Report For:

Casino Mining Corp.  
a subsidiary of Western Copper and Gold Corporation  
15<sup>th</sup> Floor, 1040 West Georgia Street  
Vancouver, BC, V6E 4H1

## **SUMMARY**

The Casino Property is located approximately 300 km northwest of Whitehorse on NTS map sheets 115J/09, 10 and 15, in the Whitehorse Mining District (see Figure 1). The Property consists of 1136 quartz claims and 55 placer claims registered in the name of Casino Mining Corp. This report covers assessment work performed in the summer of 2019 on Casino Quartz claims; a summary of which is listed on the Title Page for this report.

Casino Mining (CMC) conducted an extensive diamond drilling exploration campaign during the 2019 calendar year (May 27<sup>th</sup> – September 15<sup>th</sup>). During this period 13,500+ meters of NTW drilling was performed, for a total of 72 exploration based holes (see Figures 7 and 8 for drill hole locations). Each hole was logged and sampled from top to bottom (overburden included) and analyzed at ALS Chemex in Whitehorse for gold, silver, copper and molybdenum as well as a full ICP suite. Check pulp samples were sent to SGS Canada Inc in Burnaby, BC. All drill hole locations were surveyed by CAP Engineering with supervision by CMC staff. Access trails, pad clearing, drill transport and pad remediation were performed by Kluane Drilling using a D-6N caterpillar. Drilling was completed using two KD-1000 drills owned and operated by Kluane Drilling. Core collection, splitting, logging and analysis were completed on site by CMC technical staff (geologists and core cutters).

## **1.0 INTRODUCTION**

The exploration program on the Casino Mining (CMC) quartz claims consisted of diamond drilling, environmental studies, placer claim work, assaying, claim staking and site remediation. The program took place between May 27<sup>th</sup> and September 15<sup>th</sup> of 2019. The main purpose of the 2019 drill program was to fill in the previous drill hole spacing so as to update the resource estimate for the project. This report documents the diamond drilling portion of the 2019 field work for claim assessment purposes. A total of 72 exploration based holes were drilled on the CMC quartz claims: DH 19-01 through DH 19-53, CRD 19-54 through CRD 19-59 and DH 19-60 through DH 19-69.

The field program was managed by CMC technical staff, Wolfbear Geological Consulting and Bill Dunn. Heavy equipment and diamond drilling services were provided by Kluane Drilling Ltd (Kluane) from Whitehorse, Yukon. The author of this report assisted in managing the field program.

## **2.0 LOCATION AND ACCESS**

The Casino Property is located in the Dawson Range Mountains; 300 km northwest of Whitehorse (see Figure 1). The property is centered at latitude 62° 44' 16" N and longitude 138° 49' 41" W on NTS map sheets 115J/09, 10, 11 and 14, 15 and 16.

Principle access to the property is by air to a 900 m landing strip at the exploration camp. Alternatively, a gravel road from the camp accesses a barge landing on the Yukon River. Historically, overland access to the property has been by winter road routes to the east and west. The shorter winter road route extends 194 km northwest from Carmacks: 82 km along the Freegold Road, 40 km along the Casino Trail and 72 km along a bulldozer trail. The other route is a bulldozer trail that extends 224 km northeast of Burwash Landing on the Alaska Highway. The latter route offers better grades than the former.

Figure 1: Property Location Map

### 3.0 CLAIM INFORMATION

The CMC quartz claims lie within the Whitehorse Mining District on NTS map sheets 115J09, 115J10, 115J11, 115J14, 115J15 and 115J16. The project is located on Crown land administered by the Yukon Government and is within the Selkirk First Nation and Tr'ondëk Hwëch'in Traditional Territories. The Casino Property consists of 1136 quartz claims acquired and maintained in accordance with the Yukon Quartz Mining Act. The claims are registered in the name of and are 100% owned by Casino Mining Corporation. All 1136 quartz claims have been assigned to one of two groupings, shown in Figure 3 in Appendix V. Claim information is listed in Appendix II and shown in Figure 2 below.

The historical claims held by prior owners of the project and transferred as part of Western Coppers' plan of arrangement to acquire CRS Copper in 2006, consist of 83 Casino "A" claims covering 1,154 ha, 55 Casino "B" claims covering an area of 930 ha, and 23 claims in the "JOE" block covering an area of 324 ha.

The 188 "VIK" mineral claims, covering an area of 3,440 ha, were staked in June 2007 by CRS Copper. In June 2008, an additional 94 "CC" claims, covering an area of 1,930 ha, 8 BL claims, covering area of 157 ha and 63 "BRIT" claims covering an area of 1,218 ha were staked by CRS Copper. In October 2009, CRS Copper staked 136 "AXS" mineral claims, covering an area of 2,763 ha. In May of 2010, CRS Copper staked an additional 63 "AXS" claims, covering an area of 1,254 ha. In 2011 CRS Copper staked 18 "FLY" claims covering an area of 327 ha, to cover the proposed airstrip and access. In May 2016, 87 PAL claims were staked by Casino Mining, covering 1,818 ha. In July 2019, Casino Mining acquired additional 311 mineral claims from Cariboo Rose that comprise the Canadian Creek Property and covering area of 6,001 ha. In September 2019, Casino Mining staked 53 CAS19 claims, covering an area of 760 ha.

CRS Copper Resources Corp. acquired the Casino A, B and JOE claims, comprising the historical Casino property, on August 9, 2007 by exercising its option pursuant to a Letter Agreement dated July 15, 2002 with Great Basin Gold. The Casino deposit lies entirely on the Casino A claims. All claims were transferred to Casino Mining Corp. in the fall of 2011.

On December 21, 2012, Casino Mining entered into the Net Smelter Returns Royalty Agreement (the "NSR Royalty Agreement") with 8248567 Canada Ltd. ("8248567 Canada"), whereby the 2.75% Net Smelter Return Royalty ("NSR") was established on all Casino claims excluding fifty five (55) Casino B Claims. As consideration for purchasing the 2.75% NSR, 8248567 Canada cancelled the existing 5% NPR (except on Casino B Claims).

On November 2, 2016, pursuant to the Early Exercise and Purchase Agreement (the "Early Exercise and Purchase Agreement"), Cariboo Rose exercised its right to acquire fifty five (55) Casino B Claims, as described in the option agreement dated May 2, 2000 (the "Casino B Option Agreement") between Cariboo Rose and Casino Mining (a successor to title by virtue of 2002 Option). As part of the Early Exercise and Purchase, Casino Mining reacquired nine (9) Casino B Claims (the "Nine Casino B Claims"). Forty six (46) Casino B Claims (the "Forty Six Casino B Claims") were transferred to Cariboo Rose and became part of the Canadian Creek Property owned by Cariboo Rose.

On August 28, 2019, Casino Mining and Cariboo Rose completed the Canadian Creek Property Purchase Agreement (the "Canadian Creek Property Purchase Agreement"), whereby Forty Six Casino B Claims were reacquired as part of the Canadian Creek Property consisting of a total of 311 mineral claims.

