastructure drilling program (section 6.7.1), although each well hole was drilled without the use of drilling additives or rod grease. Once drilling was complete the holes were then flushed with clean water until the water return out of the casing was clear. Recovered core was reviewed by Knight Piésold staff to select a suitable zone over which the well screen would be installed. Screened zones were selected to target areas of increased permeability identified by geotechnical logging and packer testing.

Hydraulic conductivity testing for the in-pit geotechnical program was conducted by Knight Piésold engineers using a single bladder packer style system above and below the major fault zone at both Krakatoa and ABM to determine hydraulic conductivity of the bedrock in the proposed pit wall.

Packer testing was completed at 6–10 m intervals with a nitrogen-inflatable single-packer system manufactured by RST Instruments Ltd of Maple Ridge, BC. The procedure involved flushing the drill hole with water, inflating the packer to seal the borehole, and 10–15 minutes of constant pressure water injection into the isolated zone, with injected water volume measured with a flow meter. The injection pressure and volume of water pumped into the bedrock are used to calculate the hydraulic conductivity of the rock mass.

6.9.2 Hydrogeological installations

Ten-node thermistor cables were installed in seven of the geotechnical drill holes during phase one, with the purpose of establishing ground temperature profiles across the project site. All seven of these installations were completed during the drill program, with each attached to PVC pipe, lowered downhole and then grouted in place with a mixture of cement and bentonite powder. The PVC pipe was filled with silicone oil to reduce the effect of the ambient air temperature on the ongoing thermal measurements. A DT2055B data logger was installed at each location to collect and record temperature measurements at regular intervals. A plastic protective casing was installed over the data logger at each site.

Vibrating wire piezometers (VWPs) manufactured by RST were installed to monitor the pore water pressure profile with depth and time. Six VWPs were successfully installed in three drill holes by KP personnel. The VWPs were attached to Schedule 40 PVC pipe as it was lowered down the holes. The pipes and piezometers were then grouted in place from the bottom of the hole up using a cement and bentonite powder mixture that was pumped down through the PVC. The VWPs were monitored throughout the grouting process to track grouting progress and to ensure no damage to the instruments occurred. A permanent DT2055B ten-channel data logger was installed at surface to regularly record pressure and temperature measurements. A plastic protective casing was also installed to protect the data logger.

Stand pipe piezometers were installed in seven drill holes during the infrastructure drilling program. Two holes that had stand pipe piezometers installations planned had no groundwater and were not equipped with

piezometers. Piezometers were installed with either a 1.5 m or 6 m screen at a completion zones depth ranging from 1.5 to 40.2 m.

6.10 Baseline Studies

Environmental and archaeological surveys initiated in 2015 were continued in 2017 in an effort to characterize the baseline conditions of the project area.

6.10.1 Environmental monitoring

Surface water quality monitoring was undertaken on a monthly basis throughout 2017, a continuation of the work that commenced in April 2015. Samples to assess water quality were collected from 11 surface water stations, with field measurements collected including pH, specific conductivity, temperature, redox potential, dissolved oxygen, temperature and turbidity. Laboratory testing of various other parameters was done by Maxxam Analytics of Whitehorse, YT, ("Maxxam") and included anions, alkalinity, acidity, ammonia, dissolved organic carbon, total and dissolved metals, total cyanide and weak acid dissociable (WAD) cyanide.

Ground water quality monitoring was carried out in June, September and early-November. Prior to sample collection, monitoring wells were purged so that field parameters stabilized to less than 10% variability. Measured field and laboratory parameters are the same as those measured for the surface water, with lab tests also completed by Maxxam.

Wildlife monitoring was conducted by an onsite environmental monitor as well as onsite personnel. Wildlife sightings were recorded in a log which was reviewed and consolidated weekly by the environmental monitor.

Wildlife habitat surveys focused on caribou, moose and breeding birds. Caribou surveys included a post-calving aerial survey in late July and a post-rut aerial survey in early October. Both surveys focused on the same areas used for the 1995, 2015 and 2016 surveys and were conducted with contour flight line patterns over alpine and subalpine areas. Moose surveys included an air-based late winter survey conducted in March and a post-rut surveys carried out in November. Breeding bird surveys were carried out at locations within the proposed mine site and along the tote road. Surveys utilized standard point counts, with breeding birds identified through sight and/or sound and species of interest observed between point counts also recorded.

6.10.2 Archaeological survey

All exploration activities requiring ground disturbance in areas with elevated potential for the presence of archaeological or historic sites were previously assessed in 2015 and 2016. In addition, no exploration activities occurred in alpine areas near ice patch features.

6.10.3 Fish/habitat surveys

Fish and fish habitat surveys were completed on Geona creek and the Geona-Finlayson creek confluence, with an emphasis on re-sampling the sites previously surveyed in 1995, 2015 and 2016. Further surveys were carried out on the South Lakes and Geona ponds. A scientific collection license was obtained from the Department of Fisheries and Oceans (DFO) prior to sampling. Captured fish were identified, measured, weighed and assessed for abnormalities, then released at the point of capture. Catch per unit effort (CPUE) was calculated to enable semi-quantitative comparisons of populations over space and time. Sampling locations and in situ water parameters (i.e. temperature, dissolved oxygen, conductivity) were also characterized. Sampling to characterize benthic, sediment and zooplankton conditions was carried out at each survey location. Ground- and air-based Arctic grayling spawning surveys were conducted in early June in the most suitable habitats, after the water temperature had increased to at least 4 °C and conditions were favorable for spawning.

7.0 GEOLOGICAL SETTING

7.1.1 Regional geology

The KZK Property is underlain by polydeformed Devonian to Mississippian meta-sedimentary, -volcanic and -plutonic rocks assigned to the Yukon-Tanana terrane, which extends from central British Columbia to eastern Alaska. These rocks are interpreted as the product of middle Palaeozoic continental arc magmatism in a pericratonic setting that was separated from Ancestral North America by a back-arc rift basin occupied by the Slide Mountain Ocean. In central Yukon the Finlayson Lake belt is comprised of lithologies assigned to both the Yukon Tanana and Slide Mountain terranes (Nelson et al., 2013). Syngenetic-penesyngenetic volcanic-hosted massive sulphide (VHMS) mineralization occurs in both terranes and is hosted in multiple settings.

The Finlayson Lake belt is a crescent-shaped area that is approximately 300 km long and 50 km wide, extending from Ross River in the north to Watson Lake in the south. It is juxtaposed with Proterozoic and Palaeozoic strata of the ancient North American continental margin to the southwest, along the Tintina Fault, and with Carboniferous rocks of the Slide Mountain Terrane to the northeast (Figure 10). The portion of the Yukon-Tanana terrane which underlies most of west-central Yukon is contiguous with the Finlayson Lake district through 456 km of Late Cretaceous right lateral strike-slip movement along the Tintina Fault (Layton-Matthews et al., 2008).

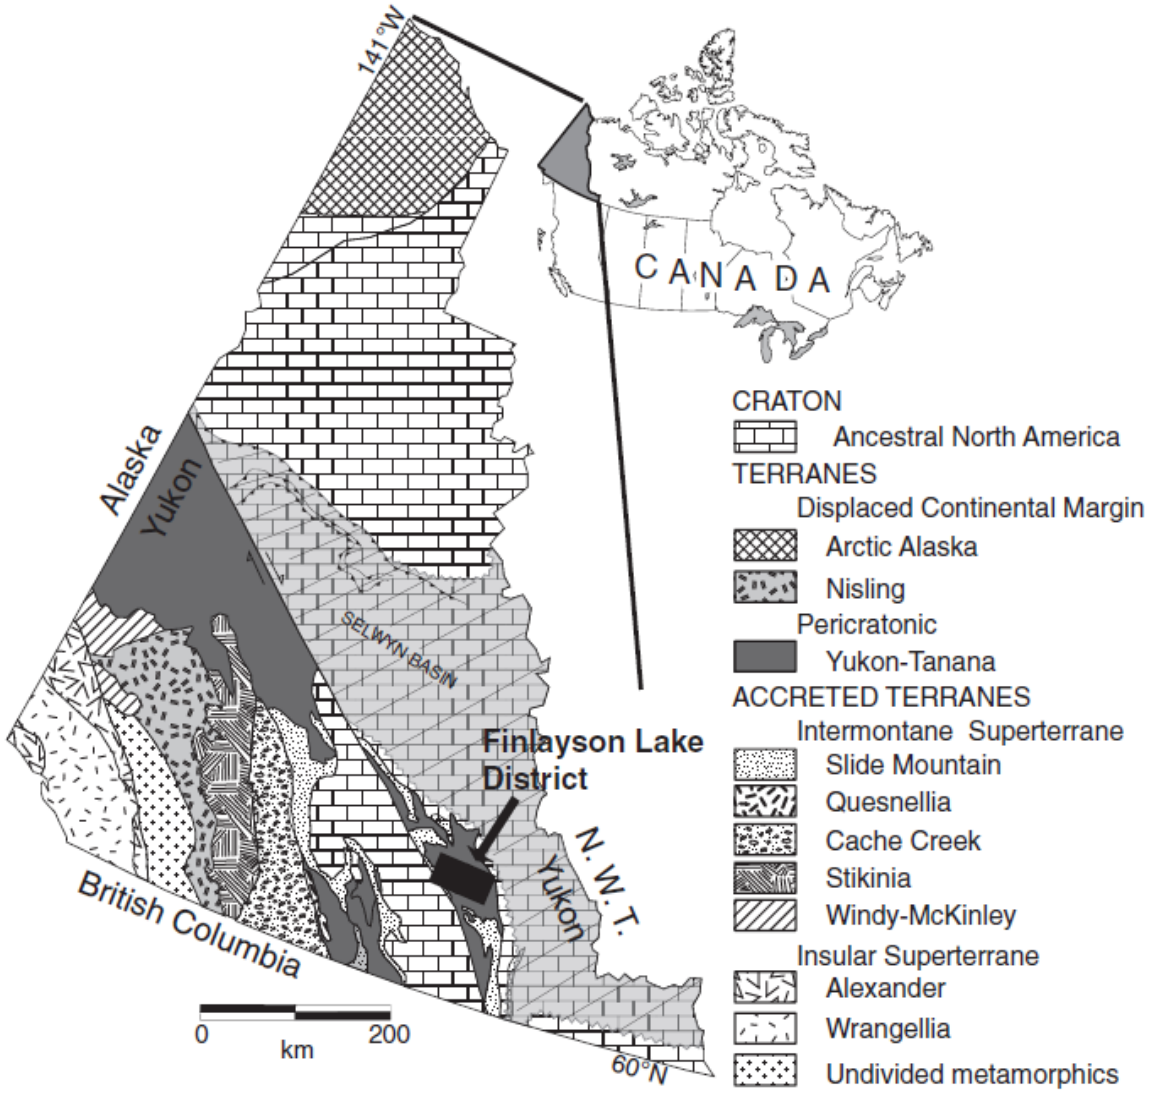

Figure 10: Regional geology of the Yukon showing the Finlayson Lake district (from Layton-Matthews et al., 2008)

7.1.2 Local geology

The Finlayson Lake belt of the Yukon-Tanana terrane is composed of foliated and lineated low-middle greenschist-grade meta-sedimentary, -volcanic and -plutonic rocks (Figure 11, Figure 12) that were imbricated by Permian thrust faulting into the Cleaver Lake, Money and Big Campbell thrust sheets. The final stage of thrusting placed this rock package onto North America and occurred along the Big Campbell and Inconnu thrusts in Late Triassic to Early Jurassic (Murphy et al., 2006). With the exception of the Limy 1–9 claim block and the corridor of claims along the tote road to the Robert Campbell Highway, the KZK Property lies entirely within the Big Campbell thrust sheet in what is the structurally deepest part of the Yukon-Tanana terrane (Murphy et al., 2006). Two middle Palaeozoic unconformity-bounded groups (Grass Lake and Wolverine) are exposed within the Big Campbell thrust sheet.

The lowermost part of the Grass Lakes Group (North River Formation) consists of pre-Early Mississippian (pre-365 Ma) quartz-rich, non-carbonaceous metaclastic rocks (**Dm**, **Dfv**, **Dqm** and **Dq**) dominated by quartzite psammite and metapelite with minor felsic metavolcanic schist, calcareous schist/metapelite and marble members (Murphy et al., 2006). The North River Formation is conformably overlain by 30 to >200 metres of the *c.* 365 to 360 Ma mafic-dominated arc- and back-arc-related Fire Lake Formation (**DF**), which consists of mafic metavolcanic schist and phyllite with minor carbonaceous phyllite and quartzite, rare marble and felsic metavolcanic, and locally significant meta-gabbro, -pyroxenite and -ultramafic bodies. The Besshi-style Fyre Lake Cu-Co-Au VMS deposit (Peter et al., 2007) is hosted in boninitic mafic to ultramafic rocks at the top of the Fire Lake Formation (Piercey et al., 2001a).

Conformably overlying the Fire Lake Formation is the felsic volcanic and sedimentary rock-dominated Kudz Ze Kayah ("KZK") Formation (**DK**, **DKcp** and **DKcs**), whose lower parts consist predominantly of Devono-Mississippian (*c.* 360–356 Ma) felsic volcanic and variably carbonaceous sedimentary rocks. These rocks are interpreted to have formed within a continental back-arc rift to back-arc basin (Layton-Matthews et al., 2008). The thickest accumulation of felsic metavolcanic rocks within the KZK Formation occur on the KZK Property, which hosts the ABM and GP4F VMS deposits. The KZK Formation grades conformably upwards into the Wind Lake Formation, which comprises a thick sequence of carbonaceous to locally calcareous phyllite with lesser siltstone, mafic metavolcanic, blue quartz-bearing grits, conglomerate, psammite and quartzite (**DMq**, **DMm**, **DMcp**, and **DMcg**). Coeval with the KZK and Wind Lake formations are Devonian-Mississippian (360±1 Ma) peraluminous K-feldspar porphyritic to megacrystic granites of the Grass Lakes plutonic suite (**MGg** and **MGag**), which are inferred to be subvolcanic feeders (MacRobbie and Holroyd, 2005b; Murphy et al., 2001; Piercey et al., 2001c).

The Wolverine Group unconformably overlies the Grass Lakes Group and consists predominantly of Early Mississippian (*c.* 357–346 Ma) felsic volcanic and carbonaceous sedimentary rocks (**MWb**, **MWt**, **MWf**, **MWcp** and **MWcl**) (Murphy et al., 2006). The succession contains, from bottom to top, a lower conglomerate, felsic volcanic-dominated unit, carbonaceous argillite, the immediate footwall felsic volcanic and subvolcanic rocks to the Wolverine VMS deposit, and a hanging wall consisting of aphyric rhyolite and carbonaceous sedimentary rocks that, near their top, host basalt flows. Rocks of the Wolverine succession are interpreted to have formed within an ensialic back-arc rift basin that evolved to seafloor spreading (Layton-Matthews et al., 2008). The Wolverine Kuroko-style VMS deposit occurs at the contact between footwall felsic volcaniclastic rocks and either hanging wall carbonaceous argillite or exhalative rocks (Murphy et al., 2001; Piercey et al., 2001c).

A subhorizontal to moderately steep north to northeast dipping, penetrative ductile deformation fabric (S_1) overprints all Grass Lakes Group lithologies and is associated with low-mid greenschist grade (chlorite-biotite grade) metamorphic assemblages. It is less prominent or absent in the Wolverine Group. D_2 structures comprise tight meso-scale F_2 folds and an S_2 crenulation cleavage that cuts S_1 cleavage. D_3 deformation-related structures consist of late brittle faults, including the East and Fault Creek faults, and fault-related smaller-scale structures like kink bands and possibly broad, open F_3 folds (Baker et al., 2017).

LEGEND FOR KZK LOCAL GEOLOGY (OPEN FILE 2001-33)

POST-THRUST INTRUSIVE ROCKS

CRETACEOUS

Kg — Equigranular biotite-muscovite granite

JURASSIC

Jg — Equigranular hornblende-biotite granite

YUKON-TANANA TERRANE

Footwall of Jules Creek Thrust

CARBONIFEROUS?

C?cs — Phyllite, ribbon chert, sandstone, grit, conglomerate

C?iv — Chlorite-feldspar-quartz phyllite (intermediate metavolcanic rocks)

Hanging wall of Jules Creek Thrust

PENNSYLVANIAN

Pcl — Phyllite, chert, conglomerate, greywacke, diamictite, limestone

Hanging wall of Money Creek Thrust

PENNSYLVANIAN

Pq — Quartz sandstone/quartzite

UPPER MISSISSIPPIANTO MID-PENSYLVANIAN

Cc — Bioclastic crinoidal limestone

EARLY MISSISSIPPIAN

SIMPSON RANGE PLUTONIC SUITE

MSg — Granite, quartz monzonite

LOWER MISSISSIPPIAN

Miv — Chlorite-muscovite-quartz phyllite (intermediate composition)

UPPER DEVONIAN

DF — Chloritic phyllite with lesser clastic rocks, marble

Footwall of Money Creek Thrust

EARLY MISSISSIPPIAN

WOLVERINE SUCCESSION

MWb — Chloritic phyllite

MWt — Thinly interbedded siliceous rock and phyllite (metatuff and exhalites)

MWf — Muscovite-quartz phyllite

MWcp — Carbonaceous phyllite and quartz sandstone

MWcl — Feldspathic meta-sandstone, grit and carbonaceous phyllite

EARLY MISSISSIPPIAN

GRASS LAKES PLUTONIC SUITE

MGg/ MGag — Granitic to monzonitic equigranular meta-plutonic rocks/Augen-textured granitic to monzonitic meta-plutonic rocks

LATE DEVONIAN

NORTH LAKES META-DIORITE

DNd — Foliated hornblende-biotite meta-diorite

UPPER DEVONIAN (TO LOWER MISSISSIPPIAN?)

GRASS LAKES SUCCESSION

DMq — Quartzite

DMm — Chloritic phyllite

DMcp — Carbonaceous phyllite and quartzite

DMcg — Meta-conglomerate

Kudz Ze Kayah felsic metavolcanic unit

DK — Undifferentiated feldspar-muscovite-quartz schist/ phyllite, siliceous muscovite-quartz schist/phyllite, augen schist/phyllite (meta-porphyry)

DKcp — Carbonaceous phyllite and quartzite

DKcs — Calcareous meta-sandstone and grit

Fire Lake metavolcanic unit

DF — Plagioclase-chlorite phyllite/schist, carbonaceous phyllite, muscovite-quartz phyllite

UPPER DEVONIAN AND OLDER?

Dq — Psammitic and meta-pelitic schist

Dqm — Marble, calcareous schist and lesser carbonaceous phyllite

Dm — Biotite-plagioclase-actinolite-chlorite schist

Dfv — Feldspar-muscovite-quartz schist (felsic metavolcanic rock)

Local Geology Legend

EQUITY | Date: 13/12/2016 | Proj: | Prov: YK | Figure 12

7.1.3 Property geology

The KZK Property was first mapped in its entirety at 1:20,000 in 1996 scale by Cominco geologists (Schultze and Hall, 1997a). A mapping project covering the property was undertaken in 2017. The following discussion is modified from that work (Baker et al., 2017). Lithologic codes used on the 2017 KZK Project are summarized in Table 10. A map showing the property geology around the ABM and GP4F deposits is included as Figure 13.

The stratigraphy at KZK displays a tilted (moderate-shallow to the north) section through the Grass Lakes Group (Piercey et al., 2001b), with overprinted greenschist facies metamorphism and ductile deformation. All known deposits on the KZK Property (ABM, GP4F) occur within the KZK Formation. The entire stratigraphic column has been cross-cut by young NE-SW trending brittle faults such as the East and Fault Creek Faults.

The Grass Lakes Group on the KZK Property is divided into three main components from bottom to top (Figure 13): (1) Fyre Lake Formation mafic flows and ultramafic intrusions (2) the lower, sedimentary portions of the KZK Formation (or "lower sedimentary sequence" in MacRobbie and Holroyd, 2000), which is equivalent to the **DKcp** and **DKcs** units in Murphy et al (2001) (Figure 13) (3) Kudz Ze Kayah (KZK) Formation felsic volcanic, which hosts all significant VMS mineralization on the Property and (4) overlying Wind Lake Formation (or "upper sedimentary and mafic volcanic sequence" in MacRobbie and Holroyd (2000), equivalent to **DMm** and **DMcp** units of Murphy et al., (2001). In a gross sense, stratigraphy trends easterly, dips moderately to the north and is right way up; however, it may be locally overturned in tight, mesoscale F_2 folds.

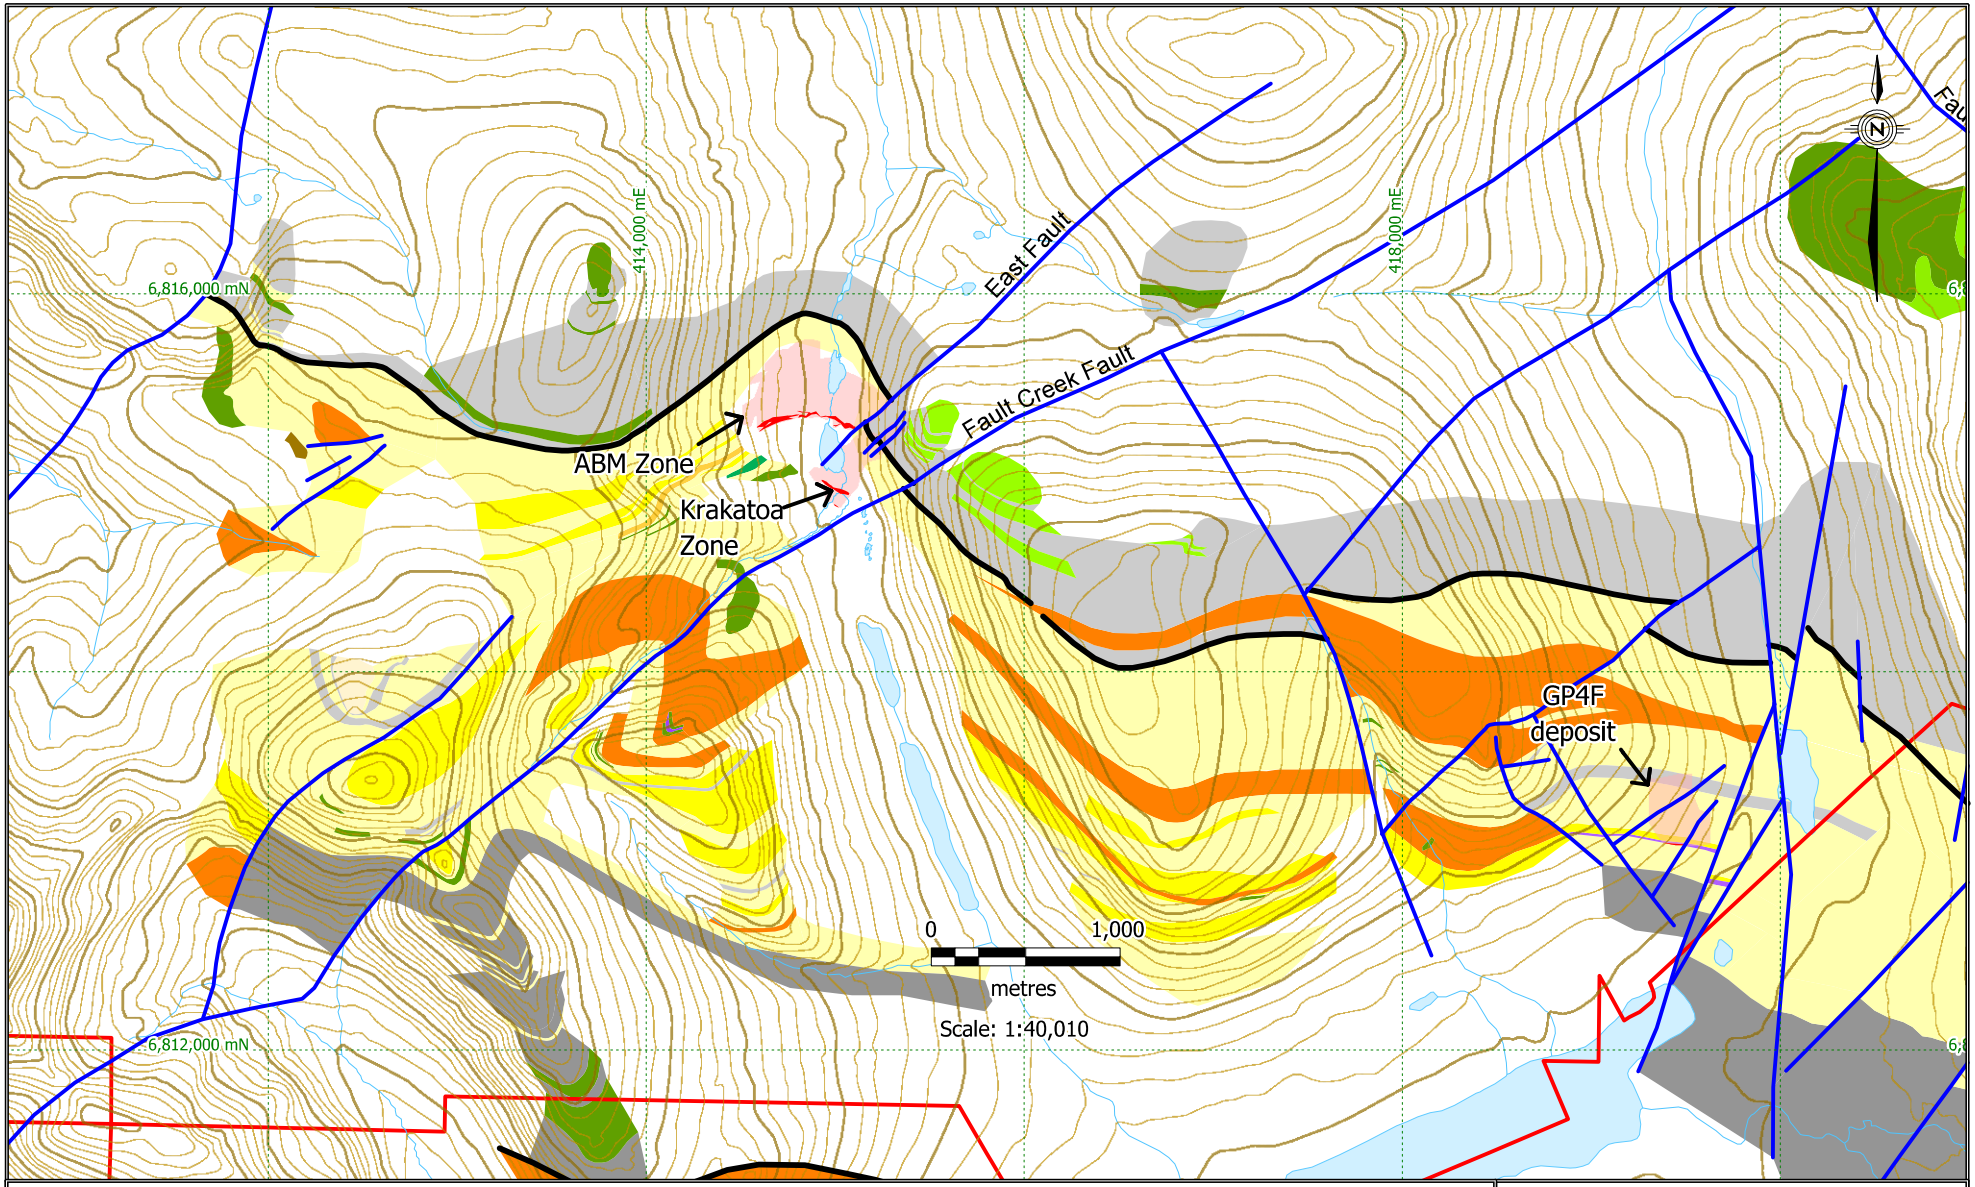
The lower sedimentary KZK Formation consists of siltstone, phyllitic schist, light grey quartzite and massive tuffaceous wacke that is interfingered with feldspar porphyry. Lithologies of minor abundance include mudstone, carbonaceous mudstone and felsic tuff.

Felsic volcanic of the KZK Formation can be subdivided into mappable end member units that comprise felsic volcaniclastic (**RHYv**), coherent felsic volcanic flows and intrusives (**RHYc**), and aphanitic to feldspar-quartz porphyritic intrusives (**RHYi**). Minor abundances of mafic intrusive (**MAFi**) and mudstone (**MDS**) also occur. The most abundant lithology is volcaniclastic rhyolite (**RHYv**), which comprises thinly bedded tuffs, lapilli tuffs and crystal tuffs (**RHYvx**) that are locally intercalated with thin layers of mudstone. With increasing grain size these fine-grained felsic tuffs grade into crystal-rich ash tuffs containing up to 35% light grey to white feldspar and clear grey quartz crystals.

Rhyolite flows and associated intrusives (**RHYc**) are thickest, most abundant and best exposed on Rhyolite Peak, west of the ABM deposit. These units are typically dense, siliceous, and aphanitic. Some outcrops along Fault Creek contain up to 70% spherulites ranging from 5–25 mm in diameter. Feldspar-quartz porphyry intrusions (**RHYi**) are characterized by 15–30% feldspar and/or 5–20% quartz phenocrysts set in a very fine-grained quartz-sericite-feldspar ± chlorite-ankerite groundmass. Feldspar phenocrysts are euhedral, light grey and range from 3–18 mm in size. Quartz crystals are subhedral, clear grey and 2–4 mm in diameter. Porphyry units are likely cogenetic with the epiclastic rocks.

Mafic intrusions (**MAFi**) are mapped throughout the KZK Formation, the best defined of which occurs immediately below the ABM deposit. This so-called "mafic footwall intrusion" consists of strongly foliated porphyroblastic amphibole-chlorite-biotite-calcite schist. Other types of mafic intrusion consist of coarse-grained mafic schist with less deformed enclaves exhibiting a relict gabbroic texture. Biotite-rich units with quartz, feldspar and/or calcite are logged as both mafic intrusion and sedimentary rocks, and in 2016 were reinterpreted as "pelite" (**PEL**) on the basis of their mineralogy and typically finely intercalated contacts with enveloping felsic volcanic rocks. Mafic tuffs (**MAFt**) consist of fine-grained chlorite-calcite phyllitic schist and are volumetrically minor in the KZK Formation.

The base of the Wind Lake Formation lies about 200 m up-section from the ABM deposit. It is finer-grained than the lower KZK Formation and comprises carbonaceous and calcareous mudstone (**MDS**) that is intercalated with mafic volcanic (**MAFt**) along with minor quartzite, siltstone, chert and felsic volcanic. The package underlies the northern half of the KZK Property (Murphy et al., 2001).



Wind Lake Formation

- Carbonaceous argillite, phyllitic quartzite
- Mafic-intermediate flow, dyke, sill

Kudz Ze Kayah Formation

Felsic volcanic

- Felsic crystal-rich to aphyric tuff
- Felsic flow/sill, augened, possibly some RHYif
- Undifferentiated sediment and carbonaceous mudstone

Lower KZK

- Carbonaceous mudstone, tuffaceous schist, biotitic metapelites, mudstone

VMS mineralization

- Massive sulphide (surface/sub-surface)
- GP4F "Horizon": Sulphide-rich chlorite-altered schist

Grass Lakes Plutonic Suite

- Feldspar+quartz porphry, augened porphyry
- Biotite and biotite chlorite schist

- Formation Contact
- Faults
- 100m Index contour
- 20m contour
- Lake
- Stream

Table 10: Lithological legend for KZK Project

Stratigraphic Unit	Geology Detail Code	Geology Detail Sub-code	Lithology	Description
	OVBN	-	Overburden	Unconsolidated overburden.
	FLZ	-	Fault Zone	
Grass Lakes Plutonic Suite	GRA	-	Granite	Coarse grained equigranular to weakly porphyritic augen granite
		GRApor	Porphyritic granite	Megacrystic feldspar ± quartz porphyritic granite
		GRAmg	Medium grained granite	Fine to medium grained granite
Wind Lake Formation	MAF	MAFt	Mafic volcaniclastic	Green, chlorite-biotite-calcite schist, mafic volcaniclastic, varying from fine grained ash to lapilli-sized. Variable texture, inferred protolith of volcaniclastic or epiclastic mafic volcanic material
		MAFta	Mafic fine grained volcaniclastic	Green, fine grained, chloritic mafic volcaniclastic.
		MAFw	Mafic volcanic flows	Green, massive to pillowed, chlorite-biotite-calcite greenstone. Inferred protolith of effusive mafic volcanic rocks.
	MDS	-	Carbonaceous mudstone	>15% carbonaceous component, weakly heterolithic to semi massive mudstone with slaty cleavage
Kudz Ze Kayah Formation	SED	-	Undifferentiated sedimentary rock	Variable; includes locally calcareous sandstone, wacke, recrystallized limestone
		SDS	Sandstone	Light grey to orangish, sand-sized quartzite. Inferred protolith of quartz-arenite to wacke.
		SDSc	Carbonaceous sandstone	Dark grey, carbonaceous to weakly graphitic, quartzite.
		SLT	Siltstone	Fine-grained siliciclastic sedimentary rock
		WCK	Wacke	Sandstone with 15-75% clay matrix
	MDS	-	Mudstone, tuff and rhyolite	Undifferentiated carbonaceous mudstone, tuffaceous mudstone and carbonaceous coherent rhyolite
		MDSt	Rhyolite tuff-dominant mudstone	<15% carbonaceous component, heterolithic appearance with rare mudstone laminae
		MDSc	Carbonaceous mudstone	>15% carbonaceous component, weakly heterolithic to semi massive mudstone with slaty cleavage
		MDSw	Coherent rhyolite with minor carbonaceous mudstone	<15% carbonaceous component, laminae of mudstone intercalated with coherent rhyolite
	PEL	-	Pelite	Interpreted sedimentary protolith. Biotite rich rock with quartz, feldspar and/or calcite
	CHT	-	Chert	
	MXSX	-	Massive sulphide	Massive sulphide (>50% PY-MG-SP-GL-CP-PO) in various proportions and with a variety of textures and gangue minerals
	SXSX	-	Semi-massive sulphide	20-50% sulphide in a variety of host rocks, with or without significant barite gangue material
	RHY	-	Undifferentiated rhyolite	Commonly altered and difficult to identify
	RHYc	-	Coherent rhyolite	Undifferentiated coherent rhyolite

Stratigraphic Unit	Geology Detail Code	Geology Detail Sub-code	Lithology	Description
		RHYcw	Curdy-textured and/or flow-banded	Flows or sub-volcanic intrusions with definitive siliceous flow banding or relict flow banding textures
		RHYcf	Feldspar ± quartz porphyry	Medium to coarse-grained feldspar and quartz porphyritic texture rhyolite
		RHYcq	Quartz porphyry	Medium to coarse-grained quartz-phyric texture
	RHYi		Aphanitic rhyolite	Aphyric massive to semi-massive siliceous rhyolite interpreted as intrusive dykes and sills
	RHYv	-	Volcaniclastic rhyolite	Undifferentiated fine to medium-grained volcaniclastic
		RHYvl	Lapilli volcaniclastic	Heterolithic volcaniclastic with >15% lapilli typically in an ash-dominated groundmass
		RHYva	Coarse-grained to ash sized volcaniclastic	Phaneritic ash volcaniclastic with >10% of crystals occurring as >1-<2mm typically in an ash-dominated groundmass
		RHYvx	Quartz ± feldspar crystal volcaniclastic	Quartz, ± feldspar-phyric (>10%) in an ash-dominated groundmass
	MAFi	-	Mafic intrusions	Chlorite-altered mafic intrusion, primarily in the footwall but also occurs as narrow dykes or sills within the felsic sequence
Fyre Lake Formation	PYX	-	Pyroxenite	Green, medium- to coarse-grained, weakly foliated, actinolite-chlorite meta-pyroxenite (?). Locally porphyritic.
	MAF	MAFt	Mafic volcaniclastic	Green, chlorite-biotite-calcite schist, mafic volcaniclastic, varying from fine grained ash to lapilli-sized. Variable texture, inferred protolith of volcaniclastic or epiclastic mafic volcanic material
		MAFta	Mafic fine grained volcaniclastic	Green, fine grained, chloritic mafic volcaniclastic.
		MAFw	Mafic volcanic flows	Green, massive to pillowed, chlorite-biotite-calcite greenstone. Inferred protolith of effusive mafic volcanic rocks.
	MDS	-	Carbonaceous mudstone	>15% carbonaceous component, weakly heterolithic to semi massive mudstone with slaty cleavage

The Yukon-Tanana rocks on the KZK Property are polydeformed and overprinted by low-mid greenschist facies metamorphism. Locally developed higher-grade metamorphism (i.e. upper greenschist to amphibolite) is more likely related to thermal (or contact) effects. Cominco noted evidence of five phases of deformation however, based on 2017 mapping, we recognize only three.

A typically subhorizontal to moderately steep north to northeast dipping, bedding parallel, penetrative fabric (S_1) overprints all formations and suites on the KZK Property, and is associated with lower greenschist facies assemblages and phyllite development. Relatively little deformation appears to be involved in the development of the S_1 foliation. It is unclear precisely how S_1 is formed; however, it may record an early phase of D_2 deformation or it could represent the preferred growth orientation of micaceous minerals under lithostatic load during anchizonal-epizonal (e.g. Árkai et al., 2003) low grade metamorphism (Baker et al., 2017).

D_2 structures comprise tight, meso-scale F_2 folds and an S_2 crenulation cleavage defined by fine folds of S_1. S_2 foliation generally strikes similarly to S_1 but is steeper than S_1, dipping moderately to steeply north to northeast. Development of S_2 crenulations is not uniform – it is localized and can be intense to broadly-spaced. Development of S_2 appears to be controlled by rock type and intensity of S_1. More felsic and well foliated (S_1) rocks with abundant sericite tends to exhibit the most intense and finely developed D_2 crenulations whereas these folds are broader in coarser-grained and less felsic rock.

D_3 deformation-related structures consist of late brittle faults, including the East and Fault Creek faults, fault-related smaller-scale structures like kink bands (S_3), and possibly broad open folds (F_3). The East and Fault Creek faults are important, ore-bounding, structures associated with the ABM deposit and are modelled in detail by Baker (2016).

Kink bands (S_3) are rare across the property and defined by cm-scale kinking of the main (S_1) schistosity. The S_3 planes have two dominant orientations: subvertical, NW-SE striking; and subhorizontal. Their hinge lines plunge gently to moderately to the north, northwest, and northeast. This rotation of the fold axes may be related to drag folding during fault movement.

7.2 Mineralization

Mineralization on the KZK Property consists of the ABM and GP4F deposits, with the ABM deposit further subdivided into the ABM and Krakatoa Zones. Each is described in more detail below.

7.2.1 ABM deposit

Cominco originally discovered the ABM deposit in 1994 by following up on anomalous silt and soil samples, as well as a mineralized float, with ground-based geophysics and drilling. BMC has since expanded on Cominco's discovery and now recognizes the ABM deposit as comprising the ABM and Krakatoa Zones, separated by the northeast striking East Fault. Movement on the East Fault appears to have been down and to the right, so that Wind Lake Formation in the Krakatoa Zone is juxtaposed against KZK Formation in the ABM Zone (Figure 13).

The ABM Zone comprises massive sulphide and stringer-style sulphide mineralization primarily hosted within felsic volcanic and directly overlying the chlorite-altered mafic footwall intrusion (MAFi). The ABM Zone appears to consist of just one main lens (named the "ABM lens") that typically coalesces at shallow depth and splits into an upper and lower part further down (see sections in Hughes et al., 2016). There are no other named lenses within the ABM Zone. The ABM lens is up to 39 m thick with a 400 m downdip extent and 700 m strike length (Hughes and Baknes, 2015a). At surface, it strikes ~290° with a ~35° dip to the north. A flexure occurs ~200 m downdip that flattens the dip of the lens to 10-15°. The ABM lens transitions laterally from massive sulphide to semi-massive sulphide on its margins to an intercalated package of volcanic and sedimentary rocks (Hughes and Baknes, 2015a).

The Krakatoa Zone comprises numerous lenses and pods of massive to semi-massive sulphide. The largest and most continuous of these lenses are referred to as the main, lower and upper lenses. The main lens typically occurs within the mafic footwall intrusion (MAFi) or at its lower contact. The upper lens occurs immediately above this mafic unit, in the same stratigraphic position as the ABM lens. The lower lens generally occurs at the base of the mafic footwall intrusion or below it within the underlying felsic volcanic rocks. The mineralized lenses in the Krakatoa Zone are oriented subparallel to the ABM Zone at ~300º/35º NNE. They are commonly concordant with stratigraphy. The Krakatoa main lens has a true thickness of up to 22 m, width of 150 m and downdip continuity of at least 430 m. The width of the mineralized zone is constrained by the East Fault to the west and the Fault Creek Fault to the east. Mineralization extends to the top of bedrock but fails to daylight, as it is buried under 2–30 m of glacial overburden.

The most recent mineral resource estimate for the ABM deposit was completed in November 2016 (BMC Minerals Ltd., 2016) in accordance with the JORC Code (JORC, 2012), and is reported in Table 11.

Sulphide mineralization in the ABM deposit is generally dominated by pyrite with lesser sphalerite, pyrrhotite, galena and chalcopyrite, and gangue minerals that include chlorite, magnetite, quartz, Fe-carbonate, calcite, sericite, cordierite, albite, celsian and barite (Martin, 2015; Townend and Townend, 2015). Mineralized lenses typically occur within an envelope of chlorite and muscovite alteration and are subdivided into massive and semi-massive styles. These mineralization styles are further subdivided into ten end-member "ore" types (Figure 14) based on macroscopic mineralogical and textural features (Hughes and Baknes, 2015b; Hughes and Voordouw, 2017; Hughes et al., 2016; Schultze, 1995).

Table 12: Summary of key ore types in the ABM and GP4F deposits

Type	Subcode	Key Features	Description
Massive	OA	MG-rich massive sulphide	Massive sulphide (PY-MG-SP-GL ± CP-PO) with abundant disseminated euhedral medium-grained and/or laminated MG
	OB	MG-free massive sulphide	Wispy, laminate, fine buckshot-textured fine- to coarse-grained massive sulphide (PY-SP-GL ± CP-PO) with trace to no MG
	OC	CP + PO-rich massive sulphide	Net-textured fine- to coarse-grained massive sulphide with 10–50% CP-PO
	OF	PO-rich sulphide	Massive sulphide with >50% PO in addition to MG ± CP-PY-SP-GL
	OG	CP-rich sulphide	Semi-massive to massive sulphide with >30% CP in addition to PO-PY-SP ± GL-MG
	OH	PY-rich massive sulphide	Fine-grained, homogeneous, with >80% PY
	OL	Coarse PY in SP ± PO matrix	Semi-massive to massive sulphide comprising 10–40 % coarse buckshot-textured PY in a SP ± PO-BI matrix; mostly at the GP4F deposit
Semi-massive	OI	Semi-massive sulphide in schistose host rock	20–50% sulphide (PY ± CP-SP-PO-GL) as stringer, disseminations and/or bands in schistose host rock
	OJ	Semi-massive sulphide in proximal altered rock	20–50% sulphide (PY-CP-SP ± PO-GL) as stringer, disseminations and/or bands in proximal (CL-CI) altered host rock
	OK	Semi-massive sulphide with BA-SI gangue	20–50% sulphide as stringer, disseminations and/or bands associated with BA ± SI-CB gangue in proximal (CL-CI) altered host rock
Brecciated	OD	Brecciated Sulphide	Original Cominco code to indicate interpreted sulphide clasts

Massive sulphide forms the bulk of the ABM, Krakatoa main and Krakatoa upper lenses. Pyrite is the predominant sulphide mineral, comprising 60–70% of the mode, and ranging from fine- to coarse-grained and massive to buckshot-textured. The upper parts of the ABM lens are strongly magnetic, containing up to 10% fine- to coarse-grained magnetite as laminar bands and heavily disseminated pods. Magnetite also occurs within the main and upper lenses of the Krakatoa Zone but appears to be absent from the lower lens. Sphalerite forms two distinct types: (1) dark brown sphalerite intergrown with magnetite and (2) red-brown sphalerite occurring as wispy laminations and/or disseminations within pyrite. Galena occurs throughout the ABM and Krakatoa zones as fine- to medium-sized grains. Chalcopyrite is typically minor and occurs as coarse-grained clots, blebs and disseminations. Silica, barite and carbonate gangue are most abundant within the lower portions of both zones, with Krakatoa containing more barite than ABM.