## Royalties

Certain portions of the Casino property remain subject to certain royalty obligations. The surviving royalties and agreements are as follows:

- 2.75% NSR on the claims comprising the Casino project in favour of Osisko Gold Royalties Ltd. (“Osisko Gold”) pursuant to the Royalty Assignment and Assumption Agreement dated July 31, 2017 when 8248567 Canada assigned to Osisko Gold all of its rights, title and interest in the 2.75% NSR.
- 5% Net Profits Interest (the “NPI”), as defined in the Casino B Option Agreement, remains in effect on the Casino B Claims and \$1 million payment is required to be made to the original optioner within 30 days of achieving a commercial production decision.
- 5% Net Profit Interest Royalty (the “NPI Royalty”) presently held by Archer-Cathro and Associates on the ANA claims pursuant to the NPI Royalty Agreement dated December 4, 1990 (the “NPI Royalty Agreement”) among Big Creek Resources Ltd., Rinsey Mines Ltd., and Renoble Holdings Inc.

Figure 2: Casino Quartz Claims

#### 4.0 PHYSIOGRAPHY AND CLIMATE

The Dawson Range forms a series of well-rounded ridges and hills that reach a maximum elevation of 1,675 m above mean sea level (ASL). The ridges rise above the Yukon Plateau, a peneplain at approximately 1200 m ASL, which is deeply incised by the mature drainage of the Yukon River watershed. Major drainage channels extend below 1,000 m ASL. Most of the project lies between the 650 m elevation at Dip Creek and an elevation of 1,400 m at Patton Hill. The most notable local physical feature is the Yukon River, which flows west about 16 km north of the project site.

Most of the Dawson Range escaped Pleistocene continental glaciation, although minor alpine glaciation produced small cirques and terminal moraines locally.

The climate in the Dawson Range is subarctic. Permafrost is widespread on north-facing slopes, and discontinuous on south-facing slopes. Outcrop is rare, except on hilltops and rugged ridge crests. The residual nature of much of the rubble on upper slopes allows for generalized geological mapping and good geochemical and geophysical interpretation. Most broad valleys are filled with thick alpine glacial debris and alluvium, which mask bedrock geology and associated geochemical and geophysical signatures.

The mean annual temperature for the area is approximately -5.5°C with a summer mean of 10.5°C and a winter mean of -23°C. Temperatures range between -40°C in the winter to 30°C in the summer. Mean annual precipitation is low, ranging between 300-450mm; with most precipitation occurring in July and early August. Most of the terrain supports forests of black and white spruce, lodgepole pine, balsam poplar, white birch and speckled alder. At higher elevations and in the alpine terrain, only dwarf birch, scrub willows, and alpine mosses, grasses, and sedges are found.

Snow survey data for the years 1977 to 1994 (based on information from Hallam, Knight Piesold, Casino Project, Data Report 1993-1995, March 1997) showed the maximum snow depth was 97 cm containing the equivalent of 225mm of water in April 1991. Average depths (equivalent H<sub>2</sub>O) by month were: February 1: 52 cm (73 mm), March 1: 62 cm (107 mm), April 1: 65 cm (126 mm), May 1: 55 cm (128 mm), and May 15: 27 cm (74 mm). Snow begins accumulating in mid to late September and is mostly melted by mid to late May.

## 5.0 PROPERTY HISTORY

The Casino Property has had a long and varied exploration history. The first documented placer claims in the immediate area were recorded in April 1911, following a placer gold discovery on Canadian Creek by J. Britton and C. Brown. In 1917, D.D. Cairnes, of the Geological Survey of Canada, recognized huebnerite ( $\text{MnWO}_4$ ) in the heavy- mineral concentrates of the placer workings. He suggested that the gold and tungsten mineralization was derived from an intrusive complex on Patton Hill (which is now recognized as the core of the Casino porphyry deposit). The total placer gold production is unknown; the most recent work (1980-1985) yielded about 50 kg (1615 troy ounces) of gold. During the Second World War, a small amount of tungsten was recovered.

The first mineral claims at Casino were staked by N. Hansen in 1917. In 1936, silver- lead-zinc veins were discovered by J. Meloy and A. Brown approximately 3 km south of the Canadian Creek placer workings. Over the next several years the Bomber and Helicopter vein systems were explored by hand trenches and pits. The Helicopter claims were staked in 1943 and the Bomber and Airport groups in 1947.

From 1948 to 1963 the focus of exploration on the property was for lead-silver mineralization at the Helicopter and Bomber veins. The property was optioned to Noranda in 1948 and then to Rio Tinto in 1963. During this time trenching, mapping and sampling were conducted.

In 1963, L. Proctor purchased the claims and formed Casino Silver Mines Limited to develop the silver-rich veins. Between 1965 and 1980, the silver-bearing veins were explored and developed intermittently by underground and surface workings. In total, 372.5 tonnes of hand-cobbed argentiferous galena, assaying 3689 g/t Ag, 17.1 g/t Au, 48.3% Pb, 5% Zn, 1.5% Cu and 0.02% Bi, were shipped to the smelter at Trail, British Columbia.

B. Hestor noted that the area had porphyry deposit potential in 1963, but his observations did not become generally known. In 1967, the porphyry potential was recognized again, this time by A. Archer and separately by G. Harper. Archer's evaluation led to the acquisition of Casino Silver Mines Limited by the Brynelsen Group, and from 1968 to 1973 exploration was directed jointly by Brameda, Quintana, and Teck Corporation towards a porphyry target. Exploration included extensive geophysical and trenching programs, but it was mainly thanks to the soil geochemistry, that the porphyry deposit was discovered in 1969.

Following the porphyry discovery, various parties including Brameda Resources, Quintana Minerals and Teck Corporation drilled the property. During this period (between 1969 and 1973), 5,328m of reverse circulation drilling in 35 holes and 12,547m of diamond drilling in 56 holes was completed.

In 1991, Archer Cathro & Associates (1981), Ltd. optioned the property and assigned the option to Big Creek Resources Ltd. A drill program in 1992 consisting of 21 HQ (63.5 mm diameter) holes totaling 4,729m systematically assessed the gold potential in the core of the deposit for the first time. The larger-sized core gave better recovery and more reliable assays than earlier drilling.

In 1992, Pacific Sentinel Gold Corp. (PSG) acquired 100% the property from Archer Cathro and commenced a major exploration program. The 1993 program included surface mapping and 50,316 m of drilling in 127 holes. All but one of the 1992 drill holes were deepened in 1993.

In 1994, PSG drilled an additional 108 drill holes totaling 18,085 m. This program completed the delineation drilling set out in 1993 and investigated various geological, geotechnical, structural, and environmental aspects of the project. In addition, PSG performed a considerable amount of metallurgical, geotechnical and environmental work and completed a scoping study in 1995. The scoping study envisioned a large-scale open pit mine, conventional flotation concentrator that would produce a copper-gold concentrate for sale to Pacific Rim smelters.

First Trimark Resources and CRS Copper Resources obtained the property and using the Pacific Sentinel Gold data published a Qualifying Report on the property in 2003 to bring the resource estimate into compliance with National Instrument 43-101 requirements. The two firms combined to form Lumina Copper Corporation in 2004. An update of the Qualifying Report was issued in 2004.

Western Copper Corporation acquired Lumina Copper Corporation, and the Casino Deposit, in November, 2006. In 2007, Western Copper conducted an evaluation of the Bomber Vein System and southern slope of Patton Hill by VLF-EM and Horizontal Loop EM surveying and soil geochemistry. Environmental baseline studies were also initiated in 2007.