Semi-massive mineralization occurs throughout the ABM deposit but is more restricted and less abundant in the Krakatoa Zone. In the ABM lens, stringer- and disseminated-style mineralization forms a 1–10 m thick halo around massive sulphide mineralization. Additional zones of semi-massive sulphide also occur between arms of the ABM lens, typically associated with strong chlorite ± cordierite alteration. Sulphide mineralogy consists of chalcopyrite + pyrrhotite + pyrite ± sphalerite ± galena with trace magnetite, with Cu typically assaying >2% but ranging anywhere from 0.1–14% Cu. This variability in grade correlates with the textural and mineralogical diversity inherent to this style of mineralization, which ranges from thick chalcopyrite-rich stringers to Cu-poor disseminated sulphide. Grades of Cu, Au and Ag appear to be lower in Krakatoa semi-massive sulphide than at ABM (Duncan and Baker, 2015).

Some intercepts of the Krakatoa main lens preserve the partial replacement of felsic tuff and/or mafic footwall host rock by sulphide, the former typically interleaved with intervals of mafic footwall. These occurrences typically comprise a combination of OB-type ore with relatively high gangue content and OI-type with relic lapilli or ashy groundmass and provide support for a replacement-style origin. The downdip gradation

of the ABM lens into sedimentary and epiclastic rocks likewise suggests that the ABM Zone may have a similar origin (Duncan and Rabb, 2015; Hughes and Baknes, 2015b).

The alteration framework for the ABM deposit is based on the work by Cominco (e.g. Schultze, 2001). Four of the original five original Cominco alteration types were systematically logged in the 2015 and 2016 programs (Table 13). The exception is the weak pyrrhotite alteration (Cominco's "Type 1") that was generally found to be pervasive and lacking in significant variability over decametre scale intervals.

Table 13: Summary of alteration types associated with the ABM deposit

Cominco Classification	Name	Key feature	Comments
Type 1	Weak PO	PO	~1% disseminated PO as foliation-parallel wisps in felsic groundmass
Type 2	Greenish-grey	CL-SE	Greenish-grey alteration possibly related to aphanitic rhyolite (RHYi) intrusions, especially near MAFi; locally obscures sulphide-MAFi contact zones
Type 3	Pervasive MU/SE	MU/SE	Distinctive silvery grey to waxy greyish-yellow-green MU/SE ± disseminated sulphide; usually within 50 m of sulphide mineralization; preferentially developed in felsic volcanic; shows inverse relation with AK alteration.
Type 4	Proximal CL	CL >> MU/SE	Dark green CL typically occurring within <5 m wide of massive sulphide; associated minerals include BI, AK, MG and disseminated PO-CP; also, as stratabound zones marking distal expression of massive sulphide lenses
Type 5	Restricted CI	CI-CL	Spatially associated with proximal CL alteration or as distal stratabound zones extending beyond sulphide; CI forms grey glassy porphyroblasts up to 2 cm in size and hosted within CL-rich matrix; associated minerals include ferroan DO, SI and sulphide

Host rocks of the ABM deposit typically show a penetrative schistosity (S_1), the intensity of which is dependent on host rock type. For example, most of the volcaniclastic rhyolite units (RHYv) exhibit a tightly spaced penetrative foliation whereas foliation within the more coherent rhyolite flow units (RHYc) is more broadly developed between silica- and sericite-dominant domains. Schistosity (S_1) is broadly concordant to lithological contacts (S_0) and is folded about cm-scale tight to isoclinal parasitic folds (F_2) that are common in drill core. F_2 meso-scale folds are difficult to identify in drill core; however, they are recognized in outcrops west of the ABM deposit (Baker et al., 2017; Szybinski, 1996a, b). Within fold hinges, an earlier foliation (S_1) that is concordant to bedding (S_0) is preserved, so that folds are defined by both this primary bedding and early foliation. Along F_2 fold limbs, S_1 foliation and D_2 axial-planar cleavage (S_2) form a coplanar fabric that comprises the dominant tectonic foliation throughout the ABM deposit area.

Schistosity is drag-folded and truncated by brittle faulting along the East and Fault Creek Faults (Baker, 2015b; Baker et al., 2017), as well as smaller structures possibly related to these larger faults. Although no direct age of this faulting exists, it is likely these faults formed during the ~425 km of Eocene dextral slip along the Tintina Fault, which is located about 30 km southwest of the ABM deposit (Baker et al., 2017).

7.2.2 GP4F deposit

The GP4F deposit lies near the southern margin of the Property, about five kilometres southeast of the ABM deposit (Figure 13). It is hosted within an interval of the KZK Formation interpreted to lie stratigraphically below the ABM deposit based on its proximity to the contact between the host KZK Formation and the underlying Fire Lake Formation (Jones, 2016). The GP4F deposit is divided into GP4F, lower and upper zones (Jones, 2016) and then the GP4F lens and lower lens (Hughes et al., 2016). In 2016, however, drilling established predictable continuity of the "lower target" so that it is now upgraded to "lens".

The GP4F lens is the thickest and most continuous part of the deposit and contains 90% of all massive sulphide intercepts. The width of most intercepts falls between 3–20 m, averaging 9.8 m and decreasing to the east with only one (suspect) occurrence in the three drill holes on the eastern-most section (419650E). Strike length ranges from 200–325 m on plan maps 1150 RL to 1250 RL (see Voordouw et al., 2016), respectively, and downdip extents range from 300–400 m on sections 419350E to 500E. The GP4F lens dips an average of 30° towards 025°–030° and is either naturally undulating or gently folded along east-west trending fold axes.

The lower lens lies 20–85 m (average = 45 m) below the GP4F lens and occurs on all six sections. Drilling intercepts range from 0.7–24.0 m in width, average 8.0 m and thicken in the opposite direction of the GP4F lens (i.e. from west to east), averaging 4.9, 9.0 m and 11.8 m on sections 419400E, 500E and 650E respectively. Strike length measures ~200 m on plan map 1250 RL and downdip extents range from 200–300 m on sections 419500E and 650E. The relatively thick lower lens on 419650E, coupled with a paucity of GP4F lens, suggests that the lower lens may become the more important sulphide layer further east.

Table 14: Updated mineral resource estimate for the GP4F deposit

Category	Tonnage	Cu	Pb	Zn	Au	Ag	Cu metal	Pb metal	Zn metal	Au	Ag
	Mt	*(wt%)*	*(wt%)*	*(wt%)*	*(g/t)*	*(g/t)*	*(Kt)*	*(Kt)*	*(Kt)*	*(Koz)*	*(Moz)*
Indicated	1.0	0.2	2.7	5.7	1.0	83	1.6	26.9	56.7	31.3	2.7
Inferred	0.7	0.2	2.4	4.8	2.0	59	1.1	16.4	33.3	43.8	1.3

An updated resource for the GP4F deposit was generated as the result of 2016 work (BMC Minerals Ltd., 2016), and is broadly similar to the inferred resource of July 2015 (Green, 2015b). Both resources are in accordance with the JORC code (JORC, 2012), with the 2016 estimate summarized in Table 14.

Mineralization in the GP4F lens consists of narrow, high-grade, layers of massive sulphide enveloped by stringer- and disseminated-style semi-massive sulphide. Lenses of massive sulphide are similar to the OB ore type at the ABM deposit, with 50–70% massive to buckshot-textured pyrite along with semi-massive to massive bands of sphalerite and/or pyrrhotite. Sphalerite also forms larger blebs whereas galena and chalcopyrite occur mostly as interstitial fillings and disseminated blebs. Some of the better grade intervals in the deposit comprise stacked bands of massive OB-type mineralization, typically ranging from 0.1–0.4 m in width, within an interval of semi-massive OJ-type mineralization. Examples of such intervals include 9.7% Zn, 4.1% Pb, 117 g/t Ag and 1.7 g/t Au over 8.9 m in K98-188, as well as 7.4% Zn, 2.8% Pb, 123 g/t Ag, and 1.0 g/t Au over 4.65 m in K15-306 (Jones, 2016).

More typically, the GP4F and lower lenses consist of stringer- and disseminated-style sulphide mineralization associated with strong chlorite-biotite alteration (Jones, 2016). Modal sulphide abundances range from 5–40% and form blebs, stringers (0.1–1 cm wide) and bands (1–4 cm wide). Sulphide assemblages include sphalerite-dominant, sphalerite-galena and pyrrhotite-pyrite-chalcopyrite, and combinations thereof. There is some evidence of the sulphide overprinting the altered groundmass (Boulton, 2002), suggesting replacement-style mineralization.

The GP4F deposit occurs within a much larger, tabular zone of alteration and weakly disseminated mineralization (Jones, 2016). Alteration in close proximity to the GP4F and lower lenses is similar to the proximal and restricted alteration types associated with the ABM deposit, while also including biotite, garnet (in places Zn-rich) and gahnite (Boulton, 2002). Garnet and gahnite are unreported from ABM. The distinct silvery-grey to waxy yellow muscovite (Type 3) alteration is less pervasively developed at GP4F than at ABM but still shows a mappable spatial association with sulphide mineralization (Hughes, 2016). At GP4F, this so-called “original muscovite” alteration is associated with disseminated pyrite. Other alteration minerals include cordierite and possibly albite (Boulton, 2002), which was widely reported by Cominco as comprising whitish porphyroblasts and vitreous masses, though this is similar to cordierite habits seen at the ABM and GP4F deposits.

There is evidence for brittle faulting in the GP4F area but there appear to be no significant disruptions of the deposit, as it forms a fairly continuous and predictable tabular ore body. The most prominent zone of fault gouge occurs below the deposit and appears to strike 35°/270° N, which is more-or-less parallel to stratigraphy. There are no constraints on the movement direction or offset across this fault. Plan-based interpretations (Voordouw et al., 2016) shows several kinked lithological contacts that could be manifested through 25–35 m of dextral offset along NNE-trending faults. Property-scale airborne geophysical data suggests there is a prominent ENE-trending structure that runs between the GP4F deposit and the R15 deposit to the ESE. This lineament runs broadly parallel to the Fault Creek and East faults in the ABM area and lies 4.0–4.5 km south of the Fault Creek Fault. At this time, however, there is no geological evidence (e.g. drill intercepts, outcrops) that this lineament is related to faulting.

8.0 RESULTS OF THE 2017 WORK PROGRAM

The 2017 KZK Project comprised a multifaceted geology and engineering program. The primary foci of the program were the in pit geotechnical engineering program, infrastructure related geotechnical investigations, exploration/condemnation drilling to the north of ABM, and characterizing the environmental baseline parameters for the project area. The following sections describe significant results from the 2017 program that were available at the time of reporting.

8.1 Construction and Rehabilitation

48 new drill sites and 14 test pits were constructed in 2017, and combined with modifications to existing trails, new total surface disturbance for 2017 totalled 4.23 ha.

All fly drill sites, excepting sites where work was undertaken in October 2017, had sumps buried, timbers removed and stored, and were contoured. October 2017 Fly drill sites had sumps backfilled. All trails not intended for ongoing use were reclaimed, excepting those that were active in October-November.

0.65 ha of land was reclaimed during the 2017 report year. The combined un-reclaimed disturbance from previous years totals 10.083 ha. The trails and sites that were not fully reclaimed in 2017 due to snow/cold weather will be reclaimed and reseeded in the spring of 2018.

8.1.1 Earthworks

Trail construction totalled 5211 m at an estimated width of 4 m. 1597 m of 1.5 m wide lines were also cleared for geophysical work. All sites constructed for skid accessible drilling were re-contoured and reclaimed with sumps backfilled (Figure 15).

Figure 15: Recontoured drill pad K17-444

8.2 Terrain Surveys

Terrain surveys included differential GPS (DGPS) surveys of 2017 collar locations and terrain hazard mapping. Each is described in more detail below.

8.2.1 DGPS survey

Survey measurements of collar locations, using a real time kinematic differential GPS (RTK DGPS), were done during the 2017 field season. Coordinates surveyed in the 2017 field season focused on surveying the 2017 drill hole collars and laying out proposed drill holes.

Seven of the 2017 drill collars (K17-426, 432, 436, 447, 448, 449, and 450) were not surveyed by Challenger as the collar locations were either not marked following completion of drilling or drilling and/or

downhole surveying activities were ongoing during while surveying was taking place. In these cases, the final collar location is an integration of X and Y coordinates derived from handheld GPS, with the Z coordinate corrected to the LiDAR topographic surface.

Results of the RTK DGPS surveys show that the average error between the planned and actual coordinate for each drill hole is 5.6 m for easting, 4.2 m for northing, and 1.8 m for the elevation. The total average offset of planned and actual coordinates is 7.0 m within a range of 0.3 to 46.5 m. However, seven of these drill holes were deliberately moved in order to avoid drilling in proximity to water bodies. Excluding these moved drill pads the total average offset of planned and actual coordinates is 3.69 m within a range of 0.3 to 9.8 m. Overall, collar locations accurately reflect the drill plan.

8.2.2 Terrain hazard mapping

Terrain stability and hazards were mapped over a 64 km^2 study area that encompasses the proposed mine site and its access road from the Robert Campbell Highway. The resulting map and report completed for the KZK Project presents the distribution and characteristics of terrain units, geomorphological processes and hazards within. Observations from more than 300 sites were recorded based on visual reconnaissance during short stops along foot traverses, vehicle-supported access or helicopter fly-overs. A disturbed terrain stability class representing projected conditions in the absence of planned mitigation measures was distinguished from the existing stability class to highlight areas that warrant attention. The assessment of credible risks to the project indicates how planned mitigations can be incorporated to address the site-specific hazards. The entirety of the report and conclusions can be viewed in Appendix F.

8.3 Geological Mapping

8.3.1 Phase I (outcrop mapping)

Mappers completed a total of 70 traverses, covering a total area of approximately 120 km^2. Traverse summaries are presented in Appendix G. Bedrock exposure within the mapped area is very good along ridges but typically poor along slopes and in valley bottoms. In all, nearly 1,500 individual outcrops were located, mapped and described. A map displaying interpreted geology and outcrop locations is presented in Appendix F.

8.3.1.1 Lithology

The Fyre Lake Formation is exposed along the southern boundary of the KZK Property where it is in intrusive contact with Grass Lakes Plutonic Suite. The upper contact of the Fyre Lake Formation appears to be in conformable contact with the overlying Kudz Ze Kayah Formation. Lithologies within the Fyre Lake formation are similar to those of the Wind Lake Formation and include intercalated, metamorphosed, clastic sedimentary (sandstone, siltstone, mudstone) and mafic volcanic (effusive, volcaniclastic) rocks. Rare pyroxenite intrusive bodies occurs within the Fyre Lake Formation.

The Kudz Ze Kayah Formation crops out in an east-west trending band transecting the core of the KZK Property. Rock types (Figure 16) include volcaniclastic, effusive volcanic, and aphanitic intrusive rhyolite, reworked felsic sedimentary rock, carbonaceous mudstone, rare cherty beds and mafic intrusion. The Kudz Ze Kayah Formation is also host to the ABM and GP4F deposits. The volcanic and sedimentary rocks of the Kudz Ze Kayah Formation are distinctly more felsic that the overlying and underlying Wind Lake and Fyre Lake formations, and similar in composition to the Grass Lakes Plutonic Suite (Piercey et al., 2001b). The lack of coarse feldspar phenocrysts and intrusive texture distinguish Kudz Ze Kayah Formation rocks from Grass Lakes Plutonic Suite.

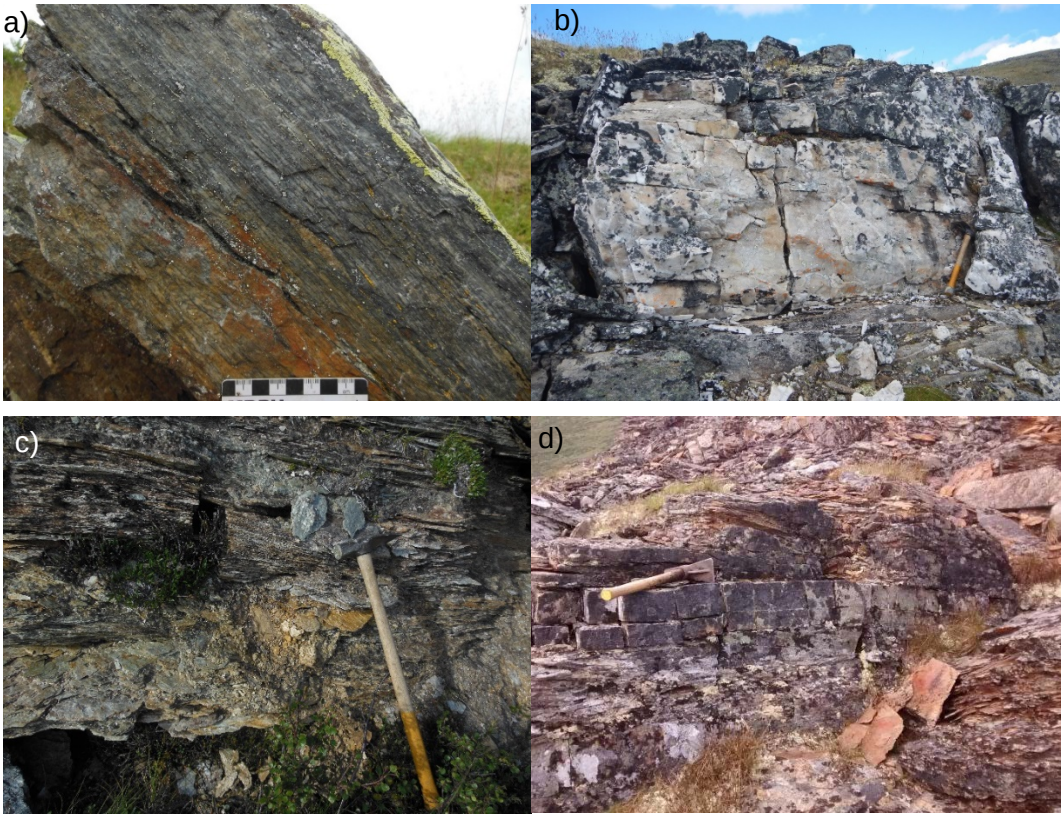

Figure 16: Rocks of the Kudz Ze Kayah Formation: a) Silicic banded coherent rhyolite (RHYc), b) Aphanitic rhyolite (RHYi), c) Strongly foliated volcaniclastic rhyolite (RHYv), d) Intercalated, strongly foliated and blocky volcaniclastic rhyolite (RHYv).

The Wind Lake Formation (Figure 17) underlies the northern portion of the KZK Property, is generally east-west striking and moderately to the north dipping. This formation is comprised of a thick sequence of carbonaceous to locally calcareous mudstone with lesser siltstone, mafic volcanic and volcaniclastic rocks, blue-quartz-bearing grits, conglomerate, psammite, and quartzite (Hughes et al., 2016; Murphy et al., 2006).

Figure 17: Rocks of the Wind Lake Formation: a) Mafic volcaniclastic/epiclastic rocks (MAFt), b) Intercalated mafic volcaniclastic/epiclastic rocks (MAFt) and carbonaceous mudstones (MDS).

A large body of the Grass Lakes Plutonic Suite granite crops out along the southern boundary of the KZK Property and two sills of similar granite occur higher up within the Kudz Ze Kayah Formation. The granitic composition and typically porphyritic texture are characteristic of this suite within the KZK Property (Figure 18). These rocks are interpreted as intrusive and they seem to cut all stratigraphic units on the KZK Property, including the Wind Lake Formation. The Grass Lakes sills are generally concordant to layering in the KZK

Formation. Grass Lakes plutonic rocks appear to be more resistant to weathering and erosion than surrounding host rocks. They commonly form large, protruding and cliff-like outcrops on ridges across the Property.

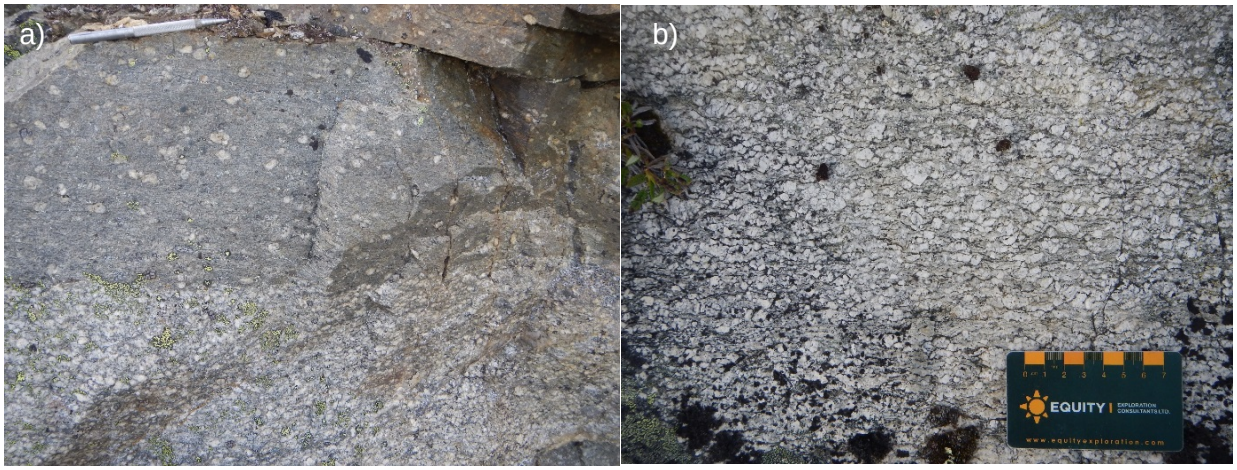

Figure 18: Field photographs of rocks of the Grass Lakes Plutonic Suite: a) Feldspar-phyric granitic sill (GRApor) at the top and phaneritic to feldspar-phyric granite (GRA) below, b) Phaneritic to feldspar-phyric granite (GRA).

8.3.1.2 Structure

Cominco's mapping on the KZK property defined five stages of deformation (Szybinski, 1996a); however, on the basis of the 2017 mapping described in this report, we recognize only three stages of deformation, described below.

S_0 is defined by primary bedding planes and lithological subhorizontal contacts (Figure 19a). A subhorizontal to moderately north- to northeast-dipping, penetrative deformation fabric (S_1) (Figure 19b) overprints all three formations and the Grass Lakes suite on the KZK Property; however, it is best developed in phyllites and fine-grained schists. S_1 is typically subparallel to the original bedding (S_0). The mean S_1 has a dip direction of 007° and a dip of 24.3°, although locally there is a wide range of orientation within mesoscale folds). Note the overlap in distribution with S_0 (Figure 19a).

D_2 structures comprise an S_2 crenulation cleavage defined by fine folds of S_1. This foliation generally strikes similarly to S_1 but is steeper than S_1, dipping moderately to steeply north to northeast (Figure 19c). In local, mesoscale folds, S_1 and S_2 may be oriented at high angle to one another. Development of S_2 crenulations is not uniform – it is highly localized and varies from intense (Figure 20a) to broadly-spaced. Development of S_2 appears to be controlled by rock type and intensity of S_1. More felsic and well foliated (S_1) rocks with abundant sericite tend to exhibit the most intense and finely-developed D_2 crenulations whereas these folds are broader in coarser-grained and less felsic rock. This is consistent with S_2 development in drill core where the best-developed S_2 structures occur within muscovite-alteration halos around massive sulphide whereas coherent rhyolite has not deformed as readily. F_2 folds are typically mesoscale (Figure 20b), south-verging, and appear to fold S_0 and S_1 only locally.

The East and Fault Creek faults are important, ore-bounding, structures associated with the ABM deposit and are modelled in detail by Baker (2016).

Kink bands (S_3) are rare across the Property and defined by cm-scale kinking of the main (S_1) schistosity. Although based on a small subset of data, S_3 planes have two dominant orientations, subvertical with a northwest-southeast strike and subhorizontal (Figure 19d) and all of their hinge lines plunge gently to moderately to the north (Figure 19f). This suggests that these D_3 structures form conjugate sets of kink bands.

There are at least two fault sets on the KZK Property: 1) NNW-SSE trending, down to the west, normal faults and 2) NE-SW trending, down to the south, normal (?) faults, such as the East and Fault Creek faults. Fault set (1) is interpreted from geophysics and apparent offset on interpreted geology (Brauhart et al., 2017) but is otherwise not known from drilling or outcrop. These faults could potentially be syn-depositional growth faults or Tertiary brittle faults, or growth faults re-activated in Tertiary time. Faulting associated with (2) is brittle

in nature, cuts all stratigraphy and may be the result of far-field Tertiary extension. D_3 faults are characterized by fault gouge and fault breccia (Figure 21a) that can be several metres wide (true thickness) based on drill intersections. Outcrop exposures of D_3 are rare due to their recessive-weathering nature but are found in Fault Creek (Figure 21b).

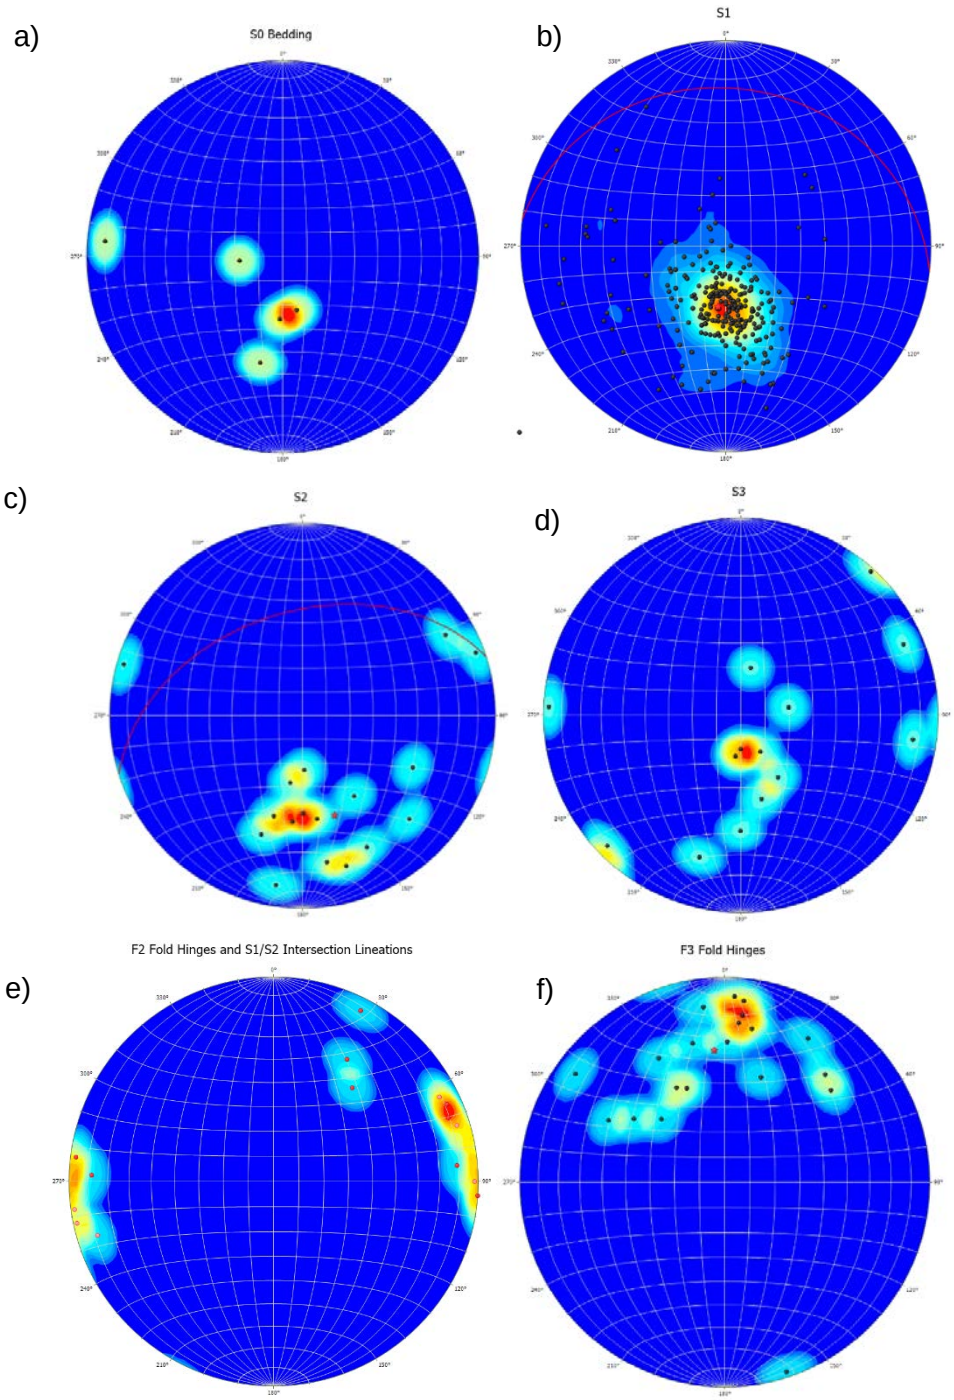

Figure 19: Equal area stereonet plots of structural data collected during the 2017 field mapping program. Data is displayed as contoured poles to planes for planar features and contoured lineations for linear features. a) S_0 (n = 5) b) S_1, the red star marks the mean pole and the red great circle represents the plane perpendicular to the mean pole, which strikes 277° and dips 24° to the north (n = 286) c) S_2, the red star marks the mean pole and the red great circle represents the plane defined by the mean pole, striking 252° and dipping 45° north (n = 17) d) S_3 (n = 14). e) F_2 fold hinge lines and S_1/S_2 intersection lineations (n = 13). Both linear feature sets are parallel, with a spread possibly due to open folding around the F_3 axis. f) F_3 fold hinges. The red star marks the mean orientation of the fold hinges, plunging 36° towards 355° (n = 20).

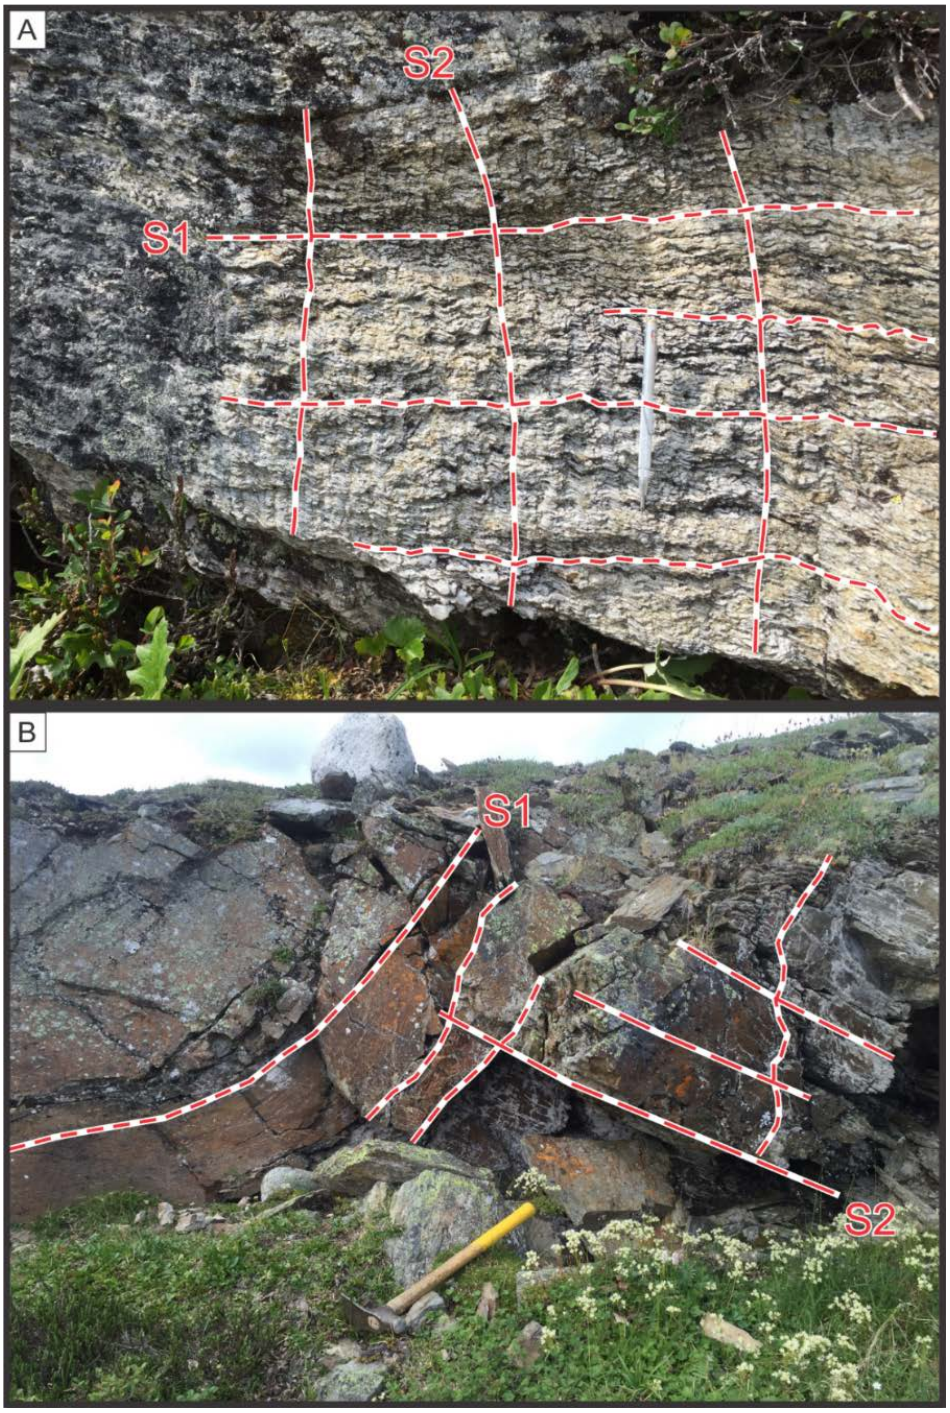

Figure 20: D_2 structures. A) Well-developed S_2 crenulations defined by small asymmetric folds of the main S_1 foliation. B) More widely-spaced F_2 folds of S_1 with a resultant, centimetre-spaced S_2 foliation. View is to the west. Outcrop is located near "Repeater Peak" to the south of the 2017 KZK camp. Fold asymmetry of F_2 folds in both outcrops is consistent with a north-over south (thrust) sense of displacement.

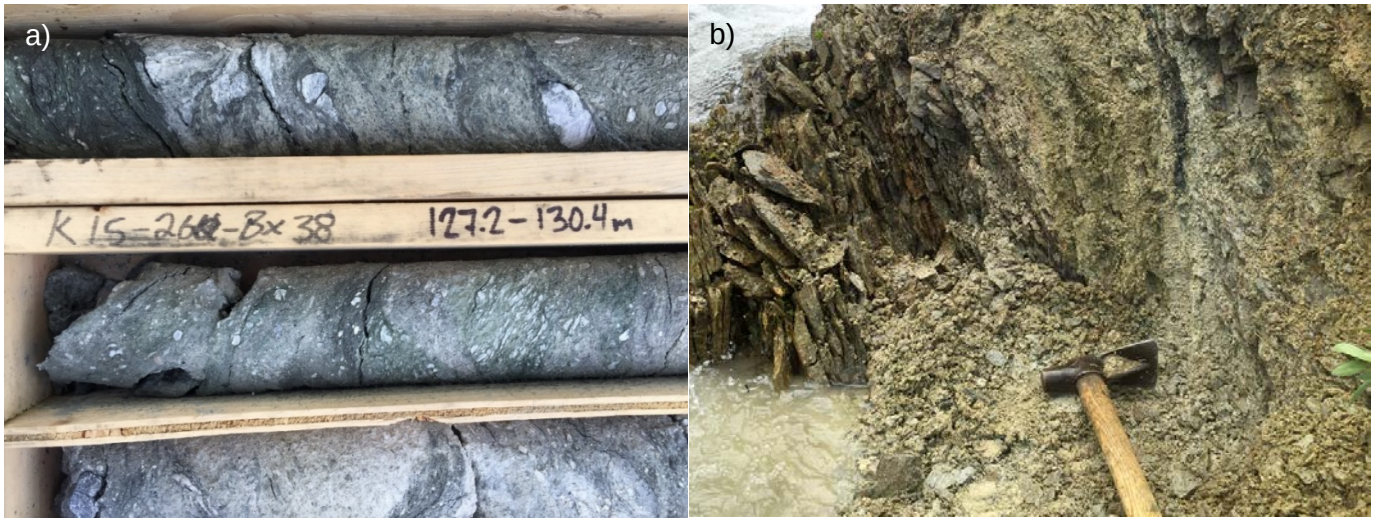

Figure 21: D3 Fault in drill core (a) and outcrop along Fault Creek (b).

8.3.2 Phase II (targeted mapping)

Phase II mapping areas (Figure 22) were investigated and sampled during Phase I mapping (Baker et al., 2017), and identified for further investigation and sampling (Figure 23). The results of this targeted mapping program are summarized below.

8.3.2.1 Fault Creek area

Three and a half days were spent investigating this area. Additional small outcrops and subcrops were found. Due to the general lack of significant outcrop, work subsequently focused on refining geological mapping with nearby outcrops to accurately project the geology through this zone. A total of 13 samples were collected from this area and submitted for geochemical assay.

Detailed mapping described a 20 x 175 m band of disseminated sulphide mineralization and strong alteration in this area. Mineralization comprises <1 vol. % disseminations, blebs, lenses, and bands of pyrite ± chalcopyrite along with their weathered equivalents, all of which are typically associated with silica. Alteration consists of strong muscovite + chlorite ± cordierite within a package of volcaniclastic rhyolite, mudstone and mafic intrusion (RHYv, MDS, MAFi). Samples of coherent rhyolite (RHYc) are generally more crystalline whereas aphanitic rhyolite (RHYi) is more glassy and aphanitic.

Ten samples were collected from or nearby the Fault Creek area. Yielding assay results up to 0.14 g/t Au, >10 g/t Ag, 0.5% Cu, 0.1% Pb and 0.5% Zn (Table 15). Two other weakly anomalous samples were collected and include 0.6% Zn from one sample of aphanitic rhyolite as well as 0.01 g/t Au, 1.5 g/t Ag and 2.7 ppm Sb from another one.

Figure 23

8.3.2.2 GP4F area

Two and a half days were spent in the GP4F area. The area is thickly overgrown and predominantly covered in overburden. Consequently, only a few subcrops were mapped during this investigation.

The sparse outcrop and/or subcrop mapped helped to further constrain the contacts between the Grass Lakes plutonic suite, the KZK Formation, and the Wind Lake Formation. A mafic tuff unit in the west-central portion can be traced for approximately 1.2 km, demonstrating stratigraphic continuity within a portion of the Wind Lake Formation.

To the southeast of GP4F, felsic volcaniclastic rocks were mapped down-slope of the Grass Lakes granite. A blue-quartz eye bearing crystal tuff, similar to the ones associated with the GP4F mineralized horizon, occurs on the contact between the KZK Formation and a feldspar-phyric granite pluton of the Grass Lakes suite. Five samples were taken from or near the GP4F area, none of which returned significant metal values.

Table 16: Assay results for grab samples taken from or near targets in the GP4F area

*n/d = not determined

8.3.2.3 Tour Cirque (GP3E) Area

A half-day was spent investigating this area, which is mostly covered with thick overburden and vegetation. A small outcrop of mafic tuff was found in a creek bank on the northwest side of the GP3E target area, interpreted to comprise part of the Wind Lake Formation. Two samples were taken from just south of the GP3E target, none returned significant metal values.

Table 17: Assay results for grab samples taken from or near the GP3E target

8.3.2.4 GP3L

One and a half days were spent mapping and sampling in and around the GP3L area although, due to a paucity of outcrop in the target area, more time was spent mapping to the north of the target. The GP3L area comprises a package of mudstone and pelite that is overlain by felsic volcaniclastic and intruded by pyroxenite and Grass Lakes Intrusive Suite felsic porphyry. An outcrop of pyroxenite lies approximately on-trend with historical drill hole K96-171 and was previously used to explain the GP3L gravity anomaly (Schultze and Hall, 1997b). Three samples were taken from the GP3L target area, none of which returned any significant metal values.

8.3.3 Limestone prospecting on Limy claims

To test the geochemical continuity of limestone in the Limy claims, 22 representative grab samples were collected for whole-rock geochemical analysis (Figure 24). Table 19 is a full list of the samples, locations, and rock types. Table 20 summarizes specific gravity measurements done at KZK Camp.

Field observations and geochemical analyses indicate that the limestone is uniform with high $CaCO^3$ and low $MgCO^3$ content, as well as low concentrations of deleterious elements (Table 21) but varying degrees of recrystallization and crinoid fossils in several locations. The limestone exhibits no obvious impurities except for weak Fe-staining and trace Mn-oxides. Late fracturing and small (<2 mm) calcite veins are present throughout the unit, with two ~20 cm-wide calcite veins observed in the southernmost portion of the claims. There were also no dikes or other geological heterogeneities observed in the mapped extent of the limestone unit, except for those listed above.

Table 19: List of samples collected for whole-rock geochemical analysis

Full assay results can be found in Appendix I.

8.4 Soil Sampling

Results are described below for field sampling of soils on the KZK Property during the 2017 season, as well as the QA/QC procedures used to verify the quality of the data.

8.4.1 Field sampling

A total of 2491 unique sites were sampled as part of the 2017 soil program out of the proposed 2834, equal to 88% of all planned sites (Figure 5, 6, 7). Out of the 343 planned sites that were not sampled, 242 were low priority samples that were cancelled, and another 101 samples were skipped because they were located on excessively steep or wet terrane.

Out of the 2491 soil samples collected, 2394 were collected on the KSW grid and 97 were collected on three orientation lines across the ABM and GP4F deposits. Field descriptions record 2484 of these samples as B-horizon, five as C-horizon and two as Ah. There is no difference in the texture or colour of B- and C-horizon soils, and so these are considered the same. Ah samples, on the other hand, average more organic with less pebbles and sand.

All four samplers describe the predominant soil colour as “brown” followed by “grey”, “black” and “red brown” or “orange” (Table 22). Brown soils consist mostly of silt, organic and pebbles whereas grey soils contain higher proportions of clay, and black has more organic. The “rusty” soils (red brown, orange) contain the least amount of organic material. Black and grey soils were typically taken at greater depth (21 cm) than brown and rusty soils (14-17 cm), possibly because samplers were digging deeper in search of more typical brown soil.

The bulk of soil samples were taken in “alpine” (82%) with the balance taken in “brush” (15%), talus (2%) and swamp (<1%). The texture of samples taken in alpine and brush settings are very similar whereas those taken from talus have more sand (average 24%) and pebble (21%). Samples taken from swamp have more organic (32%).

Within the B-horizon group there are 420 samples that contain ≥30% organic material, with 166 of these containing ≥40% and 34 containing ≥50% organic. Of the 34 samples with ≥50% organic, the proportion of black soils (24%) is significantly higher than the proportion among all 2491 samples.

Moisture content was recorded for 1810 of the 2491 sample sites, with 4% of these sites described as water saturated or “wet”. Wet samples also correlate weakly with increased organic.

Table 22: Summary of selected field descriptions of KZK soil samples, organized by sampler

Sampler	Samples	Clay%	Silt%	Sand%	Pebbles%	Organic%	Black	Brown	Grey	Rusty*
JL	439	6%	68%	3%	8%	16%	6%	76%	17%	1%
MH	686	2%	67%	6%	12%	14%	10%	61%	24%	5%
MB	902	1%	53%	13%	18%	14%	0%	98%	1%	1%
SP	464	1%	52%	4%	21%	22%	0%	99%	0%	1%
All Soil JL-MH	1125	3%	67%	5%	10%	15%	8%	67%	21%	3%
All Soil MB-SP	1366	1%	53%	10%	19%	16%	0%	99%	1%	1%
All Soils	2491	2%	59%	8%	15%	16%	4%	84%	10%	2%

*Rusty soils include those described as “orange” and “red brown”

8.4.2 QAQC of soil geochemical data

Forty-four blank samples were submitted and assayed. A failure threshold of 10x detection limit (*dl*) returned no failures for the Ag, Au, Cu, Pb or Zn, nor many other elements. Exceptions include Ce and Y, which averaged blank/*dl* equal to 21 and 13 respectively, However, the low ratio of standard deviation to mean (1.04 ± 0.14 ppm Ce, 0.66 ± 0.05 ppm Y) suggests that this blank material inherently contains 1.0 ppm Ce and 0.7 ppm Y.

Blank sample D00007260 returned 2.38 ppm Mo against a *dl* of 0.05 ppm, and a blank average of <*dl*. The Ce content is also 40% higher (1.43 ppm) than average. Related soil samples, however, lack Mo enrichment and so no follow-up work was done.

Seventy-four field duplicate samples were submitted and analysed, with 95% of the data showing an average percent difference of 29% for all elements. This lies just inside of the 30% threshold considered "acceptable" (SGS Mineral Services, 2005). For elements of interest, 90% of duplicate As, Au, Bi, Cu, Pb, Sb and Zn pairs returned a mean percentage difference of ≤30%, as well as 89% of Ag pairs and 86% of Hg.

Duplicate pairs for most elements show correlation (ρ) >0.9 for >95% of the population, with several key elements (Ag, As, Hg, Sb) showing ρ>0.9 for a slightly lower proportion of 90-95%. Correlation for gold, on the other hand, is exceptionally low (ρ=0.06) and includes two poorly reproduced assays of 116 ppb and 55 ppb Au, and numerous pairs that assayed at or near detection.

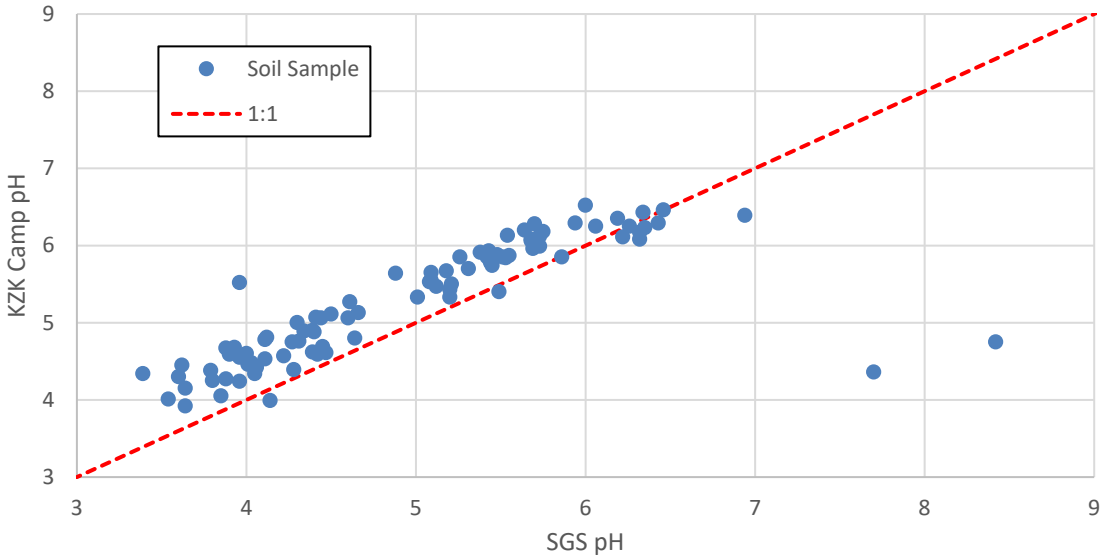

Figure 25: Comparison of pH readings taken at SGS against those taken at KZK Camp.

Ninety-two umpire pH measurements done at SGS show ρ = 0.76 with KZK Camp data for 100% of the duplicates, and ρ = 0.92 for 96% of the data. The KZK Camp measurements average pH 0.4 higher than SGS (Figure 25); possibly, this is related to different water volume in the soil paste. The KZK Camp readings are therefore reliable but should be levelled when plotted with other pH data sets.

The pH analysis of 34 "gravel pit" standards, using the PT2, returned an average pH of 6.7 with a standard deviation of 0.4. Analysis of the same material with the Oakton pH meter, on the other hand, returned a mean and standard deviation of 8.3 ± 0.5. This discrepancy was recognized at KZK Camp and so all samples analysed with the Oakton were re-analyzed with the PT2. Analyses of the pH of standard solutions shows that 96% of the data has an accuracy of ±0.2.

8.4.3 Orientation line constraints

The three orientation lines sampled as part of the 2017 KZK program are north-south trending, with sample spacing of 25 m over the projected exposure of sulphide deposits, and 50 m spacing further away. Two of these lines cross the ABM Zone (ABM Central, ABM West) and a 3rd crosses the GP4F deposit.

The ABM Central line consists of 51 samples taken over 1800 m and runs down the axis of the Geona Creek valley and through the heart of the ABM definition drill area. The ABM deposit reaches the top of bedrock underneath till-covered site D00007869 (2650 ppm Zn, 188 ppm Pb, 81 ppm Cu, 2.6 ppm Ag, 25 ppb Au). From there the line extends 850 m north along the down-dip extent of the ABM Zone, and 950 m south for a low angle pass across the Krakatoa Zone. Nearly the entire line returned >90th percentile Zn, Pb, Ag, Cd, Hg

and W along with slightly weaker Cu and As. Gold and Bi are both enriched across most of the line except for the southern-most part. Tin (Sn) is enriched in the central part of the line whereas thallium exceeds the 90th percentile from 0-200 m south of the projected exposure. Barium is, surprisingly, non-anomalous, likely because aqua regia does not digest barite, the main repository of Ba associated with sulphide. There is no notable drop in pH across the ABM and Krakatoa zones, although there are intervals of high IDH (i.e. calcite concentration) located just south of the Krakatoa Zone and immediately above the down-dip terminus of the ABM Zone.

The ABM West orientation line consists of 16 samples taken about 250 m upslope from the ABM Central line and runs across the western tip of the ABM Zone and drilling area. Consequently, there is significantly less chance of contamination and geochemical enrichment from up-hill sources in comparison to the ABM Central line. Silver, Sb, Hg Sn and W are elevated along most of the line, whereas Zn, Cu, Pb, Au, As, Cd, Tl and low pH are most anomalous 0-200 m south of the projected surface exposure. Like the ABM Central line, IDH is highest above the down-dip end.

GP4F is a 1.7 Mt VMS deposit that is predominantly enriched in zinc and Pb. The orientation line extends 335 m south (and downhill) of the projected surface exposure and 625 m to the north (and uphill) to cover the down-dip extent. Zinc, Pb, Ag, Au and several pathfinder elements are elevated for 0-200 m south and downhill of the projected exposure. Tin and tungsten both show strong enrichment over most of the line. Relatively low pH extends for 350 m north of the surface exposure and 100 m south. Weak IDH anomalies occur ~200 m south and ~600 m north of the surface exposure.

8.4.4 Elemental anomalies

The massive sulphide mineralization of ABM, Krakatoa, and GP4F are strongly enriched in Cu, Pb, Zn, Ag, and Au. Thus, studying the enrichment of these elements in soil may help to vector toward other VMS style mineralization at KZK. The definition of an anomalous sample is presented below as are the locations of anomalous concentrations these individual elements.

Anomalous lead is characterized by the 93rd percentile of 88 ppm. Large multi-sample anomalies occur in the south-eastern and south-central portions of the soil grid (Figure 26). As well, there are many smaller and single point anomalies throughout the grid.

Anomalous copper is characterized by the 93rd percentile of 78 ppm. Large multi-sample anomalies occur in the south-eastern and south-central portions of the soil grid (Figure 26). Additionally, many smaller and single point anomalies throughout the grid.

Anomalous zinc is characterized by the 93rd percentile of 451 ppm. Large multi-sample anomalies occur in the south-eastern portion of the soil grid (Figure 26). As well, many smaller and single point anomalies throughout the grid.

Anomalous silver is characterized by the 93rd percentile of 0.69 ppm. Large multi-sample anomalies in the south-eastern portion of the soil grid (Figure 26). Additionally, many smaller and single point anomalies throughout the grid.

Anomalous gold is characterized by the 98th percentile of 0.015 ppm. No large multi-sample gold anomalies exist. However, many smaller and single point anomalies throughout the grid.

Soil sample certificates of analysis and QA/QC report can be found in Appendices M and N, respectively.

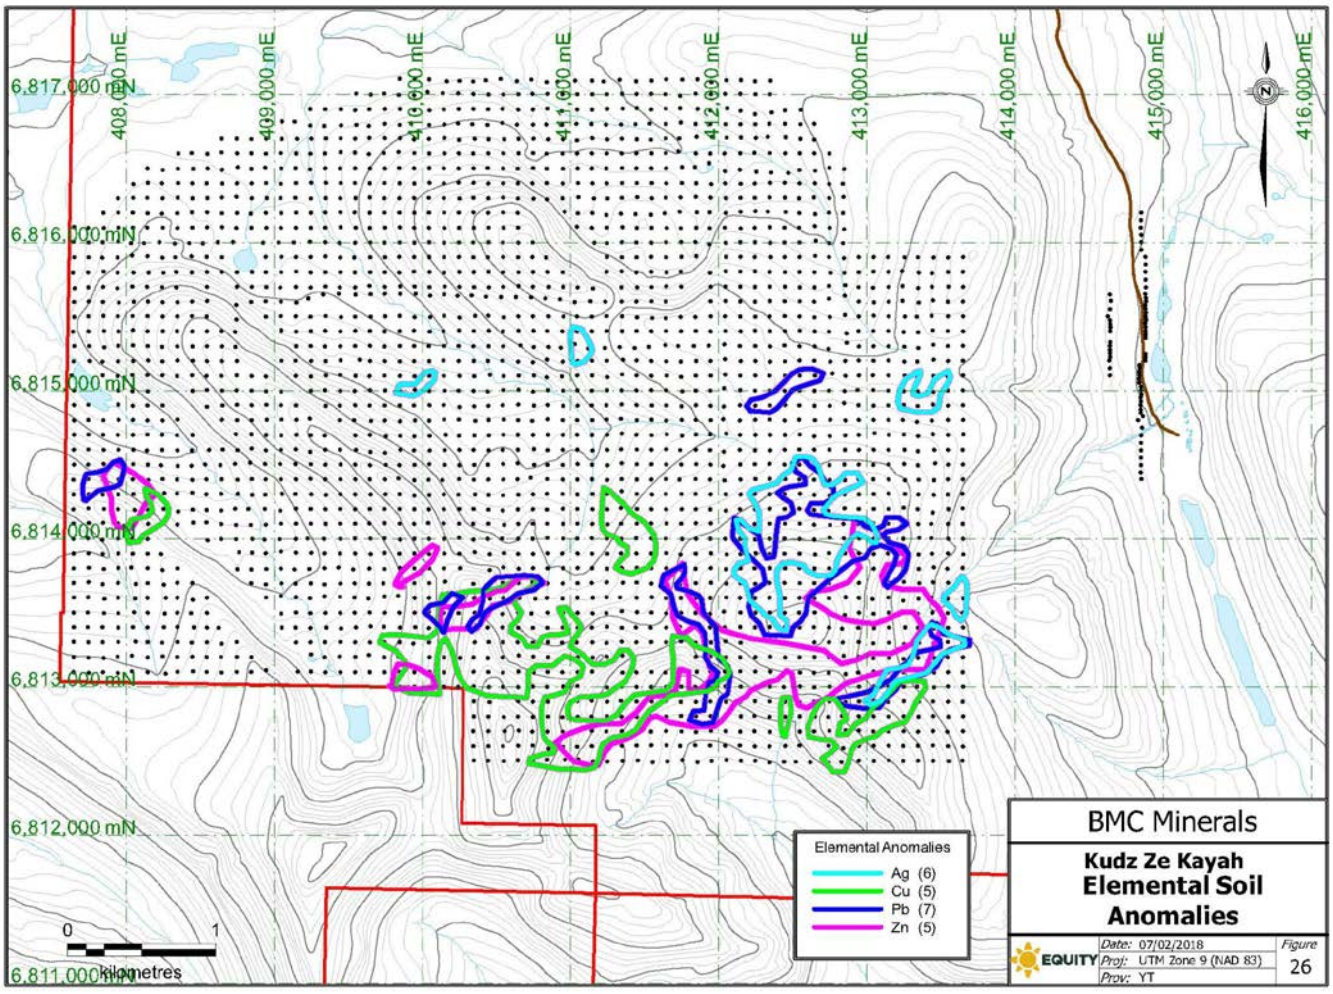

Figure 26: Outline of soil anomalies of Cu, Pb, Zn, Ag, and Au.

8.5 Geophysical Surveys

Geophysical work done in 2017 consists of surface EM survey and a borehole EM (BHEM) surveys. This work is summarized below.

8.5.1 Surface EM

A Fixed Loop Transient Electro-Magnetic (FLTEM) survey was conducted at the KZK property by Discovery International Geophysics. The purpose of the survey was to target a potential down-dip extension of the ABM deposit. The survey consisted of two 2000 m x 1500 m loops and encompassed a combined survey length of 32.90 line-km. Results from the survey are included within a report written by the contractor and attached as Appendix O.

8.5.2 Borehole EM (BHEM)

Borehole EM (BHEM) surveys were completed in three drill holes from within the 2017 FLTEM survey area (K17-447, K17-448, K17-449) to continue evaluating the postulated down-dip extension of the ABM deposit mineralization (Discovery International Geophysics Inc., 2017). BHEM surveys can typically detect conductors lying within ~100–150 m of the drill hole and thus the BHEM program was complementary to the surface FLTEM program. All of the BHEM surveys were completed successfully with no loss of data. Results from the surveys are included in the contractor report attached as Appendix O.

8.5.1 Acoustic impedance study

The 2017 acoustic impedance testing program was completed on nine drill holes, with a total of 1008 individual samples recorded. The program consisted of rock property testing on historical drill core followed by a numerical simulation of a proposed seismic survey based on a synthetic model of the ABM deposit produced through the combination of the results from the rock property testing with a geological cross-section of the ABM deposit. Average rock property measurements are presented in Table 23 below.

Table 23: Acoustic impedance data from the 2017 testing program

Lithology	Velocity (m/s)	Density (kg/m^3)	AI (kg/m^{2}s)	Measurement count	σ (AI)
Mudstone	2830	2.75	7.783	115	2.51
Rhyolite	3350	2.74	9.179	389	2.34
Massive Sulphide	4640	4.25	19.72	11	3.04
Mafic	3770	2.84	10.707	238	3.59

Full results can be found in Appendix P.

8.6 Exploration Drilling

The 2017 drilling program included exploration drilling, to the north of and within the ABM, to test for down-dip extensions of ABM or other massive sulphide lenses at the same stratigraphic horizon. These holes were also used for Bore-hole Electromagnetic testing (BHEM; see section 8.5.2 for results) and acoustic impedance measurements (see section 8.5.3 for results).

8.6.1 Collar and downhole surveys

All drill pads were constructed based on collar location spotted with a handheld GPS. All 4 exploration holes were surveyed downhole using a Reflex EZ-Gyro probe. A total of 134 measurements were collected at approximately 30 m spaced survey sites downhole. Of these 134 measurements 109 were “optimized” and 25 were “standard”. Additionally, 18 EZ-shot measurements were collected on K17-447.

8.6.2 Core orientation

A total of 282 oriented structural measurements were collected from the exploration drill holes. Features measured included foliations (214), veins (37), contacts (18), crenulation cleavages (5), bedding (4), and shear zones (4).

Fifty-nine lock angles were recorded, with mixed results. Twenty-eight of these lock angles indicate good agreement between the two orientation marks, lining up to within 10 degrees (β) of one another. However, ten of the lock angles measured 10-25 degrees (β) difference between core orientation marks and twenty-one additional orientation line measurements disagreed by greater than 25 degrees.

8.6.3 Geotechnical and petrophysical measurements

The average core recovery from the exploration drilling of 96.6% are similar to 2016 drilling at ABM (97.4%). As well, RQDs of 79.4% are almost identical to 2016 drilling at ABM (79.3%). The average measured bulk density of unmineralized silicate rocks is 2.78 g/cm^3, semi-massive sulphide (OI and OJ style mineralization) is 2.89 g/cm^3, and massive sulphide is 4.23 g/cm^3. These bulk density values are typical of the host rocks, and mineralization at ABM.

8.6.4 Exploration drilling geology

Exploration drilling consisted of 4 drill holes, 3 downdip of ABM (K17-447, K17-448, and K17-449) and one within ABM (K17-450), totalling 2451 m. One approximately 1 m zone of semi-massive pyrrhotite + chalcopyrite was observed in K17-447. As well, an intercept of the ABM lens was encountered in K17-450.

Table 24: Exploration Drill Holes

DDH ID	Easting	Northing	Azimuth (grid north)	Elevation (m.a.s.l.)	Total Depth (m)
K17-447	415055	6816226	173.34°	1380	452
K17-448	415452	6817253	176.47°	1420	1017
K17-449	414691	6817002	175.74°	1420	800
K17-450	414789	6815649	179.12°	1404	182

Drilling due north of ABM (K17-447) intersected an upper package of intercalated mudstones and mafic volcanic rocks (Wind Lake Formation), hosting a narrow zone of semi-massive sulphides from 50.12 to 51.29 m depth. A middle zone of felsic volcanic rocks, mudstone, and conglomerate was intersected. The bottom of the drill hole intersected another package of intercalated mudstone, conglomerate, and mafic tuff, similar to the Wind Lake Formation.

The two drill holes furthest north of the ABM deposit (K17-448 and K17-449) encountered similar geology, primarily consisting of intercalated mudstones, fine grained sediments, and mafic volcanic rocks (Wind Lake Formation) with lesser feldspar porphyritic rhyolitic dykes. No significant zones of alteration or mineralization were observed in these drill holes.

Drilling within the ABM deposit (K17-450) encountered typical KZK stratigraphy observed in the ABM deposit. The hanging wall to the ABM mineralization consists of intercalated felsic volcaniclastics, coherent rhyolites, pelites, and mafic dykes. The mineralization zone consists of18.47 m (147.17 to 165.64 m) of massive sulphide. The direct footwall of the massive sulphide consists a mafic intrusive (MAFi). Strong muscovite alteration is observed for approximately 20 m above the massive sulphide, with strong proximal chlorite ± cordierite locally within the massive sulphide.

Table 25: Selected composites from the 2017 KZK drill program

DDH ID	From	To	Length	Cu	Pb	Zn	Ag	Au	Lens/Target
	(m)	*(m)*	*(m)*	*(%)*	*(%)*	*(%)*	*(g/t)*	*(g/t)*	
K17-450	147.17	165.64	18.47	1.33	1.85	8.83	131.65	1.47	ABM

8.6.5 Geochemical sampling and assay

Twenty-eight samples from exploration drilling were submitted for whole-rock geochemical analysis.

A total of 152 samples were collected from drill core for geochemical assay. These were submitted with 10 CRM samples, and 9 blank samples for a total of 171 samples assayed. All blanks passed QA/QC. One CRM failed QA/QC due to poor Au accuracy. All affected samples over a threshold of 100 ppb Au were re-assayed and passed QA/QC on re-assay. All other CRMs passed QA/QC. All final results are considered accurate and free of contamination. Assay results from the exploration drilling are provided in Appendix S. A report on QA/QC for the 2017 drill program is available in Appendix T.

8.7 Geotechnical Investigations

Geotechnical investigations through the 2017 program included test pitting and drilling in support of the proposed mine site design, drilling and geotechnical core logging to characterize both Krakatoa and ABM rock quality for mine planning, hydraulic conductivity testing, as well as optical and acoustic televiewer surveys. Each of these programs is summarized below and data is included as Appendix R (Geotechnical Drill Data) and Appendix U (Televiewer Logs). A map showing the proposed infrastructure, test pits and geotechnical drill collar locations is presented as Figure 27.

8.7.1 Infrastructure geotechnical program

Five holes for 191.61 m were drilled to investigate the geotechnical characteristics of the proposed waste rock storage sites One hole for 40.62 m was drilled to investigate the geotechnical characteristics of the proposed run of mine (ROM) pad. Three holes for 116.25 m were drilled to investigate the geotechnical characteristics of the proposed sites for material stockpiles. Six holes totalling 30 m were drilled for Stand Pipe installations. Four holes totalling 163.25 m were drilled to investigate the proposed water management pond.14 holes for 370.8 m were drilled to investigate the geotechnical characteristics of the proposed mine site, consisting of 12 diamond drill holes, and two ODEX holes. Two holes were drilled to investigate the geotechnical characteristics of the e for the proposed paste plant. Total meterage of the 2017 infrastructure program including one abandoned hole was 937.7 m.

Table 26: 2017 infrastructure drill holes

Hole	Target	Length (m)	Azimuth (°)	Dip (°)	OVBN (m)	SPT	Packer	Installations

35 Holes		**937.7**				**127**	**36**	

Two samples from the infrastructure drilling were collected from drill core for geochemical assay, comprising 2 core samples. Both samples contained 1-5 % logged sphalerite. Assay results from the infrastructure drilling are provided in Appendix S.

14 test pits were excavated under the direction of Knight Piésold within the proposed waste rock storage areas, run-of-mine pad, and ore stockpile area. All test pits were backfilled and recontoured after use.

Table 27: 2017 geotechnical test pits

Pit ID	Target	Depth	Depth to Bedrock	Depth to Groundwater	Comments
TP17-01	Waste Rock Storage	2.5	1.4	-	Easy excavation, walls sloughing
TP17-02	Waste Rock Storage	1.1	0.4	-	Difficult excavation due to boulders and bedrock. Small ice lenses present at ~40 cm
TP17-03	Waste Rock Storage	1.8	0.4	-	Easy excavation, small ice lenses present at ~20 cm
TP17-04	Waste Rock Storage	0.8	0.6	-	sloughing walls, small ice lenses from ~30 to 60 cm
TP17-05	Waste Rock Storage	1.4	0.6	-	Stable walls, small ice lenses from ~15 to 60 cm
TP17-06	Waste Rock Storage	0.8	0.4	-	Test pit exposed for one day prior to logging, stable walls.
TP17-07	Waste Rock Storage	2	1.3	1.5	Test pit exposed for two days prior to logging, stable walls, groundwater filled to 1.5 m
TP17-08	Waste Rock Storage	3	-	0.6	Groundwater seep at base of topsoil (60 cm), walls sloughing below seep.
TP17-09	Run of Mine Pad	1.8	-	-	Test pit exposed for one day prior to logging, stable walls.
TP17-10	Ore Stockpile	1.4	-	-	Test pit exposed for five days prior to logging, stable walls.
TP17-11	Waste Rock Storage	4.4	-	-	Easy excavation, stable walls, no ice, no groundwater.
TP17-12	Waste Rock Storage	4.9	1.7	1.5	Easy excavation, groundwater seep at 1.5 m, minor sloughing around seep, no ice.
TP17-13	Waste Rock Storage	3	1.35	-	Excavation difficult in bedrock, stable walls, no ice, no groundwater.
TP17-14	Waste Rock Storage	5	-	3	Easy excavation, seeps at 3 and 4.5 m, walls sloughing around seeps.

8.7.2 In pit geotechnical drilling

Nine holes, for 1540 m were drilled on the proposed open pit for the geotechnical program. Geotechnical holes were geologically logged by Equity geologists. Further detailed geotechnical logging and sampling was completed by Dempers and Seymour Pty Ltd. of Perth, WA (Dempers and Seymour).

Table 28: 2017 in-pit geotechnical drill holes

Hole	Target	Length (m)	Azimuth (°)	Dip (°)	OVBN (m)	SPT	Packer	Installations
K17-420	Open Pit High Wall	200	050	-60	4.47	-	-	None

K17-440	Open Pit High Wall	152	050	-60	4.2	-	-	None
9 Holes		**1540**				**0**	**0**	

Five of the nine drill holes encountered significant known mineralization of the ABM or Krakatoa sulphide lenses. A total of 77 samples were collected from drill core for geochemical assay in these mineralized zones, comprising 69 core samples, 4 CRMs, and 4 blanks. All CRMs passed QA/QC. 1 blank failed QA/QC for contamination, all samples between the contamination source and the blank were re-assayed and passed QA/QC on re-assay. All other blanks passed QA/QC. All final results are considered accurate and free of contamination. Assay results from the in-pit geotechnical drilling are provided in Appendix S.

Four of the nine drill holes intersect significant fault zones, particularly the East and Fault Creek faults. These fault zones are characterized by large zones of low RQD, fault gouge, and cataclastic rocks.

Geotechnical characterization of these zones is very important in open-pit high wall development. A summary of the fault zones intersected in the in-pit drilling can be found in Table 29 below.

Table 29: Significant fault structures intersected by in-pit drilling

Drillhole ID	Significant Fault Structure	From (m)	To (m)	Drill Width	RQD*
K17-420	Northwest Fault	128	129.5	1.5	30%
K17-422	Northwest Fault	136.6	143	6.4	39%
K17-430	Northwest Fault (?)	117.4	118.1	0.7	7%
K17-437	Fault Creek Fault	94.31	127.15	32.84	25%
K17-438	East Fault	124.3	149.3	25	9%
K17-440	Krakatoa A Fault	71.15	74.3	3.15	33%

*RQD measurements are of averages of 3 m drill run intervals containing fault intercepts

A down-hole optical and acoustic televiewer survey was conducted as part of the in-pit geotechnical investigation administered by Dempers & Seymour. The survey was limited to the in-pit drill holes and was completed between June 21st and July 27th, 2017. A total of 8 holes and 1388 m was surveyed with one additional hole abandoned due to in situ collapse of the walls of the drill hole. Examples of the optical and acoustic images produced by the televiewer survey are shown in Figure 28.

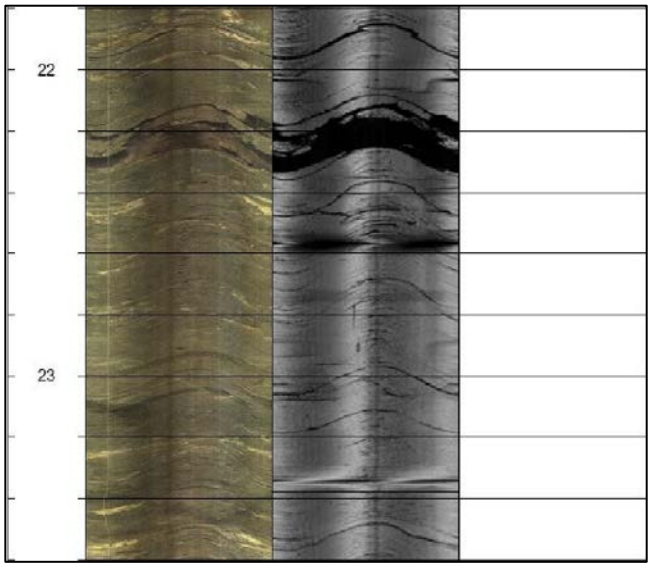

Figure 28: Example optical (left) and acoustic (right) images produced by the televiewer survey. Pictured is hole K17-427 from 21.80 m to 23.60 m depth

For optimal results, the optical survey requires either clear water, or a dry borehole. Five of eight optical televiewer surveys were successfully completed, while three were of sub-optimal quality due to turbid groundwater in the hole. The acoustic televiewer survey is not affected by groundwater turbidity, however only works when submerged in water. All eight of the completed acoustic surveys were of good quality below the water table. A summary of the optical televiewer results is presented in Table 30.

Products delivered to BMC following the survey, and analysis by Dempers and Seymour include the raw images and orientation data from each survey, as well as WellCAD processed logs for each hole (Appendix U).

Table 30: Televiewer survey outcomes for 2017

Hole ID	Surveyed Depth (m)	Survey Outcome
K17-420	198	Complete
K17-422	219	Complete (Turbid water)
K17-424	170	Complete (Turbid water)
K17-427	152	Complete
K17-430	180	Complete
K17-437	152	Abandoned
K17-438	137	Complete (Turbid water)
K17-439	119	Complete
K17-440	148	Complete

8.8 Hyperspectral Imaging Study

TerraSpec analysis of the selected drill holes provided 3629 unique spectral readings, with 3330 of these spectra returning one or more minerals identified from the TSA spectral library and 299 interpreted as aspectral.

White mica minerals dominate the identified spectra due to their ubiquity within the host rhyolite and high reflectance. Of the 3330 valid mineral identifications, 2422 contain white micas (i.e. phengite, muscovite, muscovitic illite, phengitic illite) as their primary mineral. Of the 2422 mineral identifications, 1943 were singleton IDs.

Chlorite occurs in many of the analyses with valid mineral identifications, with 839 containing chlorite as their primary or secondary mineral. It is common within the mafic footwall intrusion (or MAFi), proximal-altered rhyolite and the Wind Lake Formation although its low reflectance means that it is likely underrepresented in the spectral data.

Fifty-eight of the valid mineral identifications contain carbonate (calcite, ankerite, siderite, dolomite) as their primary identified mineral. All identified minerals and the number of spectra from which the identifications were made are summarized in Table 31. Mineral groupings used for interpretation, along with their abundance, are shown in Table 32.

Table 31: Summary of minerals identified in the processing of rock spectra

Row Labels	Count of Min1 sTSAS	Count of Min2 sTSAS
Actinolite	4	20
Alunite-NH	0	11
Ankerite	14	74
Biotite	53	38
Calcite	31	31
Chlorite-Fe	61	32

8.9 Hydrogeological Investigations

Hydraulic conductivity testing was completed during drilling on twelve drill holes from the infrastructure geotechnical program. In total, 35 packer tests were conducted in these twelve drill holes. Results of this testing are summarized in Table 33 below. Hydraulic conductivity testing was also undertaken on in-pit geotechnical drill holes; results are pending.

Table 33: Measured hydraulic conductivity in infrastructure program drill holes

Hole ID	Collar Elevation (masl)	From (m)	To (m)	Hydraulic Conductivity (m/s)
K17-421	1484	3.9	12.22	$2.00x10^{-5}$
K17-421	1484	10.83	25.93	$<1.00x10^{-8}$
K17-421	1484	24.9	40.65	$1.00x10^{-7}$
K17-423	1476	4.04	16.79	$7.00x10^{-6}$
K17-423	1476	16.04	28.79	$1.00x10^{-7}$
K17-423	1476	28.04	40.79	$1.00x10^{-7}$
K17-425	1431	7.07	18.32	$2.00x10^{-7}$
K17-425	1431	16.07	30.32	$9.00x10^{-8}$
K17-425	1431	29.57	40.82	N/A (Artesian Conditions)

K17-445	1334	22.94	32.12	$1.00x10^{-7}$
K17-445	1334	31.9	41.1	$6.00x10^{-8}$
K17-446	1345	10.98	23.16	$2.00x10^{-7}$
K17-446	1345	22.98	32.16	$5.00x10^{-7}$
K17-446	1345	31.98	39.66	$4.00x10^{-6}$

The 2017 hydrogeological installation program was designed to expand on the baseline work done in 2016 around the proposed mine site. Holes drilled for hydrogeological investigation were also used for geotechnical work and infrastructure. In total, 13 holes were drilled as part of the hydrogeological program, comprising 512 m of drilling. All planned holes were successfully completed, and while it was necessary to abandon K17-426, the hole was subsequently completed as K17-426B. Completed holes were installed with Stand pipe piezometers, vibrating wire piezometers, and thermistor strings (Table 33). A summary list of hydrogeological drill holes is presented below in Table 34.

Table 34: Overview of drilling done for the 2017 hydrogeological investigation

Hole	Target	Length (m)	Azimuth	Dip	Installation
K17-421	Waste Rock Storage	40.65	360	-90	10 Node Thermistor String
K17-423	Waste Rock Storage	40.79	360	-90	10 Node Thermistor String
K17-425	Waste Rock Storage	40.82	360	-90	10 Node Thermistor String
K17-426	Waste Rock Storage	28.9	360	-90	Abandoned
K17-426B	Waste Rock Storage	40.48	360	-90	10 Node Thermistor String
K17-428	Run of Mine Pad	40.62	360	-90	Stand Pipe Piezometer

K17-446	Water Management Pond	39.66	360	-90	10 Node Thermistor String

9.0 DISCUSSION

The following sections provide some discussion on the results of the 2017 KZK work program, presented in the same order as the above sections. Summaries for 2017 program elements and recommendations for future work are presented in Section 10.0.

9.1 Geological Outcrop Mapping

9.1.1 Relative and absolute timing

The Wind Lake and Fyre Lake Formations may represent ambient sedimentation and mafic volcanism in the region, which was locally interrupted by felsic volcanism of the Kudz Ze Kayah Formation. Coeval with the Kudz Ze Kayah and Wind Lake Formations are Devonian-Mississippian (360±1 Ma) (Murphy et al., 2006) peraluminous K-feldspar porphyritic to megacrystic granitoids of the Grass Lakes Plutonic Suite (MGg and MGag of Murphy (2006), which are inferred to be subvolcanic feeders (Piercey et al., 2003).

9.1.2 Metamorphism and deformation

The mapping from 2017 suggests that, contrary to the interpretation of Szybinski (1996a, b), S_0 is generally well-preserved and does not appear to have been subjected to significant dismemberment or transposition.

A subhorizontal to moderately steep north to northeast dipping, locally folded, bedding parallel, penetrative fabric (S_1) overprints all formations and suites on the KZK Property, and is associated with lower greenschist facies assemblages and phyllite development. Previous workers have suggested that this first foliation (S_1) is the product of regional scale isoclinal folding and intense deformation causing dismemberment and transposition of bedding into the plane of foliation (Szybinski 1996a, b, Schultze, 2001). Mapping from the 2017 field season demonstrated significant lateral continuity to bedding and did not identify any F_1 folds. Additionally, the metamorphic grade associated with S_1 is low, forming phyllite to fine grained schists. As a result, we suggest that, in comparison to the Cominco model (Szybinski, 1996a, b), relatively little plastic deformation was involved in the development of the S_1 foliation. It is unclear precisely how S_1 formed; however, it could represent the preferred growth orientation of micaceous minerals under lithostatic load during anchizonal-epizonal (e.g. Árkai et al., 2003) low grade metamorphism.

If the crenulations and F_2 structures that overprint S_1 are contemporaneous, the south vergence of F_2 folds would suggest south-southeast directed compression. The opening of NE-SW brittle faults in D_3 suggests NE-SW compression, possibly related to transpression along regional-scale transcurrent structures like the nearby Tintina fault. The orientations of S_3 kink bands are permissible within a regime of NE-SW compression.

Table 35: A comparison of our proposed deformation history and Szybinski's model for Cominco.

Cominco Model	Proposed Model
S_0 rarely preserved, locally within metasedimentary sequence, parallel to S_1	S_0 generally well preserved
D_1 generates variably intense S_1 (mylonitic to weak axial planar) F_1 folds are hard to trace due to D_2, but tight to isoclinal and approach similar style. North vergence. Dismemberment and transposition of S0 into S_1.	D_1 generates a prominent penetrative S_1 cleavage without significant folding of strata. Moderate flattening of features (clasts) into the plane of S_1.
D_2 deformation generates F_2 folds that are meso-scale and tight to isoclinal with subhorizontal axes that trend E-W. Small scale rounded crenulation of S_1, kink folding. S_2 is heterogeneously developed, and dips north, moderately steeply. South vergence.	D_2 generates local meso-scale folds with axial planar cleavage as well as local crenulations. F_2 fold axes and S_1/S_2 intersection lineations trend ENE and WSW very shallowly (5-10°)
D_3 deformation generates macroscopic folds with fold axes in a similar orientation to F_2. Not well developed.	D_3 causes late brittle faulting (Fault creek fault, etc.) and rare, horizontal and steeply dipping kink bands as well as broad open folds that warp F_2 fold axes around subhorizontal to moderately north plunging fold axes
D_4 deformation generated brittle faults such at the fault creek fault. Down-dropped block in the normal regime is the southeastern one.	

9.1.3 Prospective geology

Detailed mapping of the Fault Creek area shows a 20 x 175 m band of disseminated sulphide mineralization and strong alteration. Mineralization comprises <1 % disseminations, blebs, lenses, and bands of pyrite ± chalcopyrite along with their weathered equivalents, all of which are typically associated with silica. Alteration consists of strong muscovite + chlorite ± cordierite within a package of felsic volcaniclastic rock, mudstone and mafic intrusion (RHYv, MDS, MAFi). TerraSpec analysis of the samples in this area show a cluster of muscovitic (Al-rich) white mica, similar to the felsic rocks in the immediate vicinity of the ABM and Krakatoa Zones This band of outcrop may represent the ABM horizon directly west-southwest of the ABM deposit or a sub-ABM mineralized horizon.

Hand sample TerraSpec signatures in the area of the Cayley and Newberry soil geochemical anomalies show an area of weakly muscovitic white mica. The mapping from 2017 suggests that this area sits at a similar stratigraphic level to the GP4F Deposit.

9.1.4 Limestone prospecting

Calcium carbonate content of the samples can be calculated by summing the CaO and LOI, under the assumption that all CaO is derived from $CaCO_3$ and all of the LOI is CO_2 evolved from $CaCO_3$. Based on this method, the average $CaCO_3$ content of the 22 samples is 98.16%, with a minimum $CaCO_3$ content of 93.1% $CaCO_3$ (Table 21). Most samples are MgO-poor (<0.5% MgO), and have low concentrations of deleterious elements, with the exception of D00005907, which has a higher concentration of MgO, indicating a more dolomitic composition.

9.2 Soil Sampling

The orientation surveys, which transected ABM, Krakatoa, and GP4F mineralization area displayed anomalous values for many metals and indicator elements associated with VMS deposits. Soil pH analyses in these areas display anomalous IDH responses on the margins of the ABM massive sulphide deposit, but no response at GP4F. The central ABM orientation line displays the strongest anomalous signature, which may reflect gravity transport of sulphide bearing material to the valley floor. These results suggest that the soil sampling techniques performed during 2017 are a valuable tool for exploring for buried VMS deposits elsewhere on the KZK property.

The majority of the multi-soil anomalies occur in the southeastern and south-central portions of the soil sample grid (Figure 26). In this zone there are a few coincident anomalies of Ag-Pb, Ag-Pb-Zn, Pb-Zn, Pb-Zn-Cu, and Zn-Cu. As well, in the western portion of the grid there is a multi-soil anomaly of Cu, Zn, and Pb (Figure 26). These multi-metal anomalies are considered the most prospective as they contain many of the metals associated with VMS style mineralization at ABM, Krakatoa, and GP4F. There are many scattered point anomalies, however only multi-point anomalies should be considered significant.

Many of the anomalies in the south-central and southeastern portions of the grid occur within the Fyre Lake formation. The Fyre Lake formation is composed of intercalated mafic volcanic and sedimentary rocks. Therefore, the lithology may be elevated in Cu relative to KZK formation. This lithologically controlled Cu distribution may give rise to false anomalies. It would be valuable to compare poly-metallic anomalies to better define VMS style mineralization, because VMS-style mineralization is not commonly defined by a single enriched metal.

9.3 Exploration Drilling

Drilling down-dip of ABM provides geological insight into the setting of felsic volcanism in the KZK formation. The KZK formation was intersected in K17-447, as an approximate total of 185 m of felsic volcanic rocks over two sections. Intercalated sedimentary and mafic volcanic rocks similar to the Wind Lake Formation were intersected above, below, and in between two intervals of KZK formation rocks. Drilling in K17-448 and K17-449 did not intersect any significant continuous felsic volcanism, suggesting that the KZK formation may thin toward the north. Drilling in both K17-448 and K17-449 encountered interbedded sedimentary and mafic volcanic rocks, but no significant felsic volcanic rock.

Coarse grained feldspar-phyric granitic dykes (Leitch, 2017) cut the sedimentary and mafic volcanic rocks. This field relationship was also observed during the 2017 field mapping. These granitic dykes are inferred as a part of the Grass Lakes Plutonic Suite from field relations.

9.4 Acoustic impedance study

Based on the acoustic impedance measurements taken during the 2017 field program, massive sulphide can be reliably differentiated from felsic volcanic, mafic and mudstone using acoustic methods. Contacts between felsic volcanic, mafic and mudstone are unlikely to be differentiated by acoustic methods due their similar acoustic impedance. Formational boundaries will be difficult to differentiate from internal contacts using acoustic methods, unless they lie on an angular unconformity (Villahermosa, 2017).

Massive sulfides of the ABM deposit could be successfully delineated with a seismic survey. Additional down hole seismic data would be useful to provide more detailed in-situ information of the rock properties of the deposit. The contractor report detailing the methods and results of the acoustic impedance testing can be found in Appendix P.

9.5 Geotechnical Investigations

9.5.1 Infrastructure drilling

The combination of ODEX, Sonic, and diamond drilling was successful in collecting material to geotechnically characterize the unconsolidated sedimentary overburden and the bedrock.

Further interpretation of the data collected requires review and interpretation by a qualified mining engineer.

9.5.2 Geotechnical test pits

Diamond drilling was not adequate to sample and define the geotechnical properties of the unconsolidated sedimentary overburden in the proposed open pit area and infrastructure sites. Therefore, test pits were dug with an excavator to better define these geotechnical properties. The test pits were successful in characterizing the overburden material.