From 2008 to 2011, Western Copper completed reclamation of historic work sites and camp, 22.5 km of DC/IP surveying and MT surveying using the Quantec Geosciences Ltd Titan system, baseline environmental studies, archaeological studies, engineering, geotechnical, metallurgical and acid-rock drainage (ARD) studies, an airphoto survey, and access road upgrades. The company also conducted 24,306 m of exploration drilling in 87 holes and 5,248 m of drilling in 58 holes for geotechnical and hydrogeological purposes.

In January 2013, M3 Engineering and Technology Corporation prepared a Feasibility Study for Western Copper and Gold incorporating Pacific Sentinel's historic data and Western Copper's data. The updated resource calculated measured, indicated and inferred resources for the Leached Cap of 101 Mtonnes grading 0.38 g/t gold at a 0.25 g/t gold cut-off. The M, I & I resource of the combined supergene sulphide and hypogene zone, at a 0.25% copper equivalent cut-off, returned 2,753 Mtonnes grading 0.16% copper, 0.19 g/t gold, 0.021% molybdenum and 1.50 g/t silver for and equivalent copper grade of 0.42%.

The Feasibility Study contemplated the development of the Casino deposit as a conventional truck-shovel, open pit mine, initially processing the gold bearing oxide cap as a heap leach operation. Sulphide ore processing would commence approximately 2.5 years later at a nominal rate of 120,000 tpd in a concentrator, which would produce copper concentrate and molybdenum concentrate.

In May 2019, CMC conducted a 13,500+ meter diamond drilling campaign with the purpose of updating the 2013 resource estimation and testing new areas of exploration potential. In June of 2020, Independent Mining Consultants (IMC) Inc issued an updated resource model for the Casino Project that

included the results of the 2019 drilling. As of the date of this report, M3 Engineering and Technology Corporation is preparing an update to the 2013 Feasibility Study for the Casino Project.

## 6.0 GEOLOGY

*The entirety (with exception for minor edits) of Section 6 is from The Casino 2012 Assessment Report by Scott Casselman.*

### 6.1 REGIONAL GEOLOGY

The Casino Cu-Mo-Au-Ag porphyry deposit lies in the central Dawson Range, within the large and vastly-complex Yukon-Tanana Terrane: an accretionary and pericratonic, metamorphic fragment of the Omineca Belt. Local to the Casino Property, the Yukon-Tanana is subdivided into the Yukon Catalastic Terrane to the northeast and the Yukon Crystalline Terrane to the southwest, separated by a northwest-trending suture. Sporadic bands of Permian to Triassic ultramafic rocks exist along this contact zone. Figure 4 shows the location of the Casino Project in relation to regional geology.

The Yukon Crystalline Terrane in the Dawson Range area is represented by the Devonian-Mississippian Wolverine Creek Metamorphic Suite and is made up of sedimentary and igneous protoliths. The meta-sedimentary unit consists mainly of quartz-feldspar-mica schist and gneiss, quartzite, and micaceous quartzite, while the meta-igneous unit includes biotite-hornblende-feldspar gneiss and other orthogneiss, as well as hornblende amphibolite.

During the mid-Cretaceous, the Wolverine Creek Metamorphic Suite was intruded by the Dawson Range Batholith and subsequent Casino Intrusions. The Dawson Range Batholith is the main country rock of the Casino Property and is represented by a relatively homogeneous, medium- to coarse-grained, hornblende-bearing, potassic quartz diorite to granodiorite; and lesser fine- to medium-grained diorite and quartz monzonite veins, dykes, and plugs.

Age determination, as well as geochemistry, place the Casino Intrusions back into the mid-Cretaceous as fractionated magmas of the Dawson Range Batholith. Recent field relationships, however, have shown that the quartz monzonite of the Casino Intrusions, once thought to be separate intrusions, are actually intensely altered and recrystallized diorite of the Dawson Range Batholith.

In the late Cretaceous, the Prospector Mountain Plutonic Suite intruded as stocks and apophyses into the Dawson Range Batholith. In the Casino area, this suite is represented by Patton Porphyry: small, biotite-bearing, feldspar-porphyritic, hypabyssal rhyodacite to dacite intrusions near the centre of the deposit and discontinuous centimeter- to metre-wide dikes northwest of the property. In the Casino deposit, early phases the Patton Porphyry grade into a mineralized intrusive breccia. Later, unaltered dykes of similar rock can cut surrounding hydrothermally altered and mineralized rocks suggesting there are multiple phases of this unit. Hydrothermal alteration and mineralization occur in and adjacent to these late Cretaceous intrusions.

Figure 4: Regional Geology, from Casselman 2013

## 6.2 PROPERTY GEOLOGY

In 2010, all available historical drill core was re-logged and the observations were combined with the ongoing exploration program to re-interpret the local geological setting. This resulted in a significant simplification of the geology of the deposit and the recognition of six distinct geological units proximal to it. Away from the deposit, an additional six geological units are recognized on the property. The new interpretation has been combined with the updated regional mapping by Ryan (2013) to place the local units in a regional context. The combined geological interpretation is presented in Figures 5 and 6 (from Casselman, 2013) located in Appendix V and in Table 1 below.

| Age       | Unit | Geological Unit        | Description | Isotopic Age |
|-----------|------|------------------------|-------------|--------------|
| Paleogene | 12   | Rhyolite Creek complex | rhyolite    |              |

*Table 1: Property Geology Stratigraphic Column (from Casselman, 2013)*

The six important rock units in the immediate deposit area are: Dawson Range Granodiorite and Diorite (Whitehorse suite), Casino suite Patton Porphyry, Patton Porphyry Dykes, Heterolithic Breccia and Explosive (milled) Breccia. Comprehensive investigations have shown that the Casino Deposit area is predominantly underlain by massive granodiorite and diorite of the mid-Cretaceous Dawson Range Batholith. In the late Cretaceous Period, the Casino suite intrusions and breccias intruded into the Dawson Range rocks underlying at Patton Hill and straddling Patton Gulch to the northwest, initiating the formation of the ore deposit.

### **Whitehorse suite - Dawson Range phase**

The mid-Cretaceous Dawson Range Batholith is the main country rock of the deposit area and is characterized by hornblende-biotite-quartz diorite, hornblende-biotite diorite, and biotite-hornblende granodiorite (Payne et al. 1987). Hornblende-biotite bearing phases are common throughout the deposit, and lesser biotite-hornblende bearing phases are generally north of Patton Hill (Godwin, 1975). Diorite is concentrated north and northeast of the deposit, and is considered to be the earliest phase of the batholith.

The diorite is typically dark gray to brown and inequigranular. Average grain size is less than 1 millimetre, dominated by locally aligned and/or zoned plagioclase; hornblende; and interstitial, anhedral quartz. In places, primary biotite is more abundant than hornblende. Accessory minerals include up to 1 percent apatite and trace sphene. Some intrusions show foliation and increased mafic content near their margins, particularly north of the deposit and in the block east of the Casino Fault (Bower et al., 1995). Locally, mafic diorites are cut by later, more felsic phases of the Dawson Range Batholith (Johnston, 1995).

Granodiorite units are generally pale gray, medium to coarse grained and equigranular to porphyritic. They can be distinguished by scattered, subhedral hornblende phenocrysts averaging 0.5 to 1.2 centimetres long; poikilitic K-feldspar; zoned plagioclase; and 10 to 20 percent mafic minerals, which may be layered. Plagioclase shows minor myrmekitic rims when in contact with K-feldspar. Anhedral quartz and Kfeldspar are interstitial to earlier subhedral plagioclase, hornblende and biotite. Locally,

quartz forms interlocking aggregates of slightly, to moderately strained grains. Accessory minerals include honey-coloured sphene and apatite to 1 percent each.