Further interpretation of the data collected requires review and interpretation by a qualified mining engineer.

9.5.1 In pit geotechnical drilling

Drilling was successful at intersecting the proposed pit high walls as well as faults. Further interpretation of the drill core data will be processed by Dempers and Seymour's engineer to develop a proposed detailed structural model to aid in the pit design and mine scheduling.

9.5.2 Televiewer program

Data collection was not complete on all boreholes due to ground conditions including groundwater and fault zones. Ground water flow created murky water conditions in certain boreholes, which prevented clear optical imagining. However, acoustic imaging is not affected by murky water conditions, but is unable to be completed above the water table. Unstable rock conditions, particularly around fault zones locally narrowed the internal diameter of the borehole, preventing the dummy and televiewer probes from passing through. Thus, imaging was not complete through and below these zones.

Further interpretation of the televiewer data requires review and interpretation by a qualified mining engineer.

9.6 Hyperspectral imaging study

Interpretations of the spectra collected from drill core in the ABM deposit area are summarized below. These have been integrated with the results of previous geological interpretations in order to determine the spatial correlations between mineralization, alteration, and spectrally identifiable mineralogy.

The 2200 nm absorption feature in singleton white mica analyses at KZK from the 2017 TerraSpec field program (1943 spectra) ranges from 2197 to 2224 nm These spectra are nearly ubiquitous in the rhyolitic rocks of the KZK formation that were sampled. The peak-shift of the 2200 nm absorption feature (λ2200) reflects the changing composition of white mica from Fe-Mg rich phengitic micas ($K(Al,Fe)(Mg,Fe)(Si_4O_{10})(OH)_2$), which ranges from 2210-2225 nm, to Al rich muscovite ($KAl_2(AlSi_3O_{10})(OH)_2$) in the range of 2195-2210 nm (Figure 29) (Dilles, 2012; Rieder et al., 1998). In drill holes that cut massive sulphide mineralization, muscovitic white mica is found in proximity to mineralization, whereas phengitic white mica is found distal.

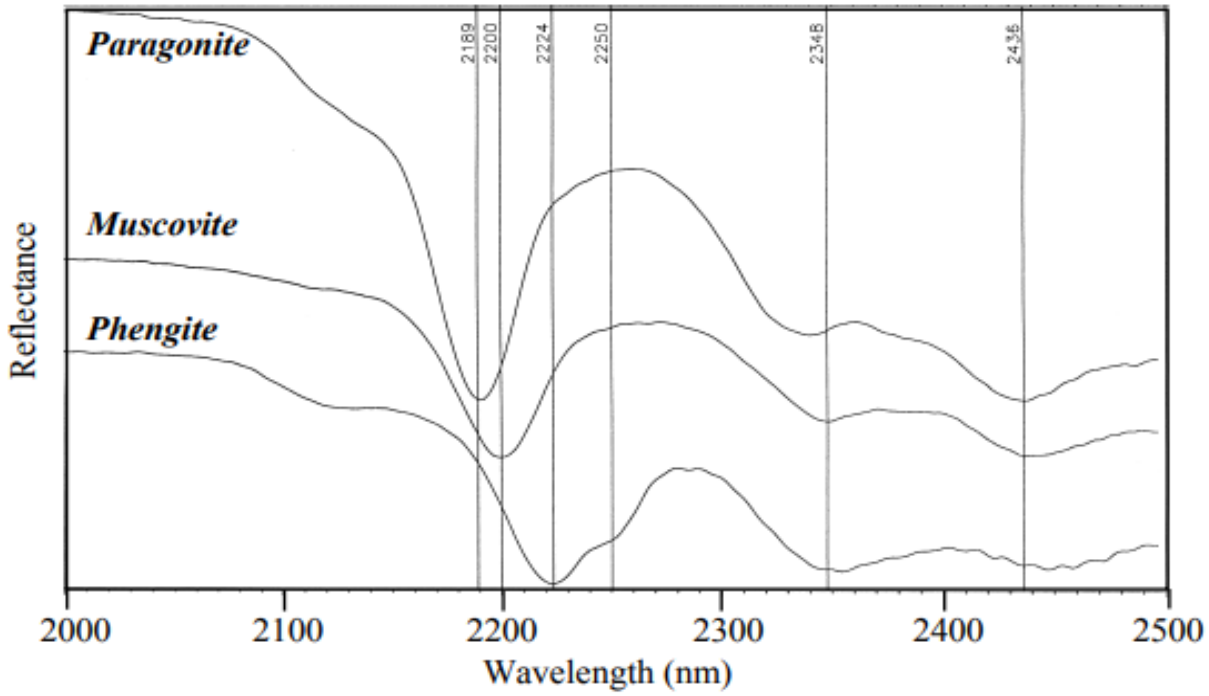

Figure 29: Idealized reflectance spectra for three types of white mica (Scott and Yang, 1997). Note the shift at the 2200 nm absorption feature.

Table 36: Additional mineral groups interpreted

Group	Min 1 USED	Min 2 USED	Count	Comments
White Mica	Phengite, Muscovite, Paragonite, Phengitic Illite, Muscovitic Illite	n/a	1943	Associated with rhyolitic rocks, muscovitic white mica proximal to mineralization, phengitic mica regionally
Chlorite	Chlorite Fe-Mg, Chlorite Fe, Chlorite Mg	Not white mica	579	Associated with MAFt, MAFi, and proximal chlorite alteration
Amphibole	Hornblende, actinolite, riebeckite	n/a	14	Associated almost exclusively with MAFi
Biotite	Biotite, phlogopite	Biotite, phlogopite	90	No distinct pattern, more common in PEL, MAFt
Carbonate	Ankerite, calcite, dolomite, siderite	Ankerite, calcite, dolomite, siderite	158	No distinct pattern
Fe-Carbonate	Ankerite, siderite	Ankerite, siderite	51	No distinct pattern
Tourmaline	Tourmaline, Tourmaline-Fe	Tourmaline, Tourmaline-Fe	12	Insufficient analyses to discern a strong pattern, many data points associated with faults
Epidote	Epidote	n/a	1	Insufficient analyses to discern any pattern
Kaolinite	Kaolinite-WX	n/a	21	Predominantly associated with faults
Smectite	Montmorillonite	n/a	2	Insufficient analyses to discern any pattern
Dickite	Dickite	Dickite	14	Commonly interpreted in low reflectance samples, no discernable pattern
Alunite-NH	N/A	Alunite-NH	11	Poor spectral matches, no discernable pattern

10.0 SUMMARY AND RECOMMENDATIONS

Earthworks done as part of the 2017 work program included drill pad and trail construction, test pit digging, as well as reclamation. 0.65 ha of land was reclaimed during the 2017 report year. The combined un-reclaimed disturbance from previous years totals 10.083 ha. The trails and sites that were not fully reclaimed in 2017 due to snow and/or cold weather should be reclaimed and reseeded in the spring of 2018.

The majority of the drill collars for the 2017 drill program were surveyed using a real time kinematic differential GPS. Drill holes, which were not surveyed in 2017 should be surveyed during the 2018 field season.

Terrain stability and hazard mapping was completed for a 64 km^2 area of the KZK project, where mine site and access roads are proposed. The report generated by Coregeo (Appendix E) describes proposed mitigation techniques to avoid credible risks and areas that warrant further attention.

Surface outcrop mapping was conducted across the majority of the KZK property and the Limey claims. More detailed mapping and prospecting was conducted on prospective target areas. The property scale mapping suggests a simpler deformation history than the work conducted by Cominco (Szybinski, 1996a). The prospective target mapping has identified new areas of prospective geology. Fixed Loop Transient Electro-Magnetic (FLTEM) surveys are recommended to test for conductive units in areas identified as prospective.

A total of 2491 soil samples were taken on the KZK property for pH testing and multi-element analysis. Zones of anomalous soil were found. Further soil sampling is recommended to cover more of the prospective stratigraphy on the KZK property. As well, it is recommended that FLTEM surveys are conducted on these soil anomalies, particularly the anomalies coincident with prospective geology and characteristic pH conditions.

A total of 32.90 line-km of FLTEM was conducted over the north of ABM, where exploration for down-dip extension of the ABM deposit and/or stratigraphy occurred. Borehole EM was also conducted in all three exploration drill holes within this area. Further processing of this geophysical data is required.

Four drill holes, totalling 2451 m, were completed as a part of the 2017 exploration drill program. Three of the holes targeted the down-dip continuation of the KZK stratigraphy, one targeted representative ABM stratigraphy and mineralization. This drilling suggests that the KZK formation thins and pinches out to the north of the ABM deposit.

The TerraSpec scoping study has shown that spectral analysis is a valuable tool to vector toward alteration zones. White mica is the most abundant and useful spectrally identified mineral in the KZK formation due to the felsic nature of the host rocks and characteristic 2200 nm absorption feature shift between muscovite and phengite. Muscovitic white mica is observed to increase toward the mineralization whereas phengitic white mica is pervasive in the host-rocks. Further TerraSpec analysis is recommended on drill core from GP4F, Fault Creek zone, deep holes from ABM and Krakatoa, and any future exploration drilling in felsic volcanic rocks. Spectral analysis of soils should be tested to determine the efficacy of the TerraSpec technique in this medium.

Significant contrasts in acoustic impedance between massive sulphide and silica-rich rocks were observed during the 2017 program. Acoustic methods should be able to delineate zones of massive sulphide from surrounding volcanic and sedimentary host rocks. Sulphide bodies the size of the ABM deposit should appear as discrete zones of high reflectivity in seismic reflection imaging, Additional down hole acoustic testing is recommended in order to provide more detailed in-situ information of the rock properties of the deposit.

Respectfully submitted,

Signed "Alexander Nielsen"

A. Oscar Nielsen

Appendix B: Statement of Expenditures

STATEMENT OF EXPENDITURES

KZK Project

January 01 to December 31, 2017

PROFESSIONAL FEES AND WAGES:			
Senior Project Manager	108.28 days @ $700/day	$ 75,796.00	
Senior Geologist	232.77 days @ $700/day	162,939.00	
Geologist (Core Loggers)	128.07 days @ $575/day	73,640.25	
Assistant Geologist (Geotechnicians)	67.50 days @ $400/hour	27,000.00	
Geophysicist Specialist	6.67 days @ $1000/day	6,670.00	
Exploration Assistant	190.50 days @ $400/day	76,200.00	
Project Coordinator	140.71 days @ $625/day	87,943.75	
Head Cook	167.50 days @ $550/day	92,125.00	
Senior Cook	7.00 days @ $475/day	3,325.00	
Cook	92.00 days @ $400/day	36,800.00	
Assistant Cook	166.00 days @ $325/day	53,950.00	
Kitchen Helper / Cleaner	47.00 days @ $325/day	15,275.00	
First Aid Level III	160.00 days @ $400/day	64,000.00	
Environmental Assistant	8.00 days @ $325/day	2,600.00	
Padbuilding	53.50 days @ $450/day	24,075.00	
Site Service	100.50 days @ $400/day	40,200.00	
Senior Sampler (Core Cutters)	385.50 days @ $325/day	125,287.50	
Sampler (Core Cutters)	17.00 days @ $275/day	4,675.00	
GIS	263.25 hours @ $75/hour	19,743.75	
Clerical	163.93 hours @ $35/hour	5,737.50	$ 997,982.75
EQUIPMENT RENTALS:			
Field Camp Rental	($ 6,500.00 per month)	$ 78,000.00	
Core Saw	9.00 days @ $60/day	540.00	
Field Computer	907.00 days @ $20/day	18,140.00	

Generator Rental			
	3.11 days @ $45/day	140.00	
Micromine Software			
	127.00 hours @ $50/hour	6,350.00	
TerraSpec			
	67.00 days @ $80/day	5,360.00	108,530.00
EXPENSES:			
Chemical Analyses		$ 71,783.53	
Materials and Supplies		287,067.15	
Plot Charges		144.06	
Printing and Reproductions		730.63	
Camp Food		143,645.22	
Meals		2,570.01	
Accommodation		8,460.05	
Taxis and Airporters		1,420.73	
Parking		123.81	
Snowmobile Rental (Non-Equity)		12,050.00	
Truck Rental (Non-Equity)		95,961.88	
Automotive Fuel		66,106.87	
Aircraft Charters		162,600.50	
Busfare		179.23	
Airfare		76,621.57	
Helicopter		438,746.74	
Earthworks		181,520.07	
Courier		4,287.96	
Freight		97,468.50	
Bulk Fuel		217,075.65	
Drug Test		3,432.00	
Camp Maintenance		46,506.27	
Dump Disposal Fees		2,347.70	
Satellite Phone Rental (Non-Equity)		2,648.93	
Radio Rental (Non-Equity)		19,930.43	
Downhole Survey Tool Rental (Non-Equity)		23,352.25	
Other Equipment Rental (Non-Equity)		29,380.00	
Loader		35,700.00	
Drilling: Actual		1,205,658.67	
Drilling: Coreboxes		3,920.00	
Geological Consulting		668,066.68	
Expediting		67,892.81	
Internet Charges		73,971.68	
Legal		2,725.00	
Other Contract Workers		20,755.53	
Report (estimated)		5,000.00	4,079,852.11
SUB-TOTAL:			$ 5,186,364.86
PROJECT SUPERVISION CHARGES:			348,857.16
TOTAL:			$ 5,535,222.02

Appendix C: Claim Data

This appendix contains a list of all claims comprising the KZK Property as of March 2018. Claims are ordered by grant number in Table C-1 below.

Table C-1: Tenure details for KZK Property claims

Appendix D: 2017 Drill Collar Locations and Orientations

This appendix contains the most up-to-date collar coordinates[1] for all 2017 drill holes. The survey type used to locate the collar is indicated as either differential GPS ("RTK DGPS"), handheld GPS ("GPS") or the planned co-ordinates ("PLND-LiDAR").

Table D-1: Survey collar information for 2017 diamond drill holes

Dear Ms. Bergh:

Re: Terrain Stability and Hazard Mapping for the Kudz Ze Kayah Project, Yukon
Project #s: BMC-17-01/170341

Coregeo and Associates is pleased to provide BMC Minerals (No. 1) LTD with the results of the terrain stability and hazard mapping and related risk assessment for the Kudz Ze Kayah (KZK) Project, in southeastern Yukon.

This report, in combination with the appended terrain map (Map 1) and terrain stability, hazards and risks maps (Maps 2 and 3), provides the information necessary to support a response to an information request (R162) made by the Yukon Environmental and Socio-economic Assessment Board (YESAB) in its adequacy review of the Project Proposal. The report and accompanying maps characterize the types and distribution of terrain hazards within the proposed mine site area and along the access road corridor, many of which are influenced by permafrost or periglacial processes. A distinction is made between existing terrain stability and projected terrain stability in response to potential disturbance from project-related construction and/or climate change. Opportunities for mitigating site-specific risks to the project are identified to demonstrate the feasibility of reducing risk to negligible levels.

Should you, YESAB or YESAB's technical reviewers have any questions or require additional information related to this study, please feel free to contact me, Eri Boye, at 867-336-2673 or via email at eri@coregeo.ca.

We appreciate the opportunity to support the advancement of the KZK Project.

Yours truly,
Coregeo and Associates

Eri Boye, M.Sc., P.Geo.

1. Introduction

Coregeo and Associates, a collaboration of Core Geoscience Services Inc. (Coregeo) and Palmer Environmental Consulting Group Inc. (PECG) with Dr. Derek Turner in the role of a technical advisor, is pleased to provide BMC Minerals (No. 1) LTD (BMC) with the results of our team's terrain stability and hazard mapping for the Kudz Ze Kayah (KZK) Project (the Project), in southeastern Yukon. The mapping and assessment work was completed in accordance with the hazard assessment guidelines of Yukon Environmental and Socio-economic Assessment Board (YESAB) (Guthrie and Cuervo, 2015; hereinafter referred to as YESAB's Geohazards Guide), in order to address the information request (IR) R162 made by YESAB in association with its review of the adequacy of the Project Proposal and subsequent responses from BMC. Terrain, terrain stability and hazards were mapped within the proposed mine area and along its access corridor. Projected terrain stability and hazards were distinguished from existing conditions in order to document where and how climate change and/or mine development could increase instabilities in the absence of appropriate mitigation. A risk assessment was completed for each hazard that poses a credible risk to project infrastructure.

Pertinent background information to this study is provided in Section 1, followed by a description of the region's physical setting in Section 2. The methods used for field work, mapping, hazard identification and risk evaluation are detailed in Section 3. Dominant terrain units and geomorphological processes encountered within the study area are characterized in Section 4. Section 5 presents the results of the terrain stability and hazard mapping, and summarizes the general distribution, characteristics and implications of hazards. Site-specific risks to project infrastructure, whether natural or driven by effects of the project on terrain stability, are identified and evaluated in Section 6 along with consideration of opportunities for mitigation. Key conclusions are highlighted in Section 7, followed by acknowledgment of study limitations in Section 8.

Mapping of terrain (Map 1), existing (baseline conditions) terrain stability and hazards (Map 2), and disturbed (projected conditions) terrain stability, hazards and unmitigated risks (Map 3) are provided in **Appendices A**, **B** and **C**, respectively.

1.1 Background

BMC is proposing to develop the KZK Project, a volcanogenic massive sulphide (VMS) deposit containing economic concentrations of copper, lead, zinc, gold and silver (Alexco Environmental Group (AEG), 2017). The proposed mine area is situated in the headwaters of Geona Creek, a tributary of Finlayson Creek, approximately 115 km southeast of Ross River, Yukon (**Figure 1-1**)[1]. Mining is proposed using both open pit and underground methods. Ore will be processed into separate copper, lead and zinc concentrates via sequential flotation at ~2 million tonnes per year, over an approximate ten-year mine life. Dry stack tailings are proposed to be deposited in the Class A Storage Facility on the western slope of the valley. Waste rock will be stored according to acid generation and metal leaching potential; strongly acid-generating material will be disposed within tailings or alternatively stored in mined-out areas of the open pit and underground workings, while other waste rock material will be placed on the surface in managed facilities.

[1] *All proposed infrastructure/building footprints and related terminologies used in this report and the accompanying mapping are based on the ArcGIS shapefiles provided by BMC on September 5, 2017.*

An existing 25 km-long road used to access the proposed mine area from the Robert Campbell Highway will be upgraded to accommodate increased traffic and heavy equipment. Concentrate will be trucked 911 km to the port of Stewart, British Columbia, for sale to market.

In March 2017, BMC submitted its Project Proposal to YESAB for developing the KZK Project. Following a preliminary review of the Project Proposal, YESAB identified areas that required additional information, and provided a number of IRs for BMC to address in order for YESAB to deem the submission adequate for formal review. This study was completed in response to YESAB's identification of the omission of terrain stability mapping, the "preliminary and coarse" nature of the terrain analysis and hazard inventory (Knight Píesold Ltd. (KP), 2016a), and a lack of field assessment to confirm the extent of hazard processes within the Project area. Specifically, YESAB's IR R162 requested the following:

> *"Provide a terrain map, terrain stability and hazard map for the mine footprint and access road (including associated methodology and analysis) that:*
>
> *a. Identifies surficial geology and related geomorphologic processes;*
> *b. Identifies the type, nature, relative frequency and magnitude of hazards (baseline map);*
> *c. Evaluates how current hazard dynamic may be altered due to changes in climate;*
> *d. Identifies specific risks to the proposed infrastructure; and,*
> *e. Identifies specific risks to the environment from the proposed project (e.g.: changes to slope stability). The risk map should include consideration of climate change over the life of the Project."*

Deferring completion of such mapping to subsequent detailed design of the Project has been deemed unacceptable by YESAB. As such, BMC approached Coregeo to help complete the necessary mapping to help satisfy YESAB's IRs and to support general engineering planning. Coregeo then solicited the support of Dr. Derek Turner and PECG, recognized experts in slope- and permafrost-related terrain stability mapping in Yukon, to co-lead the technical aspects of the hazard mapping and risk assessment work.

1.2 Study Area

The Project is located in the eastern foothills of the Pelly Mountains, approximately 115 km southeast of Ross River and 250 km northeast of Whitehorse, Yukon (**Figure 1-1**). Detailed terrain stability and hazard mapping were completed to fully encompass all proposed mine site facilities and the existing access road from the Robert Campbell Highway. The buffer around the overall Project footprint was delineated such that any upslope or downslope instabilities or hazards could be identified, and minor adjustments in site or route selection could be accommodated. The 64 km^2 study area consists of two main sections:

1. **Access Road Corridor** – The proposed access to the proposed mine site generally follows an existing, two-lane gravel access road that extends from the Robert Campbell Highway southwestward for a distance of approximately 25 km to the mine site area. The proposed access road diverges from the existing alignment near KM 20.5[2], apart from a minor realignment between

[2] *Kilometre marker (KM) references made throughout the report are based on GIS-based generation of points at consistent distance intervals along the proposed (including existing) road shapefile (Figure 1-1); they may differ slightly from references by others.*

KMs 19 and 20, and terminates beside the proposed open pit at KM 26.75. Mapping was completed within a 27 km^2 corridor that has a minimum width of 1 km roughly centred along the existing road alignment, to inform plans for road upgrades, widenings and local realignments. The corridor was locally widened up to a width of 2.5 km to encompass heights of land where natural processes upslope could potentially affect infrastructure, and lower slopes potentially susceptible to retrogressive mass movements (**Figure 1-1**). From north to south, the road leaves the Robert Campbell Highway near KM 232 and follows gentle terrain west of the Finlayson Creek valley for approximately 17.5 km. The road crosses Finlayson Creek just upstream of its confluence with Geona Creek, and steadily climbs the western valley side of Geona Creek to the proposed mine site area just north of Fault Creek.

2. **Mine Site Area** – The proposed mine site is situated in the headwaters of Geona Creek, just north of Fault Creek. The 37 km^2 mine site study area encompasses the footprints of all proposed mine infrastructure, with a surrounding buffer that includes relevant heights of land. Key infrastructure within the overall mine footprint includes an open pit, waste rock and tailings storage facilities, an overburden stockpile, water management ponds and a mill site (**Figure 1-1**).

1.3 Objective

Coregeo and Associates completed project-specific terrain stability and hazard mapping to inform the siting and design of mine site facilities and the access road, and to comply with YESAB's hazard mapping expectations for Project Proposal submission (Guthrie and Cuervo, 2015). Three main tasks facilitated the successful completion of this project:

1. Delineation and characterization of distinct terrain units and geomorphological processes within the study area;
2. Identification of potential hazards posed by the environment on the Project, and by the Project on the environment (terrain stability effects); and
3. Evaluation of risks to project infrastructure, giving consideration to the implications of climate change.

2. Physical Setting

2.1 Physiography

The KZK Project straddles the Yukon Plateau-North and Pelly Mountain ecoregions as defined by Yukon Ecoregions Working Group (2004) (**Figure 1-1**). The northern part of the project area is located in the southeastern part of the Yukon Plateau-North ecoregion region, also known as the Ross Lowland physiographic region (Mathews, 1986). This area is characterized by rolling, east-west trending highlands and broadly incised river valleys, with elevations between 900 and 1,500 metres above sea level (m.a.s.l.) (Yukon Ecoregions Working Group, 2004). The southern portion of the project, encompassing the proposed mine area, is located within the Pelly Mountain ecoregion, characterized as a rolling plateau with numerous mountain peaks that are dissected by small rivers. Elevation in this region is generally above

1,500 m.a.s.l. (Yukon Ecoregions Working Group, 2004). The relief in the study area between valley bottoms and adjacent ridges ranges from about 300 to 900 m.
The proposed access road parallels and then crosses the Finlayson Creek valley, before ascending the western side of the tributary Geona Creek valley to the proposed mine site area near Fault Creek. Finlayson Creek, which flows into Finlayson River just downstream of the Robert Campbell Highway, has incised up to about 60 m through glacial drift into bedrock, which is locally exposed at the base of high cut-banks. Geona Creek exhibits little evidence of down-cutting, so its lower valley walls are generally gentle and lack prominent cut-banks.

2.2 Climate

2.2.1 Current

The climate of the Yukon Plateau-North ecoregion has a strong seasonal variability that is largely controlled by elevation changes throughout the region. Mean annual air temperature is near -5 ^{o}C. In lower valleys, the mean January temperatures are generally below -30 ^{o}C. At higher elevations, the mean January temperatures are above -20 ^{o}C (Yukon Ecoregions Working Group, 2004). Extreme temperature inversions commonly develop during winter once strong high pressure ridges develop. The gradient is reversed by July when mean temperatures are around 15 ^{o}C in the lower valley floors, and near 8 ^{o}C in higher terrain (Yukon Ecoregions Working Group, 2004). Between 1950 and 1998, the Canadian western Arctic experienced warming of 1.5 to 2 ^{o}C (Zhang et al., 2000). Observed mean annual air temperatures from 2000 to 2009 are in the -4 to -3 ^{o}C range (Scenarios Network for Alaska + Arctic Planning (SNAP), 2016).

Mean annual precipitation ranges from 300 to 600 mm across the region. The wettest period occurs during July and August, with convective rain showers and thunderstorms producing 40 mm to 80 mm of rain per month (Yukon Ecoregions Working Group, 2004). Observed annual precipitation conditions from 2000 to 2009 are in the 600 to 700 mm range (SNAP, 2016).

Lightning strikes are a common trigger for wildfires in the region. Yoshikawa et al. (2003) estimate natural wildfire recurrence of 50 to 300 years in the similar boreal forest of interior Alaska. Field observations from the study area corroborate the absence of recent wildfires in Yukon Government's fire history mapping database. The lack of recent wildfires is noteworthy, because fire has important implications for ground stability in areas of permafrost. Conditions may now be primed for an intense burn, and ongoing climate change has already increased lightning strikes elsewhere in south-central Yukon (Yukon Ecoregions Working Group, 2004).

2.2.2 Projected

Changing climate conditions for mean annual air temperature and precipitation have been modelled using different Representative Concentration Pathway (RCP) scenarios (Intergovernmental Panel on Climate Change (IPCC), 2013), and then downscaled for the region (SNAP, 2016), as reported by AEG (2017). The scenarios describe different climate futures dependant on how much greenhouse gas is emitted into the atmosphere. RCPs represent a range in radiative forcing values, measured in Watts per square metre (W/m^2), in the year 2100 compared to pre-industrial conditions. The specific climate change projection for the study area focuses on RCP values of +4.5 W/m^2 (RCP4.5) and +8.5 W/m^2 (RCP8.5), which correspond

to low and high radiative forcing scenarios, respectively. Some modelling results are different for the access road corridor and the mine site area due to physiographic differences (**Table 2-1**). In general, continued warming is projected over the mine life, with greater temperature increases forecasted along the access road corridor. Precipitation is only modelled to increase in the mine site area above 2,030 m.a.s.l. at the highest radiative forcing scenario. Because the modelled precipitation increase in the study area is within the spatial error of the modelling, some local increases may be expected.

Table 2-1. Summary of projected changes in mean annual temperature and precipitation in the region

	Observed 2000-2009		Projected 2020-2029		Projected 2030-2039	
RCP (W/m^2)	**Temp. (°C)**	**Precip. (mm)**	**Temp. (°C)**	**Precip. (mm)**	**Temp. (°C)**	**Precip. (mm)**
Access Road Corridor						
4.5	-4 to -3	500 to 600	-3 to -2	500 to 600	-3 to -2	500 to 600
8.5	-4 to -3	600 to 700	-3 to -2	500 to 600	-2 to -1	500 to 600
Mine Site Area						
4.5	-4 to -3	600 to 700	-4 to -3	600 to 700	-3 to -2	600 to 700
8.5	-4 to -3	600 to 700	-3 to -2	600 to 700	-3 to -2	700 to 800

Note: All data from SNAP (2016).

Climate variations have a significant impact on permafrost stability, with the potential to impact ground stability and infrastructure integrity (Benkert et al., 2015). The effects of climate change, specifically temperature increase, are already being observed on terrain stability within the study area. Active thermokarst subsidence and gullying have been observed throughout the study area, especially along the access road corridor, and the frequency of active-layer detachments may be increasing based on the lack of evidence of previous events in the same areas.

2.3 Bedrock Geology

2.3.1 Regional-scale

The following summary of regional bedrock geology has been adapted from Equity Exploration Consultants Ltd. (2016), AEG (2016) and Murphy et al. (2001). The KZK Project is located within the Finlayson Lake District, a crescent-shaped area located between Ross River in the north and Watson Lake in the south. The Finlayson Lake District is composed of Devonian to Mississippian volcanic, intrusive and sedimentary rocks. It is underlain by polydeformed, metamorphosed sedimentary, volcanic and plutonic rocks of the Yukon–Tanana terrane, which extends from central British Columbia to eastern Alaska.

In the vicinity of the Finlayson Lake District, the Yukon–Tanana terrane comprises foliated and lineated greenschist to lower amphibolite-grade metasedimentary, metavolcanic and metaplutonic rocks. The Yukon–Tanana terrane was imbricated by Permian thrust faulting into the Cleaver Lake, Money and Big Campbell thrust sheets. The KZK Project is located within the Big Campbell thrust sheet, which is the structurally deepest of the Yukon–Tanana terrane. The Grass Lake and Wolverine middle Palaeozoic unconformity-bound groups are exposed in the Big Campbell thrust.

The VMS deposit (including the ABM Deposit and its deep Krakatoa zone) occurs within the KZK formation, which is primarily hosted within felsic metavolcanic and metaplutonic rocks of the upper Grass Lakes sequence. The KZK formation in the vicinity of the ABM deposit comprises a thick sequence of felsic volcanic schist interbedded with variably carbonaceous metasedimentary and calcareous mafic schist units.

2.3.2 Site-scale

Surface bedrock in the mine site area is expressed as highly fractured, strongly foliated, polydeformed, metavolcanic and metasedimentary schist with frequent mafic intrusions. Foliation dips gently to the north. The northern portion of the mine and mill infrastructure area consists of the upper KZK formation and the Wind Lake formation, which are primarily carbonaceous metasedimentary schist. Outcrops with significant relief are infrequent in the study area. The best bedrock exposures are a result of faulting, meltwater incision or post-glacial erosion along creeks. Significant phylosillicate content results in fissile bedrock that is commonly highly weathered within its upper few metres. Occasional, more resistant, metre-scale layers form blocky outcrops and float. The weathering of micaceous bedrock has resulted in the formation of micaceous B and C soil horizons. Competent, stream-cut bluffs of limestone occur along lower Finlayson Creek and punctuate a prominent hill southwest of the access road's divergence from the Robert Campbell Highway.

2.3.3 Seismicity

According to Cominco (1997), Hyndman et al. (2005) and KP (2016b), the project is in an area of low seismic activity. Despite being only about 30 km away, the Tintina Fault is not considered to be active by the Geological Survey of Canada (Cominco, 1997). No earthquakes with magnitudes >6.0 have occurred in the vicinity of the project since 1600, and only a few with magnitudes >3.5 have occurred between 1973 and 2012 (KP, 2016b). As such, triggers other than earthquakes are likely responsible for most mass movements within the study area.

2.4 Surficial Geology and Quaternary History

The study area has been glaciated repeatedly throughout the Pleistocene. Most of the remnant glacial features seen in the current landscape were formed during the most recent, McConnell glaciation that occurred roughly 25-10 ka (Bostock, 1966; Bond and Plouffe, 2002). Glacial advance in the region is characterized by localized valley glaciers that coalesced into several distinct ice lobes, forming an ice sheet, with an ice divide thought to be just east of the project area, in the Wolverine Lake region (Bond and Plouffe, 2002). At glacial maximum, the Cordilleran Ice Sheet reached elevations between 1,550 and 1,900 m.a.s.l. near Faro and Ross River (Jackson, 1994), and ice flowed north-northwest from the Pelly Mountains across the study area.

Deglaciation in the study area was complicated. Initial active frontal retreat of the ice sheet, with minor re-advances, progressed until the equilibrium line rose above the ice elevation, leading to final stagnation and downwasting of the ice sheet (Jackson, 1994; Benkert et al., 2015). Deglaciation first occurred in alpine regions where ice was thinner and may have stagnated for much longer in valley bottoms (Bond and Plouffe,

2002), leading to deposition of thick and highly disturbed supraglacial sediments in valley bottoms and progressively lower lake elevations blocked by melting ice in the valley floor (Benkert et al., 2015).

Much of the region is underlain by till of variable thickness, locally overlain by glaciolacustrine sand, silt and clay, and glaciofluvial sand and gravel (outwash) (Turner, 2014). Till is also the dominant surficial material within the study area; however, thick deposits are confined to the Finlayson Creek valley bottom, while thinner veneers and blankets up to 10 m in thickness occur on valley sides and at higher elevations. Large glaciofluvial complexes overlie the till near the Robert Campbell Highway, at the confluence of Geona and Finlayson Creeks, and in localized areas within the mine site area. Colluvial aprons are localized at the base of steeper slopes, and colluvial veneers to blankets predominate in steep, mountainous terrain. Bedrock exposure is restricted to mountain ridges and spurs, and stream-cut bluffs.

A conspicuous layer of White River Ash is commonly visible at or near surface in road cuts and soil pits, providing a convenient stratigraphic marker and evidence of localized ground stability for the past 1,147 years (Clague et al., 1995).

2.5 Permafrost

2.5.1 Distribution

Permafrost is ground that remains below 0ºC for more than one year. The study area is within the zone of extensive discontinuous permafrost, in which 50 to 90% of the ground is underlain by permafrost (Heginbottom et al., 1995). Recent permafrost modelling completed by Bonnaventure et al. (2012) for southern Yukon indicates that there is a 60 to 90% probability of encountering permafrost within most of the study area, with the highest probabilities at higher elevations. Locally, permafrost distribution is related to slope aspect, angle and shape, soil texture and moisture, and the thickness and type of organic cover (Williams, 1995; Williams and Burn, 1996). Permafrost is most common on high-elevation, north-facing slopes and in thick deposits of fine-grained material, particularly where insulated by a thick organic cover. Steep, well drained, south-facing slopes are permafrost-free.

A variety of landforms indicates the presence of permafrost within the study area, including thermokarst ponds and gullies, active-layer detachments, solifluction[3] lobes and terraces, and slopewash runnels. Vegetation distribution and growth habitat can be reasonable predictors of permafrost presence or absence within surficial material, although local disequilibrium of permafrost and present climate can mislead these inferences. In general, deciduous trees root more deeply than coniferous trees, and are unable to grow in thin active layers where soils are permanently wet or saturated. Stands of trembling aspen are invariably restricted to permafrost-free ground (Zoltai and Pettapiece, 1973; Williams, 1995). Conversely, black spruce is tolerant of cool, saturated soils and commonly grows in areas underlain by permafrost. A sparse, stunted canopy of black spruce with thick moss cover is a reliable indicator of shallow permafrost. Permafrost is commonly absent from riparian zones along active channels due to sufficiently deep flows that remain unfrozen at depth during winter (i.e., talik), and a high groundwater table with efficient down-valley flow through permeable sand and gravel.

[3] *Solifluction is most commonly associated with gradual downslope movement of saturated material over the permafrost table ("gelifluction"), but its occurrence over other impermeable surfaces such as bedrock preclude it from being a definitive indication of permafrost.*

Maximum thicknesses of permafrost within the study area and broader Yukon Plateau-North and Pelly Mountain ecoregions are variable. In the southern part of the Yukon Plateau-North ecoregion, permafrost thicknesses of up to 24 m are reported, but are more commonly 15 to 18 m (Yukon Ecoregions Working Group, 2004). A thickness of 40 m has been measured in the Pelly Mountains southwest of the project area (Heginbottom et al., 1995).

2.5.2 Active Layer

The active layer is the upper layer of ground that freezes and thaws seasonally above the permafrost table. It may be restricted to soils and unconsolidated surficial materials, or it may extend into underlying, weathered or intact bedrock. At a local scale, its thickness primarily depends on elevation, aspect, soil texture, drainage, snow pack, vegetation cover and wildfire history (Williams and Burn, 1996; McKillop et al., 2013). The active layer is generally 1 to 2 m thick within the region encompassing the study area (Yukon Ecoregions Working Group, 2004; this study). Well drained, coarse-grained soils tend to have thicker active layers than poorly drained and fine-grained areas. In areas of thick, mossy organic cover, permafrost may be encountered at depths as shallow as just a few tens of centimetres. Areas with thick organic cover and variable moisture contents exhibit the greatest spatial variability in active layer thickness (Smith et al., 2009).

Active layer thickness varies seasonally and in response to natural and anthropogenic disturbances. Each year, active layer thickness increases following spring snowmelt and typically peaks in late summer (September), before refreezing in the autumn. Active layers thicken by up to several times their original thickness following wildfire, which burns most or all of the insulating surface organic mat, reduces interception of snow by trees (where present), lowers the surface albedo, increases exposure to solar radiation, and decreases evapotranspiration (Burn, 1998; Smith et al., 2015).

2.5.3 Ground Ice

Permafrost may or may not contain ice. The ice content of permafrost is highly variable at both the regional and local scale. Areas of intact or weathered bedrock and well drained, coarse-grained colluvial mantles with permafrost generally contain little to no visible ice. Such ice-poor permafrost is common in upland settings, on summits and along ridges and spurs, and on moderate to moderately steep valley sides with convex slopes. Permafrost more commonly contains excess ice[4] in the form of thin seams and lenses in thick, silt-rich lower-slope and till deposits, and in organic terrain. Ice-rich permafrost with extensive, segregated ice is most commonly encountered in thick deposits of silty till that underlie northern portions of the access road in valley bottom settings. A freshly exposed, vertical sidescarp along the wall of a deep thermokarst gully near KM 7.5 of the access road revealed more than 1 m of permafrost visually estimated to have volumetric ice content in excess of 50% (**Photo 2-1**). Enlarging thermokarst (thaw) lakes in valley bottoms and along adjacent, flat-topped benches provide evidence of locally high ice contents. Golder Associates Ltd. (Golder) (1996) reports encountering permafrost with discontinuous ice lenses and volumetric ice contents of 5 to 30% in geotechnical boreholes within the footprints of several of the proposed mine facilities.

[4] *The term excess ice is used throughout the report to represent the condition in which the volume of ice in the ground exceeds the total pore volume the ground would have under natural, unfrozen conditions.*

Photo 2-1. Ice-rich permafrost within till exposed in sidescarp of thermokarst gully near KM 7.5 of the existing access road to the KZK Project

Ground ice is sensitive to melting in response to permafrost degradation (thaw). Permafrost degradation occurs naturally over different time scales in response to localized surface disturbances such as wildfire or windthrow, which alter the ground thermal regime by removing the insulating surface organics. Similarly, climate change can result in permafrost degradation. Warmer air temperatures, especially in winter, can inhibit complete freezing of the active layer and, in turn, promote its thickening. Anomalously intense or prolonged late-summer rainfalls or anomalously deep winter snowpacks can further accelerate thaw and the melting of ground ice.

Anthropogenic disturbances also alter the ground thermal regime and are a common trigger for permafrost degradation. The most common triggers are (1) stripping or compaction of surface organic layer, which insulates the ground in summer; (2) unnatural concentration of surface and near-surface runoff through culverts and along ditches, increasing the potential for thermal (ponding) or fluvio-thermal (flowing) erosion; (3) repeated ploughing of snow into the same locations, commonly along roadside ditches, such that it accumulates and inhibits cold penetration that normally freezes the active layer during winter. Permafrost degradation has little to no effect on ground surface topography or stability in areas of ice-poor permafrost or where the permafrost table is below surficial material within weathered or intact bedrock. Areas of ice-rich permafrost within fine-grained materials, even if mantled by coarser-grained material, may be susceptible to thermokarst subsidence in response to permafrost degradation.

3. Methods

Coregeo and Associates employed a systematic approach for completing terrain stability and hazard mapping for the Project, leveraging extensive experience mapping permafrost-related mass movement hazards throughout Yukon. Each main phase of work is described below.

3.1 Background Review and Consultation

Coregeo and Associates strengthened our pre-existing understanding of terrain characteristics and related hazards within the study area by reviewing the following data sources:

- Terrain analysis report and accompanying maps for the KZK Project (KP, 2016a);
- Terrain and soils chapter of the Project Proposal submission to YESAB (AEG, 2017);
- Geotechnical and hydrogeological site investigation for the KZK Project (Golder, 1996);
- Geotechnical site investigation data reports for the KZK Project (KP, 2016c,d, 2017);
- Prefeasibility design report for the KZK Project (KP, 2016b);
- Access road upgrade construction management plan for the KZK Project (Onsite Engineering Ltd. (OEL), 2017);
- High-resolution (30 cm) aerial photography (orthorectified, 2016; stereo-models, 2017) (2017) encompassing the study area;
- Historical aerial photography (georeferenced, 1992 and 1995) encompassing the mine area, with select coverage of older imagery to encompass particular hazard sites;
- High-resolution (50 cm) LiDAR-derived digital elevation model (DEM) from 2016, with derived bare earth hillshade and slope classification models;
- Regional-scale (1:100,000) surficial geology encompassing the study area (Jackson, 1993a,b);
- Regional-scale bedrock geological mapping (Gordey and Makepeace, 2003);
- Quaternary geology characterization of the region encompassing Finlayson Lake (Bond and Plouffe, 2002);
- 30 m-resolution permafrost probability model for southern Yukon (Bonnaventure et al., 2012);
- Shapefile of territory-wide wildfire history (from GeoYukon) fire history;
- Territory-wide glacial limits mapping (Duk-Rodkin, 1999); and
- Earthquakes and seismic hazard mapping encompassing Yukon (Hyndman et al., 2005; KP, 2016b).

Coregeo and Associates also took advantage of our existing collaborative working relationships with senior staff at Yukon Geological Survey (YGS) to acquire local knowledge from their field experience in the study area. Mr. Jeff Bond (Manager, Surficial Geology, YGS) was consulted about his knowledge of the surficial geology and terrain hazards within the study area. Mr. Bond alerted us to the potential for outburst floods from sudden breaches of beaver dams, based on his awareness of such an event not far from the project area.

3.2 Field Investigations

Field work was completed prior to completion of the terrain stability mapping to ensure on-the-ground observations were made in the absence of snow and ice cover, and to allow time for the processing of newly acquired 2017 aerial photography on which subsequent mapping was based. A thorough review of available data sources identified above in Section 3.1 in advance of field work ensured field investigations provided satisfactory representation of the diversity of terrain and hazards within the study area. Areas with the greatest potential for instability were prioritized for field investigation.

Field investigations were conducted throughout the study area by a two-person crew comprising PECG's Senior Geomorphologist, Robin McKillop, M.Sc., P.Geo. and Coregeo's Senior Environmental Geoscientist, Ethan Allen, M.Sc. from September 8 to 11, 2017. Conditions were favourable for field work: the ground was free of frost and snow, active layer thicknesses were near their annual maxima, and weather conditions were typically a mix of sun and cloud without any significant showers. A helicopter was used strategically to conduct an overview reconnaissance flight of the mine site and access corridor at the start of the program, to facilitate access for foot traverses through proposed infrastructure footprints, and to optimize photographic perspectives of observed hazard sites. A 4WD pick-up truck was used to access sites along maintained sections of the existing access road.

Observations from more than 300 sites were recorded based on visual reconnaissance during short stops along foot traverses, vehicle-supported access or helicopter fly-overs (**Figure 1-1**). Most observations related to surficial material thickness, vegetation associations, drainage, and evidence of instability or permafrost characteristics. Accompanying photographic documentation was collected at the majority of observation sites. During foot traverses, existing natural (e.g., landslide headscarp, stream cut-bank) and anthropogenic (e.g., road cut, borrow pit) exposures of surficial materials were targeted for examination. Hand-dug soil pits were excavated and studied in areas without good exposures. A 1.2 m-long steel frost probe was used to investigate variability in active layer thickness across the study area and for detecting shallow bedrock. An increment (tree) borer was used to extract a thin (~5 mm) core from trees or shrubs growing on or against slope hazard deposits, where basic dendrochronology could help provide insight into the timing and frequency of events.

3.3 Terrain and Terrain Stability Mapping

PECG completed terrain and terrain stability mapping within the 64 km^2 study area in accordance with YESAB's Geohazards Guide (Guthrie and Cuervo, 2015). Terrain mapping is the process of dividing the landscape according to surficial materials, textures, surface expressions and geomorphological processes. Terrain stability mapping involves further consideration of drainage, slope and, in this case, permafrost characteristics, resulting in a terrain stability classification for each polygon. Classes I, II and III are considered stable, Class VI is considered potentially unstable, and Class V is considered unstable.

3.3.1 Mapping Protocols and Attributes

PECG completed all mapping based on field-calibrated interpretations of high-resolution digital aerial photography and LiDAR-derived elevation data, using softcopy photo-interpretation workstations with either

DAT/EM Summit Lite or PurVIEW software packages. Polygon delineation was completed at a scale of 1:10,000 within the 37 km^2 area encompassing the proposed mine site and at a scale of 1:20,000 within the 27 km^2 access corridor, which aligns with YESAB's expectations for "large scale" geohazards assessment associated with the environmental assessment process (Guthrie and Cuervo, 2015). The previous terrain analysis map prepared for the mine area of the KZK Project by KP (2016a) was reviewed, and relevant data were incorporated and refined as necessary for terrain stability mapping purposes.

Terrain stability polygons were delineated primarily based on the YGS' adaptation of the Terrain Classification System for British Columbia (Howes and Kenk, 1997) and the Mapping and Assessing Terrain Stability Guidebook (BC Ministry of Forests, 1999). A User's Guide to Terrain Stability Mapping in British Columbia (J.M. Ryder and Associates, Terrain Analysis Inc., 2002) and A Guide for Management of Landslide-Prone Terrain in the Pacific Northwest (BC Ministry of Forests, 1994) were also consulted. Certain refinements were made based on unique conditions encountered in the study area and to better meet project-specific objectives (e.g., the geomorphological process of 'debris flood' was attributed as '-Rt'). Explicit consideration was also given to the distribution and the relative depth and ice contents of permafrost, given its pronounced influence on ground stability.

Terrain stability polygons were delineated with consideration for seven main attributes, each of which is defined below, in addition to the terrain stability classes described in Section 3.3.2. Complete explanations and descriptions of attribute values are available on the terrain map and its cover page of code definitions (Map 1, **Appendix A**).

- **Surficial Material** – e.g., morainal (till) deposits (M), colluvial deposits (C), fluvial deposits (F)

  This attribute defines the surficial material present and its depositional (genetic) origin. The surficial material represents the core element of a particular terrain unit and label.

- **Surface Expression** – e.g., veneer (v), blanket (b), terrace (t)

  This attribute refers to the form, or pattern of forms, expressed by the surficial material. Up to three surface expressions describe a particular surficial material, in order of decreasing relevance.

- **Texture** – e.g., silt (z), sand (s), mixed angular fragments (x), gravel (g)

  This attribute refers to the size, sorting and shape of the particles comprising the surficial material. Standardized textures were assigned to all polygons, including those not investigated in the field, based on typical conditions observed at field sites and documented in previous investigations in the region (e.g., Bond and Plouffe, 2002). Such an approach is consistent with textural characterization in YGS' surficial geology mapping (Lipovsky and Bond (compilers), 2014) and aids standardization of terrain units. Up to three textures describe a particular surficial material, in order of increasing proportion[5].

[5] *This convention is used in place of YGS' opposite convention – in order of decreasing proportion – due to its consistency with verbal description (e.g., sgF is a sandy gravel fluvial deposit dominated by gravel).*

- **Geomorphological Process** – e.g., gully erosion (-V), thaw flow slide (-Xf)

  This attribute refers to geomorphological processes that are either occurring, or have occurred, within a polygon. Up to three geomorphological processes and respective subclasses can be identified, in order of decreasing relevance to the polygon.

- **Drainage Class** – e.g., well drained (w), imperfectly drained (i), poorly drained (p)

  This attribute refers to the speed and extent to which water is removed from the soil in relation to additions. It considers both the rate at which water is able to be removed from an area as a result of landscape characteristics (e.g., slope), and the permeability of the surficial materials themselves. In this study area, drainage class is strongly influenced by the depth to permafrost, where present. Drainage class is represented by a single value, or a range between two values with the dominant class listed first.

- **Relative Ice Content of Permafrost in Surficial Material** – e.g., ice-rich (r), ice-moderate (m), ice-poor (p), no permafrost (n)

  This attribute refers to the relative volumetric ice content of permafrost, interpreted based on field observations of ground ice in different hydrogeomorphic settings, and on applicable results from test pitting, geotechnical drilling and thermistor installations (Golder, 1996; KP, 2016a,c,d, 2017). Implicit is an initial interpretation of whether permafrost is present within surficial material, only present at depth (i.e., below at least a few metres) within overburden or underlying bedrock and relatively insensitive to road/facility construction or climate change over the mine life (*no permafrost*), or altogether absent (*no permafrost*). Permafrost classifications were defined conservatively at the polygon scale, based on site-specific indicators, but do not necessarily indicative the presence of continuous permafrost within the polygon. In polygons that exhibit stratigraphic relationships, the classification considered the relative ice content of permafrost within the underlying material if within a few metres of ground surface and potentially sensitive to project-related or climatic disturbance. This attribute is not based on precise thresholds of ice content, but instead distinguishes areas relatively and according to forms of ground ice. *Ice-poor* permafrost is inferred to contain little to no visible (pore) ice; *ice-moderate* permafrost is inferred to contain thin seams and/or small, isolated lenses of segregated ice; and *ice-rich* permafrost is inferred to contain large accumulations of segregated ice in the form of interconnected seams, lenses and/or massive bodies. The terms ice-poor, ice-moderate and ice-rich are used throughout the report and on Map 1 (**Appendix A**).

- **Slope Class** – e.g., 2 (gentle, 6-26%), 4 (moderately steep, 50-70%)

  This attribute refers to the dominant range in slope steepness based on the slope-defined surface expressions in Howes and Kenk (1997). Slope class was visually assigned based on a five-level raster model of slope class generated from the LiDAR-derived elevation data that were smoothed using a roaming box-average of 5 m.

Additional point and linear features too small to be mapped as polygons were identified using on-site symbols. Examples include thermokarst ponds (point) and slope failures (line). Whether or not processes represented by on-site symbols were also included in the polygon's terrain label depended on the proportional area of the polygon that is affected by the process. For example, a single gully did not necessarily require inclusion of the gullying process in the polygon label.

3.3.2 Terrain Stability Classification

Terrain stability mapping in British Columbia typically involves the assignment of a single terrain stability class to each polygon, in order to provide a relative ranking of the likelihood of a landslide occurring after timber harvesting or road construction (BC Ministry of Forests, 1999). This protocol yields a map depicting terrain stability classes after a disturbance – for example, following road construction – but does not readily distinguish the stability of polygons in the absence of disturbance. The hazards posed by a slope above (or below) a facility/road and unaffected by facility/road construction (i.e., potential effects of the environment on the Project), for example, could be inaccurately represented on this type of conventional terrain stability map. It is particularly important to differentiate terrain stability classes for both the existing baseline and disturbed conditions in this landscape of discontinuous permafrost, some of which is ice-rich and prone to thermokarst activity. As such, both *existing* and *disturbed* terrain stability classes were assigned to each polygon to enable accurate evaluation of risks posed locally and by hazards upslope or downslope of the proposed infrastructure.

In addition to considering the potential influence of project-related construction on terrain stability, Coregeo and Associates also considered the potential effects of climate change on stability conditions, recognizing that a variable landscape response is expected. Climate change is already driving observed degradation of permafrost throughout Yukon, and it is expected to continue. Benkert et al. (2015) demonstrate that even a modest 1-2 ^{o}C increase in mean annual air temperature in Ross River is likely to thicken the active layer to a point where the probability of encountering permafrost in a given area is reduced by 20%. Localized and widespread degradation of permafrost is expected primarily as a result of climatic warming, but also through changes in precipitation patterns and the frequency of lightning strikes, which can initiate wildfires that alter ground thermal regimes. Although the proposed mine has an expected operational life of approximately ten years (plus construction and closure phases), Coregeo and Associates has conservatively assumed that some of the projected implications of climate change will advance sufficiently to influence terrain stability and hazards. The persistence of certain infrastructure components of the project into perpetuity, such as reclaimed waste rock piles, also necessitates a longer-term perspective on the implications of climate change. While the influence of climate change on permafrost terrain is the most obvious linkage, consideration was also given to the more conventional influence of increased precipitation on slope stability in permafrost-free areas when classifying disturbed stability conditions.

The *'existing terrain stability'* class represents current conditions (summer 2017), in the absence of any major project-related activity or projected climate change effects. The *'disturbed terrain stability'* class represents conditions following disturbance to ground conditions from road/facility construction without mitigation and/or in response to projected climate change effects (**Table 3-1**). The context for the polygon-specific disturbed stability class is specified as project-related construction, climate change or both. Whether or not an increase in the stability class is warranted between the existing and disturbed scenarios depends on the interpreted magnitude of the potential effect of the disturbance. Conservatively, the disturbed stability class assumes typical cut-and-fill road construction without any measures to mitigate potential instability on steep slopes or from disturbance to permafrost with excess ice. Stripping or compaction of organics, and only regular surface water management, would be typical disturbances. Full details for both the existing and disturbed terrain stability classes are provided on the mapping of terrain stability and hazards and the cover page of code definitions (Map 2 (**Appendix B**) and Map 3 (**Appendix C**)). Acknowledgment of the ways in which BMC plans to address hazards typical of disturbed terrain

stability classes of III and IV is provided in Section 6. This section also specifies the measures planned to mitigate risks identified for specific mine infrastructure footprints and sections of the existing/proposed access road.

Further modifications to the conventional terrain stability classes used in British Columbia were necessary to accommodate the potential for instability related to thermokarst processes. If overlooked in the siting and design of project infrastructure, thermokarst could significantly increase infrastructure maintenance costs and potentially affect worker safety through its influence on ground stability (McGregor et al., 2010; Guthrie and Cuervo, 2015). Therefore, the assignment of terrain stability classes additionally considers the inferred presence or absence of ice-moderate or ice-rich permafrost (as shown on the cover page of the mapping of terrain stability and hazards (Map 2 (**Appendix B**) and Map 3 (**Appendix C**)). Each disturbed terrain stability class is qualified according to its main category of hazard process consideration: slope, thermokarst or both.

The disturbed terrain stability class was also qualified according to the influential type of disturbance: project-related construction, climate change, or both. This distinction enables users to determine where the Project has the potential to affect terrain stability, which in turn could affect the nearby environment.

Table 3-1. Terrain stability classification system developed for the KZK Project

Symbol	Class	Condition	Interpretation		Common terrain characteristics*	
			Existing (current conditions)	**Disturbed** (following disturbance to ground conditions from climate change and/or road/facility construction without mitigation)	**Existing** (current conditions)	**Disturbed** (following disturbance to ground conditions from climate change and/or road/facility construction without mitigation)
I	stable	permafrost	No significant stability problems.		Planar to gently sloping till veneer with ice-poor permafrost.	Planar to gently sloping till veneer with ice-poor permafrost.
		no permafrost			Planar to gently sloping bedrock, till and active fluvial units; glaciofluvial terraces.	
II	generally stable	permafrost	Very low likelihood of slope instability.	Very low likelihood of slope instability; no thermokarst subsidence or thermal erosion expected.	Gently sloping till and fluvial units; moderately steep bedrock; glaciofluvial mantles over ice-rich till.	Gently sloping till or colluvium with ice-poor permafrost.
		no permafrost	Very low likelihood of slope instability.		Gently to moderately sloping till, colluvial, fluvial and glaciofluvial units; moderately steep bedrock.	
III	generally stable with minor potential for instability	permafrost	Low to moderate likelihood of slope instability.	Low to moderate likelihood of slope instability and/or minor thermokarst subsidence or thermal erosion possible.	Moderately to moderately steep sloping till and colluvial blankets; gently sloping till and colluvial units exhibiting significant solifluction.	Gentle to moderately sloping till and colluvial units with ice-moderate permafrost; ice-rich till units overlain by glaciofluvial material.
		no permafrost	Low to moderate likelihood of slope instability.		Moderate to moderately steep till, colluvial and glaciofluvial units.	
IV	potentially unstable	permafrost	Expected to contain areas with a high likelihood of slope instability.	Expected to contain areas with a high likelihood of slope instability and/or moderate thermokarst subsidence or thermal erosion.	Moderately steep till and colluvial units with ice-rich permafrost.	Gentle to moderately sloping till and colluvial units with ice-rich permafrost; moderately steep to steeply sloping till and colluvial units.
		no permafrost	Expected to contain areas with a high likelihood of slope instability.		Till and colluvial units on moderately steep to steep slopes.	
V	unstable	permafrost	Expected to contain areas with a very high likelihood of slope instability and/or thermokarst activity; may or may not exhibit evidence of previous slope failure and/or thermokarst activity.	Expected to contain areas with a very high likelihood of slope instability and/or major thermokarst subsidence or thermal erosion; typically exhibits evidence of previous slope failure and/or thermokarst activity.	Any unit with evidence of slope failure and/or thermokarst subsidence or thermal erosion.	Any unit with evidence of slope failure; moderately steep and steep till scarps with ice-rich permafrost.
		no permafrost	Expected to contain areas with a very high likelihood of slope instability; typically exhibits evidence of previous slope failure.		Any unit with evidence of slope failure; typically occur on moderately steep to steep slopes.	

** Common characteristics are broad generalizations and may differ from individual polygons where site-specific attributes were considered.*

3.4 Hazard Identification

The type and distribution of mass movement (slope failure) and thermokarst hazards within the study area were identified using geomorphological process codes (polygon label), on-site symbols (point or linear features) and terrain characteristics (Map 2 (**Appendix B**) and Map 3 (**Appendix C**); see Section 4.2 for hazard process descriptions). Mass movements involve the downslope transport of material, such as soil and/or rock, under the influence of gravity. Mass movements may or may not be associated with water, snow or ice[6]. Landslide terminology used in this report follows the standards defined by Hungr et al. (2014), a recent update to the classic classifications established by Varnes (1978) and Cruden and Varnes (1996), which describe the process as well as the type of material involved in the mass movement. Where two modes of failure contribute to movement, terminology was assigned based on the apparent dominant mode.

Where more accurate representation of the role of permafrost was required, refinements to standardized landslide terminology were made based on the multi-language glossary of permafrost and related ground-ice terms (van Everdingen, 2005), which is consistent with the approach applied in the regional characterization of landslides along Yukon's Alaska Highway corridor (Huscroft et al., 2004). For example, permafrost environments also uniquely include active-layer detachments, thermokarst subsidence, thermokarst gullying/erosion and solifluction, each of which is described below (Section 4.2). Slopewash (sheetwash) is also described, as it is widespread in permafrost terrain along the access road corridor, although it does not in itself constitute a hazard.

Each polygon was broadly categorized according to its dominant hazard potential in order to clearly depict the nature of the hazard governing the terrain stability class of each polygon. One of three hazard categories was used: 1) slope failure potential is dominant; 2) thermokarst potential is dominant; and 3) slope failure and thermokarst potential are co-dominant. A hatch pattern was overlaid to indicate the 'applicable hazard category' in mapping of terrain stability and hazards (Map 2 (**Appendix B**) and Map 3 (**Appendix C**)). This designation does not indicate whether or not the polygon exhibits any evidence of such hazards; the geomorphological process codes or on-site symbols serve that purpose. The 'slope failure potential is dominant' category is the default, thus all units that do not pose a thermokarst hazard (e.g., gentle, ice-poor colluvium and even flat, permafrost-free fluvial plains) are represented by this category. A terrain unit generally must exhibit ice-rich permafrost to be considered for the 'thermokarst potential is dominant' category. Polygons with ice-rich permafrost and slope classes of 3 or higher are candidates for the 'slope failure and thermokarst potential are co-dominant' category. Thermokarst potential was generally considered within the upper surficial material; in map units exhibiting stratigraphy, however, subsurface materials were also considered where the overlying material was interpreted as sufficiently thin that project-related construction and/or climate change could affect underlying permafrost (e.g., glaciofluvial veneer overlying ice-rich till).

A generalized characterization was made of the nature of the hazard posed by different geomorphological processes – in terms of likelihood, magnitude and project considerations – based on review of historical aerial photography in conjunction with field observations and professional experience in the region.

[6] *Snow avalanches were not included in this description of mass movement processes because there is no mappable evidence (e.g., vegetation patterns) of their occurrence within the study area; small loose snow or slab avalanches may occur on moderate to steep slopes in wind-loaded alpine areas.*

3.5 Risk Evaluation

All mapped, credible hazards to the Project, whether related to slope, thermokarst processes, or both, were identified for subsequent risk evaluation. The results provide a basis for site-to-site comparisons, with respect to potential implications, and for considering and prioritizing mitigation requirements. The proposed footprints of each main component of mine infrastructure were overlaid on the terrain stability and hazard maps (Map 2 (**Appendix B**) and Map 3 (**Appendix C**)), such that processes capable of impacting the infrastructure and mine facilities could be identified and evaluated. Segments of the existing/proposed access road at risk from one or more geomorphological processes were identified and evaluated. Equal consideration was given to mapped hazards defined by polygons, lines and points. In order to appropriately focus attention and potential follow-up efforts, only those polygons with disturbed terrain stability classifications of IV or V were considered to pose credible risks worthy of site-specific evaluation.

Coregeo and Associates developed a qualitative 'risk matrix' that facilitates combined evaluation of the likelihood and potential consequence of occurrence (**Figure 3-1**). The relative thresholds of 'likelihood' and 'consequence' have been established with practical implications in mind, enabling BMC to more effectively prioritize sites for follow-up investigation and mitigation. The likelihood classes consider expected, approximate timeframes within which a particular mass movement may occur (or recur), with respect to the expected lifespan of the mine. The consequence classes consider general maintenance and reconstruction implications for proposed mine infrastructure and the access road. The risk evaluation completed for each site incorporated insight from both the desktop interpretations and the field reconnaissance investigations. A "negligible" likelihood or consequence was assumed to yield a "negligible" risk in all cases.

The full results of the risk evaluations were tabulated (Section 6), with separate evaluations for each distinct type of geomorphological process that may pose a risk to the Project. Spatial or locational information was communicated, where needed, by referencing unique polygon identification numbers (e.g., Poly_ID 123). The outline of the facility footprint or the pertinent segment of the access road was colour-symbolized according to the unmitigated risk, or the highest (most conservative) of multiple unmitigated risks. A determination was made of the residual risk to the Project that can be achieved for each mapped, credible hazard through the assumed implementation of appropriate mitigation measures, which would reduce the likelihood and/or consequence of the hazard.

Table 3.2. Risk evaluation matrix for credible slope and/or thermokarst hazards

RISK EVALUATION MATRIX			CONSEQUENCE			
			Negligible	Low Minor road or facility ditch/edge maintenance, necessitating <1 day closure	Moderate Road or facility maintenance due to coverage/settlement, necessitating ≥1 day closure	High Road or facility damage/collapse, necessitating local reconstruction
LIKELIHOOD	High	Occurrence in <2 years (construction phase)	Negligible	Moderate	High	Very High
	Moderate	Occurrence in 2-15 years (operations & closure)	Negligible	Low	Moderate	High
	Low	Occurrence in >15 years (post-closure)	Negligible	Very Low	Low	Moderate
	Negligible		Negligible	Negligible	Negligible	Negligible

*Note: Risks to proposed mine infrastructure and the access road are symbolized using a purple colour spectrum on Map 3 (**Appendix C**) in order to visibly contrast with the underlying green-to-red terrain stability classifications.*

4. Terrain Description

The main terrain units within the study area are described in the following sections, with text overviews accompanied by a table that summarizes key characteristics and presents typical aerial and ground perspectives (Section 4.1). The areal proportion of the study area occupied by each of the dominant surficial materials is presented in **Figure 4-1**. Active geomorphological processes within the study area that represent potential hazards are described in Section 4.2.

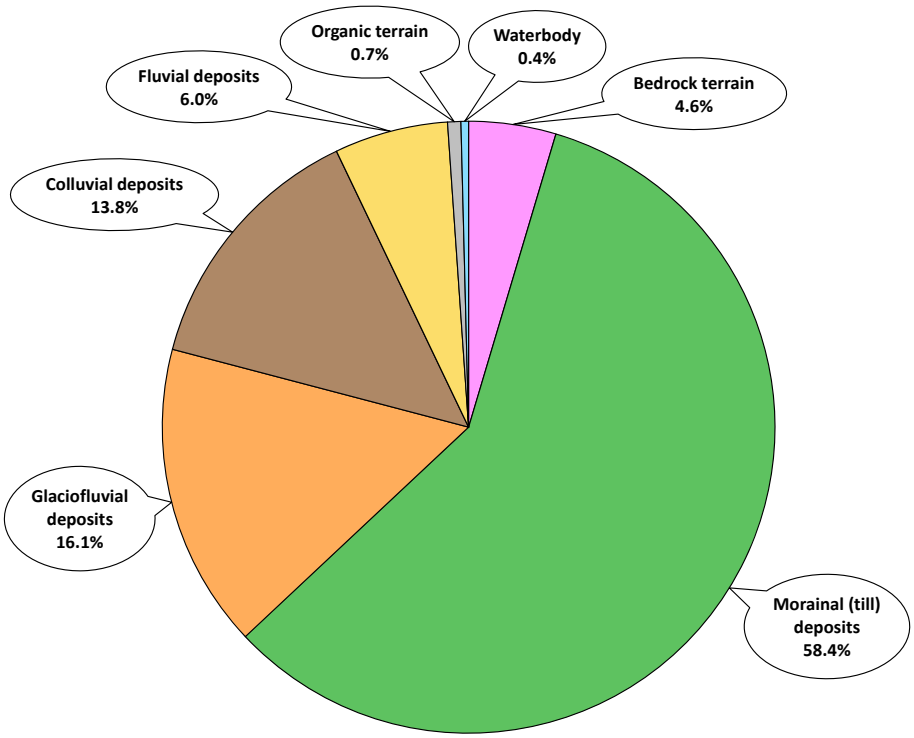

Figure 4-1. Areal proportion (%) of dominant surficial materials within the study area

4.1 Terrain Units

4.1.1 Bedrock Terrain

Bedrock (R) exposure within the study area is limited to isolated outcrops (Rh) along ridges and spurs, mid-slope bluffs (Rs) and stream-cut banks (Rs), overall representing only about 5% of the study area (**Figure 4-1, Table 4-1**). Relatively weak schists that underlie most of the mine area and the southern portion of the access corridor are contrasted by competent limestone that forms prominent outcrops and bluffs along the northern portion of the corridor. The schists, in particular, are weathered in their upper few metres, such that backhoes can generally excavate road cuts by ripping. Bedrock outcrops are commonly ringed by angular fragments that have become detached through frost-shattering and thermal cracking.

Bedrock terrain units may or may not contain permafrost. Where present, it is at depth within weathered or competent bedrock and likely has little potential to contain volumes of ground ice of significance to proposed surface or near-surface development activities[7]. Geomorphological processes within bedrock terrain units are mainly limited to isolated rockfall and nivation.

[7] *Follow-up investigations may be required to assess permafrost conditions within bedrock that will ultimately form the walls of the open pit, in case there is ground ice with potential implications for stability.*

Table 4-1. Typical characteristics of bedrock in the study area[8]

4.1.2 Morainal (Till) Deposits

Morainal deposits (M) are accumulations of till, a diamicton deposited directly from glacial ice. Approximately 58% of the study area exhibits till as the dominant surficial material, although this proportion under-represents its actual extent due to the commonness of its burial beneath a mantle of glaciofluvial or colluvial material (**Figure 4-1, Table 4-2**). Most of the till within the study area appears to have been deposited beneath the ice sheet (i.e., subglacial till), although ablation till was likely also deposited in areas of stagnant and down-wasting ice, commonly in association with areas of ice-contact glaciofluvial deposits. Till thicknesses varies greatly. Till veneers (<1 m, Mv) are common around the proposed mine area, especially on rounded ridges and gentle upper slopes. Till thickness generally increases northward, such that blankets (>1 m, Mb) are more common along the road corridor. Most blankets are probably in the order of a few metres thick, based on road cuts, but areas of blankets in excess of 10 m are indicated by exposures in stream-cut banks along the northern portion of the access corridor.

The till within the study area generally has a silty fine sand to fine sandy silt matrix and a low (10-15%) clast content. In some areas, the till has sufficient clay content to be manually rolled to 3 mm without cracking (~plastic limit). Clasts range from granule to boulder in size, and are generally subangular to subrounded. Field observations suggest that the thinner tills around the proposed mine area may be slightly sandier than the thicker tills along the access road corridor.

Permafrost appears ubiquitous in thick (>3 m) till blankets, based on observation of widespread slopewash runnels along portions of the road corridor. Ground ice is inferred to be common and significant in thick tills, based on the extent of thermokarst gullying and first-hand observation of localized seams to interconnected lenses of segregated ice. Permafrost is not typically encountered in comparatively thin till veneers, which are commonly sandier and better drained. Geomorphological processes common to till deposits include slopewash, solifluction, gullying (regular and thermokarst) and active-layer detachments.

</table>

4.1.3 Glaciofluvial Deposits

Glaciofluvial deposits (FG) are the result of sedimentation in flowing glacial meltwater. Glaciofluvial deposits occupy approximately 16% of the study area and are concentrated in a number of locations, locally representing the dominant surficial material (**Figure 4-1, Table 4-3**). Glaciofluvial landforms originate in two distinct settings: ice-contact and proglacial. Both occur within the study area. Large complexes of ice-contact glaciofluvial deposits, forming kame-and-kettle topography, occupy lowland settings at several locations within the study area. Relief of these ice-contact deposits is typically less than a few tens of metres. Eskers (FGr) and hummocky kames (FGh) likely formed in relatively high-energy environments, given their sandy gravel composition. Deposits are clast-supported and dominated by rounded stones. Many of the kames, especially smaller and lower-relief ones, are best described as 'dirty' sand and gravel; they are more poorly sorted, commonly contain a notable silt fraction, and exhibit more subrounded clasts. Outwash deposits (FGt) were deposited in comparatively low-energy environments, based on their better-sorted, gravelly sand composition. Along the northern portion of the access corridor, a veneer to blanket of outwash sediments commonly covers underlying till. Isolated glaciofluvial deposits occur throughout the study area, including within the proposed mine area.

Permafrost is uncommon in glaciofluvial landforms, due to their well-drained, granular composition. Important exceptions occur where glaciofluvial deposits occupy depressions or are relatively thin (e.g., veneer) and overlie a lower-permeability material such as a thick blanket of till. Identification of thermokarst subsidence in areas of glaciofluvial material necessitate consideration be given to underlying materials in cases of only thin surficial coverage. Ice contents are expected to be low in well-drained glaciofluvial deposits. Active, mappable geomorphological processes are uncommon in glaciofluvial landforms, but localized gullying or ravelling may be present.

Table 4-3. Typical characteristics of glaciofluvial deposits in the study area

<tr><td>Drainage range</td><td>Well to rapid</td></tr>
<tr><td>Dominant slope range</td><td>Level to moderately steep</td></tr>
<tr><td>Permafrost</td><td>Uncommon and ice-poor, where present</td></tr>
<tr><td>Other characteristics</td><td>Well-drained scarps prone to ravelling if undercut by creek erosion or exposed in steep road cuts</td></tr>
<tr><td>Hazard considerations</td><td>Instabilities in underlying material may affect surface</td></tr>
</table>

4.1.4 Colluvial Deposits

Colluvium (C) is material that has been transported and subsequently deposited by gravity. Minor colluviation (e.g., soil creep) is widespread throughout the study area on gentle to moderate slopes. Colluvial materials are most pronounced and mappable within approximately 14% of the study area (**Figure 4-1, Table 4-4**). Colluvial veneers (<1 m, Cv) are widespread on moderately steep to steep slopes, exhibiting evidence of downslope movement of materials. In some areas, veneers of colluvium overlie another material such as till instead of bedrock. In these cases, a stratigraphic relation is expressed in the terrain unit label (e.g. Cv\Mb). Colluvial veneers are mainly encountered on mountainsides within the proposed mine area. Colluvial blankets (>1 m, Cb) and aprons (Ca) are more common on lower slopes and at prominent concave slope-breaks, respectively. Thicker colluvial deposits generally contain more silt and are less well drained. The eastern valley side near the proposed open pit exhibits a conspicuous colluvial apron at its base.

Colluvial materials derive their properties largely from the materials from which they originate. Therefore, colluvium derived primarily from weathered bedrock in the study area tends to be angular, clast-supported granules to large blocks, with a matrix of silty sand. Bedrock-derived colluvium is generally well-drained and permafrost-free. Colluvium derived primarily from the downslope movement of till tends to exhibit subrounded to angular clasts supported within a silty sand matrix, much like its parent material but with a looser, less compact structure. Where sufficiently thick and silty, colluvial deposits contain permafrost. Colluvium commonly exhibits crude stratification parallel to the slope, including buried organic horizons, indicating the incremental movement and layering of materials downslope.

Colluviation occurs through a variety of processes within the study area, including both slow and rapid mass movements. Areas of soil creep (ubiquitous and unmapped), rockfall, and debris slides and flows (including active-layer detachments and retrogressive thaw slumps) have been observed. Solifluction is also a conspicuous form of downslope movement of material on mountainsides, although terrain units exhibiting mappable solifluction generally retain their original material classification (e.g., till) unless lobes are pronounced and thick or particularly elongated downslope (in which case they are generally mapped as colluvial materials). Periglacial processes influence and accelerate colluviation through mechanisms such as nivation and slopewash.

Table 4-4. Typical characteristics of colluvium in the study area

</table>

4.1.5 Fluvial Deposits

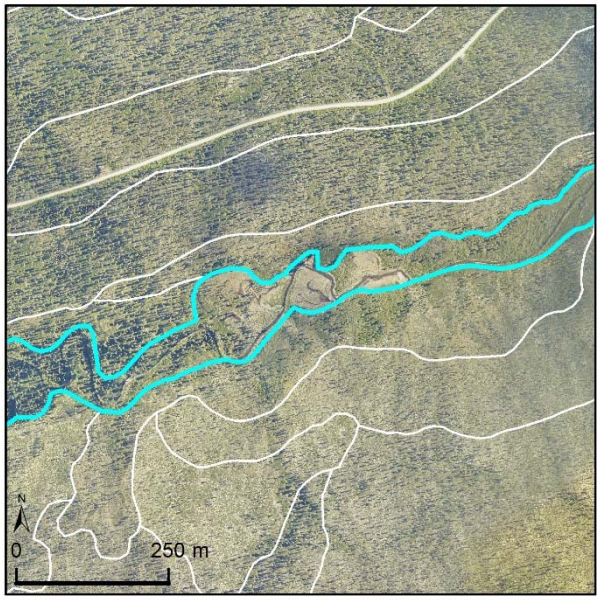
Fluvial deposits (F) have been transported and subsequently deposited by modern (post-glacial) streams. Fluvial deposits invariably occur along modern creeks and localized widenings along their tributary drainages, representing <1% of the study area (**Figure 4-1, Table 4-5**). Most of the Geona and Finlayson Creek valley bottoms are mapped as active fluvial plains (FAp), which exhibit sinuous to irregularly meandering channels within a level floodplain and localized organic cover. Remnants of former channel deposits, now perched above the floodplain, are mapped as terraces (Ft). Several active fluvial fans (FAf) from tributaries project into the floodplains, indicating that material deposition from the tributaries is outpacing the erosional capacity of the main creeks. Some of the tributary drainages and even the slopewash runnels descending the gentle valley sides exhibit evidence of fluvial transport and deposition; as such, they have been mapped as having fluvial veneers (FAv).

The grain size distribution of fluvial deposits is a function of the source material and the channel morphology, namely energy gradient (slope). Most fluvial deposits within the study area are a mixture of subrounded to rounded, pebble- to cobble-sized clasts along the active channel and interbedded silt, sand and organics in adjacent floodplain areas. Fluvial fan deposits tend to be coarser gravels and have a lower silt fraction, mainly due to the comparatively steeper gradient than on plains. Evidence of beaver activity is widespread along the bottoms of both main creeks; many of the small on-line or riparian ponds may actually relate to former beaver activity. Open meadows have established in areas once impounded by beaver dams, and clusters of dead or dying trees are commonly a sign of drowning behind existing or former beaver dams.

Permafrost is generally inferred to be absent within fluvial deposits within the study area based on previous geotechnical investigations (e.g., KP, 2016c,d), a consistently high groundwater table along the valley bottoms (indicated by vegetation communities and slope-toe springs), and an absence of evidence of thermokarst activity. There is sufficient flow within the active channels and through-flow of water within permeable fluvial sands and gravels, even during winter, to inhibit freezing and at least maintain a talik. Exceptions occur in some inactive floodplains and terraces covered with organic material. Geomorphological processes are mainly meander migration, irregularly sinuous channelling and localized (beaver dams) and seasonal (freshet) inundation of floodplain areas.

Table 4-5. Typical characteristics of fluvial deposits in the study area

Map example



Oblique aerial view

Soil pit

General distribution	Valley bottoms, tributary drainages
Common terrain units	zsgFAp-M, zsgFt, zsgFAf
Dominant processes	Meander migration, irregularly sinuous channel, inundation
Drainage range	Imperfect to well
Dominant slope range	Level to gentle
Permafrost	Generally absent or at depth below
Other characteristics	Irregular channel and floodplain morphology may reflect former beaver activity
Hazard considerations	Bank erosion, bed down-cutting, avulsion potential, beaver dam outbursts

4.1.6 Organic Terrain

Organic terrain (O), composed of peat and muck, occurs wherever organic material has accumulated with thicknesses of at least half a metre. Organic material accumulates in poorly drained areas where water slows the decomposition of plant matter, generally in closed depressions, in riparian zones or on gentle ground with a thin active layer (shallow permafrost). Mappable organic terrain represents <1% of the study area (**Figure 4-1, Table 4-6**). The thickness of organic material is variable, and generally expected to be less than a metre or two. KP (2016a), however, notes one of the test pits near the proposed Lower Water Management Pond penetrating more than 5 m of organics. Organic terrain is mapped as veneers (<1 m, Ov), blankets (>1 m, Ob) or plains (Op), depending on the inferred thickness and relation of the organic surface to underlying topography.

Organic material can be described according to its general degree of decomposition: fibric (poorly decomposed), mesic (moderately decomposed) or humic (well decomposed). All three degrees of decomposition occur within the study area, although fibric to mesic decomposition predominates. Organic soils (>40 cm) were encountered in many areas where there was no seepage or particular wetness at the bottom of hand-dug soil pits, possibly reflecting thickening of the active layer or end-of-summer conditions when the groundwater table is relatively low.

Organic terrain is commonly associated with permafrost, especially in areas rich in peat. Peat has highly insulative properties, and inhibits penetration of warm summer temperatures. Organic terrain may be ice-rich, especially where it overlies thick deposits of till. Few mappable geomorphological processes occur in organic terrain, except thermokarst in some areas.

<tr><td>Hazard considerations</td><td>Compressible soils, episodic and seasonal inundation, thermokarst potential</td></tr>
</table>

4.2 Active Geomorphological Processes

A variety of geomorphological processes were mapped within the study area, including erosional, fluvial, mass movement, periglacial, deglacial and hydrologic processes (Howes and Kenk, 1997). Subclasses of these primary processes were distinguished where necessary to more accurately represent different potential hazard characteristics and implications. Only active processes that may represent hazards are detailed below. Complete descriptions for these and other mapped, non-hazard processes (e.g., cryoturbation, nivation) are available in Howes and Kenk (1997).

4.2.1 Rockfall (-Rb)

Rockfall is the rapid detachment, fall, rolling and bouncing of rock fragments (Hungr et al., 2014). Rockfall occurrences within the study area are restricted to isolated bedrock bluffs and steep colluvial slopes with bedrock outcrops (**Photo 4-1**). Active rockfall zones are recognized by the presence of an unweathered patch of bedrock bluff upslope and/or a pile of lichen-free rubbly debris at the base of the bluff. Rockfall is typically recurrent and most likely to occur during periods of freeze-thaw (frost shatter) or rapid and prolonged warming (thermal cracking).

Photo 4-1. Recent rockfall (-Rb) from bluff near upslope limit of proposed Class B Storage Facility

4.2.2 Debris Slides (-Rs)

A debris slide is the slow to rapid sliding of a mass of surficial material on a shallow, planar surface parallel with the ground (Hungr et al., 2014). Debris slides are distinguished from the more specific process of active-layer detachment, which occurs only on slopes underlain by permafrost. Debris slides within the study area most commonly occur on the steep walls of gullies and tributary drainages (e.g., Fault Creek) (**Photo 4-2**) and along steep, south-facing scarps alongside Finlayson Creek.

Photo 4-2. Gullied (-V) scarp prone to debris slides (-Rs) scarp along the north (left) side of Fault Creek

4.2.3 Debris Flows (-Rd)

A debris flow is a very rapid to extremely rapid surging flow of saturated debris in a steep channel (Hungr et al., 2014). Evidence of the occurrence of debris flows within the study area is provided by conspicuous levees that form along the edges of the deposits within the runout zones (**Photo 4-3**). Most are small, short-travelled (<100 m runout) and initiate on steep slopes at high elevations within remnant till deposits or highly weathered bedrock. Although not explicitly mappable, evidence of debris flows was also noted in deep thermokarst gullies incised into moderately steep valley walls.

Photo 4-3. Recent debris flow (-Rd) deposit with levees on alpine slopes west of the mine site area

4.2.4 Debris Floods (-Rt)

A debris flood is a very rapid flow of water, heavily charged with debris, in a steep channel (Hungr et al., 2014). Peak discharges are comparable to those of water floods. Sediment transport rates during debris floods far exceed normal bed material movement through rolling and saltation, but still rely on the tractive forces of water. Debris floods can transport large quantities of sediment onto their fans, such has been documented historically on the Fault Creek fan (KP, 2016a and this study) (**Photo 4-4**). Debris floods likely initiate along the narrowly confined lower reaches of Fault Creek, following saturation and mobilization of material that accumulates behind temporary dams on the creek bed caused by debris slides from the gullied sidewalls. Debris floods cause sudden aggradation on fan surfaces, which commonly infills channels and triggers an avulsion with a different distributary trajectory. Unlike a debris flow, a debris flood usually does not develop high impact forces (Hungr et al., 2014).

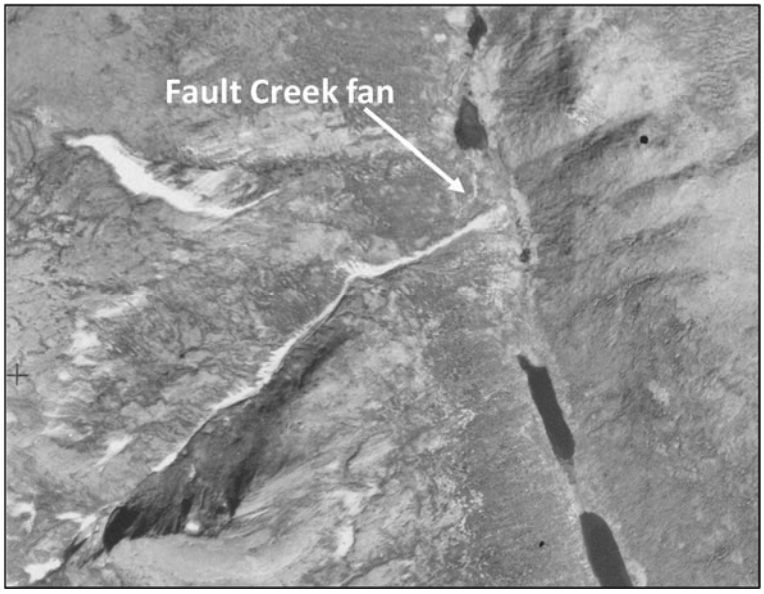

Photo 4-4. Fresh debris flood (-Rt) deposit on Fault Creek fan in 1949 aerial photography

4.2.5 Rock Creep (-Fg)

Rock creep is the slow movement of angular debris under periglacial conditions (Howes and Kenk, 1997). Within the study area, rock creep occurs in subalpine to alpine areas with exposed or thinly covered weathered bedrock, especially on northerly aspects. It is recognized by flow-like patterns on lower talus slopes or by a conspicuously irregular, undulating slope typified by patches of fresh talus amongst intact and weathered bedrock (**Photo 4-5**). Slopes prone to rock creep are likely only slightly sensitive to surface disturbance, due to their skeletal and typically ice-poor composition.

Photo 4-5. Flow-like pattern on lower talus slope indicative of rock creep (-Fg)

4.2.6 Gullying (-V)

Gullying is the modification of unconsolidated (surficial material) and consolidated (bedrock) surfaces by various processes such as surface runoff, mass movement and snow avalanching, resulting in the formation of parallel and sub-parallel long, narrow ravines (Howes and Kenk, 1997). The gullying process has been applied to terrain units (polygons) that exhibit such morphology to an extent that distinguishes them from surrounding, more uniform slopes (e.g., **Photo 4-2**). Gullies occur in all surficial materials and on bedrock slopes, typically elevating the potential for instability. Most gullies are formed through fluvial incision over millennia and, in some cases, may be subject to debris flows. The most conspicuous gullies are delineated on the maps with line symbols.

4.2.7 Solifluction (-S)

Solifluction is the slow (mm/yr to cm/yr, Price, 1991; Matsuoka, 2001; Kinnard, 2003), downslope movement of saturated, non-frozen overburden across a frozen or otherwise impermeable substrate. More accurately, in this study area, gelifluction is the form of solifluction that has generally been mapped due to the movement of material within the active layer on the permafrost table. Solifluction occurs most commonly on convex northerly slopes veneered or blanketed in colluvium in subalpine or alpine environments within the study area. Both solifluction lobes and terraces are present and active within the study area, particularly on northerly aspects (**Photo 4-6**). The solifluction lobes that typify this form of mass movement may comprise silty to fine sandy material rich in organics or clast-rich material bound together by ground ice. Solifluction slopes have generally been mapped as having ice-poor or ice-moderate, shallow permafrost.