Rocks of the Dawson Range commonly display in-situ/crackle to intensely deformed cataclastic brecciation where in contact with the Patton porphyry intrusive plug. Elsewhere, this unit may be truncated by the late Cretaceous dykes and explosive breccias (modified from Bower, 1995).

In the past there was believed to be a separate mid-Cretaceous Casino Plutonic Suite including fine- to medium- to coarse-grained, locally porphyritic, leucocratic granite, quartz monzonite, and alaskite with associated aplite phases (Payne, 1987; Johnston, 1995; Hart and Selby, 1998). The unit was prominent to the north and west of Patton Hill, just west of the Casino Fault, and was considered to be the host rock to the majority of the Mo +/- Cu mineralization. Recent field relationships have shown that this unit is actually intense potassic alteration, with or without overprinting retrograde phyllic alteration, of the diorite of the Dawson Range phase. This alteration often bleaches the rock to a light pink colour, and recrystallizes the matrix to a relatively equal mix of secondary quartz and K-feldspar.

Fine- to very fine-grained, recrystallized diorite is pale pink in colour, and commonly contains equal portions of quartz, plagioclase, and K-feldspar; up to 10 percent biotite; and trace apatite and sphene. Strongly zoned plagioclase and locally kinked biotite form subhedral lathes, surrounded by K-feldspar, locally strained quartz, and biotite.

Porphyritic recrystallized diorite is medium gray to pink with 70 percent medium to coarse-grained phenocrysts of subhedral plagioclase, hornblende and biotite in a fine-grained, K-feldspar, quartz, and minor biotite matrix. Plagioclase lathes are generally zoned, and may display corroded, albitized borders; biotite lathes may cluster together with hornblende and other opaques.

Aplitic zones grading from pink to white in colour have been noted in drill core, and mapped on surface in the surrounding area by Payne et al. (1987). They are also considered to be metasomatised diorite, and may include minor zones of pseudopegmatite.

### **Casino suite**

Late-Cretaceous igneous activity of the Casino suite is locally represented by the Patton Porphyry intrusive and associated breccias. The main body of the Patton Porphyry is an irregular body that is surrounded by a potassically-altered intrusive auto-breccia in contact with rocks of the Dawson Range. The Patton Porphyry intruded from narrow dykes on the east side of Patton Hill and blossomed upwards and westwards into a sill-like body that measures 600 m by 800 m in plan and is up to 300 m thick. Elsewhere, the Patton Porphyry forms discontinuous dikes and explosive breccia pipes, ranging from less than one to tens of metres wide, cutting both the Patton Porphyry plug and the Dawson Range rocks (after Bower et al., 1995). Contacts between the Patton Porphyry and the breccias are variable and range from sharply intrusive (as in the case of the later explosive breccia) to gradational and brecciated (as in the case of the intrusion contact breccia). It has therefore been suggested by Bower et al. (1995)

as well as Selby and Creaser (2001) that this suite consists of two or more episodes of high-level intrusions.

Godwin (1975) determined that the Patton Porphyry has an overall composition of rhyodacite, with phenocrysts falling into a dacite composition and the matrix being of quartz latite composition. It is more commonly made up of distinct phenocrysts of abundant plagioclase and lesser biotite, hornblende, quartz and opaques (Godwin, 1975). Phenocrysts average 4 millimetres (mm) in size, and can comprise up to 50 percent of the rock. Lathes of plagioclase are euhedral and zoned, and range in size from 2-7 mm, with some up to 2.5 centimetres (cm) in length (Bower et al., 1995). Biotite lathes range from 2-3 mm across, and make up 1-5 percent of the rock. They are kink-banded, subhedral, and locally chloritized. Hornblende phenocrysts are difficult to recognize due to their alteration. They have generally been replaced by chlorite and other opaques but can be recognized by their diamond cross section. Quartz phenocrysts are not always present but can be anhedral, embayed, and 3-5 mm in size. K-feldspar phenocrysts are rare but the mineral is abundant in the microcrystalline matrix that is commonly medium to dark green.

Smaller, possibly more evolved, discontinuous plugs of Patton Porphyry exist where K-feldspar and/or quartz megacrysts can range from 3-20 mm in size, displaying ragged boundaries and intergrowths with surrounding grains (Godwin, 1975). Relationships between the main Patton Porphyry intrusion and smaller plugs are lacking, but structurally, these units parallel and are peripheral to the main stock often within the contact breccia.

The intrusion contact breccia surrounding the main Patton Porphyry body consists of granodiorite, diorite, and metamorphic fragments and blocks in a finer grained Patton Porphyry matrix. It may have formed along the margins, in part, by the stoping of blocks of wall rocks (Bower et al., 1995). The unit is rhyodacitic in composition and is inherently related to the Patton Porphyry intrusive (Godwin, 1975 and Payne et al., 1987). Local quartz grains are generally 1-2 mm, unstrained crystals and crystal fragments and are texturally similar to quartz phenocrysts of the Patton Porphyry (Bower, 1995). Eroded fragments, ranging in size from less than one centimeter to greater than a few metres, are found proximal to their associated wall rocks, and therefore indicate limited transport and/or mixing (after Bower et al., 1995). For example, inclusions of the Dawson Range increase along the southern contact of the breccia; older metamorphic rocks increase to the north; and bleached diorite increases in the east. Strong potassic alteration locally destroys primary textures (Bower, 1995).

This breccia was previously regarded by Godwin (1975) as a Casino Volcanic Cobble breccia, and was described to contain rounded to subangular fragments of (Casino) quartz monzonite and Snowcap assemblage metamorphic schist (formerly called Wolverine Metamorphic Complex), as well as early Patton Porphyry rocks in a very fine-grained, feldspar and quartz rich groundmass.

Subsequent crystallization and exsolution of hydrothermal fluids from Patton Porphyry magmas produced porphyry style Cu-Mo-Au-Ag mineralization (Selby and Nesbitt, 1997). Therefore, the Patton

Porphyry, and associated intrusion breccia, is genetically related to the Cu-Mo-Au-Ag mineralization of the deposit (Godwin, 1975; Selby & Creaser, 2001).

Dikes of Patton Porphyry material in the south-central part of the deposit somewhat resemble the main Patton Porphyry body and contain 2 to 5 percent quartz phenocrysts and up to 35 percent plagioclase phenocrysts in an aphanitic latite groundmass (Bower et al., 1995). These sills intruded after the main hydrothermal event and contain only minor base and precious metal mineralization, as well as locally abundant disseminated pyrite (Godwin, 1975).

Abundant fragments of the Patton Porphyry and its intrusive breccia are present in the adjacent late Cretaceous explosive breccia pipe (Halle after Bower, 1995). Late, explosive breccia plugs are very steep-sided, heterolithic, cobble-breccias occurring on the property as two main pipe-like intrusions, but locally are seen as very fine-grained 'dikes'. The largest plug, on the west side of the property, truncates most of the western margin of the main Patton Porphyry intrusion.