Photo 4-6. Solifluction (-S) lobes and terraces on gentle slope above the Class C Storage Facility

4.2.8 Thaw flow slides (-Xf)

An active-layer detachment, referred to more generically for mapping purposes by Howes and Kenk (1997) as a “thaw flow slide”, is a shallow form of debris slide that occurs within the active layer on top of the permafrost table (**Photo 4-7**). Active-layer detachments typically occur in response to intense or prolonged rainfall or snowmelt, high air temperatures, or surface disturbances (e.g., wildfire, windthrow, abnormal drainage concentration, anthropogenic ground disturbance). Active-layer detachments exhibit widespread occurrence throughout the study area, but are restricted to initiation on slopes underlain by permafrost. They initiate on gentle to steep slopes, commonly just above a convex roll much like a snow avalanche. They have runout distances of up to a few hundreds of metres and can transport woody vegetation and underlying colluvial material from ridge shoulders to slope-toe aprons. Following their initial occurrence, permafrost exposed on, or directly beneath, their sliding surface begins to thaw, and the active layer thickens. Continued slides, flows and gullying are common, until active layer thickening ceases. The headscarps of active-layer detachments may migrate retrogressively upslope through gradual thawing and sloughing. The paths of former active-layer detachments are commonly recognized by the anomalous stripe of deciduous trees (e.g., alder, birch) that colonize above the locally depressed permafrost table.

Terrain units (polygons) that exhibit a history of active-layer detachments are assigned this process label (-Xf); discrete failures are also delineated with line symbols. Retrogressive thaw slumps are commonly initiated by small active-layer detachments and have not been separately distinguished due to their small size within the study area.

Photo 4-7. Recent thaw flow slide (active-layer detachment) (-Xf) on mountainside above Finlayson Creek

4.2.9 Thermokarst Subsidence (-Xt)

Thermokarst subsidence is the formation of ground-surface depressions created by the thawing of ice-rich permafrost and associated soil subsidence (Howes and Kenk, 1997). Terrain units (polygons) inferred to have ice-rich permafrost are generally susceptible to thermokarst, although the form and severity of such thermokarst also depends on material properties, depth to permafrost and the form of ground ice. The melting of massive ice bodies produces the most conspicuous thermokarst depressions, which may or may not contain standing water. Thermokarst occurs naturally, such as in response to windthrow or wildfire, but is accelerated through anthropogenic disturbance to surface organic cover and drainage patterns. Thermokarst subsidence is most common in valley bottoms and on benches on gentle valley sides. **Photo 4-8** reveals thermokarst slumping along the shoreline of a pond adjacent to the access road near KM 5.5. Discrete thermokarst subsidence features, whether or not filled with water, are mapped using point symbols.

Photo 4-8. Leaning trees and collapsing bank indicative of thermokarst subsidence (-Xt) along shoreline of pond adjacent to access road near KM 5.5

4.2.10 Thermal Erosion (-Xe)

Thermal erosion is the process of gully formation initiated by heat transfer from water bodies, typically flowing streams, to underlying permafrost. Thermal erosion can also occur due to heat transfer along the shorelines of standing water bodies. Thermokarst gullies are commonly distinguished by anomalously low width-to-depth ratios, indicative of relatively rapid incision into ice-rich permafrost, and tension cracks along the crests of their side walls. Trees growing along the edges of such gullies gradually tilt inward toward the gully; straight trunks that have not had an opportunity to adjust their growth habitat upward are indicative of relatively rapid gully enlargement (**Photo 4-9**). Retrogressive erosion of thermokarst gullies is common and can lengthen gullies that initiate on over-steepened slope toes by orders of magnitude upslope.

Within the study area, thermal erosion is most commonly associated with ice-rich, thick deposits of till with or without a mantle of glaciofluvial material. Natural and anthropogenic alterations in surface runoff patterns, especially where surface runoff becomes concentrated, can trigger thermal erosion. Significant thermal erosion, forming gullies, was mapped using line symbols. **Photo 4-9** shows a remarkable case of thermal erosion along a thermokarst gully that crosses the access road near KM 5.8. Surface runoff concentrated along the gully bottom has formed a cavernous entrance to a 40 m-long tunnel up to a few metres in diameter beneath the ground surface.

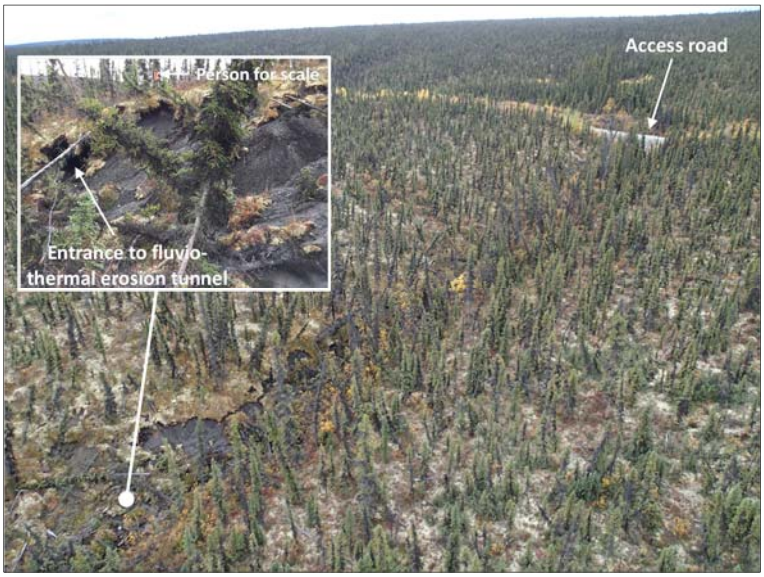

Photo 4-9. Severe thermal erosion and gullying (-Xe) along a stream crossed by the access road at KM 5.8

4.2.11 Slopewash (-Xs)

Slopewash, sometimes referred to as sheetwash, is the mobilization and redistribution of fine material by water flowing down the surface or within the shallow subsurface of smooth slopes that are typically underlain by permafrost. Slopewash exhibits widespread occurrence in permafrost terrain, but is most prevalent on slopes demarcated by downslope, parallel to sub-parallel runnels also known as water tracks (**Photo 4-10**). Such slopes that are distinguishable on the basis of these runnels have been mapped with this process label (-Xs). The runnels are readily distinguished by the growth of dwarf willows, which contrast with surrounding dominance of dwarf birch. The concentration of surface runoff in slopewash runnels leads to local depression of the permafrost table, which in some cases can trigger thermal erosion. Slopewash runnels require consideration in drainage management strategies along roadways, as their thicker active layer allows seepage to continue well into winter, when icing ("glaciation") can develop and block culverts.

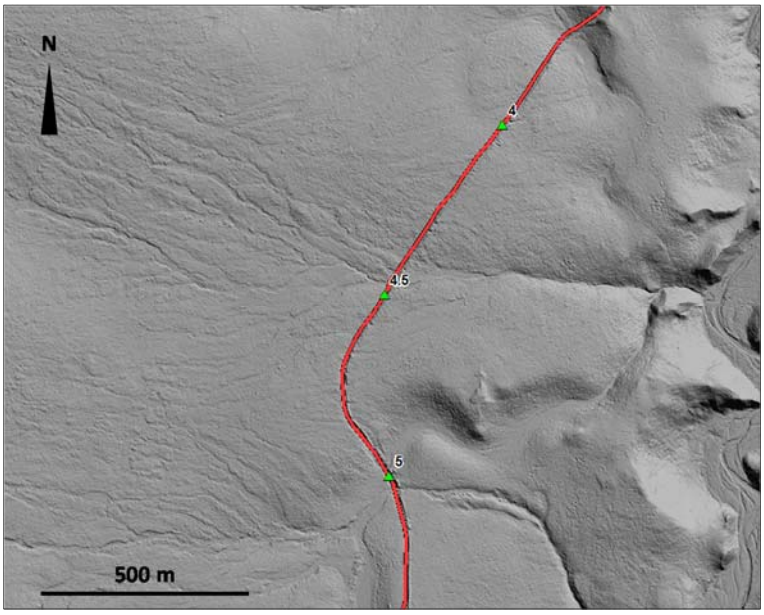

Photo 4-10. LiDAR-derived bare earth hillshade of slopewash (sheetwash) (-Xs) runnels on gentle till slope with permafrost between KM 4 and 5 of the access road

4.2.12 Meander Migration (-M) and Irregularly Sinuous Channels (-I)

Much of the existing access road parallels Finlayson Creek, which exhibits meander migration (-M) and irregularly sinuous channels (-I) along the bottom of its deeply incised valley (**Photo 4-11**). Finlayson Creek is crossed once before the final ascent toward the proposed mine area. Stream channels adjust their planform geometry naturally through bank erosion and meander processes including loop extension, down-valley migration and cut-off (avulsion). Meander migration must be accounted for when sections of road are proposed to cross or encroach alongside sizable creeks, or where mine infrastructure footprints on or immediately adjacent to valley bottoms may be exposed to such a hazard. Anthropogenic disturbances can accelerate bank erosion through perturbations to natural channel patterns.

Photo 4-11. Floodplain of Finlayson Creek exposed to meander migration (-M)

5. Terrain Stability and Hazards

5.1 Terrain Stability

As discussed in Section 3.3.2, each polygon was attributed with an 'existing' or 'disturbed' stability class. The terrain stability mapping (Map 2) in **Appendix B** reveals that the majority (68%) of the study area has an existing terrain stability class of 'generally stable' (Class II) (**Figure 5-1**). This is expected given the gentle slopes that predominate on lower valley sides and in upland areas. Approximately 4% of the study area is considered 'potentially unstable' (Class IV, <1%) or 'unstable' (Class V, 4%), mostly represented by moderately steep, gullied, valley wall scarps and areas of permafrost already exhibiting thermokarst activity.

The disturbed terrain stability class is defined in terms of the worst case scenario of ground disturbances in association with conventional cut-and-fill road construction, without any mitigation measures to address potential instabilities related to permafrost or sidecast on steep slopes. This allows for the establishment of improved baseline references, and better highlights areas that warrant special design consideration. This approach for communicating terrain hazard conditions enables engineers responsible for designing the mine facilities and access road to make more informed and site-specific decisions about appropriate construction techniques. Furthermore, it allows project risk assessments to be specifically tailored to different circumstances.

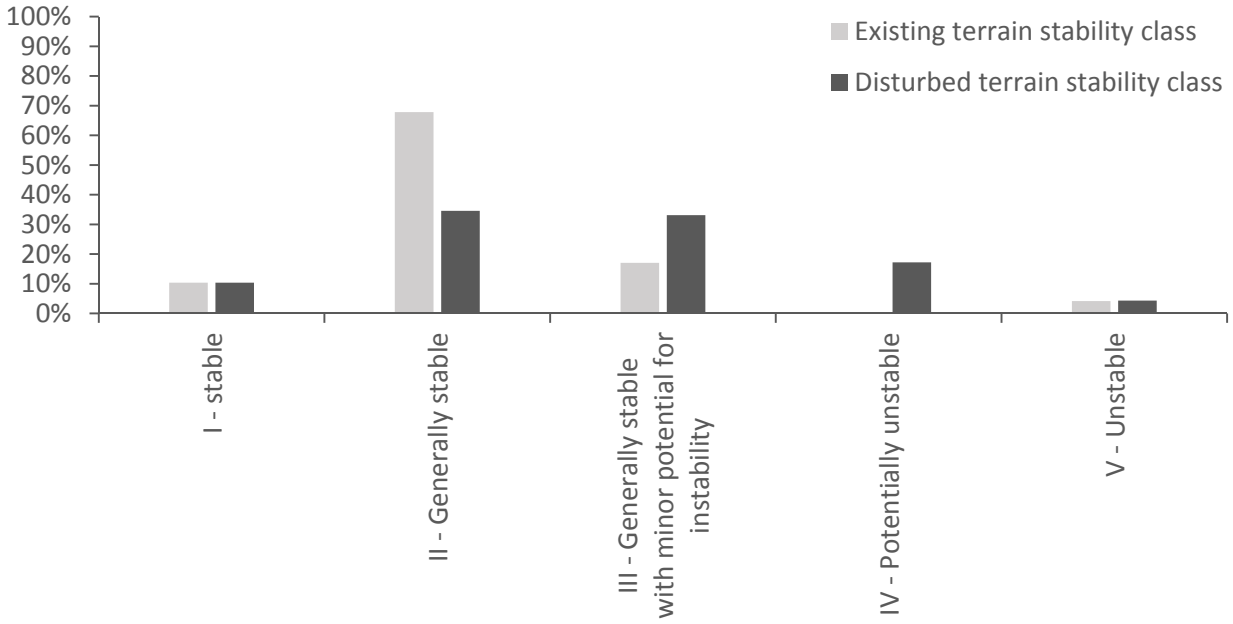

Figure 5-1. Histogram of proportional areal coverage of existing and disturbed terrain stability classifications in the study area

According to the disturbed terrain stability class, the proportion of terrain stability polygons with a 'generally stable' (Class II) rating drops from 67% (existing) to 35% (disturbed) (**Figure 5-1**). Many of these polygons become 'generally stable with minor potential for instability' (Class III, 33%) or 'potentially unstable' (Class IV, 17%) if disturbed without mitigation. This notable increase in terrain stability class reflects the sensitivity of permafrost terrain to disturbance, which can initiate or exacerbate active-layer detachments and thermokarst.

The distinction between existing and disturbed terrain stability classes allows accurate representation of potential upslope (e.g., active-layer detachments) or downslope (e.g., thermal erosion) hazards that are unaffected by proposed infrastructure footprints. This format of mapping distinguishes natural hazards, which may be triggered by occurrences such as wildfire, from those potentially exacerbated or initiated by project-related disturbance. For example, a particular polygon crossed by the proposed road may have a disturbed terrain stability class of IV (potentially unstable). Its existing terrain stability class, however, may only be II (generally stable). Therefore, the potential hazard posed by terrain conditions within this polygon could be recognized as being appreciably lower if the road passes beneath it than if it crosses it.

Each disturbed terrain stability class was qualified according to the main influential types of disturbance. Project-related construction, without mitigation, is projected to be the main driver of terrain instability in approximately 54% of the study area. Approximately 45% of the study area is sensitive to both project-related construction and climate change. Waterbodies comprise the remaining 1% of the study area. Identification of disturbance type does not necessarily indicate that this disturbance is projected to increase the terrain stability class from the existing to the disturbed condition, as the projected responses of many map units are minor (within a given stability class). No map units were classified as only being sensitive to climate change.

5.2 Hazards Overview

The mapping of terrain (Map 1, **Appendix A**) and terrain stability and hazards (Maps 2 (**Appendix B**) and 3 (**Appendix C**)) collectively identifies various forms of hazards through the assignment of geomorphological process codes (polygon-scale) and discrete geomorphological processes (point or linear features), in addition to the actual terrain stability classes. **Table 5-1** outlines the likelihood and potential magnitude of hazard occurrence over the mine life, generalized according to each of the identified hazards within the study area. Project considerations are also included in order to better communicate the implications of different processes for infrastructure design and future maintenance requirements. Site-specific hazards with the potential to affect each of the proposed components of mine infrastructure are characterized below in association with the risk assessment (Section 6).

5.3 Slope Failure and Thermokarst

As discussed in Section 3.4, each polygon was more broadly categorized according to its dominant potential hazard – slope failure, thermokarst or both – in order to highlight those areas where thermokarst activity is possible in addition to the default instability related to slope failure. This hazard category is not intended to represent the existence or imminence of thermokarst (or slope failure); its aim is to rule out certain areas from the possibility of thermokarst activity. 'Thermokarst potential' dominates the applicable hazard category within approximately 34.8% of the study area (**Figure 5-2**). Such areas are generally characterized by gentle or moderate slopes with ice-moderate or ice-rich permafrost. The potential for thermokarst outweighs the much lower possibility of slope failure in these areas. Approximately 10.6% of the study area has been categorized co-dominantly with 'slope failure and thermokarst potential'. Such areas are distinguished from those dominated only by thermokarst potential by their slope class of moderate (class 3) or higher. A category of 'slope failure potential dominant' applies to all other areas (54.2%), except anthropogenic and open water areas (not applicable, 0.4%), irrespective of the possibility of slope failure (e.g., fluvial plains).

Hazards may affect the footprints locally (e.g., thermokarst subsidence), upslope (e.g., active-layer detachment running out into or across footprint) or downslope (e.g., retrogressive erosion of thermokarst gullies) of the footprints. The distribution of terrain hazards within and immediately surrounding the footprints of proposed project infrastructure is characterized below in association with the facility-specific risk assessment (Section 6).

Table 5-1. Generalized characteristics and considerations for hazards within the study area

Hazard	Likelihood (over mine life)	Magnitude	Project considerations
Rockfall	Typically recurrent and frequent, where present; freshness of talus at base of bluff indicative of recency	Generally small in volume, but rapid and dense	Plan for rockfall below bluffs, especially in areas of fresh deposits (avoid or mitigate), and on steep slopes with small bedrock outcrops
Debris slide	Most likely to occur on steep slopes exhibiting history of debris sliding, especially within or adjacent to recent scars	Generally small to moderate in volume, but rapid and moderately dense	Avoid debris slide slopes and runout zones, or otherwise manage trajectories
Debris flow	Most likely to occur on steep and/or gullied slopes exhibiting history of debris flows, especially adjacent to recent deposits	Generally small to moderate in volume, but rapid and moderately dense	Avoid debris flow paths and runout zones, or otherwise manage trajectories
Debris flood	Most likely to occur along narrowly confined watercourses with high sediment inputs from adjacent slopes	Generally moderate to large in volume, rapid and moderately dense	Avoid development within the paths or runouts (fans) of debris floods, or otherwise manage trajectories
Rock creep	Periodic movement expected; freshness of patches of rock debris indicative of recency	Small volume, short distance, slow movements of angular rock debris	Expect increased maintenance and allow for minor settlement and shifting of rock debris
Gullying	Periodic and localized gully erosion processes (e.g., fluvial incision, side wall mass wastage)	Generally incremental and localized incision, and minor surface sloughing	Minimize crossings of gullied slopes, especially where underlain by permafrost, and expect increased maintenance
Solifluction	Near-continuous, incremental movement	Small volume, short distance, slow (mm/yr to cm/yr) movements of silt-rich debris	Expect increased maintenance and allow for minor settlement and shifting of surficial material
Thaw flow slide	Most likely to occur on recently disturbed or burned slopes, slopes with previous failures (including within existing scars), or in steep and/or gullied terrain especially downslope of any sites of newly concentrated surface runoff	Small to moderate in volume; generally rapidly transports organic-rich surficial material tens to hundreds of metres downslope	Avoid slopes that exhibit a history of active-layer detachments, or otherwise accommodate their possible occurrence, minimize disturbance to surface organics and drainage, and expect increased maintenance for debris removal
Thermokarst subsidence	Gradual or periodic settlement, especially in areas of ice-rich permafrost	Isolated, slow deepening of ground surface depressions, formation and expansion of ringing tension cracks, and possible slow, inward slumping	Minimize disturbance to surface organics and drainage in areas of ice-moderate to ice-rich permafrost through appropriate gravel embankments/pads and water management, and expect increased maintenance that could involve localized road reconstruction; consider monitoring settlement
Thermal erosion	Gradual or periodic incision, especially in areas of ice-rich permafrost	Localized, slow, commonly retrogressive incision of rills or gullies, formation and expansion of adjacent tension cracks, and possible slow, inward slumping	Avoid or minimize concentrating surface runoff in areas of ice-moderate to ice-rich permafrost, especially into pre-existing gullies, and expect increased maintenance that could involve localized road reconstruction; consider monitoring incision
Slopewash	Seasonal slopewash and transport of fine sediments within runnels; near-continuous seepage	Localized, slow transport of fine sediments, and seepage and icing especially in runnels	Accommodate seepage-induced icing accumulation especially within intercepted runnels, expect increased maintenance due to fine sediment delivery adjacent to road, and manage downslope drainage
Meander migration & irregularly sinuous channels	Episodic erosion of banks, mainly along the outside of meanders, in association with high flow events	Destabilization of road or crossing structures by incremental erosion or undercutting and slumping	Accommodate natural meander migration processes, where possible, by maintaining setbacks appropriate to the site; otherwise, proactively protect the road from erosion using appropriately sized riprap or alternative measures

Note: Mapped geomorphological processes that are inactive (e.g., meltwater channelled) or do not represent hazards (e.g., cryoturbation) are not included.

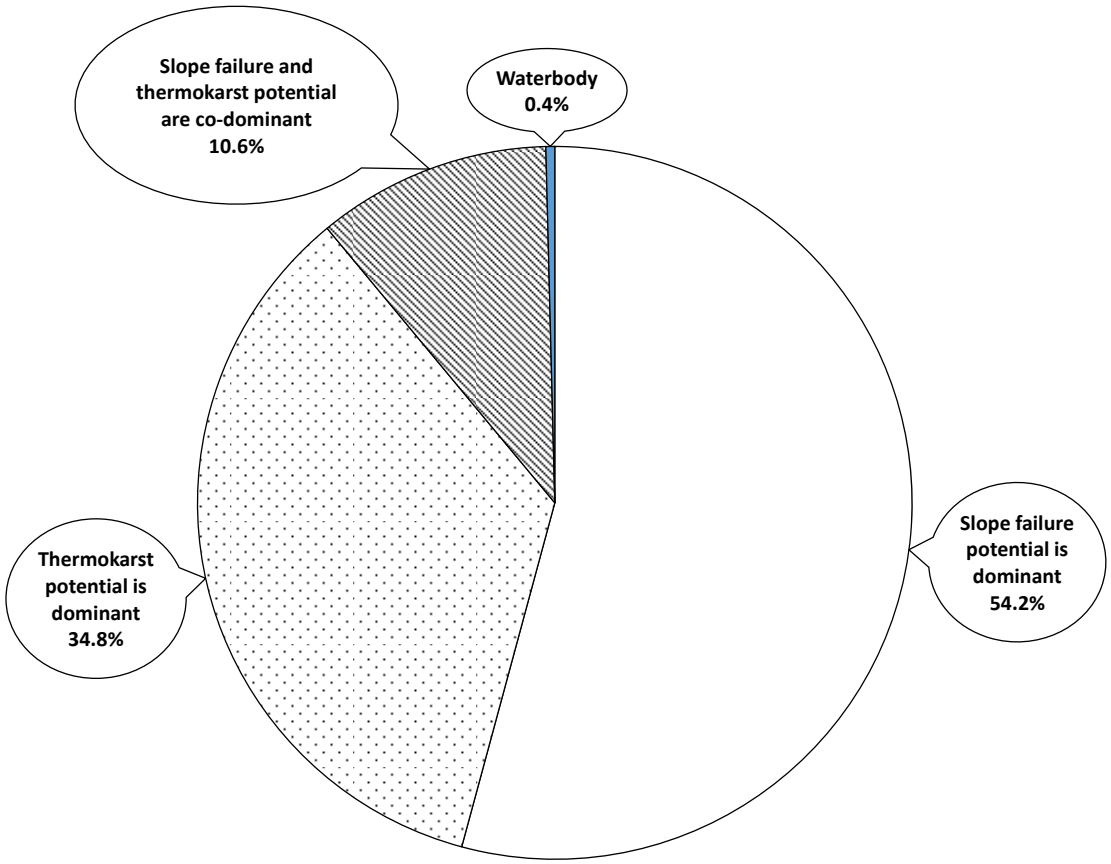

Figure 5-2. Areal proportion (%) of applicable hazard categories in the study area (symbolization matches overlays on terrain stability/hazards maps)

5.4 Other Hazard Considerations

Several other processes were noted as potential hazards through the mapping process, but delineation of their limits requires site-specific investigation and analysis of detailed hydrological and topographic data beyond the scope of this assessment:

- **Icing** – Icing, commonly referred to as 'glaciation', is the accumulation of ice (aufeis) during winter along streams and large slopewash runnels that receive near-continuous groundwater seepage from unfrozen portions of active layers or adjacent permafrost-free ground (**Photo 5-1**). Icings form through the accretion of layers of ice, attaining thicknesses of up to several metres and widths of several tens of metres, depending on site topography. Icings within the study area likely initiate mid-autumn and may persist well into spring where thickest and most shaded. Staff at the KZK Project camp report having to break up or melt ice that accumulates within, and blocks, a few culverts along the existing access road. Large accumulations of aufeis along stream beds and low-lying areas of floodplains can also increase the width (and height) of flooding if intense rainfall or snowmelt occurs before the ice has thinned and broken up. Allowances should be made in the design of crossings of icing-prone drainages for both the formation and failure of aufeis, as well as potential flooding in excess of that predicted by regular hydrological analysis.

Photo 5-1. Example of icing spanning the bottom of a headwater drainage in central Yukon

- **Flooding and Beaver Dam Effects** – Sections of road that cross or follow low-lying areas alongside modern streams may be subject to temporary flooding (inundation) during intense or prolonged rainfall or snowmelt. Small ice jams, which can also significantly raise water levels, could exacerbate flooding. Riparian vegetation patterns and soil profiles provide indicators of the approximate limits and frequency of flooding. In general, map units attributed with "meander migration" (-M) or "irregularly sinuous channels" (-I) geomorphological processes exhibit broad floodplains prone to flooding. As alluded above in Section 3.1, consideration should also be given to the possibility of flooding from beaver dams, both upstream within areas of potential inundation and downstream following a sudden breach and outburst. Geona Creek exhibits a history of beaver activity, including along its headwater reaches such as in the vicinity of the proposed water management ponds (**Photo 5-2**). Evidence includes (i) breached beaver dams (woody debris and mud exposed in creek banks); (ii) floodplain-spanning, arcuate patterns in vegetation (e.g., willows) elevated slightly from the surrounding, poorly drained ground; and (iii) anomalous clearings supporting wet meadow vegetation of similar species and age, indicative of areas formerly inundated behind beaver dams.
- **Creek Bed Degradation and Aggradation** – Degradation, also known as channel down-cutting, is the lowering of stream bed elevation due to erosion overwhelming deposition at a reach scale. Aggradation, or channel infilling, is the raising of stream bed elevation due to deposition outpacing erosion at a reach scale. Both degradation and aggradation along streams may pose hazards to crossing structures (e.g., culverts or bridges) if not recognized and accommodated in the design. Degradation can lead to undermining of abutments, potentially destabilizing crossing structures, and perching of culverts. Aggradation can reduce the hydraulic capacity of the channel or crossing structures by partial infilling, which in turn can increase the frequency of overbank flooding and the potential for road overtopping.

Photo 5-2. Cascade over breached beaver dam near proposed water management ponds

6. Risk Evaluation and Mitigation Measures

An evaluation of the credible risks posed to the Project by specific hazards was completed according to the procedure described above in Section 3.5. The term, credible risk, is used to distinguish scenarios that warrant special consideration due to the nature of the associated hazard(s) in a particular area, from scenarios that should be satisfactorily addressed through planned construction methods and related best management practices. For example, risks related to road upgrades or realignment in permafrost-free areas (commonly terrain stability classes of I, II or III) or in areas of ice-poor or ice-moderate permafrost (commonly disturbed terrain stability classes of II, III or IV) can be addressed through standardized construction techniques expressed in typical cross-sections prepared for the Project by OEL (2016). Risks associated with ice-rich permafrost (commonly a disturbed stability class of IV) warrant additional attention and were preliminarily identified as credible and prioritized for evaluation.

Based on the project-specific risk evaluation matrix (**Table 3-2**), **Table 6-1** presents the systematic risk evaluation applied to each credible hazard posed to the main proposed mine infrastructure footprints. **Table 6-2** presents the same evaluation for the existing/proposed access road. The risks reported in both tables represent an *unmitigated* condition. Opportunities to mitigate the risks, which are either recommended or already planned in association with mine development and operations (noted, where applicable), provide a means of reducing risks to acceptable, residual levels.

Table 6-1. Evaluation of risks posed by terrain hazards to proposed mine infrastructure

Facility	Hazard	Hazard Description	Likelihood (unmitigated)	Consequence (unmitigated)	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
Open Pit The two-part open pit is proposed in the centre of the valley at the headwaters of Geona Creek. The pit walls will extend upward until they meet the existing ground surface within the valley bottom or on either valley side. It is assumed that any existing hazards within the footprint of the open pit do not pose any risks, given that the ground on which they occur will be fully stripped and then removed during mining operations. The focus is on hazards adjacent to the open pit that could pose risks to mining operations within or immediately adjacent to the pit. NOTE: There are no notable risks to (1) the adjacent paste plant, which is proposed to be situated in a gentle draw with thin (<1 m) overburden without permafrost (and well beyond the maximum runouts of small debris flows observed at the head of the draw); (2) the pit rim pond, which is proposed to be situated on the valley bottom on an alluvial plain punctuated by a remnant glaciofluvial terrace; or (3) the spur roads that access the pit entrance.	Active-layer detachments & retrogressive thaw slumping (-Xf)	The eastern portions of both portions of the open pit extend up the eastern valley side, crossing map units where active-layer detachments have recently occurred (Poly_IDs 426 and 499). One of the active-layer detachments initiated immediately above an exploration road cut. As mining operations proceed and the pit limits expand outward, there is a potential for similar active-layer detachments to occur naturally or in response to exposure of permafrost and the implicit alteration of drainage patterns that follows. More broadly, there is potential for retrogressive thaw slumping of ice-moderate till and colluvium freshly exposed along the eastern and western rims of the pit (Poly_IDs 403, 409, 426 and 499). *Active-layer detachments and retrogressive thaw slumping could transport material over the rim of the pit, thereby posing a risk to mining operations immediately within or adjacent to the pit rim.*	Moderate	Moderate	Moderate	Construct a berm along the upslope perimeter of the open pit in order to divert or accommodate localized mass movements, or extend the area of stripping slightly beyond the rim of the open pit, so that any localized mass movements terminate before entry.	Moderate	Negligible	Negligible
	Solifluction (-S)	Two small edges of the westernmost portion of the open pit footprint extend onto a moderate slope blanketed in till that exhibits solifluction (Poly_ID 403). Ongoing solifluction could deposit material inside the rim of the pit, albeit at a rate that does not constitute a risk.	High	Negligible	Negligible	N/A	High	Negligible	Negligible
	Debris floods (-Rt)	The southern portion of the open pit extends well into the map unit representing the large, active alluvial fan at the mouth of Fault Creek (Poly_ID 461), which drains a mountainous basin west of Geona Creek. In addition to being prone to normal (clearwater) floods, Fault Creek also exhibits a history of recurrent debris floods. A debris flood that transported and deposited gravels to the maximum limits of the alluvial fan along two distributary channels occurred between 1986 and 1992, based on comparison between historical aerial photographs. This is consistent with a minimum age of 21 years derived dendrochronologically from the tallest willow in the cleared path of the flood event. Earlier events appear to have occurred along similar paths prior to 1949 (the earliest available aerial photograph). Debris floods likely occur during intense/prolonged rainfall events following saturation and sudden mobilization of in-channel debris that has accumulated from frequent debris slides originating along the steep gully sidewalls. *Debris floods (and normal floods) pose a risk to operations within the open pit, given their potential to deposit large volumes of water and sediment in the pit within a short timeframe.*	Moderate	High	High	Construct a diversion ditch and berm (as planned, Drawing C560, KP, 2016b), beginning at the apex of the fan, to divert floods/sediment into the abandoned channel west of the current channel, thereby minimizing cut/fill requirements. Sufficient cross-sectional area must be available in the excavated diversion channel to accommodate floodwaters and rapid aggradation along the bed.	Moderate	Negligible	Negligible

Facility	Hazard	Hazard Description	Likelihood (unmitigated)	Consequence (unmitigated)	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
Class A Storage Facility The facility is proposed with its upper limit near treeline.on the middle to upper slope of the western valley side of upper Geona Creek. NOTE: There are no notable risks to the collection pond at the base of the facility, or to the spur roads accessing it.	Solifluction (-S)	All of the map units encompassing the facility footprint exhibit veneers of till and/or colluvium on gentle to moderate slopes. One map unit along the upper edge of the facility, south of the meltwater channel, exhibits evidence of minor solifluction over ice-poor permafrost or bedrock (Poly_ID 331). The gradual build-up of material against or on top of the western perimeter of the facility is less of a concern than the potential for mine waste placed on the soliflucting till to eventually creep downslope. *Continued solifluction at the base of the mine waste poses a long-term (post-closure) risk to the integrity and surface form of the facility, due to the potential for slow creep of mine waste within portions of the facility.*	Moderate	Low	Low	Pre-strip overburden (as planned, AEG, 2017) at least within the areas of minor solifluction and/or be prepared to monitor and maintain the facility surface such that any localized creep does not impact the management of surface runoff. Ensure upslope surface and near-surface runoff (active layer or to bedrock) are diverted around the facility (as planned, AEG, 2017), in order to inhibit water entry.	Negligible	Low	Negligible
Class B Storage Facility The facility is proposed with its upper limit near treeline on the middle to lower slope of the western valley side of upper Geona Creek. NOTE: There are no notable risks to the Mill Site or collection pond at the base of the facility, or to the spur roads accessing it.	Thermokarst subsidence (unmapped; potential only)	Two map units within the upper third of the facility footprint are blanketed in till inferred to have a moderate ice content (Poly_IDs 403 and 409). Till containing seams or small lenses of ground ice has the potential to settle irregularly, albeit likely only modest (<1 m) amounts, if the ground thermal regime changes and the ice thaws. *Potential differential settlement following degradation of ice-moderate permafrost at the base of the mine waste poses a risk to the surface form of the facility.*	Moderate	Low	Low	Pre-strip overburden (as planned, AEG, 2017) at least within the areas of ice-moderate permafrost and/or be prepared to monitor and maintain the facility surface such that surface runoff is managed. Ensure upslope surface and near-surface runoff (active layer or to bedrock) are diverted around the facility (as planned, AEG, 2017), in order to inhibit water entry and retention.	Negligible	Low	Negligible

Facility	Hazard	Hazard Description	Likelihood (unmitigated)	Consequence (unmitigated)	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
	Solifluction (-S)	Two map units within the upper third of the facility footprint that are veneered by colluvium (Poly_ID 405) or blanketed by till (Poly_ID 403) exhibit solifluction. The gradual build-up of material against or on top of the western perimeter of the facility is less of a concern than the potential for mine waste placed on the soliflucting material to eventually creep downslope. *Continued solifluction at the base of the mine waste poses a long-term (post-closure) risk to the integrity and surface form of the facility, due to the potential for slow creep of mine waste within portions of the facility.*	High	Low	Moderate	Pre-strip overburden (as planned, AEG, 2017) at least within the areas of solifluction and/or be prepared to monitor and maintain the facility surface such that any localized creep does not impact the management of surface runoff. Ensure upslope surface and near-surface runoff (active layer or to bedrock) are diverted around the facility (as planned, AEG, 2017), in order to inhibit water entry.	Negligible	Low	Negligible
Class C Storage Facility The facility is proposed within a hanging valley that enters the Geona Creek valley from the east. NOTE: There are no notable risks to the collection pond at the base of the facility, or to the spur roads accessing it.	Solifluction (-S)	The northern and central thirds of the footprint are underlain by well drained till veneers to blankets and glaciofluvial landforms with no notable hazards. Conspicuous solifluction slopes, exhibiting both lobe and terrace forms, descend the north-facing valley side into the southern portion of the footprint (Poly_IDs 427, 428 and 432). The gradual build-up of material against or on top of the southern perimeter of the facility is less of a concern than the potential for waste rock placed on the soliflucting till to eventually creep downslope. *Continued solifluction at the base of the placed waste rock poses a long-term (post-closure) risk to the integrity and surface form of the facility, due to the potential for slow creep of waste rock within portions of the facility.*	High	Low	Moderate	Pre-strip overburden containing permafrost with excess ice and/or design the facility such that it anticipates and accommodates minor solifluction, depending on the results of site-specific investigations to support engineering design. Maintain positive surface drainage to discourage infiltration and water retention. Ensure upslope surface and near-surface runoff (active layer or to bedrock) are diverted around the facility (as planned, AEG, 2017), in order to inhibit water entry.	Negligible	Low	Negligible

Facility	Hazard	Hazard Description	Likelihood (unmitigated)	Consequence (unmitigated)	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
Upper Water Management Pond The pond is situated on the valley bottom of upper Geona Creek. NOTE: The spur road paralleling the eastern shoreline of the pond traverses the same map units and thus is exposed to the same hazards.	Active-layer detachments & retrogressive thaw slumping (-Xf)	The proposed shoreline traverses the base of the eastern valley side, which is covered by a veneer of colluvium overlying moderately sloping till inferred to contain ice-moderate permafrost (Poly_IDs 304 and 309). Inundating the lower valley sides will saturate unfrozen surficial materials (e.g., active layer), and initiate or accelerate permafrost degradation, both of which promote mass movement. Several, small active-layer detachments have occurred near the base of the eastern valley side, within and immediately up-valley of the proposed dam footprint. Although all the active-layer detachments were short-travelled, having maximum runouts of <10 m, they were up to 40 m wide and have locally triggered degradation of ice-moderate permafrost. This degradation has resulted in thickening of the active layer and minor upslope retrogression of the headscarp through thaw slumping. *This existing combination of active-layer detachments and retrogressive thaw slumping, which could be exacerbated following inundation, poses a risk to the stability of the dam through its effects on foundation materials and the possibility of overtopping by a displacement wave generated by a small mass movement (although any displacement waves from typical permafrost-related failures are likely to be small, rapidly attenuated and readily accommodated by the much larger pond). Excessive sedimentation could occur in the pond due to gradual thawing and erosion of shoreline materials, necessitating increased maintenance.*	High	Moderate	High	Pre-strip all overburden with permafrost (to bedrock or competent, ice-free material) within the pond and dam footprints, and extend stripping along the pond perimeter/berm, including the immediate upslope area. Ensure the dam foundation is keyed into competent, ice-free material. Monitor and manage (as required) the stripped areas above the pond perimeter/berm for deposition of localized mass movements. Where required, implement spur road construction techniques specifically designed for ice-rich permafrost (as per OEL, 2016). All mitigations identified above are planned by BMC (pers. comm., 2017).	Negligible	Moderate	Negligible

Facility	Hazard	Hazard Description	Likelihood (unmitigated)	Consequence (unmitigated)	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
Lower Water Management Pond The pond is situated on the valley bottom of upper Geona Creek. NOTE: The spur road paralleling the eastern shoreline of the pond traverses the same map units and thus is exposed to the same hazards.	Active-layer detachments & retrogressive thaw slumping (-Xf)	The proposed shoreline traverses the base of the eastern valley side, which is covered by a veneer of colluvium overlying moderately sloping till inferred to contain ice-moderate permafrost (Poly_IDs 304 and 309), and the base of the western valley side, which is covered by a blanket of till also inferred to have moderate ice content (Poly_ID 290). Inundating the lower valley sides will saturate unfrozen surficial materials (e.g., active layer) and initiate or accelerate permafrost degradation, both of which promote mass movement. Several, small active-layer detachments have occurred along the base of both valley sides, below and along the proposed shoreline. Although all the active-layer detachments were short-travelled, having maximum runouts of <20 m, they were up to 70 m wide and have locally triggered degradation of ice-moderate permafrost. This degradation has resulted in thickening of the active layer and minor upslope retrogression of the headscarp through thaw slumping. *This existing potential for active-layer detachments and retrogressive thaw slumping, which could be exacerbated following inundation, poses a risk to the stability of the dam through its effects on foundation materials and the possibility of overtopping by a displacement wave generated by a small mass movement (although any displacement waves from typical permafrost-related failures are likely to be small, rapidly attenuated and readily accommodated by the much larger pond). Excessive sedimentation could occur in the pond due to gradual thawing and erosion of shoreline materials, necessitating increased maintenance.*	High	Moderate	High	Pre-strip all overburden with permafrost (to bedrock or competent, ice-free material) within the pond and dam footprints, and extend stripping along pond perimeter/berm, including the immediate upslope area. Ensure the dam foundation is keyed into competent, ice-free material. Monitor and manage (as required) the stripped areas above the pond perimeter/berm for deposition of localized mass movements. Where required, implement spur road construction techniques specifically designed for ice-rich permafrost (as per OEL, 2016). All mitigations identified above are planned by BMC (pers. comm., 2017).	Negligible	Moderate	Negligible
Overburden Stockpile The stockpile is proposed midslope on the gentle, southwest-facing valley side of upper Geona Creek. NOTE: There are no notable risks to spur roads accessing the facility.	Thermokarst subsidence (unmapped; potential only)	One map unit encompassing most of the collection pond and a topsoil stockpile immediately downslope, and extending to the base of the facility, exhibits a colluvial veneer overlying a blanket of till inferred to have a moderate ice content (Poly_ID 334). Till containing seams or small lenses of ground ice has the potential to settle irregularly, albeit likely only modest (<1 m) amounts, if the ground thermal regime changes and the ice thaws. *Potential differential settlement following degradation of ice-moderate permafrost at the base of the stockpiled topsoil/overburden and the collection pond poses a risk to the surface form of the facilities.*	Moderate	Low	Low	Pre-strip overburden containing permafrost with excess ice and/or be prepared to monitor and maintain the facility surface such that surface runoff is managed as anticipated. Ensure upslope surface and near-surface runoff (active layer or to bedrock) are diverted around the facility (as planned, AEG, 2017), in order to inhibit water entry and retention.	Negligible	Low	Negligible

Facility	Hazard	Hazard Description	Likelihood (unmitigated)	Consequence (unmitigated)	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
Process Plant, Water Treatment Facility and Mill Site The facility is proposed on the gentle, lower slope of the western valley side of upper Geona Creek, between the bases of the Class A and B Storage Facilities. NOTE: There are no notable risks to spur roads accessing the facility.	Thermokarst subsidence (unmapped; potential only)	Most of the facility is encompassed by map units characterized as relatively thin till blankets inferred to have moderate ice contents (Poly_IDs 332, 353, 361 and 366). Till containing seams or small lenses of ground ice has the potential to settle irregularly, albeit the materials are so thin in this case that potential settlement does not constitute a risk.	Moderate	Negligible	Negligible	N/A	Moderate	Negligible	Negligible

Table 6-2. Evaluation of risks posed by terrain hazards to the proposed access road (including existing sections)

Kilometre Range	Hazard	Hazard Description	Likelihood	Consequence	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
1.24-1.26	Thermokarst subsidence (-Xt)	The existing/proposed road crosses a narrow portion of a map unit characterized by a thin veneer of fluvial sediments overlying an ice-rich blanket of till (Poly_ID 10). There is already evidence of thermokarst subsidence within the map unit. *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Moderate	Moderate	Moderate	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
3.37-3.41	Thermal erosion (-Xe)	The existing/proposed road crosses the head of a large gully incised through a glaciofluvial cap into a thick blanket of ice-rich till (Poly_ID 46). There is no obvious evidence of active thermokarst gullying within the map unit, but the road crosses the gully at a prominent knickpoint, increasing its susceptibility to impact from possible upstream migration and associated down-cutting of the stream bed. *The short segment of road is at risk of differential settlement and down-cutting through knickpoint migration in response to potential degradation of ice-rich permafrost.*	Low	High	Moderate	Monitor knickpoint position and implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Low	Negligible	Negligible
4.37-4.61	Thermal erosion (-Xe)	The existing/proposed road crosses a narrow portion of a map unit characterized by a thick, ice-rich till blanket that exhibits active slopewash and thermokarst gullying (Poly_ID 51). Ponding along the road edge is contributing to permafrost degradation. *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Moderate	Moderate	Moderate	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
4.95-5.04	Thermal erosion (-Xe)	The existing/proposed road crosses a narrow map unit characterized by a thin veneer of fluvial sediments overlying an ice-rich blanket of till. There is already evidence of active thermokarst gullying within the map unit (Poly_ID 59) and an immediately adjacent one (Poly_ID 67), and a road sign approaching the crossing warns of icy conditions (seasonally), which KZK Project camp staff confirmed relates to prolonged seepage onto the road surface. *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Moderate	Moderate	Moderate	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
5.76-5.81	Thermal erosion (-Xe)	The existing/proposed road crosses a thermokarst gully that has incised into the underlying thick, ice-rich till blanket. The gully exhibits active thermokarst gullying, especially downslope of the road crossing where vertical scarps of ice-rich permafrost are exposed and the stream now flows subsurface through a 2 m-diameter 'tunnel' before emerging 40 m farther downslope (Poly_ID 67). *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Moderate	High	High	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016). As an additional contingency, be prepared to realign the road slightly westward.	Negligible	High	Negligible