Godwin (1975) concluded that this pipe most likely represents a sub volcanic neck, brecciated from explosions caused by the rapid expansion of hot water (hydrothermal solutions) by vesiculation of rhyolitic magmas, and that any extrusive volcanics related to this event may have since been weathered away. This unit indicates multiple episodes of brecciation (Bower, 1995) as it contains 5-50 percent ragged fragments of altered intrusive breccia and host rock; with lesser fragments of late, often quartz-phyric, Patton Porphyry. Locally the groundmass has a very fine-grained, interlocking igneous texture; elsewhere it resembles milled rock flour (Bower, 1995) with up to 10 percent plagioclase and lesser quartz phenocrysts. Godwin also noted large, angular cavities being a distinctive quality of this unit, measuring up to 10 cm in size. The explosive breccia has been known to grade into a later, porphyritic dyke showing strong sheeting parallel to its contacts (Bower et al., 1995). This dyke is generally white to cream to gray, and can be vesicular with quartz filled amygdules on the east side of the Casino Fault. Amygdules are also stretched parallel to steep contacts.

Late Cretaceous to early Tertiary dyke swarms and sills intrude rocks of the earlier Casino suite as well as rocks of the mid-Cretaceous intrusions (Payne et al, 1987). In 1975, Godwin grouped these dykes with the Patton Porphyry, as undivided volcanics. These late Patton dykes are of latitic to dacitic composition and are generally steeply dipping, striking between 130 to 160 degrees (Bower et al., 1995). On the Casino property, these dykes are generally pale to light green with abundant plagioclase and lesser hornblende phenocrysts in a very fine- to extremely fine-grained matrix of plagioclase and K-feldspar (Payne et al., 1987). Wider versions of the dyke are coarser grained, and may contain scattered quartz and/or biotite phenocrysts to 3 mm, along with plagioclase and hornblende. Narrow versions with or without chilled dyke margins can be dark green with a glassy groundmass, and may show flow banding and/or lenticular structures near contacts (Bower et al., 1995). The finer grained dykes are generally medium green. Out-crop of this unit can be mapped on surface trending northwest along Proctor Gulch.

## Yukon-Tanana Terrane

The rocks of the Yukon-Tanana Terrane have locally been referred to as the Wolverine Metamorphic Complex. They include meta-sedimentary and meta-igneous rocks (Tempelman-Kluit, 1974; Payne et al. 1987; Johnston, 1995) of Devonian-Mississippian age (Johnston, 1995) and occur mainly in the northern parts of the Casino property, as fragments in intrusion breccias and local roof pendants/screens throughout the Dawson Range Batholith (Bower et al., 1995).

There has not been any detailed mapping, along the narrow strip of claims that encompass the road leading to the Yukon River, north of the deposit. This area is underlain by quartzite and schist of the Snowcap assemblage (unit D-Sq), orthogneiss of the Simpson Range suite (unit MS-SR) and gneissic monzogranite of the Sulphur Creek suite (unit Pr-KSC). Wedges of Snowcap quartzite and Sulphur Creek gneiss are also observed immediately west of the property and to the south, crossing the Casino Creek valley.

Further south, highly serpentinized ultramafic lenses (unit Pr-um) that are several hundred meters thick and a little more than a kilometer long, form a zone along the northern contact of the Dawson Range intrusive rocks. The rocks are dark green, strongly serpentinized, medium-grained dunite, augite and hornblende (Godwin, 1975).

## Younger Volcanic Rocks

Godwin (1975) identified a number of small occurrences of what he termed “undivided volcanic” in the southern part of the Casino Creek valley (unit v). These were described as dykes and plugs of tuffaceous-looking porphyry that is pale in colour and characterized by short, stubby, doubly-truncated quartz crystals and less abundant sanidine. These rocks contain ubiquitous pyrite and minor amounts of epidote, calcite, clay, sericite and tourmaline (Godwin, 1975). These rocks are similar to the Rhyolite Creek felsic volcanics (unit Pg-RC1) that have been mapped by Ryan (2013), a large unit of which is observed on Casino Creek. These may be the same unit, however, at this time they are indicated as separate on the Figure 5.

## 6.3 ALTERATION

Hydrothermal alteration at the Casino property is typical of a porphyry copper mineralizing system. The alteration zonation is illustrated in the Deposit Geology map, Figure 6. It consists of a potassic core centered on and around the main Patton Porphyry body; bordered by a contemporaneous, strongly developed and fracture controlled phyllic zone; a weakly developed, broader, propylitic zone; and a secondary, discontinuous argillic overprint (Godwin, 1975; Selby and Nesbitt, 1997). Mineralized stockwork veins and breccias in the deposit are closely associated with the hydrothermal alteration (Selby and Nesbitt, 1997).

Potassic alteration minerals include texturally destructive K-feldspar, biotite, magnetite and quartz (Selby and Nesbitt, 1997) with lesser hematite, purple anhydrite and gypsum (Godwin, 1975). Biotite is generally felted and pseudomorphic after hornblende. Locally, magnetite may form braided veinlets.

The texturally destructive phyllic zone is found peripheral to the deposit, and locally overprints the potassic alteration zone. It has a distinctive 'bleached' appearance and can be structurally controlled. Phyllic alteration minerals include quartz, pyrite, sericite, muscovite (after biotite), and abundant tourmaline (Selby & Nesbitt, 1997); as well as minor hematite and or magnetite towards the potassic zone (Godwin, 1975). Quartz and sericite are generally alteration minerals after potassic and plagioclase feldspars (Godwin, 1975). Biotite alters to muscovite or sphene; hornblende to chlorite, calcite, quartz and biotite (Bower et al, 1995). Tourmaline forms radiating disseminations and veinlets. Sulphide content is typically high, with pyrite ranging from 5-10% throughout.

Propylitic alteration is rare on surface, but forms a wide halo around the deposit in gradational contact with the inner potassic alteration. Alteration minerals include epidote, chlorite and calcite (Selby and Nesbitt, 1997), with lesser carbonate, clay, sericite, pyrite and albite (Godwin, 1975). Hornblende and biotite are completely chloritized (Godwin, 1975).

Secondary argillic alteration occurs in the shallower levels and is closely associated with the leached cap and upper supergene zone. It may also occur locally as patches or pockets within potassic and phyllic alteration. It is poorly developed, is bleached or pale green, and contains abundant clays like kaolinite and montmorillonite, and possible chlorite and/or carbonate. In drill core, this alteration style may be recognized by distinctive "pock-marks" along the surface of the core (Godwin, 1975).

## **6.4 MINERALIZATION**

Hydrothermal mineralization of the Casino Cu-Mo-Au-Ag deposit occurs mainly in the steeply plunging, in-situ contact breccia surrounding the Patton Porphyry intrusion by crystallization and exsolution of hydrothermal fluids from late Cretaceous magmas of the Prospector Mountain Plutonic Suite (Selby and Nesbitt, 1997). Mineralization was superimposed onto the Patton Porphyry, as well as in surrounding mid-Cretaceous intrusions of the Dawson Range Batholith. The breccia forms a band around the periphery of the main porphyry body with thicknesses of up to 250 metres, and has an interior zone of potassic alteration surrounded by discontinuous phyllic alteration, typical of porphyry deposits.

The Casino deposit is unique among Canadian porphyry deposits as it has a substantially preserved, outcropping oxide gold leach cap; an upper, copper enriched copper oxide supergene mineralization zone; a lower, well developed and extensive copper sulphide supergene mineralized zone; as well as the underlying hypogene zone.

Hypogene mineralization occurs throughout the various alteration zones of the Casino Porphyry deposit, as mineralized stock-work veins and breccias (Selby et al., 2000). Field relationships show that the

potassic alteration came first as mineralized quartz veins of the phyllically altered zones, cut those of the potassically altered zones; Re-Os age dating by Selby et al. (2000) showed that the dates of the potassic and phyllic alteration are contemporaneous at around 74.4 +/- 0.28 Ma. Significant Cu-Mo mineralization is related to the potassically altered breccia surrounding the Patton Porphyry intrusion, as well as in the adjacent phyllically altered host rocks of the Dawson Range phase.

Mineralization in the potassic zone is mainly finely disseminated pyrite, chalcopyrite, molybdenite as well as trace sphalerite and bornite (Godwin, 1975). The Phyllic zones have increased gold, copper, molybdenite, and tungsten values concentrated in disseminations and veins of pyrite, chalcopyrite, and molybdenite along the inner side of the pyrite halo (Payne, 1987). The pyrite halo follows the potassic phyllic contact, within the phyllic zone, and discontinuously surrounds the main breccia body. It is host to the highest Cu values on the property (Godwin, 1975).

Chalcopyrite commonly occurs as veins, disseminations and irregular patches. In breccia and granodiorite west of the Casino Fault, disseminated chalcopyrite is more abundant than chalcopyrite in veins and veinlets, whereas to the east of the fault, chalcopyrite is controlled by brittle deformation and found in fractures and open space fillings (Bower et al, 1995). Pyrite to Chalcopyrite ratios range from less than 2:1 in the core of the deposit, to greater than 20:1 in the outer phyllic zone (Bower et al, 1995). Locally, bornite and tetrahedrite can be coarsely intergrown with chalcopyrite (Bower et al., 1995).

Molybdenite is not generally intergrown with other sulfides and occurs as selvages in early, high temperature, potassic quartz veins as discrete flakes and disseminations.

Native gold is very rarely seen with the naked eye. It occurs as free grains in quartz (50 to 70 microns) and as inclusions in pyrite and/or chalcopyrite grains (1 to 15 microns) (Bower et al., 1995).

Late-stage, commonly vuggy, polymetallic veins (like those of the bomber adit) follow roughly parallel, steeply dipping fractures trending 150 to 170 degrees (Bower et al., 1995). Metallic mineralogy includes abundant sphalerite and galena, with less abundant tetrahedrite, chalcopyrite (commonly intergrown with tetrahedrite), and bismuth bearing minerals, and are geochemically anomalous in any or all of Ag, As, Bi, Cu, Cd, Mn, Pb, Sb, Zn, and locally W (Bower, 1995).

Supergene mineralization occurs in an up to 300 metre-deep weathered zone above the hypogene zone (Bower et al, 1995). It contains a classic and well defined, porphyry style leached cap with an underlying supergene blanket (Payne et al, 1987). Supergene alteration and mineralization (below the leached cap) is divided into a minor Supergene Oxide Zone and a thicker Supergene Sulphide Zone. Supergene alteration and mineralization is thickest within the phyllic, and locally within the potassic zones of the brecciated units, due to the permeability of the breccia (Godwin, 1975).

The Leached Cap (oxide gold zone) is gold enriched and copper depleted due to supergene alteration processes as well as the lower specific gravity of this zone relative to the other supergene zones (Bower,

1995). It averages 70 metres thick and is characterized by boxwork textures filled with limonite, goethite, and hematite (Bower et al., 1995).

The poorly defined Supergene Oxide Zone is copper enriched, with trace Molybdenite. It exists as a few perched bodies within the leached cap (Bower et al., 1995) likely due to a recent drop in the water table (Godwin, 1975) and as a layer with highly variable thickness above the Supergene Sulphide Zone. This zone is thought to be related to present day topography, and is best developed where oxidation of earlier secondary copper sulphides occur above the water table, on well drained slopes (Bower et al., 1995). Where present, the Supergene Oxide Zone averages 10 metres thick, and can contain chalcantite, malachite and brochantite, with minor azurite, tenorite, cuprite and neotocite (Bower et al., 1995). The supergene copper oxide zone grades into the better-defined supergene copper sulphide zone.

The Supergene Sulphide Zone has an average thickness of 60 metres (Bower, 1995) and is correlated with high hypogene mineralization, favorable permeability (breccia units) and to the phyllic and/or outer potassic zone (Godwin, 1975). Grades of the Supergene sulfide zone vary widely, but are highest in fractured and highly pyritic zones, due to their ability to promote leaching and chalcocite precipitation (Godwin, 1975). Thus, secondary enrichment zones are thickest along contacts of the potassic and phyllic alteration; accordingly the copper grades in the Supergene Sulphide zone are almost double the copper grades in the Hypogene (0.43% Cu versus 0.23% Cu). Grain borders and fractures in chalcopyrite, bornite and tetrahedrite may be altered to chalcocite, diginite and/or covellite (Bower, 1995). Chalcocite also locally coats pyrite grains and clusters, and may extend along fractures into the hypogene zone. Molybdenite is largely unaffected by supergene processes, other than local alteration to ferrimolybdate (Bower, 1995).

## 6.4 PROPERTY-SCALE STRUCTURE

The structural interpretation in the deposit area utilized drill hole data, ground and airborne geophysical survey interpretation, topographic interpretation and geological mapping. Interpretation of the property-scale structures in three dimensions has been aided by the Titan DC/IP and MT resistivity survey, where clay-bearing faults appear as conductors or resistivity lows. Figure 6 in Appendix V shows the property scale structures.

At the eastern part of the Casino deposit is the Casino Fault Zone: a zone of steeply dipping, south-directed faults. This orientation may have weak repetitions throughout the deposit and is considered to be a mineral controlling, early structure predating the Casino Creek Fault system. Similarly-directed faults are repeated throughout the Casino Property including one heading south from Canadian Creek, travelling through Patton Gulch, and forming a col on Patton Hill. This fault is aptly named the Patton Fault. The fault bisects the Casino Deposit but little movement has been interpreted. The West Fault, on the west side of the property is thought to be similarly-oriented. Most of these faults/shear zones are

denoted by brittle to gougy drill core intercepts and may show increased amounts of hydrothermal veining including tourmaline, pyrite, magnetite, and gangue infilling fractures.

West-directed fault systems have been noted in some early workings southeast along the Casino Creek Fault. These have been suggested by airborne magnetics south of the deposit, and interpreted in airphotos west of the deposit. In addition, this orientation proved to be prominent in veins in a Pacific Sentinel study of oriented core in 1994. A suture between Dawson Range diorite and granodiorite along this orientation has locally incorporated older metamorphic rocks. This orientation is parallel to the Minto-Battle Fault and may have been a control on the intrusion of the main Patton stock.

## 7.0 2019 EXPLORATION PROGRAM

Between May and October of 2019, Kluane Drilling Ltd. from Whitehorse, Yukon, drilled 72 (DH 19-01 through DH 19-53, CRD 19-54 through CRD 19-59 and DH 19-60 through DH 19-69) drillholes on the Casino Property using up to two hydraulic diamond drills. Table 2 below summarizes the drill hole data for 2019.

| Hole ID   | Length (m) | UTM Grid       | UTM Easting (m) | UTM Northing (m) | UTM Elevation (m) | Azimuth | Dip |
|-----------|------------|----------------|-----------------|------------------|-------------------|---------|-----|

Table 2: 2019 Drilling Summary

Water for the drilling was pumped from Canadian Creek (Canadian Creek bend, location of the old placer camp) and from Casino Creek and several small ponds around the property.