Kilometre Range	Hazard	Hazard Description	Likelihood	Consequence	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
6.52-7.13	Thermal erosion (-Xe)	The existing/proposed road crosses several contiguous map units characterized by thick deposits of ice-moderate to ice-rich till (Poly_IDs 82, 83 and 88), which locally exhibits thermokarst gullying, particularly downslope of the road where bank collapses are widespread (Poly_ID 83). *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Moderate	Moderate	Moderate	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
7.51-7.56	Thermal erosion (-Xe) (unmapped; potential only)	The existing/proposed road crosses a narrow portion of a map unit characterized by a thick, ice-rich till blanket (Poly_ID 92) that exhibits slopewash and thermokarst gullying a short distance downslope (Poly_ID 93). *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Low	Moderate	Low	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
7.56-7.69	Thermal erosion (-Xe)	The existing/proposed road traverses a gently sloping, thick blanket of till, discontinuously veneered by glaciofluvial sediments (Poly_ID 93). The crest of the scarp that forms the wall of the main incised valley is within 55 m of the road. Several thermokarst gullies descend the valley wall to the floodplain of Finlayson Creek. One of the thermokarst gullies has formed recently and is actively deepening, widening and retrogressing upslope. More than 1 m of ice-rich till, with a visually estimated volumetric ice content of >50%, is exposed in the vertical sidescarp of the gully. The gully has grown from approximately 2 m deep and 20 m wide in the summer of 2016 to approximately 6 m deep and 35 m wide in September 2017. Its headscarp is 55 m from a small CSP culvert that concentrates upslope drainage beneath the road, possibly including active-layer throughflow from the adjacent slopewash polygon. Rapidly thawing permafrost is producing debris flows that have entered Finlayson Creek (Poly_ID 64). *The continued retrogression of this or an adjacent 'dormant' thermokarst gully, or the formation and extension of a new one, poses a risk to the stability of the road.*	Low	High	Moderate	Install additional culverts beneath the road and/or use permeable subgrade material, in order to diffuse the drainage and avoid unnatural concentrations of surface runoff that can initiate or exacerbate thermokarst gullying. Monitor the rate of retrogression of the headscarp toward the road, and, as a contingency, be prepared to realign the road slightly westward (upslope) if necessary. Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	High	Negligible
8.22-8.30	Thermal erosion (-Xe)	The existing/proposed road crosses a narrow map unit characterized by a thin veneer of fluvial sediments overlying an ice-rich blanket of till (Poly_ID 107). There is possible evidence of thermokarst gullying (bank collapses) downstream of the road, within the better defined gully (Poly_ID 97). *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Low	Moderate	Low	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible

Kilometre Range	Hazard	Hazard Description	Likelihood	Consequence	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
8.30-8.70	Thermokarst subsidence (-Xt)	The existing/proposed road crosses a map unit characterized by an ice-rich blanket of till, possibly exhibiting the subtle surface expression of ice-wedge polygons (Poly_ID 105). There is early evidence of thermokarst subsidence in the immediate vicinity of the road: tilted, straight trees; hummocky micro-topography; and small ponded areas. *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Moderate	Moderate	Moderate	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
9.05-9.11	Thermokarst subsidence (-Xt) & retrogressive thaw slumping (-Xf)	The existing/proposed road crosses a narrow portion of a map unit characterized by a thin veneer of fluvial sediments overlying an ice-rich blanket of till (Poly_ID 111). There is already evidence of active thermokarst subsidence, four thaw ponds, within the map unit. The 1-3 m-high vertical headscarp of a small retrogressive thaw slump that formed shortly before 2016 is within 0.8 m of the downslope road edge (September 11, 2017), which is at immediate risk of being undercut and collapsing without intervention. Ponded water at the base of the headscarp has at least partly accumulated from the thawing of underlying ice-rich permafrost, an occurrence that promotes further thaw through the positive feedback cycle that develops. *The short segment of road is at immediate risk of at least partial collapse and differential settlement in response to continued degradation of ice-rich permafrost.*	High	High	Very High	Consider realigning the road slightly westward such that it is set-back from the adjacent valley wall while not encroaching on the actively subsiding ground around the thaw ponds. Attempts to stabilize the road by placing rock against the headscarp may be ineffective, as this cannot fully address the thawing that has begun. Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	High	Negligible	Negligible
9.68-9.79	Thermal erosion (-Xe)	The existing/proposed road crosses a narrow map unit characterized by a thin veneer of fluvial sediments overlying an ice-rich blanket of till (Poly_ID 122). There is already evidence of active thermokarst gullying within the map unit, albeit not in the immediate vicinity of the road crossing. *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Low	Moderate	Low	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
11.20-11.44	Thermokarst subsidence (-Xt)	The existing/proposed road crosses a map unit characterized by an irregular mantle of glaciofluvial sediments overlying an ice-rich blanket of till (Poly_ID 145). There are already two identified thaw ponds indicating active thermokarst subsidence within the map unit. One of these ponds is within 35 m of the road. *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Moderate	Moderate	Moderate	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible

Kilometre Range	Hazard	Hazard Description	Likelihood	Consequence	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
11.44-11.79	Thermokarst subsidence (-Xt) (unmapped; potential only)	The existing/proposed road crosses a map unit characterized by a thick, ice-rich till blanket (Poly_ID 150). Although there is no evidence of active thermokarst subsidence, it could initiate given its occurrence in the immediately adjacent, similar map unit (Poly_ID 145). *The short segment of road is at risk of differential settlement in response to potential degradation of ice-rich permafrost.*	Low	Moderate	Low	Implement road upgrades with a thick gravel prism (and include an allowance for additional material placement and maintenance), minimal disturbance to adjacent ground, and minimal to no concentration of drainage (e.g., as per the typical cross-section for ice-rich permafrost, OEL, 2016).	Negligible	Moderate	Negligible
23.61-23.66	Solifluction (-S)	The proposed road crosses a narrow portion of a map unit characterized by a relatively thin blanket of till, exhibiting solifluction and inferred to have a moderate ice content (Poly_ID 403). The short segment of road is prone to minor downslope creep, although at typical solifluction rates of mm/yr to cm/yr it does not constitute a credible risk over the anticipated 10-year mine life. Furthermore, differential settlement in response to potential degradation of ice-moderate permafrost within a relatively thin till blanket will likely be minimal and not constitute a credible risk.	High	Negligible	Negligible	N/A	High	Negligible	Negligible
23.75-23.85	Solifluction (-S)	The proposed road crosses a narrow portion of a map unit characterized by a relatively thin blanket of till, exhibiting solifluction and inferred to have a moderate ice content (Poly_ID 403). The short segment of road is prone to minor downslope creep, although at typical solifluction rates of mm/yr to cm/yr it does not constitute a credible risk over the anticipated 10-year mine life. Furthermore, differential settlement in response to potential degradation of ice-moderate permafrost within a relatively thin till blanket will likely be minimal and not constitute a credible risk.	High	Negligible	Negligible	N/A	High	Negligible	Negligible
23.94-24.04	Solifluction (-S)	The proposed road crosses a narrow portion of a map unit characterized by a relatively thin blanket of till, exhibiting solifluction and inferred to have a moderate ice content (Poly_ID 403). The short segment of road is prone to minor downslope creep, although at typical solifluction rates of mm/yr to cm/yr it does not constitute a credible risk over the anticipated 10-year mine life. Furthermore, differential settlement in response to potential degradation of ice-moderate permafrost within a relatively thin till blanket will likely be minimal and not constitute a credible risk.	High	Negligible	Negligible	N/A	High	Negligible	Negligible
24.34-24.61	Solifluction (-S) & active-layer detachments (-Xf)	The proposed road crosses map units characterized by a relatively thin blanket of colluvium (Poly_IDs 402 and 405), exhibiting solifluction and localized tension cracks within the solifluction material, indicative of minor active-layer detachment. The short segment of road is prone to minor downslope creep, although at typical solifluction rates of mm/yr to cm/yr it does not constitute a credible risk over the anticipated 10-year mine life. *Very localized and short-travelled active-layer detachments pose a risk primarily for road maintenance.*	Moderate	Moderate	Moderate	Ensure road cuts are gentle (at least 2H:1V), avoid unnecessary concentration of drainage, and be prepared for periodic ditch maintenance.	Moderate	Negligible	Negligible

Kilometre Range	Hazard	Hazard Description	Likelihood	Consequence	Risk (unmitigated)	Mitigation Opportunities	Likelihood (mitigated)	Consequence (mitigated)	Residual Risk (mitigated)
24.61-25.33	Solifluction (-S)	The proposed road crosses a map unit characterized by a relatively thin blanket of till, exhibiting solifluction and inferred to have a moderate ice content (Poly_ID 403). The short segment of road is prone to minor downslope creep, although at typical solifluction rates of mm/yr to cm/yr it does not constitute a credible risk over the anticipated 10-year mine life. Furthermore, differential settlement in response to potential degradation of ice-moderate permafrost within the relatively thin till blanket does not pose a credible risk.	High	Negligible	Negligible	N/A	High	Negligible	Negligible
26.33-26.36	Debris slides & rockfall	The proposed road crosses a narrow map unit characterized by a densely-gullied, steep scarp that exposes a thick blanket of till overlying bedrock (Poly_ID 465). Shallow debris slides and rockfall occur on the erosional scarp alongside lower Fault Creek, immediately upstream of its alluvial fan apex, although the alignment is proposed at the lowermost, gentler end of the scarp. *The short segment of road is at risk from periodic debris slides and rockfall.*	Moderate	Moderate	Moderate	Consider realigning the road slightly downslope to avoid descending the low scarp, or ensure re-grading alleviates the over-steepened sections of scarp that produce debris slides and rockfall.	Moderate	Negligible	Negligible
26.36-26.76	Debris floods	The proposed road crosses the large, active alluvial fan at the mouth of Fault Creek (Poly_ID 461), which drains a mountainous basin west of Geona Creek. In addition to being prone to normal (clearwater) floods, Fault Creek also exhibits a history of recurrent debris floods. A debris flood that transported and deposited gravels to the maximum limits of the alluvial fan along two distributary channels occurred between 1986 and 1992, based on comparison between historical aerial photographs, which is consistent with a minimum age of 21 years derived dendrochronologically from the tallest willow in the cleared path of the flood event. Earlier events appear to have occurred along similar paths prior to 1949 (the earliest available aerial photograph). Debris floods likely occur during intense/prolonged rainfall events following saturation and sudden mobilization of in-channel debris that has accumulated from frequent debris slides originating along the steep gully sidewalls. *Debris floods (and normal floods) pose a risk to the road, given their potential to overtop and rapidly erode its embankment, or deposit large volumes of sediment on its surface within a short timeframe.*	Moderate	High	High	Construct a diversion ditch and berm (as planned, Drawing C560, KP, 2016b), beginning at the apex of the fan, to divert floods/sediment into the abandoned channel west of the current channel, thereby minimizing cut/fill requirements. Sufficient cross-sectional area must be available in the excavated diversion channel to accommodate floodwaters and rapid aggradation along the bed.	Moderate	Negligible	Negligible

7. Conclusion

Terrain stability and hazard mapping completed for the KZK Project presents the distribution and characteristics of terrain units, geomorphological processes and hazards within a 64 km^2 study area that encompasses the proposed mine site and its access road from the Robert Campbell Highway. This report and its accompanying maps support project planning and a response to YESAB's IR R162. A disturbed terrain stability class, representing projected conditions in the absence of planned mitigation measures, was distinguished from the existing stability class in order to highlight areas that warrant attention. The assessment of credible risks to the Project indicates how planned mitigations can be incorporated to address the site-specific hazards. Several key results warrant highlighting:

- Morainal (till) deposits are the most widespread surficial material within the study area, ranging in thickness from <0.5 m on ridges and upper slopes in the mine site area to more than 10 m in lower slope and valley bottom settings along the northern portion of the access road corridor.
- The primary mass movement hazards that may affect the footprints of the proposed mine facilities and access road, where not avoided or mitigated, are active-layer detachments, thermokarst subsidence, thermal erosion, solifluction and debris floods.
- Several actively incising thermal erosion gullies that cross or begin downslope of the access road reveal ice-rich permafrost within till. Road upgrades in areas of ice-rich permafrost should minimize the concentration of surface- and near-surface drainage in ditches and culverts in order to avoid or minimize thermokarst activity. Potential upslope migration of gully-bottom knickpoints currently situated downslope of the road should also be anticipated and accommodated.
- Glaciofluvial sand and gravel mantles extensive portions of the ice-rich till along the central to northern portion of the access corridor, giving the appearance at surface of stable, permafrost-free ground, but it cannot fully buffer the effects of ground disturbance. Such areas should be managed with consideration for the underlying ice-rich permafrost.
- The southern portion of the Open Pit is proposed to extend well into the area currently occupied by the active alluvial fan at the mouth of Fault Creek. Recurrent debris floods necessitate diversion of the channel to safely convey floodwater and sediment away from the Open Pit, with a channel design that accommodates rapid aggradation (infilling) during the cessation of a debris flood.
- Solifluction is widespread and active on the valley sides and in the upper basins above the proposed mine site. Solifluction transports material slowly downslope at rates of a few millimetres to centimetres per year, so it does not represent a credible risk to the proposed access road over a ten-year mine life. However, placement of mine waste or waste rock directly on soliflucting materials with excess ice is not advisable within the Class A, B or C Storage Facilities, given the increased potential for creep-related instabilities to develop during operations and continue post-closure.
- The Upper and Lower Water Management Ponds are proposed to be constructed along a section of Geona Creek valley that exhibits numerous, short-travelled, active-layer detachments and related retrogressive thawing along the base of the valley sides. Care should be taken to pre-strip all overburden containing permafrost with excess ice, at least in the footprint of the proposed dams, such that they can be keyed into competent, ice-free material.

- This study has demonstrated where and how project-related construction and/or climate change may affect terrain stability and hazards over the ten-year mine life. All credible risks posed to project infrastructure by the hazards can be reduced to acceptable, residual levels through the implementation of planned and additional recommended mitigation measures.

8. Statement of Limitations

This report (including its appended maps) has been prepared by the Consultant (Coregeo and Associates) for the benefit of the Client (BMC Minerals (No. 1) LTD) in accordance with the agreement between Consultant and Client, including the scope of work detailed therein (the "Agreement"). The report and the information it provides may be used and relied upon only by Client, except (1) as agreed to in writing by Consultant and Client, (2) as required by-law, or (3) to the extent used by governmental reviewing agencies for the purpose of obtaining permits or approvals.

The extent of this study was limited to the specific scope of work for which we were retained and that is described in this report. Coregeo and Associates has assumed that the information and data provided by the client or any secondary sources of information are factual and accurate. Coregeo and Associates accepts no responsibility for any deficiency, misstatement or inaccuracy contained in this report as a result of omissions, misinterpretations or negligent acts from relied-upon data. Judgment has been used by Coregeo and Associates in interpreting terrain stability and hazards based on desktop-based interpretation calibrated by field observations at sites representative of the diversity of conditions within the study area. Ground conditions may differ from those interpreted at a polygon scale, even where investigated in the field, due to inherent variability in terrain characteristics.

Coregeo and Associates is not a guarantor of the terrain, permafrost or hazard conditions within each of the mapped polygons, or of the related risk classifications (where applicable), but warrants only that its work was undertaken and its report prepared in a manner consistent with the level of skill and diligence normally exercised by competent geoscience professionals practicing in Yukon. Our findings, conclusions and recommendations should be evaluated in light of the limited scope of our work.

9. Certification

This report was prepared by:

Robin McKillop, M.Sc., P.Geo.
Principal, Geomorphologist
Palmer Environmental Consulting Group Inc.

Dave Sacco, M.Sc.
Terrain Mapping Specialist
Palmer Environmental Consulting Group Inc.

Ethan Allen, M.Sc.
Principal, Environmental Geoscientist
Core Geoscience Services Inc.

This report was reviewed by:

Derek Turner, Ph.D., P.Geo.
Quaternary Geologist

Eri Boye, M.Sc., P.Geo.
Principal, Geoscientist
Core Geoscience Services Inc.

BMC MINERALS

Terrain mapping completed by D. Sacco and R. McKillop using softcopy photo-interpretation systems at a view (zoom) scale of 1:10,000, following field reconnaissance conducted in September 2017. Terrain codes are from the Yukon Geological Survey's adaptation of the Terrain Classification System for British Columbia (Howes and Kenk, 1997). Typical textures inferred based on observed landform associations.

COMBINATION OF INFLUENTIAL DISTURBANCE AND APPLICABLE HAZARD CATEGORY (OVERLAY)*

(no fill) "Construction-related disturbance influence" and "Slope failure potential is dominant"

Both "Construction- and climate change-related disturbance influence" and "Thermokarst potential is dominant"

Both "Construction- and climate change-related disturbance influence" and "Slope failure and thermokarst potential are co-dominant"

*Overlays distinguish whether construction, climate change or both are likely to affect terrain stability, and whether the changes are likely to be associated with an increase in the potential for slope failure, thermokarst or both. Despite consideration of all possible combinations of influential disturbances and applicable hazard categories, only the three identified above apply to this study area.

NOTES:
1. Refer to "Terrain Stability, Hazards and Risk Code Definitions" cover pages for definitions of all terminology, and refer to Terrain Map for complete terrain polygon labels (including slope class, drainage and relative ice content of permafrost).
2. Disturbed terrain stability class represents projected conditions following disturbance to ground conditions from climate change and/or from project-related facility or road construction without mitigation.
3. Risk classifications depicted for the proposed infrastructure/facility footprints reflect the highest (most conservative) risk posed by one or more hazards. Refer to accompanying report for a full breakdown of the hazard-specific risks.

- IV Potentially unstable
- V Unstable

COMBINATION OF INFLUENTIAL DISTURBANCE AND APPLICABLE HAZARD CATEGORY (OVERLAY)*

(no fill) "Construction-related disturbance influence" and "Slope failure potential is dominant"

Both "Construction- and climate change-related disturbance influence" and "Thermokarst potential is dominant"

Both "Construction- and climate change-related disturbance influence" and "Slope failure and thermokarst potential are co-dominant"

*Overlays distinguish whether construction, climate change or both are likely to affect terrain stability, and whether the changes are likely to be associated with an increase in the potential for slope failure, thermokarst or both. Despite consideration of all possible combinations of influential disturbances and applicable hazard categories, only the three identified above apply to this study area.

NOTES:
1. Refer to "Terrain Stability, Hazards and Risk Code Definitions" cover pages for definitions of all terminology, and refer to Terrain Map for complete terrain polygon labels (including slope class, drainage and relative ice content of permafrost).
2. Disturbed terrain stability class represents projected conditions following disturbance to ground conditions from climate change and/or from project-related facility or road construction without mitigation.
3. Risk classifications depicted for the proposed infrastructure/facility footprints reflect the highest (most conservative) risk posed by one or more hazards. Refer to accompanying report for a full breakdown of the hazard-specific risks.

Appendix G: Field Mapping Notes

This appendix contains summaries from 2017 traverses during the Phase I and II mapping programs.

Table G-1: Traverse Summaries

Traverse Number	Summary
MBaknes2017-08-05	Wolverine Cirque, remapped the western part of the July 24 traverse and overwrote that data, archived in the MBaknes23Jul2017 folder.
MBaknes2017-07-23	West of the deposit, encountered intervals of RHYi and MAFi in contact, RHYi and MAFi. They are thin here, indicating the feathering out of the favourable elements
MBaknes2017-07-24	Wolverine Cirque, QE SDScrb and clean SDS local thin RHYcf tuffs or sills (GRApor) , up section abund seds and RHYva need to confirm may have reached Wind Lk
MBaknes2017-07-25	Wind Lk mafics crb phyllite, strong Ak alt, get to top of KZK, RHYva-QE, WCK, RHYif tuff or sills
MBaknes2017-07-26	
MBaknes2017-07-27	
MBaknes2017-07-28	Section of RHYvx and RHYcw lies between two sills or tuff horizons of RHYif, the RHYvx is pyritic and may be weakly MU altered, no clear evidence of the intrusive or tuffaceous nature of the porphyry
MBaknes2017-07-29	Bottom of RHYi section transitions into RHYva, with minor MDS and PEL, Is the Felsic section emplaced into Wind Lake ie thats why Wind Lake is on FW and HW
MBaknes2017-07-30	Down section from RHY peak, RHYi-RHYva-RHYva(crb)-MDS-Normal fault-MDS-MAFi-SED(SDS SLT SLTcrb)-Felsic section, Considered that some of RHYi textures could indicate Ignimbrite genesis, Lower felsic section is almost 200 m down section from the base of KZK
MBaknes2017-07-31	
MBaknes2017-08-01	Into intervals of RHYva MAFt,i PEL, traverse not complete, end at a very convincing fault that traces through 3 saddles
MBaknes2017-08-02	Traversed down section, through MAFt and recessive mudstones and at the bottom before hitting the GRA a conformable body of pyroxenite traceable for 1300m. Could this pyroxenite be a feeder to the MAFi footwall at ABM and\or an indicator of high temperature or structural conduit
MBaknes2017-08-03	Encountered pillowed basalt and pillow breccia within Wind Lake. Pale green chloritic schist was often marginal to the flows and probably represented more intensely altered and deformed hyaloclastite and mafic volcaniclastic. This provides evidence that mafic units within Wind Lake and the top of KZK are in fact mafic clastics. Patchy CP was noted in the Basalts. Carbonaceous sediments and clean sandstones (quartzites) are footwall to the Basalts and probably represent Wind Lake. There appears to be very little of the KZK felsic interval on this ridge. Wind lake sandstones go directly into strongly foliated feldspar porphyry (GRApor) followed by a narrow interval of tuffaceous mudstones and then GRApor for the remainder. There is little chance of outcrop further south as till appears to blanket all lower elevations.
MBaknes2017-08-04	Structurally above GP4F drilled section, mostly FD porphyry and strongly strained FD porphyry – GRApor. Many intervals of pelite, likely indicating the silling out of the Grass Lakes pluton. Good RHYi noted, which is a positive exploration criteria. The volume of GRApor sills in the hanging-wall makes me wonder about how much of the porphyry in GP4F is post mineral assuming the GRApor is post mineral (which might be incorrect).
MBaknes2017-08-05	West end of the “Wolverine” cirque, more GRApor than mapped the first time and also noted felsic tuff with distinct mudstone lapilli. Also mapped a narrow interval of RHYcw, which seems peculiar given the setting, could it be a megaclast?? The mudchip lapilli along with the preponderance of QE sandstones and carbonaceous sandstones suggest a high energy basin. Definitely get into Wind Lake so can connect with Darcy’s traverse. Continued on the south extreme of the ridge SSE of Rhyolite Peak. Noted an abundance of MAFt and also MAFi over a distance of +400 m with recessive units in between. Might this be Fire Lake stratigraphy?? A negative interp of the 200 m thick felsic section is that it

Traverse Number	Summary
	could possibly be a highly deformed GRApor and not an extrusive sequence. That would mean the interval has minimal mineralization potential.
MBaknes2017-08-06	A) South end of ridge east of Deposit valley and then north along deposit valley. Lowest part of traverse is salt and pepper felsites, confirmed to be weakly foliated, defined by BI, granite, with poorly exposed intervals of sediment. Climbing up stratigraphy, the remainder of the traverse made up of coherent rhyolite, consisting of tan coloured fine grained, granular rhyolite with rare QZ and FD phenocrysts. This unit likely a deeper and slightly more crystalline phase of RHYi. Southern end of SSE ridge off of Rhyolite Peak. Dominantly mafic rocks with some possible felsic intervals. The mafic sequence is faulted and pervaded by gossanous quartz veins. This might be part of the structural target constituting the RBI minfile occurrence 105G 126. The lowest part of the traverse encountered dark green basalt or ultramafic and one outcrop of pyroxenite similar to pyroxenites mapped on the next ridge to the west. The mafic sequence is distinct from the KZK and Wind Lake mafics and probably belongs to Fyre Lake stratigraphy, as indicated on Murphy's map.
MManor2017-08-01	First day mapping with Darcy. Traversed south to north; started in Grass Lake granite and encountered multiple sills? of biotite-carbonate-rich rock – maybe lamprophyres or pelite? Few occurrences of feldspar porphyry thought to be related to Grass Lake plutonic suite. Transitioned into sediments (sandstone and mudstone) down-dip at the end of the day.
MManor2017-08-02	Returned to traverse where left off the previous day. Began in sediments, then found a large section of feldspar porphyry dike that may be stratabound to sediments. Walked back up-ridge to find more sediments (dominantly sandstone with intercalated mudstone) and felsic volcaniclastics. Helicopter move at 2pm – top of ridge where began the previous day. Walked down south ridge; dominantly equigranular feldspar augen granites with a section of felsic volcaniclastics.
MManor2017-08-03	Traversed north to south in SE portion of property claims. The first ridge was all massive quartzite, then transitioned into felsic and mafic volcaniclastics on the first saddle. Second ridge top had large outcrop of feldspar augen porphyry (interpreted as Grass Lakes Plutonic Suite) that was strongly strained in places with elongate feldspar crystals. Down slope were more mafic tuffs and two outcrops (plus more subcrops) of massive pillow basalts. Ended the traverse with more feldspar porphyry rocks.
MManor2017-08-04	Long traverse to try finding outcrop. Began on ridge just east of ABM. Plenty of rocks on top of ridge, mainly sediments and mafic tuffs. Dropped down into valley and no outcrop until end of traverse on top of ridge directly east of camp. Mafic tuffs to end.
MManor2017-08-05	Started traverse with a lot of outcrop seen on historical maps, south to north from Repeater Mtn to camp. Many small outcrops of sediments and mafic tuffs, varying from ash to lapilli tuffs. Followed two glacial wash channels, where there was good exposure of stratigraphy, interlayering of mudstone/siltstone and mafic tuff. Ended day in valley with 25 metre-high mafic lapilli tuff outcrops and an odd occurrence of intermediate (andesite-dacite?) feldspar augen porphyry with biotite porphyroblasts; feldspar alters completely to calcite.
RHulstein2017-08-01	Traversed south to north; predominantly felsic volcaniclastics for first half of traverse to the large recessive saddle (regional fault mapped by YGS), followed by: siltstone, volcaniclastics ± qtz ± feld phenocrysts, minor pelite and feldspar porphyry.
RHulstein2017-08-02	Traversed south to north; Mostly porphyritic feldspar units (initially coded-mapped as RHYif) separated by narrower bands of PEL, MAFt and RHYv units (the MAFt is invariably found in close proximity to the PEL). The RHYif units subsequently recoded to GRA (Grass Lakes) although there is nothing homogenous or similar between the various feldspar porphyries (± minor qtz including rare 1 mm size blue qtz eyes).
RHulstein2017-08-03	Traversed west to east; outcrops consisted of genuine MDSc overlain by massive qtz veined quartzite (mapped as SDS), at approximately midway (at rock hand sample site RH17080) an outcrop of MAFw overlies a silica banded RHY unit containing traces of malachite. THIS NEEDS TO BE GEOCHEM SAMPLED. Remainder of traverse to end consists of lesser MAFw outcrops and more abundant SDS units with variable CRB and SLT.
RHulstein2017-08-04	Went from South to North: Started and stayed in Wind Lake rocks of Mafi and siltstones.
RHulstein2017-08-05	Went from South to North: started in RHYv with fairly abundant RHYi cut by meter scale qtz veins. Small patches of MDSc to north and at approximately midway a big slug of homogenous Grass Lakes porphyry followed by siltstones, RHYv and MAFi to end of traverse.

Traverse Number	Summary
RHulstein2017-08-06	First traverse on east side of property down the creek; Various types of GRA feldspar POR to end of traverse. Several Cominco outcrops not found but could be due to difficulty of finding small outcrops in thick bush. Afternoon traverse in cirque south of 6800' peak; collected pyroxenite sample, MAFt, minor thin MAFi flows and abundant micaceous thinly 'laminated' siltstone going upstream from below pyroxenite outcrop. Outcrop of GRA feldspar POR at head of cirque.
RVoordouw2017-08-02	Started in Grass Lakes Suite, followed by finely laminated sedimentary rocks (first coded as SED, then SLT) and then back into Grass Lakes. Then walked back into SED (coded as SLT) followed by RHYv at the northwestern end of the traverse. Doubled back to confirm outcrops off the side of the ridge were the same as those on top (they were) as there were some discrepancies with Cominco mapping (mostly Grass Lakes was coded as MAFi)
RHulstein2017-08-08	Traversed from highest point on LIMY claims to SE corner, up to NE and then to midpoint north of highest peak. Only grey weathering light grey fine to medium grained limestone, commonly fractured, noted, some minor calcite veining observed (10-20 cm wide and spaced 3-5+ m in south central to SE corner of the property) , no obvious bedding or S1 cleavage, crinoids noted in some samples. Collected samples D00005851 - 5862.
MManor2017-08-06	Started day mapping the tote road near weather station, and up to the weather station. Continued north past previous day's traverse end and continued back to camp. Bumped to southwest corner of property to finish off southernmost traverse in Grass Lakes pluton. More equigranular medium-coarse grained augen granite with minor fspar porphyry dikes.
MManor2017-08-08	B) Traversed from highest point on Limy claims to the west and circled back around to the south to try finding the contact of limestone and metasediments/metavolcanics. No outcrop was below 1330m contour, so no contact was determined. Continued on upper contour around base of the peak and finished in the northern part of the claims. Limestone mostly homogenous throughout area. Collected 10 samples about every 100-200 m spacing; D00005901-5910.
MManor2017-08-09	Ground truthed CSA advanced targets and fill in gaps in RHYi/RHYv units west of ABM. Checked out 3 targets north of Rhyolite peak and south of Repeater Mtn. Same traverse as RHulstein in CSA targets 007-009.
RHulstein2017-08-09	Ground truthed CSA advanced targets (KZK-007, 008 and 009) and filled in gaps - traced out RHYi units west of ABM. No outcrop or subcrop in CSA targets KZK-007 and 009, found some small scattered outcrops of SLT and one MAFt in target KZK-008.
MManor2017-08-10	Started on Rhyolite peak, worked N-NE down talus slope finding subcrops of RHYi, mapped talus distribution on slope. Sampled RHYi units down-slope for geochem/terraspec. Descended into Fault Creek valley to assess CSA early target KZK-012, mapped new RHYv+GRApor to fill in map and hope to constrain interpreted map units.
MManor2017-08-11	Dropped at bowl on top of Fault Creek. Walked up slope to find GRApor, then down the creek to fill in gaps in outcrop, but few found. Traversed NE to CSA target KZK-004, finding outcrop at margin but none inside. Collected samples for terraspec along the way and one RHYi for geochem. Finished day reassessing MAFi unit at bottom of Fault Creek, determining that it is actually intensely altered RHYv.
RHulstein2017-08-10	Started on Rhyolite peak, established minimum area of RHYi on peak, went down north slope, encountered RHYv, significant MDSc (in terms of subcrop area and carbon content) and noted start of RHYv float at lower elevation. Collected RHYi sample for whole rock analyses. Located true MAFi at end of traverse (upslope of CSA KZK-006 target).
RHulstein2017-08-11	Dropped at bowl on top of Fault Creek. Walked up slope to find GRApor, then to south and east to look for outcrop, but none found until back at ridge, on south side of Fault Creek. Traversed NE to CSA target KZK-004 examining previously mapped outcrops and locating new ones. Finished day at altered MAFt outcrop at bottom of Fault Creek near road.
MManor2017-08-12	Started day in valley on SW property claim. Mapped side of ridge for the morning, saw MAFi, MAFt, seds, and fspar porphyry. Walked S to GP3L target, found abundant GRA augen granite with siltstone and mudstone interbedded (intruded?) in central/western part but not much east in the heavy bush near old drill hole K96-171. Walked east to the creek hoping to find more outcrop but came up dry. Ended traverse by creek.
RHulstein2017-08-12	Started day in valley on SW property claim. Mapped side of ridge for morning, saw MAFi, MAFt, seds, and fspar porphyry. Walked S to GP3L target proper, found GRA-POR layered with MAFt and PEL and augen granite in central/western part; MDS and MAF below and SW of old drill hole K96-171. The later MAF unit may be a fine grained ultramafic body.

Traverse Number	Summary
MManor2017-08-13	Goal today to check off CSA advanced target KZK-002. Started at ridge and chased Wind Lake-KZK contact on top only to find frost heave(?) patches. Descended on western part of target and zig-zagged down slope. No outcrop except after noon - MAFt and RHYv/vl with some odd MAFw(?) with epidote-actinolite-garnet alteration (could this be a mafic flow top?).
MManor2017-08-14	Dropped at top of ridge and worked south along western slope of ridge. Found variety of sediments, volcaniclastics, and porphyry outcrops. Worked back north and then down slope to CSA target 001. No outcrop in target. Finished in valley.
MManor2017-08-15	Dropped at top of cirque and worked down the slope toward pond and CSA target KZK-013. Found one outcrop of MAFt and scree patches of RHYvx - close to contact? No outcrop in target. Picked up west of pond.
MManor2017-08-16	Spent the morning assessing and sampling the rocks in SW corner of property - are these related to Fire Lake Fm? Revisited ultramafic pyroxenite(?) outcrops mapped by MBaknes to collect geochemistry samples.
RHulstein2017-08-13	Goal today to check off CSA adv. target 002. Started at ridge and chased Wind Lake-KZK and GRA-POR contact on top and explored eastern side of target south and west of DDH K97-180; found frost heaves, scree and rare subcrop. Found approximate northern extent of GRA-POR and contact with KZK rocks and narrowed area where KZK – Wind Lake contact goes through.
RHulstein2017-08-14	Traversed from south end of ridge where claims abut R15 withdrawn land block to north on west facing slope above CSA KZK-001 target and then down through the target area by drill hole K98-195. Sparse float and subcrop on the ridge near the R15 block consisted of RHYvx (feldspar phyric) and RHYvl. Above the CSA target rocks consisted of GRA POR (feldspar porphyry) as previously mapped and at lower elevations sparse outcrops of RHYvx (1-2 mm feldspar phyric). No outcrop was observed while traversing through thick bush on the CSA target. Grey patches in the valley bottom noted on imagery consisted of rounded boulders of mixed lithology.
RHulstein2017-08-15	Two traverses: First one over GP4F (CSAKZK-003) target and second over CSA KZK-013 target. At the GP4F located RHY rocks below the previously mapped GRA POR and found a subcrop, possibly an outcrop of RHYvx with 5+% blue qtz eyes, a rock very similar in appearance to the Qtz eye unit found just above the mineralization in the GP4F drilling. Second traverse in the afternoon was a creek travers from east to west over the KZK-013 target. Located a couple new outcrops of Wind Lake MAFt that should help constrain the KZK – Wind Lake contact.
RHulstein2017-09-16	Two traverses: First one over GP3L target and second over the CSA KZK-012 target area on the north side of Fault Creek on the ridge west of the old Cominco camp. At the GP3L located a couple new GRA-POR outcrops and below that outcrops and float of a mafic (MAFi?) unit. Below the mafic unit there is a paucity of outcrop although some angular float of MDS was noted (at a similar elevation to a previously mapped MDS outcrop – subcrop). Second traverse in the afternoon was a in a small area just below the ridge on the east end of the CSA KZK-012 target. A 20m+ thick unit of intermittently exposed strongly musc altered RHY, cordierite altered MAF rocks and minor MDS was traced for almost 200 m. This package of rocks strikes approximately 250 degrees and dips 20 – 40 degrees north.

Appendix H: Rock Sample Descriptions

This appendix contains coordinates[1] and descriptions for all 2017 hand samples collected during the Phase I and II mapping programs. The formation (Fm.)[2] each sample is from and lithology (Lith. Code)[3] of each sample is listed.

Table H-1: Descriptions of 2017 Hand Samples

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
D00005901	419809	6829891	Grab	FC	LST	Limestone
D00005902	419714	6829725	Grab	FC	LST	Massive limestone with calcite veins, crinoids?
D00005903	419788	6829669	Grab	FC	LST	Massive limestone with minor calcite veins
D00005904	420014	6829650	Grab	FC	LST	Coherent to fine grained crystalline limestone
D00005905	420100	6829815	Grab	FC	LST	Limestone with calcite veins and crinoids
D00005906	419949	6830010	Grab	FC	LST	Massive limestone
D00005907	419993	6830086	Grab	FC	LST	Limestone with calcite veins
D00005908	419965	6830165	Grab	FC	LST	Limestone with minor calcite veins and crinoids
D00005909	419840	6830187	Grab	FC	LST	Bioclastic limestone with recrystallized crinoids – marble?
D00005910	419726	6830163	Grab	FC	LST	Limestone
D00005851	419909	6829867	Grab	FC	LST	Grey weathering surface, light grey fractured limestone
D00005852	419883	6829797	Grab	FC	LST	Limestone; no obvious bedding or joints, fractured, minor limonite - Fe stain, on fractured surfaces in weakly brecciated (m scale) zone
D00005853	419887	6829682	Grab	FC	LST	Limestone; minor brecciation and coarse calcite filling, no obvious structures
D00005854	419836	6829545	Grab	FC	LST	Limestone; weakly brecciated and healed with coarse calcite and very minor Fe stained calcite
D00005855	419920	6829462	Grab	FC	LST	Minor coarse calcite veining; crinoid plates noted
D00005856	420071	6829346	Grab	FC	LST	Limestone, minor calcite veining
D00005857	420227	6829539	Grab	FC	LST	Limestone; clean looking
D00005858	420344	6829691	Grab	FC	LST	Limestone and calcite veining (<10%)
D00005859	420466	6829804	Grab	FC	LST	Limestone with minor irregular calcite veinlets and Fe color on fractures
D00005860	420384	6830032	Grab	FC	LST	Grey fine-medium grained limestone - as previous samples
D00005861	420295	6830118	Grab	FC	LST	Limestone
D00005862	420252	6830136	Grab	FC	LST	Limestone
B00267756	412075	6816320	Grab	WL	MAFt	
B00267757	412468	6813681	Float	KZK	SXSX	Baknes: 15X15 cm float cobble of massive goethite; may be boxwork after sulphide?
B00267758	420594	6816304	Grab	WL	MAFw	Pillowed basalt and pillow breccia, patchy chalcopyrite and Cu-oxides in probable pillow selvage or interstitial to fragmental basalt, minz discominz only located at this locality
D00005863	413208	6814998	Grab	KZK	RHYc, RHYi	From RHY scree patch identified by Cominco which seems correct. Fair amount of RHYi and qtz vein float. See photo DSCN2195.
D00005864	413401	6814667	Grab	KZK	RHYi	
D00005865	413618	6814759	Grab	KZK	RHYi	
D00005866	414090	6815426	Float	WL	SLT	Grey fissile calcareous quartz-feldspar-muscovite phyllite; float in scree of similar lithology; minor chlorite; weakly limonite weathering; trace disseminated pyrite
D00005867	412546	6813449	Grab	KZK	RHYi	Grab of RHYi from subcrop on Rhyolite Peak.
D00005868	412694	6814042	Float	KZK	RHYi	Finely dissemianted pyrite; RHYi float pieces less than 20 cm size on average. Pyrite-bearing RHYi usually occurs near sulphide deposits, plus carries other

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
						sulphides (likely absorbed from deposits). Photo DSCN5868
D00005869	412602	6814680	Float	KZK	RHYi	Limonitic weathering foliated RHYi float in frost boils , within extensive area of same. Weakly pyritic - weathered outcrop. Photo DSCN5869.
D00005870	412377	6815033	Grab	KZK	RHYi	Looks to be a varient of RHYi- intruding RHYv? From slumped outcrop
D00005871	413870	6814846	Float	KZK	RHYi	Float from scree, approx 50% or > RHYi. Limonite weathered
D00005872	414122	6815040	Grab	KZK	RHYi	Quartz veined RHYi in contact with overlying RHYv. Photo DSCN2203
D00005873	414250	6814899	Grab	KZK	RHYi	RHYi, small subcrop on ridge crest
D00005874	414298	6814854	Grab	KZK	MAFw	Mafic feldspar porphyry
D00005876	410024	6811004	Float	FCF	FALT	Limonitic weathering calcareous fault breccia - think leakage halo
D00005877	410352	6810090	Grab	FL	MDS	Weakly limonite weathering tan and grey shale.
D00005878	414044	6814627	Float	KZK	MAFt	Mix of muscovite altered RHY, MAFt (most pyrite) and finely banded MDS. Looks like weathered equivalent of ABM horizon; subcrop
D00005911	413260	6814757	Grab	KZK	RHYvx	RHYvx with quartz eyes
D00005912	412747	6813511	Grab	KZK	RHYi	Coherent with quartz veins; large 3x3 m angular block in talus field
D00005913	412980	6813599	Grab	KZK	RHYi	
D00005914	413017	6813714	Grab	KZK	RHYi	Sericite intensity 3
D00005915	413039	6813759	Grab	KZK	RHYi	Coherent aphanitic RHYi with sericite alteration intensity 3
D00005916	413081	6813843	Grab	KZK	RHYi	Sericite alteration intensity 3
D00005917	413234	6814250	Grab	KZK	RHYi	Sericite alteration - 3
D00005918	413098	6814287	Grab	KZK	RHYi	Sericite altered 3-4
D00005919	413403	6813597	Grab	KZK	RHYi	Massive rhyolite with quartz veins
D00005920	411346	6811454	Grab	FL	PXNT	Pyroxenite with pervasive actinolite+chlorite?; may be feldspathic but too fine grained to tell; subvolcanic intrusive?
D00005921	411794	6811402	Grab	FL	PXNT	Fine grained pyroxenite? with abundant actinolite-chlorite-carbonate alteration; geochem sample
D00005922	420909	6816310	Grab	WL	MAFw	Green-light green-grey, fine to very fine grained, massive, equigranular; chlorite-epidote-actinolite-quartz (?); oxidation trace
D00005923	421486	6814822	Grab	KZK	MDS	Grey-brown-light green, very fine grained, foliated; sericite-chlorite (?)-calcite (wispy pyrite laminated)-biotite; fine grained oxidized trace pyrite; feldspar (fragmental ?/clasts)-trace limonite
D00005924	421801	6814582	Grab	GLP	GRA	Dark grey-silvery-brown, very fine grained matrix; clasts of fragmental crystals (10%); foliated; sericite-quartz-chlorite (?)-feldspar (rotated crystal or fragments, pressure shadow)-possibly fine grained biotite
D00005925	418425	6813727	Grab	GLP	GRA	Grey, fine grained matrix, biotite porphyroblasts, foliated; sericite-quartz-biotite (10%)-wispy pyrite calcite-chlorite (?)
D00005926	418425	6813727	Grab	GLP	GRA	Grey, fine grained matrix, biotite porphyroblasts, foliated; sericite-chlorite-lesser quartz-wispy pyrite, calcite
D00005927	418170	6813868	Grab	GLP	GRA	Pale orange-beige, aphanitic groundmass, age texture-gneissose; quartz (silicified ?)--lesser sericite-feldspar