All drillholes in 2019 were NTW core size (core diameter 56.00 mm) with the exception of some holes in difficult ground that were started in HTW core size (core diameter 70.92) and reduced to NTW when drilling conditions improved.

Core recoveries were consistently in the 75% to 80% range in the Leached Cap, 80% to 90% in the Supergene zones and 90% to 100% in the Hypogene zone.

Down-hole orientation surveying was performed using a DeviShot Magnetic Multishot survey tool. Each drillhole was surveyed by the Kluane drilling team on 30-50 m increments.

CAP Engineering out of Whitehorse, Yukon was on site for 2 days in late August to survey the drill hole collars. A team of two people used a Stonex GPS RTK Unit and a Topcon GPS RTK Unit to complete the surveys. See Figures 7 and 8 for detailed locations of the drill holes.

Figure 7: 2019 Drillhole Locations

Figure 8: 2019 Drillhole Locations and Claim grouping

The purpose of the 2019 drill program was to fill in the previous drill hole spacing so as to update the resource for the project. All holes were logged, sampled and photographed by geologists on site before samples were sent to ALS Chemex in Whitehorse for analyses, with 20% of those pulps from ALS randomly selected and sent on to SGS in Vancouver for further check analysis. Quality control samples were randomly inserted within every 20 core samples; that being a blank material, a standard reference material and a core duplicate. Detailed drill logs are available in Appendix III.

## 8.0 SAMPLE PREPARATION, ANALYSES AND SECURITIY

### 8.1 Core Processing

At the drill site, core was placed into wooden core boxes directly upon emptying the core tube. A wooden block marked with the depth in feet and meters was placed in the core box upon the completion of each drill run, which in good conditions was 10 feet. Core boxes were transported by drilling company truck less than 5 km to the core logging facility adjacent to the Casino Airstrip. There, core boxes were stacked outside of the core logging building, with each hole as a separate, clearly labelled stack. When the core was ready to be logged it was laid out in sequence on elevated tables in the core shack.

Core boxes were labelled with black felt tip pens and embossed steel tags containing hole number, box number and interval of core within the box. Geotechnical data including core recovery, RQD, hardness and natural breaks were recorded for each drill run, as marked by the wooden core run blocks. This information was recorded on paper by the geologist or geotechnical logger, supervised by the lead geologist. Logging of the geotechnical data followed codes and format outlined in a project specific manual prepared by Knight Piésold.

The geologist recorded key geologic information including lithology, zone, mineralization and alteration. The data was entered onto paper. The codes and logging form followed as close as possible the format used by Western Copper during the 2010-2012 drilling programs. The lithology codes, copper mineralization zone codes and alteration codes used in the 2013 and 2020 drilling programs were all initially developed by Pacific Sentinel and modified by Western Copper.

Core was photographed after the geology log was completed and after the sampling intervals were marked.

## **8.2 Core Sampling and Sample Preparation**

For the 2019 drill program, rock samples were cut in half with a core saw on site and half of the core was placed, with a sample tag, in plastic bags with the corresponding sample ID noted on the outside of the bag. The remaining half of the core was placed back into the core box, stacked outside the core cutting shack and then moved to the core storage yard where each hole is stored in stacked and covered core boxes or on racks. Bagged and labelled samples were then placed in larger white rice bags, each labelled with a unique batch letter and the address of the receiving lab. A running list was maintained in Excel of each batch, the samples included and the dates they were sent out by plane to ALS Chemex in Whitehorse.

All original samples in 2019 were sent to ALS Chemex Labs in Whitehorse for analysis. The standard analytical request for all samples was for preparation by procedure Prep-31A. This process involved logging the sample into the tracking system, weighing, drying and crushing the entire sample to better than 70% -2 mm. A 250 gram split of the crushed material was then collected by riffle splitter and was pulverized to better than 85% passing 75 microns. The resultant pulp was then sent for analysis within the ALS lab in Whitehorse.

Sample Standards arrived at ALS Chemex in pulp form and went straight to analysis. Blank samples arrived as rock and went through the same process as the core samples. Duplicate samples were sent to ALS in separate batches, arriving at a later date than the original samples and then went through the same process as the original core samples.

Check pulp samples were sent from ALS in Whitehorse to SGS Canada Inc in Burnaby. At SGS, the pulps were checked for weight and fineness before a full geochemical assay was run. This involved logging the sample into the tracking system (checking the samples received matched the electronic list of samples sent by Western Copper staff), weighing and then checking the pulp was of appropriate fineness.

### 8.3 Assay Analysis

Each drill hole was logged, sampled and analyzed for a full ICP suite of minerals, including gold. Holes DH 19-04, DH 19-22 and DH 19-26 were logged, but not sampled as they were abandoned due to poor drilling conditions. Assay certificates for the 2019 drill core can be found in Appendix IV.

All 4,939 core samples were sent to ALS Chemex in Whitehorse as noted above. Following sample preparation, a full ICP suite was run on the resultant pulps using a four acid digestion with ICP-AES finish. Gold analyses were run on the pulps using a 30 gram sub-sample with fire assay and atomic absorption spectroscopy (AAS) finish to a 0.005 ppm detection limit according to procedure Au-AA23. Ore grade analyses were run using four acid digestion and either AES or AAS finish via method OG62. The processes used by ALS Chemex in Whitehorse in 2019 and those used by SGS Canada Inc. in Burnaby were similar.

#### 8.3.1 Gold Analysis

At ALS Chemex gold assays were run using 30 gram sample of the pulp with fire assay and AA finish to a 0.005 ppm detection limit according to procedure Au-AA23. Results were reported in parts per million (ppm).

At SGS gold assays were run by using a 30 gram sample of the pulp with fire assay and AAS finish to a 5 ppb detection limit according to procedure GE\_FAA30V5. Results were reported in parts per billion (ppb).

#### 8.3.2 Copper, Molybdenum and Silver Assay

Samples that returned over-limits for copper, molybdenum or silver in the ICP analysis were assayed by process OG62 at ALS Chemex. This process involved a four acid digestion and analysis by Inductively Coupled Plasma-Atomic Emission Spectroscopy or Inductively Coupled Plasma-Atomic Absorption Spectroscopy. Results were reported in percent (%). At SGS a similar process was followed for any over-limit results for copper, molybdenum or silver; a sodium peroxide fusion with ICP-AES using method GO ICP90Q.

#### 8.3.3 ICP Analysis

Samples sent to ALS Chemex were analyzed for multiple elements, including copper, molybdenum and silver by process ME-ICP61. This process involved a four acid "Near Total" digestion of 1.0 grams of sample pulp with Mass Emission-Inductively Coupled Plasma Spectroscopy for the analysis. This process returned results for: Ag (ppm), Al (%), As (ppm), Ba (ppm), Be (ppm), Bi (ppm), Ca (%), Cd (ppm), Co (ppm), Cr (ppm), Cu (ppm), Fe (%), Ga (ppm), K (%), La (ppm), Mg (%), Mn (ppm), Mo (ppm), Na (%), Ni (ppm), P (ppm), Pb (ppm), S (%), Sb (ppm), Sc (ppm), Sr (ppm), Th (ppm), Ti (%), Tl (ppm), U (ppm), V (ppm), W (ppm), and, Zn (ppm).