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
						phenocrysts-trace calcite -oxidation train (oxidized pyrite ?)-biotite trace
D00005928	416593	6814599	Grab	WL	MAFt	Grey-green, very fine grained, foliated, chlorite-sericite-calcite (foliaform)-fine grained biotite (5%)
D00005929	416146	6814300	Grab	GLP	GRA	Grey, oxidation trace, very fine grained matrix, porphyritic texture, foliated; blue rounded quartz eyes; quartz-sericite (?)-fine grained biotite-feldspar phenocryst (or fragments)-calcite in pressure shadow, fractured-rotated
D00005931	416239	6814285	Grab	GLP	GRA	Grey-moderately oxidized, very fine grained matrix, weakly foliated; quartz-limonite-sericite (?)-calcite (wispy pyrite and vienlets)-biotite (fine grained in matrix and porphyroblasts (3%))-rare rounded blue quartz eyes
D00005932	418014	6815226	Grab	WL	MAFt	Dark green-wispy pyrite calcite, fine grained matrix, foliated; chlorite-calcite (20%)-sericite (?)-lesser quartz-fine grained biotite
D00005934	414145	6817925	Grab	WL	MAFw	Dark green, fine to medium grained, equigranular-homogeneous, foliated; chlorite-calcite-fine-fine grained biotite (?); fine grained pyrrhotite disseminated along the foliation (0.5%)
D00005935	414141	6817930	Grab	WL	MAFt	Dark green-peppery biotite porphyroblasts (5%) very fine grained matrix, foliated; chlorite-pervasive calcite-biotite
D00005936	414288	6817341	Grab	WL	MAFt	Dark green, fine to medium grained, foliated; chlorite-actinolite-calcite (10%); wispy pyrite calcite, granular texture
D00005937	414542	6816765	Grab	WL	MAFt	Dark green, fine to medium grained, massive (weak fabric), granular texture; chlorite-calcite (medium grained disseminated-10%)-quartz-actinolite-possibly epidote
D00005938	414413	6818180	Grab	WL	MAFt	Dark green, fine grained matrix, foliated; chlorite-actinolite-calcite-quartz; wispy pyrite calcite-quartz
D00005939	414149	6813722	Grab	GLP	GRA	Grey-pale green, fine grained matrix, porphyritic texture, foliated; quartz-feldspar (phenocryst)-muscovite/sericite-biotite (well developed); trace fine grained pyrite, trace calcite
D00005940	414279	6813818	Grab	KZK	MAFi	Dark green, fine to medium grained, , granular texture; chlorite-actinolite-quartz-white specks (feldspar (?))-biotite (other mica?); silica flooded
D00005941	414591	6813944	Grab	GLP	GRA	Grey-pale green, very fine grained matrix, feldspar-quartz porphyries-abundant rounded blue quartz eyes; fractured phenocryst, foliated, augen texture; quartz-feldspar-biotite-sericite
D00005942	414559	6814599	Grab	KZK	MAFt	Dark green, very fine grained matrix, biotite porphyroblasts, rare rounded blue quartz eyes, foliated-decomposed; chlorite-actinolite-possibly epidote-biotite
D00005943	414686	6814642	Grab	KZK	MAFt	Green-grey, very fine grained, foliated; chlorite-actinolite-lesser biotite-trace quartz; trace disseminated pyrite
D00005944	409338	6814688	Grab	GLP	INT_F	Grey, fine to coarse grain, foliated; quartz-sericite-biotite-feldspar (?)
D00005945	410011	6810961	Grab	FL	MAFt	Dark green-grey, fine grained, foliated, weakly deformed; chlorite-silvery mica (sericite/muscovite?-possibly talc)-biotite

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
D00005946	409780	6810139	Grab	GLP	GRA	Grey-beige, very coarse grained, 20% micaceous medium grained groundmass, poorly sorted-deformed, foliated, megacrystic-clastic; quartz-mica-trace calcite
D00005947	410397	6810194	Grab	FL	MAFw	Dark green-pale green, breccia, clast supported (clast up to 4 cm wide), fine grained groundmass; actinolite-chlorite-calcite-epidote; flow breccia
D00005948	411772	6812130	Grab	FL	MAFw	Dark green, fine to medium grained, foliated, heterogeneous, chlorite-actinolite-feldspar (?)-quartz=black mica (biotite?); trace pyrite
D00005951	413649	6815592	Grab	WL	MAFt	Dark green, very fine grained, thinly foliated; chlorite-actinolite-epidote-wispy pyrite calcite (5-10%)-biotite
D00005952	412424	6814361	Grab	KZK	MAFi	Ddark green, fine to medium grained, weakly foliated, granular texture,; chlorite-actinolite-calcite-lesser quartz-fine grained biotite-rare biotite porphyroblasts
D00005953	411919	6814733	Grab	GLP	GRA	Beige-pale orange, fine grained groundmass (5%) clasts o quartz-feldspar porphyry, poorly foliated,, oxidation trace; quartz (dominant)-feldspar-biotite (porphyroblasts-randomly oriented)-lesser mica; trace fine grained pyrite and trace oxidatiom (possibly pyrite)
D00005954	411797	6814756	Grab	GLP	GRA	Grey, very fine grained to aphanitic groundmass, porphyritic or clastic, foliated; quartz-feldspar (?)-biotite-mica-calcite (clots)
D00005955	412073	6816375	Grab	WL	MAFt	Green-grey-white dots, fine grained matrix/groundmass, poorly foliated; chlorite-actinolite-epidote-calcite; possibly amygdaloidal calcite infill
MB17-01	414496	6815097	Grab	KZK	RHYi	RHYi, blocky, 3% disseminated PY, massive, aphanitic
MB17-03	414346	6815230	Grab	KZK	RHYi	RHYi, >20% 0.5-2mm ovoid quartz phenos
MB17-05	414241	6814894	Grab	KZK	RHYi	RHYi, quartz porphyritic, glassy groundmass, 20% 0.5-2mm ovoid recrystalized quartz phenocrysts
MB17-13	411358	6815606	Grab	GLP	GRApor	QZ BI MU FD augen schists, border phase of feldspar porphyry? (GRApor)
MB17-17	410608	6816553	Grab	WL	SLTcrb	Carbonaceous siltstone (SLTcrb), Wind Lakes
MB17-18	413745	6814452	Grab	KZK	RHYcw	Possible RHYcw
MB17-21	413222	6813979	Grab	KZK	RHYi	Aphanitic rhyolite, RHYi
MB17-22	415448	6815262	Grab	WL	SLT	Tan, QZ MU phyllite, likely siltstone, feldspathic siltstone, reworked KZK? (SLT-WCK)
MB17-23	415424	6815251	Grab	WL	SDS	Grey resistant weakly carbonaceous quartz sandstone with adjacent grey phyllite-mudstone (SDS)
MB17-24	415407	6815201	Grab	GLP	GRA	Possible dike cutting Wind Lake mafic tuff (MAFt). Felsic medium grained equigranular with folioform biotite, likely grass lakes granite (GRA)
MB17-25	415919	6814480	Grab	WL	WCK	Contact between Wind Lake and KZK, Wacke (WCK) and feldspar porphyry (GRApor) and RHYva
MB17-26	416127	6814301	Grab	GLP	GRApor	Feldspar Porphyry, (GRApor) adjacent outcrop RHYva with quartz eyes
MB17-27	417408	6812860	Grab	KZK	RHYi	RHYi, local suspected flow banding
MB17-29	417241	6812847	Grab	KZK	RHYcw	RHYcw
MB17-31	412992	6813635	Grab	KZK	RHYi	RHYi with spherulites
MB17-32	412699	6813191	Grab	KZK	RHYi	Tan glassy RHYi, interbanded with carbonaceous units, contamination of RHY as sills encounter sediments??
MB17-33	412552	6813447	Grab	KZK	RHYi	Top of Rhyolite Peak, aphyric, aphanitic RHYi with 2% 1mm euhedral feldspar (silica replaced?) and ovoid quartz phenocrysts
MB17-45	411335	6811447	Grab	FL	PXNT	Coarse grained pyroxenite, 1-3cm sub-euhedral pyroxene phenocrysts in a schistose matrix

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
MB17-46	411693	6811404	Grab	FL	RHYv	Pseudo lapilli texture, siliceous sediment with deformed quartz stringers some of which are segmented forming a pseudofragmental texture
MB17-47	411788	6811406	Grab	FL	PNXT	Pyroxenite, pyroxene-actinolite-serpentine
MB17-49	420578	6816325	Grab	WL	MAFw	Resistant outcrop, weakly foliated possible pillow basalt
MB17-51	421713	6815908	Grab	KZK	SDS	Grey translucent quartzite (SDSsil), note significant amount of associated bull quartz (romobilized silica)
MB17-52	418141	6813854	Grab	GLP	GRApor	Granite porphyry, aphanitic RHYi-like groundmass
MB17-54	410727	6816140	Grab	GLP	GRApor	Feldspar porphyry, GRApor, 5% FD megacrysts in a fine grained siliceous groundmass
MB17-56	413676	6811691	Grab	GLP	GRA	Equigranular granite intrudes MAFi
MB17-57	417218	6812448	Grab	GLP	GRAmg	Granitic felsite (GRAmg), medium grained equigranular, rare 1-5mm feldspar phenocrysts and 1-2mm grey quartz eyes
MB17-58	416098	6813252	Grab	KZK	RHYc	RHYc, fine grained sugary\granular groundmass (RHYi aphanitic) possible recrystalized (adjacent to batholith) or more deeply emplaced RHYi
MM17001	413307	6814761	Grab	KZK	RHYva	Qtz-ser schist
MM17003	413489	6814696	Grab	KZK	RHYi	
MM17004	413585	6814651	Grab	KZK	RHYvl	
MM17005	413954	6815290	Grab	WL	MDSc	Carbonaceous mudstone
MM17006	414151	6815424	Grab	WL	MDSc	Intercalated siltstone and carbonaceous mudstone
MM17007	412899	6814059	Grab	KZK	RHYv	Sericite alteration intensity 2
MM17008	414079	6814584	Grab	KZK	RHYv	Sericite altered RHYv
MM17009	414078	6814586	Grab	KZK	RHYv	Muscovite/fuchsite-altered RHYv
MM17010	414093	6814628	Grab	KZK	RHYv	Intense alteration to muscovite/sericite
MM17011	414131	6814699	Grab	KZK	MAFt	
MM17012	414128	6814698	Grab	KZK	RHYv	
MM17013	414118	6814736	Grab	KZK	MAFt	
MM17014	413106	6813586	Grab	GLP	GRApor	Quartz-feldspar porphyry on talus slope
MM17015	413724	6813685	Grab	KZK	RHYi	
MM17016	413781	6813622	Grab	KZK	RHYi	RHYi with sericite alteration; above Fault Creek
MM17017	414596	6813943	Grab	GLP	GRApor	
MM17018	414565	6814085	Grab	KZK	RHY	Fine grained feldspathic rock with sericite-ankerite-chlorite alteration
MM17019	414568	6814090	Grab	KZK	MAFt	Mafic tuff?
MM17020	414579	6814135	Grab	KZK	RHYv	
MM17021	414628	6814343	Grab	KZK	RHYvl	In cluster of RHYv outcrops at eastern margin of target
MM17022	409688	6811242	Grab	FL	MAFi	Outcrop with layer of MAFt
MM17023	409689	6811242	Grab	FL	MAFt	Bed in MAFi?
MM17024	409679	6811255	Grab	GLP	GRApor	Porphyritic dyke with 5% feldspar phenocrysts cuts other porphyritic unit with 30% feldspar phenocrysts
MM17025	409653	6811154	Grab	FL	MAFi	Feldspathic mafic intrusive with abundant chlorite (replacing pyroxine/hornblende?) and biotite porphyroblasts; local calcite veins
MM17026	416629	6814007	Grab	KZK	RHYc	RHYc? Taken from frost patch on top of ridge; all angular blocks of same rock
MM17027	418011	6815320	Grab	WL	MAFw	MAFw with epidote-actinolite-carbonate-garnet? Is this a flow top/autobreccia
MM17028	418015	6815191	Grab	KZK	RHYv	
MM17029	418022	6815307	Grab	WL	MAFt	
MM17030	421586	6814626	Grab	GLP	RHYvx	RHYvx? with <15mm feldspar phenocrysts
MM17031	421731	6814533	Grab	GLP	RHYif	Feldspar-quartz porphyry (GRApor/RHYif) OR RHYvx
MM17032	421176	6814832	Grab	KZK	RHYv	RHYv with RHYvx and RHYvl

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
MM17033	421155	6814853	Grab	KZK	SLT	SLT?
MM17034	421137	6814828	Grab	KZK	RHYv	RHYvx-RHYvl? Crystal to lapilli tuff with biotite-sericite-ankerite
MM17035	421125	6814822	Grab	KZK	RHYvx	
MM17036	412074	6816374	Grab	WL	MAFt	Feldspar mafic crystal tuff (MAFt); feldspar phenocrysts weakly altered to carbonate
RH17008	413719	6813616	Grab	KZK	WCK	Biotite-feldspar schist, 3% pyrrhotite
RH17009	413727	6813623	Grab	KZK	MDS	MDS with cordierite
RH17010	414145	6813697	Grab	KZK	PEL	Pelite with bedding and feldspar crystals
RH17011	414145	6813711	Grab	GLP	RHYif	RHYif, feldspar and qaurtz phenocrysts
RH17012	414281	6813818	Grab	KZK	MAFi	
RH17013	414333	6813839	Grab	KZK	RHYvl	RHYvl, head of dip slope of slabby subcrop
RH17014	414303	6814016	Grab	GLP	RHYif	RHYif, feldspar & quartz phenocrysts
RH17015	413524	6813692	Grab	KZK	RHYi	
RH17016	413631	6813898	Grab	KZK	RHYc	
RH17018	414562	6813858	Grab	KZK	RHYi	
RH17019	414547	6813561	Grab	KZK	RHYc	
RH17022	414595	6812942	Grab	KZK	RHYvl	
RH17024	414560	6812882	Grab	KZK	PEL	
RH17025	414560	6812891	Grab	KZK	RHYva	
RH17027	410504	6812944	Grab	KZK	RHYv	
RH17028	410502	6812956	Grab	KZK	RHYc	
RH17030	410500	6812987	Grab	KZK	RHYva	
RH17031	410479	6813007	Grab	KZK	RHYv	
RH17032	410402	6813289	Grab	KZK	RHYv	
RH17033	410379	6813499	Grab	KZK	RHYv	
RH17035	410359	6813561	Grab	KZK	RHYv	
RH17036	410346	6813654	Grab	KZK	RHYc	
RH17037	410167	6813790	Grab	KZK	MDS	
RH17038	410177	6813822	Grab	KZK	RHYvq	RHYvq quartz eye tuff
RH17039	410119	6813912	Grab	KZK	SLT	
RH17040	410113	6813944	Grab	KZK	RHYv	
RH17041	410109	6813988	Grab	KZK	RHYv	
RH17042	410074	6814032	Grab	KZK	RHYv	
RH17043	410060	6814056	Grab	KZK	RHYv	
RH17044	410044	6814075	Grab	KZK	RHYvq	
RH17045	410038	6814082	Grab	KZK	RHYvl	
RH17046	410024	6814115	Grab	KZK	RHYc	
RH17047	410006	6814149	Grab	KZK	PEL	
RH17048	409974	6814186	Grab	KZK	RHYvq	
RH17049	409953	6814211	Grab	KZK	RHYva	
RH17050	409940	6814222	Grab	KZK	RHYvl	
RH17051	409905	6814253	Grab	KZK	RHYvl	
RH17052	409852	6814303	Grab	KZK	RHYvl	
RH17053	409803	6814338	Grab	KZK	RHYvl	
RH17055	409496	6814582	Grab	GLP	RHYif	
RH17056	409401	6814642	Grab	GLP	PEL	
RH17057	409336	6814695	Grab	GLP	RHYif	
RH17058	409235	6814805	Grab	GLP	RHYif	
RH17059	409220	6814818	Grab	KZK	RHYvq	059a and 059b
RH17060	409192	6814854	Grab	KZK	RHYvfq	
RH17061	409151	6814893	Grab	GLP	GRA	
RH17062	409115	6814926	Grab	GLP	GRA	

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
RH17063	409086	6814956	Grab	KZK	MAFt	
RH17064	409059	6814983	Grab	KZK	RHYvl	
RH17065	409069	6814972	Grab	KZK	RHY	
RH17066	409016	6815015	Grab	KZK	RHYvl	
RH17067	409001	6815025	Grab	GLP	GRApor	
RH17068	408896	6815145	Grab	KZK	PEL	
RH17069	408783	6815220	Grab	KZK	RHYv	
RH17070	408674	6815343	Grab	GLP	GRApor	
RH17071	408648	6815408	Grab	GLP	GRApor	
RH17072	408640	6815456	Grab	GLP	GRApor	Quartz feldspar-muscovite schist with <5%, 5 mm quartz eyes.
RH17073	408599	6815499	Grab	GLP	GRA	
RH17074	408521	6815530	Grab	GLP	GRA	
RH17075	422519	6818492	Grab	WL	MDSc	
RH17076	423367	6818612	Grab	WL	SDS	Quartzite
RH17077	423382	6818489	Grab	WL	SDS	Grey quartzite
RH17078	423626	6818219	Grab	WL	MDSc	MDSc with sandstone lenses
RH17079	424426	6817603	Grab	WL	MAFi	
RH17080	424500	6817591	Grab	KZK	RHY	RHY, bleached altered mafic
RH17081	424927	6817679	Grab	WL	SDS	Tan - dark grey banded sandstone - siltstone
RH17082	425103	6817649	Grab	WL	MAFt	
RH17083	425131	6817596	Grab	WL	SLT	
RH17084	425248	6817576	Grab	WL	SLT	Dark grey siltstone
RH17085	425765	6817242	Grab	WL	MAFt	
RH17086	425944	6817165	Grab	WL	MDSc	
RH17087	426224	6817109	Grab	WL	SDS	SDS - SLT with carbonate bands
RH17088	416531	6813853	Grab	KZK	RHYv	RHYv, siliceous, fine grained granular, rare ash, lapilli
RH17089	416587	6814599	Grab	WL	MAFt	
RH17090	416912	6814732	Grab	WL	MDS	
RH17091	416873	6814683	Grab	WL	WCK	
RH17092	417017	6814775	Grab	KZK	RHYvx	RHYvx with blue quartz eyes
RH17093	417127	6814869	Grab	KZK	RHY	RHY: RHYv (rare quartz eye-feldspar) or Felsite? sill?
RH17094	418046	6814465	Grab	KZK	SLT	
RH17095	418067	6814500	Grab	KZK	SLT	
RH17096	416793	6815992	Grab	KZK	RHYw	
RH17097	416942	6816123	Grab	WL	MDSc	
RH17098	413331	6814662	Grab	KZK	RHYi	
RH17099	413207	6814692	Grab	KZK	RHY	
RH17100	413403	6814690	Grab	KZK	RHY	Muscovite - sericite altered RHY
RH17102	412762	6814975	Float	KZK	MDSc	MDSc float
RH17103	412330	6814947	Grab	KZK	SLT	SLT with carboante (or MDSc with not a lot of carbonate)
RH17104	412075	6814694	Grab	KZK	RHYvl	RHYvl - ash
RH17105	411924	6814735	Grab	GLP	GRA	GRA: Feldspar - quartz rhyolite porphyry, micaceous
RH17107	411800	6814759	Grab	GLP	GRA	
RH17108	410890	6815206	Grab	KZK	MDSt	
RH17109	410760	6815038	Grab	KZK	RHYv	Rusty muscovite phyllite
RH17110	410393	6815213	Grab	KZK	RHYvx	RHYvx (QE)
RH17111	410037	6815478	Grab	KZK	MAFt	
RH17112	417550	6814179	Grab	GLP	GRApor	
RH17113	417593	6814100	Grab	GLP	GRA	Grey finer grained well foliated GRA below coarse POR
RH17114	417629	6814055	Grab	KZK	RHYc	
RH17115	417645	6814019	Grab	KZK	PEL	

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
RH17116	417695	6813581	Grab	GLP	GRA	GRA, feldspar phyric; rounded feldspar.
RH17117	411778	6812124	Grab	FL	PXNT	Pyroxinite
RH17118	411747	6812339	Grab	FL	MAFw	
RH17119	411693	6812367	Grab	FL	SLT	Finely laminate siltstone
RH17120	411287	6812153	Grab	FL	RHYvx	
RH17121	411229	6812161	Grab	GLP	GRApor	
RH17122	411062	6812548	Grab	FL	MAFt	
RH17123	411559	6815492	Grab	KZK	RHYvl	Likely collected by DBaker on July 24, 2017; Point entered by RHulstein
RH17124	411991	6815891	Grab	KZK	RHYvx	Sample likely collected by DBaker on July 24, 2017, point entered by RHulstein
RH17125	411925	6815675	Grab	KZK	RHYvl	Sample likely collected by DBaker July 24, 2017. Point entered by RHulstein
RH17126	413648	6815590	Grab	WL	MAFt	Has feldspar crystals, granular, carbonate rich
RH17127	413177	6815013	Grab	KZK	RHY	RHY; RHYi - RHYv (lapilli and ash). Patch of RHY in scree, not far from source?
RH17128	413237	6814623	Grab	KZK	RHYv	
RH17129	413457	6814713	Grab	KZK	RHYv	Banded ash? slabby stacked scree down slope of large area of RHYi subcrop
RH17130	414000	6815332	Grab	WL	SLT	Grey fissile calcareous quartz-feldspar-muscovite phyllite
RH17131	414081	6815399	Grab	WL	SLT	Grey fissile calcareous quartz-feldspar-muscovite phyllite
RH17132	414243	6815492	Float	KZK	RHYqf	Quartz-feldspar porphyry
RH17133	412456	6813791	Grab	KZK	MDSc	MDSc and Quartz vein (- Quartzite?); from small knoll of subcrop
RH17134	412423	6814355	Float	KZK	MAFi	Sample site marks first appearance of MAF unit
RH17135	412572	6814618	Float	KZK	RHYi	South side of large area of subcropping RHYi exposed in frost boils and scree
RH17136	412517	6814966	Float	KZK	RHYc	RHYc or varient of RHYi?
RH17137	413938	6815152	Grab	KZK	RHYv	Could be a RHYc or even a RHYi varient
RH17138	414298	6814875	Float	KZK	MAFt	Small (<2x5m) subcrop of MAFt
RH17139	413548	6813602	Grab	KZK	RHYcf	
RH17140	413899	6813086	Grab	KZK	RHYi	Bleached 'chalky looking' RHYi
RH17141	413572	6813526	Grab	KZK	RHYv	
RH17142	413608	6813548	Grab	KZK	RHYi	
RH17143	413626	6813548	Grab	KZK	RHYi	Bleached, not glassy aphanitic
RH17144	413672	6813582	Grab	KZK	RHYi	
RH17145	413718	6813617	Float	KZK	RHYv	Sericite-muscovite rich well foliated light green weakly pyritic quartz muscovite schist
RH17146	414300	6814060	Float	KZK	WCK	Subcrop
RH17147	414353	6814143	Grab	KZK	MAFt	Crenulated
RH17148	414389	6814158	Grab	KZK	MAFt	
RH17149	414370	6814149	Grab	KZK	RHYv	RHYv (possible ash and lapilli?): quartz muscovite schist
RH17150	414407	6814199	Float	KZK	RHYv	Subcrop
RH17151	414406	6814309	Float	KZK	RHYv	No outcrop, numerous angular quartz-feldspar-muscovite schist boulders, (1) 2 mm blue quartz eye noted.
RH17152	414632	6814342	Float	KZK	RHYv	Blocky talus boulders, sample is micaceous (4)
RH17153	414680	6814643	Grab	KZK	MAFt	Well foliated quartz-muscovite-chlorite (minor) schist, sericite altered (5) MAFt (?). MM says it is a RHYv....
RH17154	410007	6810964	Grab	FL	PEL	PEL-MAFt; oriented with structure measurement
RH17155	409999	6810984	Grab	GLP	GRApor	

Sample ID	UTM East	UTM North	Type	Fm.	Lith. Code	Rock Description
RH17156	409618	6811144	Grab	FL	MAFw	MAFw or MAFi (fine grained)
RH17156A	409781	6810137	Grab	GLP	GRApor	Feldspar-quartz augen porphyry
RH17157	410215	6810063	Grab	FL	PEL	Outcrop
RH17159	410389	6810148	Grab	FL	MAFw	MAF(w?) outcrop
RH17160	410393	6810194	Grab	FL	MAFt	MAF breccia outcrop
RH17161	416855	6814348	Float	KZK	RHYv	<1% 1 mm or less blue QE, slabby float, monolitholic, likely not too far removed from source.
RH17162	416908	6814203	Float	GLP	GRApor	Large angular slabby boulders, mostly of same rock type, likely not far from source
RH17163	417076	6814047	Float	KZK	RHYvl	15x20 m boulder field of very angular RHYvl
RH17164	417182	6813971	Float	KZK	RHYvx	Feldspar phenocrysts; angular float boulder field
RH17165	417227	6813844	Float	KZK	RHYv	Dirty RHY with 5% biotite
RH17166	418246	6814455	Float	KZK	RHYvl	looks like sample RH17165; subcrop
RH17167	418310	6814666	Grab	KZK	RHYvl	
RH17168	418259	6814942	Grab	WL	SLT	SLT - SDS - crb
RH17169	418142	6815086	Float	KZK	RHYvl	
RH17170	418167	6814678	Grab	KZK	MAFt	
RH17171	418202	6815068	Float	WL	SDS	SDS - 5+% biotite; small patch of float, SDS as not an intrusive, a MAF or a RHY....
RH17172	422374	6813548	Float	KZK	RHYvl	5% biotite
RH17173	422020	6813972	Grab	KZK	RHYvx	5% 1-2 mm feldspar phenocrysts; white quartz-feldspar-muscovite schist.
RH17174	421964	6814018	Float	GLP	GRApor	<5% 10mm feldspar phenocrysts in rhyolite that look very much like RH17173 (RHYvx).
RH17175	421008	6814771	Float	GLP	GRApor	Possible subcrop: green grey fine crystalline matrix with 15% </=15mm feld phenos
RH17176	421017	6815259	Float	KZK	RHYvx	Subcrop
RH17178	420261	6814293	Float	WL	PXNT	Magnetite ultramafic
RH17179	418731	6813359	Grab	KZK	RHYv	RHYv with biotite
RH17180	418791	6813263	Grab	KZK	RHYvx	RHYvx feldspar phenocrysts
RH17181	418868	6813193	Grab	KZK	RHYvl	RHYvl with biotite
RH17182	418895	6813141	Grab	KZK	RHYvx	RHYvx 8% 2-3 mm blue quartz eyes
RH17190	410244	6810169	Grab	GLP	GRApor	Not megacrystic feldspar variety, medium grain crystalline
RH17191	410237	6810110	Grab	FL	MAFt	MAFt and RHYv
RH17193	410828	6810209	Grab	FL	MAFt	Pyritic MAF
RH17194	414004	6814680	Grab	KZK	RHYv	
RH17195	414044	6814629	Grab	KZK	MDS	MDS and muscovite altered RHY
RH17196	414097	6814648	Float	KZK	RHY	Limonite weathering brecciated muscovite-cordierite altered RHY; subcrop patch of angular scree - likey not far from source; minor MDS.
RH17197	414113	6814655	Grab	KZK	RHY	Siliceous RHY with specks of malachite
RH17198	414113	6814668	Grab	KZK	RHY	Siliceous altered RHY with malachite
RH17199	414152	6814734	Grab	KZK	MAFt	Mineralized MAF

[1] Easting and Northing coordinates are presented in UTM Zone 9, NAD83 projection

[2] FC = Finlayson Creek Formation; FCF = Fault Creek Fault; FL = Fyre Lake Formation; GLP = Grass Lakes Plutonic Suite; KZK = Kudz Ze Kayah Formation; WL = Wind Lake Formation

[3] See table 9 of main text for rock code descriptions

Appendix I: Rock Sample Certificates of Analysis

This appendix contains all of the certificates of analysis (COA) pertaining to grab samples collected during mapping at the KZK Project during 2017. COAs are listed in alphanumeric order, with the first page of each COA indicated in the Page Number column in Table I-1 below.

Table I-1: Table of contents for COAs in this appendix

Certificate	Elements Assayed	Prospect	Analysis	Samples (#)	Page Number
VC172816	LOI, SiO_2, Al_2O_3, Fe_2O_3, MgO, CaO, K_2O, Na_2O, TiO_2, MnO, P_2O_5, Cr_2O_3, V_2O_5, Ag, Al, Ba, Ca, Cr, Cu, Fe, K, Li, Mg, Mn, Na, Ni, P, S, Sr, Ti, V, Zn, Zr, As, Be, Bi, Cd, Ce, Co, Cs, Ga, Hf, In, La, Lu, Mo, Nb, Pb, Rb, Sb, Sc, Se, Sn, Ta, Tb, Te, Th, Tl, U, W, Y, Yb	Limy	Whole Rock	22	1
VC172818	Au, Ag, Al, As, Ba, Bi, Ca, Cd, Ce, Co, Cr, Cu, Fe, Ga, Hg, K, La, Mg, Mn, Mo, Na, Ni, P, Pb, Rb, Sb, Sc, Sn, Sr, Th, Ti, Tl, U, V, W, Y, Zn, LOI, SiO_2, Al_2O_3, Fe_2O_3, MgO, CaO, K_2O, Na_2O, TiO_2, MnO, P_2O_5, Cr_2O_3, V_2O_5	KZK	Whole Rock	22	10
VC173046	Au, Ag, Al, As, Ba, Bi, Ca, Cd, Ce, Co, Cr, Cu, Fe, Ga, Hg, K, La, Mg, Mn, Mo, Na, Ni, P, Pb, Rb, Sb, Sc, Sn, Sr, Th, Ti, Tl, U, V, W, Y, Zn, LOI, SiO_2, Al_2O_3, Fe_2O_3, MgO, CaO, K_2O, Na_2O, TiO_2, MnO, P_2O_5, Cr_2O_3, V_2O_5	KZK	Whole Rock	6	18
VC173727	LOI, SiO_2, Al_2O_3, Fe_2O_3, MgO, CaO, K_2O, Na_2O, TiO_2, MnO, P_2O_5, Cr_2O_3, V_2O_5, Ag, Al, Ba, Ca, Cr, Cu, Fe, K, Li, Mg, Mn, Na, Ni, P, S, Sr, Ti, V, Zn, Zr, As, Be, Bi, Cd, Ce, Co, Cs, Ga, Hf, In, La, Lu, Mo, Nb, Pb, Rb, Sb, Sc, Se, Sn, Ta, Tb, Te, Th, Tl, U, W, Y, Yb	KZK	Whole Rock	58	26

Certificate of Analysis
Work Order : VC172816
[Report File No.: 0000024828]

Date: September 21, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01006
Project No.: KZK
Samples: 22
Received: Aug 28, 2017
Pages: Page 1 to 9
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
22	G_LOG02	Pre-preparation processing, sorting, logging, boxing
22	G_WGH79	Weighing of samples and reporting of weights
22	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
22	GO_XRF76V	Ore grade Borate fusion, XRF
22	GE_IC40A	Multi-acid (4-acid) digestion/ICP-AES finish
22	GE_IC40M	Multi-acid (4-acid) digestion/ICP-MS finish

Storage: Pulp & Reject

PULP STORAGE : STORE FOR 90 DAYS
REJECT STORAGE : STORE FOR 30 DAYS

QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Date: September 26, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01014
Project No.: KZK
Samples: 22
Received: Aug 28, 2017
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
22	G_LOG02	Pre-preparation processing, sorting, logging, boxing
22	G_WGH79	Weighing of samples and reporting of weights
22	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
22	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
22	GE_IMS14B	Aqua Regia digestion/ICP-MS package
22	GO_XRF76V	Ore grade Borate fusion, XRF

Storage: Pulp & Reject

PULP STORAGE : STORE FOR 90 DAYS
REJECT STORAGE : STORE FOR 30 DAYS

Certified By : John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01020
Project No.: KZK
Samples: 58
Received: Oct 11, 2017
Pages: Page 1 to 17
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
58	G_LOG02	Pre-preparation processing, sorting, logging, boxing
58	G_WGH79	Weighing of samples and reporting of weights
58	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
58	GO_XRF76V	Ore grade Borate fusion, XRF
58	GE_IC40A	Multi-acid (4-acid) digestion/ICP-AES finish
58	GE_IC40M	Multi-acid (4-acid) digestion/ICP-MS finish

Storage: Pulp & Reject

PULP STORAGE : STORE FOR 90 DAYS
REJECT STORAGE : DISPOSE AFTER 30 DAYS

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Table J-3: Column Decriptions

Column Name	Explanation
Min1 sTSAS	The primary mineral identified by The Spectral Assistant™
Wt1 sTSAS	Proportion of the spectrum explained by the primary mineral, out of 1
Min2 sTSAS	The secondary mineral identified by The Spectral Assistant™
Wt2 sTSAS	Proportion of the spectrum explained by the secondary mineral, out of 1
Min3 sTSAS	The tertiary mineral identified by The Spectral Assistant™
NIL Stat sTSAS	The proportion of the spectrum not explained by any mineral in the spectral library
Error sTSAS	A standardized measure of the error on the calculated mineral assemblage relative to the measured spectrum, based on the sum of squares method.
w1485	The wavelength of the peak absorption of the 1485 nm absorption feature, if present
width1485	The range of wavelengths that the 1485 nm absorption feature affects relative to the white reference calibration spectrum, if present
hqd1485	The hull difference quotient (a measure of the depth of the absorption feature) of the 1485 nm absorption feature, if present
w1550	The wavelength of the peak absorption of the 1550 nm absorption feature, if present
hqd1550	The hull difference quotient (a measure of the depth of the absorption feature) of the 1550 nm absorption feature, if present
w1900	The wavelength of the peak absorption of the 1900 nm absorption feature, if present
width1900	The range of wavelengths that the 1900 nm absorption feature affects relative to the white reference calibration spectrum, if present
hqd1900	The hull difference quotient (a measure of the depth of the absorption feature) of the 1900 nm absorption feature, if present
w2200	The wavelength of the peak absorption of the 2200 nm absorption feature, if present
width2200	The range of wavelengths that the 2200 nm absorption feature affects relative to the white reference calibration spectrum, if present
hqd2200	The hull difference quotient (a measure of the depth of the absorption feature) of the 2200 nm absorption feature, if present
w2250	The wavelength of the peak absorption of the 2250 nm absorption feature, if present
width2250	The range of wavelengths that the 2250 nm absorption feature affects relative to the white reference calibration spectrum, if present
hqd2250	The hull difference quotient (a measure of the depth of the absorption feature) of the 2250 nm absorption feature, if present
w2350	The wavelength of the peak absorption of the 2350 nm absorption feature, if present
width2350	The range of wavelengths that the 2350 nm absorption feature affects relative to the white reference calibration spectrum, if present
hqd2350	The hull difference quotient (a measure of the depth of the absorption feature) of the 2350 nm absorption feature, if present
sericite xtal	A measure of the depth of the 1900 nm absorption feature. This is used as a proxy for the average defect density (or crystal size) of the white micas
kaol xtal	A measure of the width of the kaolinite reflectance feature at 2180 nm. This is used as a proxy for the average defect density (or crystal size) of kaolinite

Appendix K: Soil Sample Descriptions

This appendix contains coordinates[1] and descriptions for all 2017 soil samples.

Appendix M: Soil Sample Certificates of Analysis

This appendix contains all of the certificates of analysis (COA) pertaining to soil samples collected at the KZK Project during 2017. All samples were analyzed for Au, Ag, Al, As, Ba, Bi, Ca, Cd, Ce, Co, Cr, Cu, Fe, Ga, Hg, K, La, Mg, Mn, Mo, Na, Ni, P, Pb, Rb, Sb, Sc, Sn, Sr, Th, Ti, Tl, U, V, W, Y, Zn and select samples were analyzed for pH. COAs are listed in alphanumeric order, with the first page of each COA indicated in the Page Number column in Table M-1 below.

Table M-1: Table of contents for COAs in this appendix

Certificate	Samples (#)	Page Number
VC172741	76	1
VC172742	76	17
VC172743	58	33
VC172752	76	44
VC172754	76	60

Certificate of Analysis
Work Order : VC172741
[Report File No.: 0000024588]

Date: September 12, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01010
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package
12	GE_ISE15V	Paste pH on Soils and/or Sediments sample

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By :

John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

This document is issued by the Company under its General Conditions of Service accessible at http://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein.

WARNING: The sample(s) to which the findings recorded herein (the "Findings") relate was (were) drawn and / or provided by the Client or by a third party acting at the Client's direction. The Findings constitute no warranty of the sample's representativity of the goods and strictly relate to the sample (s). The Company accepts no liability with regard to the origin or source from which the sample(s) is/are said to be extracted. The findings report on the samples provided by the client and are not intended for commercial or contractual settlement purposes. Any unauthorized alteration, forgery or falsification of the content or appearance of this document is unlawful and offenders may be prosecuted to the fullest extent of the law .

Certificate of Analysis
Work Order : VC172742
[Report File No.: 0000025097]

Date: October 04, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01010
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
74	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package
7	GE_ISE15V	Paste pH on Soils and/or Sediments sample

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By :

John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

This document is issued by the Company under its General Conditions of Service accessible at http://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein.

WARNING: The sample(s) to which the findings recorded herein (the "Findings") relate was (were) drawn and / or provided by the Client or by a third party acting at the Client's direction. The Findings constitute no warranty of the sample's representativity of the goods and strictly relate to the sample (s). The Company accepts no liability with regard to the origin or source from which the sample(s) is/are said to be extracted. The findings report on the samples provided by the client and are not intended for commercial or contractual settlement purposes. Any unauthorized alteration, forgery or falsification of the content or appearance of this document is unlawful and offenders may be prosecuted to the fullest extent of the law .

This document is issued by the Company under its General Conditions of Service accessible at http://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein.

WARNING: The sample(s) to which the findings recorded herein (the "Findings") relate was (were) drawn and / or provided by the Client or by a third party acting at the Client's direction. The Findings constitute no warranty of the sample's representativity of the goods and strictly relate to the sample (s). The Company accepts no liability with regard to the origin or source from which the sample(s) is/are said to be extracted. The findings report on the samples provided by the client and are not intended for commercial or contractual settlement purposes. Any unauthorized alteration, forgery or falsification of the content or appearance of this document is unlawful and offenders may be prosecuted to the fullest extent of the law .

Certificate of Analysis
Work Order : VC172756
[Report File No.: 0000024726]

Date: September 18, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01011
Project No.: KZK
Samples: 44
Received: Aug 28, 2017
Pages: Page 1 to 11
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
44	G_LOG02	Pre-preparation processing, sorting, logging, boxing
44	G_WGH79	Weighing of samples and reporting of weights
44	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
44	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

This document is issued by the Company under its General Conditions of Service accessible at http://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein.

WARNING: The sample(s) to which the findings recorded herein (the "Findings") relate was (were) drawn and / or provided by the Client or by a third party acting at the Client's direction. The Findings constitute no warranty of the sample's representativity of the goods and strictly relate to the sample (s). The Company accepts no liability with regard to the origin or source from which the sample(s) is/are said to be extracted. The findings report on the samples provided by the client and are not intended for commercial or contractual settlement purposes. Any unauthorized alteration, forgery or falsification of the content or appearance of this document is unlawful and offenders may be prosecuted to the fullest extent of the law .

This document is issued by the Company under its General Conditions of Service accessible at http://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein.

WARNING: The sample(s) to which the findings recorded herein (the "Findings") relate was (were) drawn and / or provided by the Client or by a third party acting at the Client's direction. The Findings constitute no warranty of the sample's representativity of the goods and strictly relate to the sample (s). The Company accepts no liability with regard to the origin or source from which the sample(s) is/are said to be extracted. The findings report on the samples provided by the client and are not intended for commercial or contractual settlement purposes. Any unauthorized alteration, forgery or falsification of the content or appearance of this document is unlawful and offenders may be prosecuted to the fullest extent of the law .

Certificate of Analysis
Work Order : VC172759
[Report File No.: 0000024727]

Date: September 18, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01012
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

[Report File No.: 0000024653]

Date: September 14, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01012
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Work Order : VC172761
[Report File No.: 0000024921]

Date: September 26, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01012
Project No.: KZK
Samples: 71
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
71	G_LOG02	Pre-preparation processing, sorting, logging, boxing
71	G_WGH79	Weighing of samples and reporting of weights
71	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
71	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Work Order : VC172765
[Report File No.: 0000024652]

Date: September 14, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01008
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Work Order : VC172766
[Report File No.: 0000024763]

Date: September 19, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01008
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Date: October 16, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01008
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
75	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

This document is issued by the Company under its General Conditions of Service accessible at http://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein.

WARNING: The sample(s) to which the findings recorded herein (the "Findings") relate was (were) drawn and / or provided by the Client or by a third party acting at the Client's direction. The Findings constitute no warranty of the sample's representativity of the goods and strictly relate to the sample (s). The Company accepts no liability with regard to the origin or source from which the sample(s) is/are said to be extracted. The findings report on the samples provided by the client and are not intended for commercial or contractual settlement purposes. Any unauthorized alteration, forgery or falsification of the content or appearance of this document is unlawful and offenders may be prosecuted to the fullest extent of the law .

Certificate of Analysis
Work Order : VC172782
[Report File No.: 0000025184]

Date: October 09, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01016
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
75	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Certificate of Analysis
Work Order : VC172783
[Report File No.: 0000024654]

Date: September 14, 2017

To: **ROBIN BLACK**
BMC MINERALS (NO 1) LTD
530-1130 WEST PENDER ST
VANCOUVER BC V6E 4A4

P.O. No.: PO# BMC17-01016
Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

Project No.: KZK
Samples: 76
Received: Aug 28, 2017
Pages: Page 1 to 16
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
76	G_LOG02	Pre-preparation processing, sorting, logging, boxing
76	G_WGH79	Weighing of samples and reporting of weights
76	GE_FAA313	@Au, FAS, AAS, 30g-5ml(Final Mode)
76	GE_IMS14B	Aqua Regia digestion/ICP-MS package

Storage: Pulp & Reject

REJECT STORAGE : PAID STORE AFTER 30 DAYS
PULP STORAGE : PAID STORE AFTER 90 DAYS

Certified By : _____
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods

John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the **@** symbol (e.g. @Cu) denote assays performed using accredited test methods