Samples sent to SGS were analyzed for 56 elements, including copper, molybdenum and silver by method GO\_ICP90Q100. This process involved an ore grade sodium peroxide fusion with ICP-AES. This

process returned results for: Ag (ppm), Al (%), As (ppm), Ba (ppm), Be (ppm), Bi (ppm), Ca (%), Cd (ppm), Ce (ppm), Co (ppm), Cr (%), Cs (ppm), Cu (ppm), Dy (ppm), Er (ppm), Eu (ppm), Fe (%), Ga (ppm), Gd (ppm), Ge (ppm), Hf (ppm), Ho (ppm), In (ppm), K (%), La (ppm), Li (%), Lu (ppm), Mg (%), Mn (ppm), Mo (ppm), Nb (ppm), Nd (ppm), Ni (ppm), P (%), Pb (ppm), Pr (ppm), Rb (ppm), Sb (ppm), Sc (ppm), Si (%), Sm (ppm), Sn (ppm), Sr (ppm), Ta (ppm), Tb (ppm), Th (ppm), Ti (%), Tl (ppm), Tm (ppm), U (ppm), V (ppm), W (ppm), Y (ppm), Yb (ppm), Zn (ppm) and Zr (ppm).

#### **8.3.4 Acid Soluble Copper Analysis**

In 2019, similar to past years, once initial ICP assays were returned from ALS Chemex on the original samples, another group of sample pulps were sent for further assay by Cu-AA05 to identify non-sulphide copper; all pulps returning higher than 100 ppm copper that were also within the Leached Cap, Supergene Oxide, Supergene Sulphide and the initial 50 m of the Hypogene zone were pulled by ALS Chemex for this analysis.

#### **8.3.5 Cyanide Soluble Copper Analysis**

In 2019, the senior geologist used the core logging results to choose samples for cyanide-soluble copper analysis using method Cu-AA17 at ALS Chemex; all sample pulps from 30 m on either side of the Supergene Sulphide and Hypogene boundary were sent for this type of assay.

### **9.0 CONCLUSIONS and RECOMMENDATIONS**

While several of the 2019 drill holes could be considered exploratory in nature, the main purpose of the 2019 program was to infill pre-2019 drill spacing with the end goal of updating the resource estimation for the Casino deposit. At the time of this report, a fully updated resource has been calculated by Independent Mining Consultants Inc of Tucson, Arizona and has been released to the public. Details of the new resource can be found in the soon to be published updated Feasibility Study.

The drilling that took place directly to the north of the main deposit area on claims CAT 11, 13 and 53 indicates the possibility of extending the mineralized zone to the north or perhaps the presence of another satellite porphyry system. Holes DH 19-15, 19-63, 19-64, 19-65 and 19-67 for example, all show the continuation of the gold and copper grades present in the currently modeled Leached Cap and Supergene Zones. The Hypogene likely continues north as well, but the drilling in 2019 did not go deep enough to fully explore this potential.

Acquisition of the Canadian Creek property directly to the west of the Casino deposit also opens up the ability to explore the potential of a mineralization trend in that direction. Drilling on the westernmost border of the Casino Property shows gold grades indicative of the Leached Cap extending to the west. Holes CRD 19-55, 56 and 57 all have the Leached Cap running down to approximately 150m.

Several holes in 2019 had short, but high grade gold intercepts at depth. DH 19-21 in particular initially came back with 55.1 g/t Au over approximately 3m at about 148m, with an even higher re-assay of 65.9 g/t Au. This was not the first time high grade gold had been found at depth: CAS-007 had a 2.45m

interval at 343.5m depth that assayed 53.5 g/t Au and 94-300 had a 1.85m interval that assayed 99.96 g/t Au.

Because the majority of the 2019 drillholes were for the purpose of upgrading the resource estimate there was a fairly strict mandate to terminate the holes at a pre-determined depth. It has been a long held theory that mineralization continues below the current proposed open pit; several deep drillholes located near historic holes with high grade mineralization, such as 93-185 would test this theory and potentially extend the resource. Potential also exists to the north and west of the current Casino deposit as shown by results of the 2019 drilling in those areas. The high grade gold intercepts should also be investigated further in order to understand their nature and relation to the porphyry deposit itself.

## 10.0 STATEMENT OF EXPENDITURES

### WEST CLAIM GROUPING

|                          | SUB TOTAL      | APPLIED TO<br>QW30209 | ADJUSTED<br>EXPENDITURES |

## **Appendix I**

### **Statement of Qualification**

## CERTIFICATE OF QUALIFIED PERSON

**Heather P.L. Seeley**

I, Heather Seeley, P.Geol., do hereby certify that:

1. I am the owner and sole geologist of:

Wolfbear Geological Consulting  
521 Duncan Avenue East  
Penticton, BC.  
V2A 2W6

2. I graduated with a Bachelor of Science in Geology in 2005 from the University of BC.
3. I am a Professional Geologist (P.Geol) in good standing in British Columbia, Canada (No. 34222)
4. I have worked as a geologist for a period of 15 years continuously since 2005. I am the current owner and sole geologist of Wolfbear Geological Consulting, providing data management (including QAQC analysis and reporting), GIS and project management services to various companies including Western Copper and Gold. I have been employed previously as a database manager and geologist with several junior exploration companies including NovaGold and Alexco from 2005 through 2008 where I underwent specific training for Assay Quality Assurance-Quality Control via AMEC Mining Consulting. During this same period I also attended several courses in data management and collection procedures with Maxgeo for their DataShed, QAQCR and LogChief programs. I then worked to add all drilling data to these programs and helped manage the data collection and QAQC at several projects with NovaGold. I have also attended training classes in resource modeling and geostatistics at Mintec for MineSight Software and at Gemcom (now Dassult systemes) for GEMS Software. During my career, I have had extensive experience in data collection, management and verification procedures and have overseen logging and sampling programs on many different projects. I joined Western Copper as a full time employee in April of 2012 and continue to work for them in the role of consulting geologist as of the date of this declaration.
5. I have read the definition of "Qualified Person" set out in National Instrument 43-101 ("NI 43-101") and certify that by reason of my education, affiliation with a professional association (as defined in NI 43-101) and past relevant work experience, I fulfill the requirements to be a "Qualified Person" for the purposes of NI 43-101 and other technical reports.
6. I am responsible for the compilation of this report, titled, "Quartz Technical Assessment Report: Casino Project", dated September 27, 2020.
7. I have prior involvement with the property that is the subject of the Technical Report. I have managed the drilling and assay data for the Casino Project since 2012 and helped to manage the field project in 2019. I have visited the site on many occasions, the last of which was from August 14<sup>th</sup> through September 3<sup>rd</sup> of 2019.
8. As of the date of this certificate, to the best of my knowledge, information and belief, the Technical Report contains all scientific and technical information that is required to be disclosed to make the Technical Report not misleading.

Signed and dated this 5 day of October 2020.

  
Signature of Qualified Person

Heather Seeley  
Print Name of Qualified Person

## **Appendix II**

### **Claim List**

| Grant Number | Claim Name      | Owner                      | Expiry Date |
